The Human Relationship with Our Ocean Planet

11

Edward H. Allison, John Kurien, Yoshitaka Ota, Dedi S. Adhuri, J. Maarten Bavinck, Andrés Cisneros-Montemayor, Michael Fabinyi, Svein Jentoft, Sallie Lau, Tabitha Grace Mallory, Ayodeji Olukoju, Ingrid van Putten, Natasha Stacey, Michelle Voyer, and Nireka Weeratunge

1 Highlights

- The human relationship with the ocean is diverse and complex. It is built on values that are often non-monetary, and which contribute to non-material dimensions of well-being. These values are essential to broader human flourishing. They include contributions to cultural and social and legal identity; a sense of place; occupational pride and self-respect; spirituality; mental and bodily health; and human security.
- The plurality of these values and interests matters to individuals and societies and could be more strongly represented in high-level ocean policy discussions.
- A sustainable ocean economy must be built on these diverse relationships, in ways that encourage equity and inclusion and that recognise the non-material aspects of well-being.
- How we govern the ocean will determine who accesses and benefits from the ocean space. A heavily privatised, zoned and securitised ocean undermines the human-ocean relationship. Building upon existing institutional foundations, ones that provide livelihoods and well-being benefits to all citizens, will foster a more constructive long-term engagement with the ocean.
- There is no sole human relationship with the ocean with which all people will identify: each individual has different interests, experiences, economic stakes, emotional investments and cultural and social ties to different aspects of the ocean. To increase the ocean's contribution to both material and non-material well-being globally, we need to build a sustainable ocean economy based on this plurality of values.
- This paper identifies and focuses on the relationships with the ocean that contribute to human well-being. In doing so, it outlines these relationships in new ways and identifies the means to ensure that the plurality of 'ocean values' is represented in processes of planning and implementing a sustainable ocean economy.
- The paper suggests five key actions to assist states and international organisations in supporting and improving humanity's diverse relationships with the ocean by fostering participatory democratic governance: (1) humanise the new ocean narrative by focusing economic development on the objective of increasing human well-being; (2) foster diversity and inclusion in the sustainable ocean economy; (3) engage in partnerships with a broad constituency of ocean supporters, including small-scale fisherfolk, community elders and next-generation social and environmental activists, Indigenous Peoples, and women who work in the maritime economy and who steward marine environments; (4) build the capacity of meso-level institutions below the level of the national government and above the level of the individual citizen-consumer; and (5) ensure that responses to COVID-19 consider the well-being of ocean-dependent people and economic sectors.
- Governing the ocean is a 'collective responsibility of humanity' and can only be achieved by ensuring that those who have lived in, worked on and stewarded coastal and continental waters for centuries or millennia—prominent among them small-scale fisherfolk—are included in decisions on its future governance. These 'ocean citizens' and the institutions they have forged are pivotal to achieving a sustainable ocean economy. As such, maintaining ocean health and maintaining ocean access should be the dual aims of governing the future ocean.

> Just as the sea is an open and ever flowing reality, so should our oceanic identity transcend all forms of insularity, to become one that is openly searching, inventive, and welcoming. (Epeli Hau'ofa 2008)

2 Introduction

People across the world have diverse economic, sociolegal, institutional, social and cultural relationships with the ocean—both its littoral zones and the open sea spaces through which people have traditionally navigated, migrated, fished, traded, played and sought solace, spiritual enlightenment, adventure, material enrichment, social identity, cultural expression, artistic inspiration or good health. These relationships are reflected in formal and informal institutions (polices, laws, social norms) that regulate many of these activities, including those that regulate access to resources. These institutions represent a series of prior claims and rights to the use and enjoyment of the ocean by coastal and maritime societies.

By taking account of the range of ways coastal and maritime societies use, enjoy and govern coastal seas and ocean basins, we are better placed to design a sustainable ocean economy that is fair and equitable and that reflects 'the future we want' (UNCSD 2012). This paper argues that policymakers should consider the full range of human relationships with the ocean. The economic investment strategies and governance actions envisaged in contemporary ocean policy and planning can transform those relationships (Swilling et al. 2020) and will thus change the nature and distributions of the values that humanity derives from its interactions with the oceanic realm.

How can humanity's diverse relationships with the ocean be supported to flourish in the future, so that the ocean can make sustainable contributions to human well-being? This is the overarching policy question to which this paper responds. Policy research has made significant advances in assessing the ocean's ability to generate economic goods and services. The complementary perspectives presented here aim to draw attention to the wider role that the ocean has played—and will continue to play—in sustaining and reproducing other human values such as social and cultural identity, individual and collective well-being, sense of place and belonging, and human emotions such as curiosity, spirituality, awe and a sense of adventure.

From a brief survey of the past and current range of human relationships with the ocean and how they contribute to human well-being, and by examining the economic and policy implications of these relationships, we will argue that a sustainable ocean economy can contribute not only to the sustainable and equitable growth of economic goods and services but also to human well-being and flourishing more generally. Thus, the ocean can play a catalytic role in the next phase of human development, enhancing human capabilities and freedoms (Sen 1999, 2001), and thereby contribute to meeting the UN Sustainable Development Goals (SDGs) (Singh et al. 2018; Nash et al. 2020).

It is not our intent here to document every way that people and the ocean interact, for good or ill. Other papers in this series examine in detail how we might sustain and grow marine food production (Costello et al. 2019); how climate change has impacted the ocean and how humanity may respond (Gaines et al. 2019); how we might better deal with human rights violations and other criminal activities and inequities at sea (Widjaja et al. 2020; Österblom et al. 2020); how pollution threatens the ocean and how we might control it better (Jambeck et al. 2020); what opportunities exist to improve the financing and governance (Swilling et al. 2020; Winther et al. 2020) of the ocean economy, and so on. These issues and solution pathways all impact the plurality of people-ocean relationships and may undermine some and enhance others, in part depending on how they affect existing ocean-related economic inequalities (Österblom et al. 2020). Our point here is that the relational and subjective elements of people-ocean relationships have not yet been fully articulated in policy arenas and are therefore not yet fully considered in plans to respond to these ocean threats or to seize ocean economic and conservation opportunities.

Drawing on brief overviews of representative social and legal institutions that have developed in different maritime societies, we identify how different societies have governed oceanic spaces and volumes and how these governance mechanisms reflect the diversity of 'ocean values' held by different peoples. We use these overviews of the diversity of human relationships with the ocean, the examples of historically and culturally grounded sea tenure arrangements, and contemporary policy debates around the 'blue economy' (Voyer et al. 2018), 'blue justice' (Bennett et al. 2019) and 'blue degrowth' (Ertör and Hadjimichael 2020), to identify a series of opportunities for action to build a sustainable ocean economy and a future human relationship with the ocean that reflects the breadth and plurality of world views and values of current and future ocean citizens, and that acknowledges the diversity of social identities of the people for whom the ocean matters.

At the time of this writing, the world was reeling from the impacts of the COVID-19 pandemic, which, by 16 August 2020, had infected around 21.3 million people and resulted in 761,779 deaths (WHO 2020a). We felt it necessary to consider how relationships between people and the ocean may be affected by the public health measures taken to slow the spread of the virus and the economic and social consequences of both the disease itself and measures taken to contain it. Accordingly, we briefly consider what is known about impacts on the maritime economy and on human-ocean relationships.

It also cannot be overlooked that humanity is embarking on an ocean governance transformation at a time when action on climate change is critical. The ocean offers many opportunities to reduce greenhouse gas emissions and increase carbon capture and storage (Hoegh-Guldberg et al. 2019). Ocean-related climate change impacts are likely to exacerbate existing inequalities within coastal communities, with vulnerable populations being those living in low-lying areas of the tropics, on small oceanic islands and in the Arctic, as well as those whose livelihoods are tied to fisheries affected by global environmental change (Adger et al. 2005; Barbier 2015). Most sectors of the ocean economy will be negatively impacted by climate change, and tele-connected climate and economic processes mean that oceanic changes also have impacts inland (Allison and Bassett 2015). Investments in building adaptive capacity in ways that respond to different peoples' values will be required, and these should be kept in mind when considering how the human relationship with the ocean is understood, assessed and governed.

2.1 Conceptual Development

This paper draws on multiple disciplines, theories and conceptual frameworks, reflecting the wide scope of the paper's subject and the wide range of the authors' disciplinary backgrounds. Grounded largely in human, cultural and economic geography, economic history, economic and legal anthropology and political ecology, the paper also includes contributions from critical literary studies, rural sociology, psychology, Indigenous studies and development studies, as well as fisheries science and conservation biology.

The way the ocean is being studied and thought about is changing, with a 'new thalassology'[1] emergent that draws on cross-cultural world histories to examine ocean basins from a human historical perspective (e.g. Paine 2013). This has particularly enriched the study of the Mediterranean and Indian Ocean regions (Horden and Purcell 2006; Vink 2007). Earlier foundational work on oceanic trade, from the perspective of historical economic anthropology, concerns itself with studies of mercantilism and colonisation and its continuing societal impacts (Curtin 1984). This scholarship is expanding into a more socially differentiated research agenda, teaching us more about how gender, class, ethnicity, race and colonial history—and their intersections—have shaped the experiences and either constrained or enhanced the possibilities of different people's encounters with the ocean (e.g. Amrith 2013; Catterall and Campbell 2012; McKay 2007).

The recent 'blue turn' in human and cultural geography (Peters and Anderson 2016) has brought the analysis of human-nature spatial relations into the oceanic realm, informing the emergent interest in marine spatial planning (Fairbanks et al. 2019) but also explaining why the realities of ocean space—its fluidity, its fourth dimension (volume) and the challenges in identifying fixed boundaries—are important determinants of our maritime imaginings and our practical ability to govern the ocean (Steinberg and Peters 2015). The arts and humanities have gone blue, too, with an immersion into how the ocean has shaped our history, science, languages, aesthetics and sensibilities (Mentz 2009; Guo-jun 2013; Mack 2013; Alaimo 2019). More broadly, recent influential dialogues in the humanities and social sciences have also disrupted binary distinctions between the categories of nature and culture, generating new possibilities for living in the 'Anthropocene' (Tsing et al. 2017).

We also note a flourishing of scholarship on and policy attention to the question of Indigeneity and Indigenous knowledges in what heralds an 'indigenous resurgence' (Alfred 2009; Corntassel 2012). Some of this analysis and activism for 'decolonisation' is focused on the interactions of Indigenous and colonised peoples with the ocean (e.g. Hauʻofa 1994; von der Porten et al. 2019). Parallel to this we see a growing interest in the legal pluralism that affects coastal and oceanic regions (Bavinck and Gupta 2014).

We see an opportunity to bring all this vigorous and exciting intellectual and political endeavour to bear in discussing the economic development and governance of the future ocean in high-level and intergovernmental and governmental forums.

Drawing on a range of disciplines beyond economics to address the issue of ocean futures highlights a range of values beyond monetary or market ones. It allows the exploration of human relationships with the ocean in terms of what people value about it and their societies' interactions with it, and what motivates their actions with respect to future ocean governance. This shift from thinking about (economic) value to thinking about human values more broadly is in part informed by cross-cultural studies in psychology (e.g. Schwartz 2012) which examine individuals' motivations to act in ways that either oppose or embrace change, satisfy their own needs or the needs of others and of nature. These ideas have had few direct applications in ocean decision-making to date (e.g. Slimak and Dietz 2006; Bidwell 2017) but are likely to become more important as public attention turns towards the ocean and concepts such as the 'social license to operate' (Voyer and van Leeuwen 2019) inform decision-making on what kind of oceanic economic activities different societies will support or oppose.

This shift in thinking also responds to calls from the Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services (IPBES) to develop further the concept of 'ecosystem services' so that plural world views, values and knowledges can be better recognised in assessments

[1] Before the ocean sciences became known as 'oceanography' (derived from Latin) they were sometimes referred to as thalassology (derived from Ancient Greek). This older term has been revived by scholars in the arts and humanities.

of nature's contributions to people (and indeed people's contributions to non-human nature), alongside scientific and economic assessments (Fig. 11.1a–c; Pascual et al. 2017).

Here we adopt a pluralistic valuation approach (Fig. 11.1a), drawing on multiple world views, knowledges and values. Our focus is on anthropocentric values, as we are concerned with the human relationship with the ocean, rather than intrinsic values (Fig. 11.1b). We include instrumental values (see Sect. 11.3.2, Table 11.1), but our focus is on relational and subjective values (Fig. 11.1b, orange shading), which we further unpack using a social well-being framework (see Sect. 11.2.2). Our purpose is to raise awareness of the diversity, range and nature of the ocean's contributions to people (Fig. 11.1c, step 1). Our analysis highlights differing world views and types of value (Fig. 11.1c, step 2), we draw on a range of disciplines, methods and knowledge systems and we highlight and discuss (but do not fully assess) key potential trade-offs among types of values and power relations among holders of values (Fig. 11.1c, step 3). We begin the process of integrating and bridging Indigenous and local knowledge, the arts, humanities, social sciences, policy and management sciences and natural sciences (Fig. 11.1c, step 4) to communicate the range and nature of ocean values that contribute to human well-being in all its dimensions

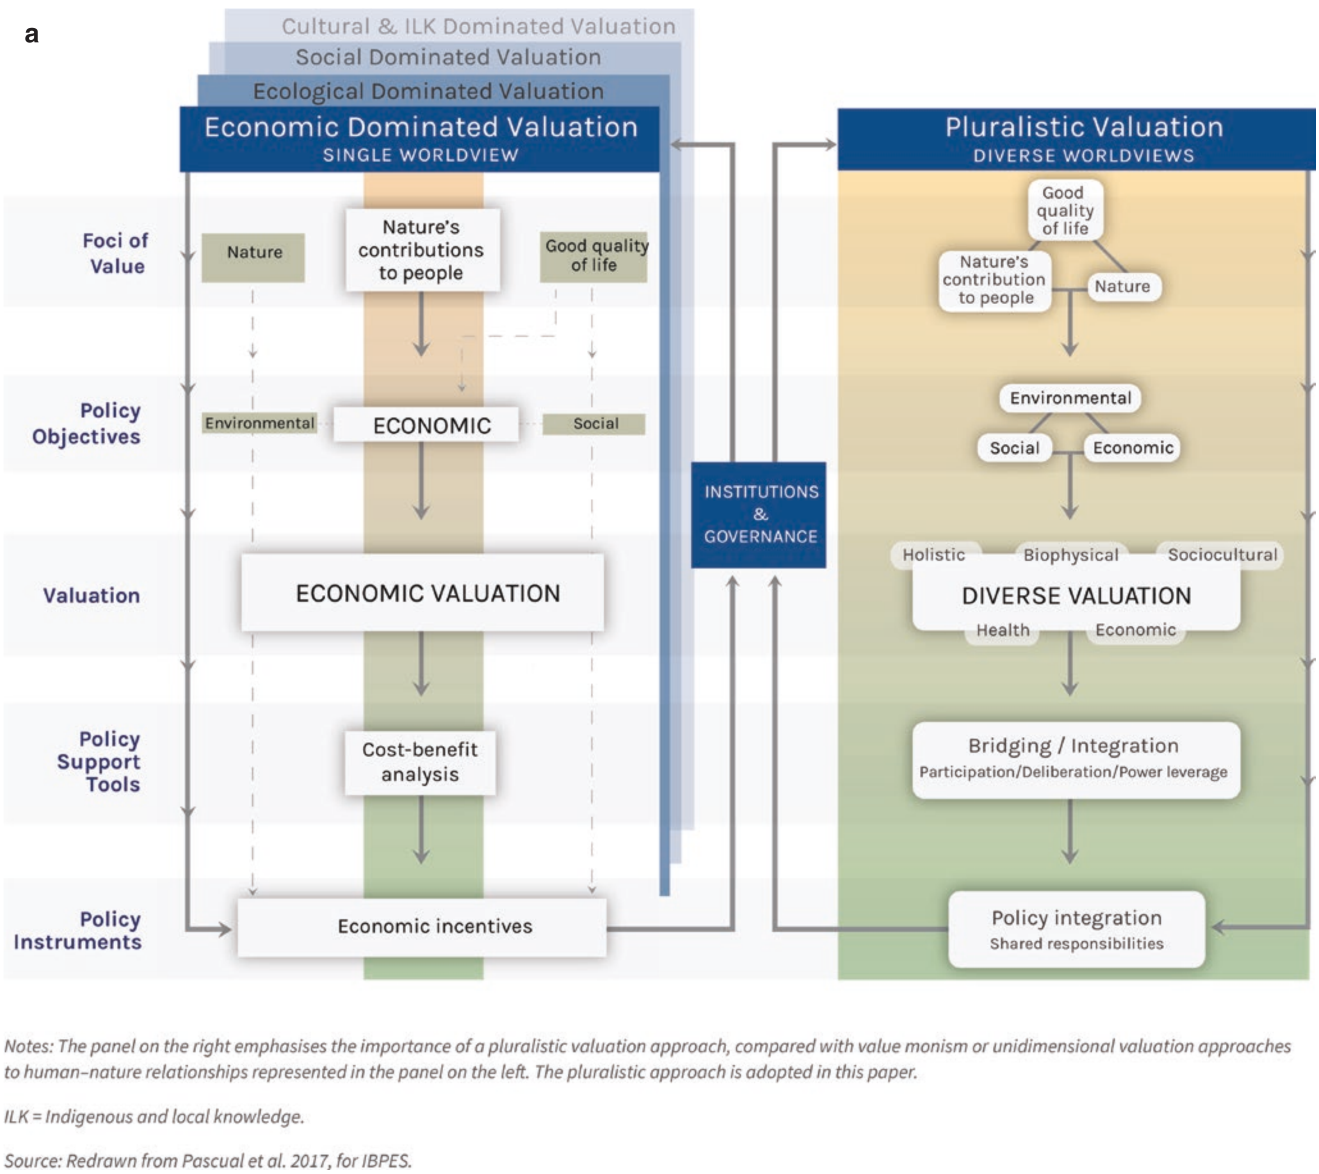

Fig. 11.1 (**a**) Contrasting approaches to the process of valuation. (**b**) Diverse values related to nature, nature's contributions to people and a good quality of life. (**c**) The IPBES approach for assessing values and conducting valuation

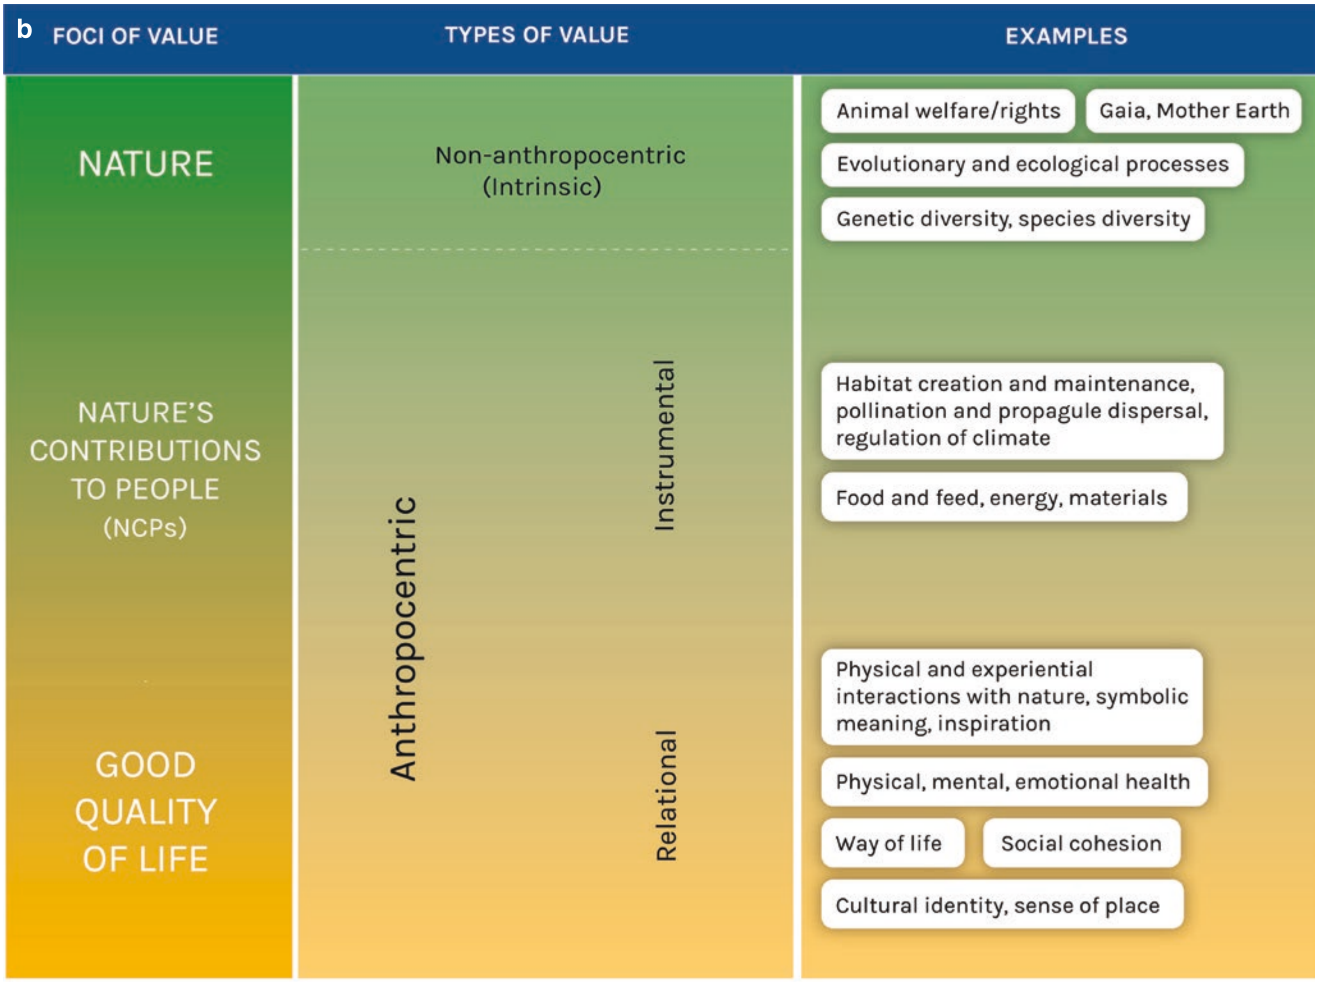

Note: The grading in the colours indicates that both instrumental and relational values can be ascribed to the value of NCPs, and to highlight that NCPs are intertwined with nature and a good quality of life. In this paper, we emphasise the anthropocentric relational values.

Fig. 11.1 (continued)

Table 11.1 Ocean contributes to material dimensions of well-being

Contribution to human well-being	Mechanism or rationale	Examples of contributions
Food	Seafood is rich in essential micro-nutrients and a key component of the human diet, particularly for coastal and island societies. Healthy diets reduce risks of non-communicable diseases such as cancer, diabetes and poor heart health (Golden et al. 2016; Hicks et al. 2019).	Calls for a global transition to sustainable food systems include increasing seafood consumption and decreasing that of land- based meats. The ocean offers great potential for improved food productivity, particularly from aquaculture of low tropic-level species such as bivalve shellfish (Costello et al. 2019).
Water	Freshwater supplies are becoming limited in some parts of the world as groundwater is depleted and surface water intensively used or contaminated. Large-scale desalinisation is a potential solution.	Large-scale desalinisation provides an increasing contribution to freshwater needs of coastal and small island states in dry areas: 48% of the world's 95 million m^3 daily production for human use is in the Middle East and North Africa region. The large volume of brine produced as a result is an environmental concern (Jones et al. 2019).

Table 11.1 (continued)

Contribution to human well-being	Mechanism or rationale	Examples of contributions
Energy	Clean sustainable energy sources are needed to decarbonise the economy and, more generally, to help decouple economic growth from increasing demand for environmental goods and services (Sachs et al. 2019). The ocean provides a range of opportunities for generating energy from clean and renewable sources.	Wind energy has traditionally been used for voyaging at sea but is now increasingly used to generate electricity for land-based human activities through offshore wind farms (Esteban and Leary 2012). Where land for solar panels is limited, ocean-based solar power is an option (Sahu et al. 2016), and there is increasing interest in using tidal, current and wave energy (Khan et al. 2017; Weiss et al. 2018). Sub-sea fossil-fuel reserves provide about a third of the world's current oil and gas and remain a target for exploration and exploitation, with 42% of the estimated undiscovered oil and gas reserves being offshore (Narula 2019). Macroalgae are potential sources of marine bioenergy (Ghadiryanfar et al. 2016).
Materials and minerals	Human societies use a wide range of non-food materials to sustain and improve quality of life and for building homes and infrastructure. Minerals are used in a wide range of industries and commodities. These include rare earth minerals needed for a transition to a renewable energy economy (Takaya et al. 2018). The ocean is seen as an underutilised source of raw materials for contemporary societies.	The ocean's calcified organisms, such as corals and molluscs, have long been a source of building materials; lime and 'coral rag' have been used to construct Mayan and Swahili cities, for example (Russell and Dahlin 2007; Fleisher et al. 2015), and are still in use today in places such as East Africa (Dulvy et al. 1995) and Indonesia (Caras and Pasternak 2009). Deep-sea mining for rare earth minerals receives a lot of policy attention (Carver et al. 2020), but much more significant, in both economic and environmental terms at present, is coastal and shelf-sea gravel extraction to meet the construction demands of rapidly urbanising and industrialising nations that are investing heavily in infrastructure development (Peduzzi 2014).
Transportation of people and goods	The ocean provides a key means of transporting goods and people. Trade and human mobility are seen as necessary to sustain our current economic system—one that has lifted billions of people out of poverty, despite its shortcomings in addressing inequality. Containerisation of goods has greatly reduced the cost and improved the reliability of sea transport (Notteboom and Rodrigue 2008).	Maritime transport enabled the generation and accumulation of capital through state-sponsored trading firms like the British and Dutch East India Companies. Mercantilism provided one of the foundations of modern economies but also began the process of resource exploitation and colonisation (Wallerstein 2011). The sea has enabled the conversion of natural resources to wealth by bringing labour to exploit the resources: the migrations of Europeans to settler colonies in the Americas, Oceania and South Africa, and the involuntary migrations of enslaved Africans, are the best-known (Gillis 2012), but there are others: between 1840 and 1940, 25 million Indians migrated to Ceylon (Sri Lanka), Malaya and Burma, with others moving to Indonesia and Indochina (Amrith 2013, 62).
Income, business profits and resource rents	Shipping and fishing have long been contributors to generating wealth and jobs and supporting livelihoods in coastal and island economies. Licenses and taxes of these maritime activities have helped finance governments. The blue economy embodies a set of principles to guide the next phase of maritime economic development for human well-being.	Income, livelihoods, profits and resource rents (access and license fees, tax revenues) are generated by jobs and investments in established maritime industries such as fishing, shipping, oil and gas extraction, military and security forces, coastal and marine tourism, as well as emergent ones such as offshore renewable energy, mariculture, deep-sea mining and bioprospecting.
Physical health	A healthy population is the basis for a productive workforce and economy. The ocean contributes to health through three main pathways: (1) as source of healthy food (see above); (2) as a source of pharmaceutical compounds for the prevention and treatment of disease; and (3) as an arena to enjoy outdoor physical activity.	The ocean has provided anti-cancer drugs and other medically useful biocompounds that contribute to human health. Coordinated plans for bioprospecting and pharmaceuticals development are underway in India (Malve 2016) and Europe (PharmSea, a program discussed in Jaspars et al. 2016). People's interactions with a healthy ocean—as tourists, recreationalists, retirees and incomers to coastal communities—have measurable benefits to their health, with the seaside sometimes referred to as a 'therapeutic landscape' (Finlay et al. 2015) or a 'blue gym' (Depledge and Bird 2009).
A physical and biological environment conducive to human flourishing	Coastal ecosystems provide services to humanity which are not easily included in monetary- based decisions, such as coastal stabilisation, regulation of coastal water quality, biodiversity conservation, spawning habitats, carbon sinks, dilution of pollution and buffering of changes in biogeochemical cycles (Baker et al. 2019).	A healthy ocean is critical to stabilising the global climate. Ocean-based mitigation options could reduce global greenhouse gas emissions by nearly 4 billion tonnes of CO_2 equivalents per year in 2030 and by more than 11 billion tonnes per year in 2050, relative to projected business-as-usual emissions. The five main options for doing so are in ocean-based renewable energy, ocean-based transport, coastal and marine ecosystems, shifting human diets towards food from the ocean while improving fisheries and aquaculture, and carbon storage in the seabed (Hoegh-Guldberg et al. 2019).

(Fig. 11.1c, step 5). We recognise that much work remains to be done on enumerating and identifying these values and their ranges in specific local, national and regional contexts.

2.2 Methodology

We use a social well-being framework (Fig. 11.2) to weave together the multiple strands of inter- and trans-disciplinary scholarship outlined in Sect. 11.3.1. A key point of origin for the concept of well-being in an economic development context lies in the work of Amartya Sen. Well-being represents a broadening of welfare economics and a further development of Sen's 'capabilities approach' (Sen and Nussbaum 1993). The material dimensions of well-being (adequate food, health, shelter, income) have been the focus of much economic policy, but it is now well known from work on the 'economics of happiness' that material wealth alone does not deliver improvements in human well-being once basic material needs are satisfied (Kahneman and Krueger 2006; Kahneman et al. 2006). This implies a need to consider how to avoid an overly narrow focus on the generation of material wealth from the ocean and thereby risking trading off ocean contributions to the other dimensions of well-being in societies.

A sense of belonging, having social status, good social relations and a sense of personal fulfilment are key contributors to human well-being. To elucidate the concepts, the framework we have chosen here is the three-dimensional social well-being framework widely applied in the field of international development (e.g. White 2010) and in the study of small-scale fisheries (e.g. Weeratunge et al. 2014; Johnson et al. 2018). It has mostly been applied at the individual, household and community level, while here we extend the concepts to include higher levels of political, social and economic organisation (Fig. 11.2). In doing so, we build on the Millennium Ecosystem Assessment (MEA) and its coupling of 'ecosystem services' with 'human well-being' (Leemans and de Groot 2003).

The ecosystem services concept acknowledges and values non-monetary human uses of nature, including 'cultural ecosystem services'. We extend the MEA's conceptualisation of human well-being by further unpacking its multiple dimensions. Responding to perspectives from Indigenous Peoples, we also adopt the Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services (IPBES) language of

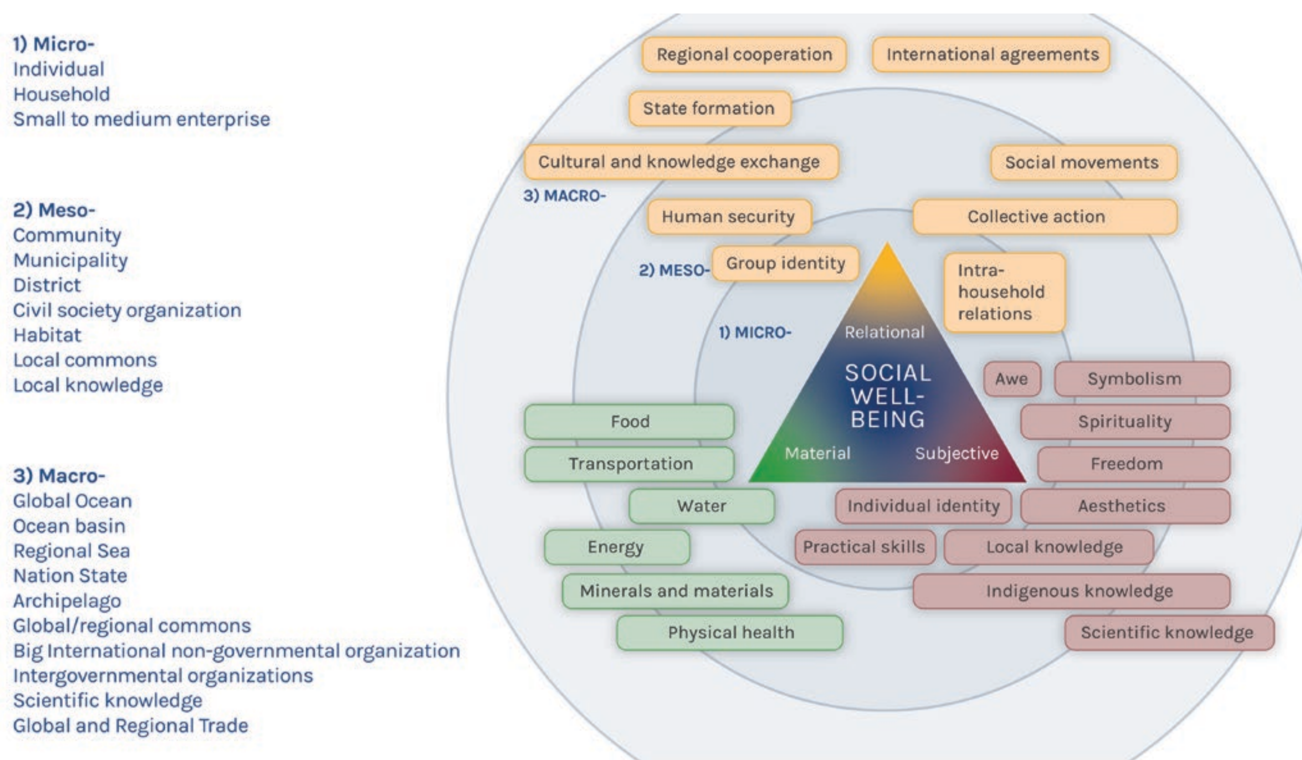

Fig. 11.2 Framework to identify human relationships with the ocean. *Note: Scales at which these relationships take place range from the micro (individual, community, local place or small enterprise) to the macro (nation, citizenry, region, ocean basin or whole ocean, large domestic or multinational firm). Source: Modified from Weeratunge et al.* (2014)

'nature's contribution to people' (Díaz et al. 2018) to reinforce the shift towards considering multiple value systems in human-relationships on an equal footing, rather than using economic values as the benchmark against which to compare all others (see Fig. 11.1 and Sect. 11.2.1). The intent here is not to replace economic valuation and ocean accounting as tools for ocean governance but to draw attention to other values, so that they may, in the future, also be fully accounted for. We therefore refer to a plurality of 'values' but we make no attempt to convert them to a universal monetary equivalent value.

The High Level Panel for a Sustainable Ocean Economy acknowledges that no one-size-fits-all solution is appropriate for the ocean. A similar case for a diversity of solutions to fisheries governance problems has also been made (Young et al. 2018). People with an interest in the ocean include those in traditional maritime occupations such as merchant seamen and fisherfolk, workers in newer offshore economies such as the energy sector, coastal Indigenous Peoples, seaside residents and tourists, the cosmopolitan populations of port cities, and seafood consumers everywhere. A common vision for the relationship between humanity and the ocean must be broad enough to accommodate this diversity of interests. It must also be democratic enough to include the interests of those who have little influence on global economic systems, state and intergovernmental policies or global ocean science. This paper brings some of those voices to the surface.

After considering the variety of relationships humanity has with the ocean from a well-being perspective (Sect. 11.3), we identify some examples from the huge variety of existing, remnant or (re)nascent regional and local governing systems (Sect. 11.4) that have evolved in response to this diversity of ocean values. We then turn to how a more beneficial and sustainable human relationship with the ocean can be pursued by building on these values and institutions, to develop a global commitment to a sustainable ocean economy and future (Sect. 11.5).

3 Human Relationships with the Ocean and Their Contributions to Well-being

3.1 The Ocean Economy and Its Acceleration

The 'blue economy'—a term that has emerged in the past decade—attempts to embrace the opportunities associated with the ocean, whilst recognising, accounting for and addressing the threats posed by such an economy. It is essentially the ocean equivalent of the 'green economy'—a vision for a decarbonised, regenerative and more equitable economic system.

The 'blue economy' gained prominence at the 2012 UN Convention on Sustainable Development (UNCSD), or Rio+20 conference, when small island developing states began emphasising the importance of the ocean and marine economy in response to land-focused calls for a 'green economy' (Silver et al. 2015; Dornan et al. 2018). Since then use of the term has become increasingly common (Mulazzani and Malorgio 2017), although the narratives surrounding the blue economy diverge considerably across different actors (Voyer et al. 2018). Strategies for implementing the blue economy vary enormously across jurisdictions and organisations.

Despite this, they commonly focus on encouraging private sector development of the ocean using innovation and investment strategies, supported by macro-level calculations and projections of the current and future 'worth' of maritime industries to global markets (Hadjimichael 2018).

It is clear that the ocean is entering a new phase of large-scale industrialisation (Box 11.1). This creates challenges for ocean governance in how to manage the increasingly private use of what has traditionally been considered a common pool resource (Arbo et al. 2018; Hadjimichael 2018). A key question for the blue economy is how to manage this acceleration without also accelerating unintended societal costs (Arbo et al. 2018; Kooiman et al. 2005; Jentoft et al. 2010; Alongi et al. 2015). This requires active consideration of questions of power and marginalisation, agency and values (Ratner 2004). Without adequate and integrated consideration of social and cultural objectives, the blue economy may become a tool for 'ocean grabbing' and marginalisation and dispossession of traditional cultural, recreational and small-scale commercial uses and users (Bennett et al. 2015; Hadjimichael 2018). Adopting a well-being perspective and emphasising the achievement of SDGs can help ensure that this does not happen.

The cumulative process of marginalisation can often be unintended, incremental and hidden. For example, as our coasts and shorelines are increasingly enclosed and developed for luxury residential and tourist uses, this 'coastal squeeze' (Cohen et al. 2019) reduces the operating space of those using the ocean and coastal commons. In particular, it marginalises small-scale fishers and lower-income recreational visitors to the coast, and confines them to less desirable, more polluted or industrialised and degraded sites. It thus risks reallocating the well-being benefits of the ocean—that common heritage of humankind—to the wealthy.

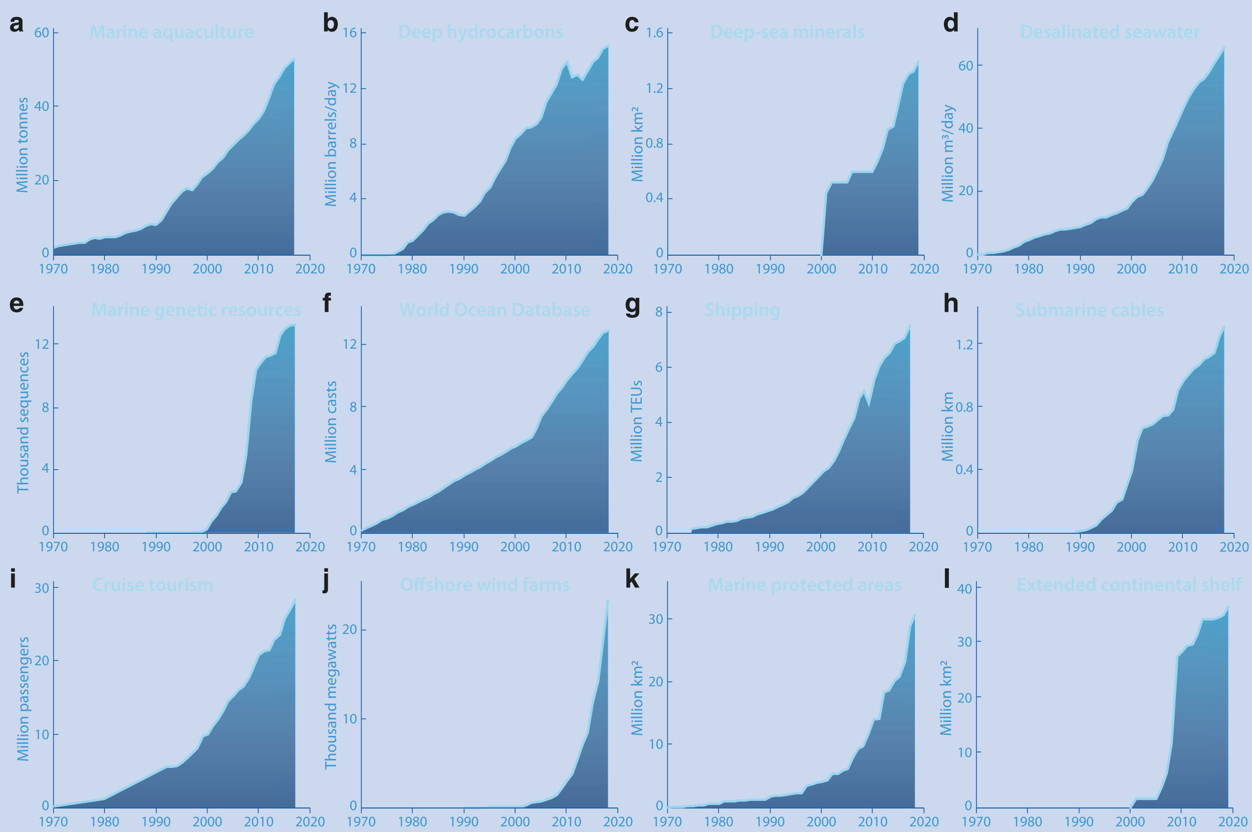
Whether we use the terms *blue economy*, *blue growth* or *sustainable ocean economy*, there is an urgent need to focus on equity—both currently and intergenerationally—as a crucial component of ocean development (Cisneros-Montemayor et al. 2019; Österblom et al. 2020). Mainstreaming and foregrounding equity within sustainability narratives will require active consideration of alternative and diverse visions for the future ocean economy. Some of these 'counter-narratives' are already being articulated and include steady-state economics (Daly 1991) and de-growth (Kallis 2011; Ertör and Hadjimichael 2020). These merit critical consideration alongside promising but less radical alternatives for future environmental sustainability, such as the circular economy, which calls for ‘a new relationship with our goods and materials’, emphasising a shift away from disposability and planned obsolescence towards durability and reuse (Stahel 2016). Other alternative visions, such as Indigenous ocean economies, likely exist, but uncovering and understanding them may require work with a diverse array of stakeholders.

Here we aim to ensure that any blue economy or future ocean economy vision considers the objectives of the ocean economy in social terms. An economy ultimately exists to support people’s needs and aspirations.

People’s needs and aspirations are more than monetary, so it follows that the economy should be built upon broader values too. Here we suggest that economic policy consider social well-being as a way to identify and categorise human relationships with the sea.

Box 11.1 ‘Blue Acceleration’: The Urbanisation and Industrialisation of the Ocean

In the last 50 years, there has been rapid growth in new ocean industries such as mariculture, deep ocean drilling for hydrocarbons and minerals, desalinisation and offshore wind farms. Existing maritime communications, transport and tourism industries have expanded rapidly, as have the territorial claims and information needs around the ocean. Together, these have been described as a ‘blue acceleration’ (Jouffray et al. 2020). The impacts of this economic growth on ocean-dependent people and economies have not yet been assessed.



Note: Global trends in (a) marine aquaculture production; (b) deep offshore hydrocarbon production, including gas, crude oil and natural gas liquids below 125 m; (c) total area of seabed under mining contract in areas beyond national jurisdiction; (d) cumulative contracted seawater desalination capacity; (e) accumulated number of marine genetic sequences associated with a patent with international protection; (f) accumulated number of casts added to the World Ocean Database; (g) container port traffic measured in 20-foot equivalent units (TEUs); (h) total length of submarine fibre-optic cables; (i) number of cruise passengers; (j) cumulative offshore wind energy capacity installed; (k) total marine area protected; and (l) total area of claimed extended continental shelf.

3.2 Social Well-being and How the Ocean Contributes to It

Economic activity in the ocean is growing rapidly (Box 11.1). If the upsurge in economic activity is to lead to an upsurge in human well-being, then its emergent and potential future impacts must be understood. In order to build that understanding, we must first 'unpack' the concept of well-being and identify the ways the ocean contributes to well-being in all its dimensions. It is these 'human relationships with the ocean' that we seek to characterise, drawing on the framework introduced in Sect. 11.2.2.

Ocean values and their contributions to human well-being at multiple levels are outlined in Tables 11.1–11.3, with the material (Table 11.1), relational (Table 11.2) and subjective (Table 11.3) dimensions outlined. These tables provide explanation and examples of the concepts outlined in the methodology (Fig. 11.2). Although we include an outline of ocean contributions to material well-being (Table 11.1), the focus of this paper is on the ocean's contribution to relational and subjective dimensions of well-being (Tables 11.2 and 11.3). Other Blue Papers focus mostly on the material dimensions of well-being when they connect to human values. However, human well-being is only achieved if attention is

Table 11.2 Ocean contribution to relational dimensions of well-being

Contribution to human well-being	Mechanism or rationale	Examples
Cultural and knowledge-exchange	The ocean has played a key role in sustaining the flow of knowledge and social and cultural exchange among societies and countries. Sea-voyaging, exploration and coastal trade and population interchange have provided key pathways for such exchanges. Before the rapid growth of air travel and the internet in the late twentieth century, ships were the most important tool of globalisation (Frykman et al. 2013). Port cities, receiving and sending ships to different destinations, were and are sites of cosmopolitanism and multi- or polyculturalism, of coastal and maritime trading societies that have been and could once again be a foundation for efforts at improved labour force diversity and inclusion, regional and global cooperation, the building of a shared ocean vision and a reinvigorated multilateralism.	Coastal trade gave rise to distinctive seaboard civilisations in the Red Sea, Arabian Sea and Bay of Bengal. These societies began to connect, some 5000 to 3000 years ago, when traders learned to use the monsoon to trade across the ocean rather than along coasts (Gillis 2012). These movements of people created relationships and exchanges of ideas and languages as well as goods and services. Religions spread along coasts more readily than between inland civilisations, and local and universal religions blended to create distinct cultures like the Swahili of coastal East Africa (Fleisher et al. 2015). Mediterranean port cities have frequently been described as 'cosmopolitan', with their merchants and populations being diverse, tolerant, multilingual and outward-looking, in contrast to land-based elites in the nation-states in which they were located. While such generalisations bear closer critical scrutiny, cities such as Izmir, Alexandria and Trieste flourished, to some degree, as centres of cultural and intellectual as well as material exchange—functions that port cities may still play, despite increasing physical separation of ports from downtown cities, under containerisation (Driessen 2002).
International agreements	Because of the fluid and interconnected nature of the ocean, and because areas beyond natural jurisdiction are both the 'common goods of humanity' and the 'collective responsibility of humanity', the ocean has played a prominent role in building the system of international law—particularly environmental law—needed to sustain humanity in the long term	Small island developing states have led advocacy for strong climate action, notably through the Alliance of Small Island States (AOSIS), and were a key group in negotiations leading up to the Paris Agreement on Climate Change. Despite their heterogeneity, they built a common diplomatic discourse and strategy for influencing policy, enabling them to mobilise political leaders, negotiators and advisers (Ourbak and Magnan 2018).
Regional cooperation	While there is 'one ocean', there are four ocean basins (Atlantic, Arctic, Indian, Pacific) and many seas. Regardless of the extent of globalisation, there are long-standing and continuing relationships between countries sharing an ocean basin or a semi-enclosed sea. Sharing these resources can help maintain regional political and economic stability, which contributes to well-being of populations around regional seas and ocean rims	The European Union binds together in economic and political union a region housing historically warring nation-states. By extending its collaborative governance arrangements into its shared seas, regional cooperation is further reinforced. The European Union has a legally binding framework, supported by EU financing and technical capacity, for establishing maritime spatial plans in the exclusive economic zones of its member states by 2021 (Friess and Grémaud-Colombier 2019). This provides the basis for creating lasting mechanisms for cross-border cooperation.

(continued)

Table 11.2 (continued)

Contribution to human well-being	Mechanism or rationale	Examples
State formation	The ocean has played an important role in the formation of modern states, with the extension of maritime territory into exclusive economic zones (EEZs), providing the basis for future national projects in the blue economy, future prosperity and therefore future well-being.	The sea has been particularly important to countries labelled as 'small island developing states'. The law of the sea has enabled them to claim large EEZs, which, together with their historical connections to the ocean, has encouraged them to position themselves in ocean policy dialogues as 'large ocean states' (e.g. Chan 2018). This relational repositioning has enabled oceanic island nations to shift from an emphasis on their vulnerability and small size to highlighting their stake in—and sovereignty over—30% of the ocean, thereby positioning them more strongly in ocean economy and governance policymaking.
Human security	Ocean peoples have long shared many social norms, many of which are now codified in modern law. These maritime codes of conduct were designed to improve safety and well-being at sea and facilitate travel and commerce. Global norms around neutrality, calling truces and the practice of rendering assistance to those in distress all have maritime origins and provide important contributions to human security and to our frameworks for moral conduct more generally.	The sea has been particularly important to countries labelled as 'small island developing states'. The law of the sea has enabled them to claim large EEZs, which, together with their historical connections to the ocean, has encouraged them to position themselves in ocean policy dialogues as 'large ocean states' (e.g. Chan 2018). This relational repositioning has enabled oceanic island nations to shift from an emphasis on their vulnerability and small size to highlighting their stake in—and sovereignty over—30% of the ocean, thereby positioning them more strongly in ocean economy and governance policymaking. The early twentieth-century Hague Conventions on Neutrality are based on the rules set out in the Consolato del Mare of 1494, which in turn is partly based on ancient Greek (Rhodian) sea law (Bauslaugh 1991, xiii). The dangers and solitudes of sea voyages in the ancient world led to a set of unwritten codes of maritime conduct, including those regarding the 'sacred duty of hospitality' included in Hugo Grotius's Mare Liberum. This, in turn, forms the basis for the 1979 Convention on Maritime Search and Rescue and the 1974 International Convention for the Safety of Life at Sea. There is much concern that these principles are being eroded with the rise of human trafficking, with coastal states failing in the legal duty to assist migrants and others lost at sea, and in their obligations to disembark rescued persons in a place of safety (e.g. Aalberts and Gammeltoft-Hansen 2014). These dialogues point to the continuing importance of maritime social norms in shaping the moral basis for governing human affairs.
Social movements	Shared experience of the ocean can help to build solidarity among boat crews, among port cities and between maritime nations that give rise to 'social movements'. Such social movements—and their protests—are a primary means by which social justice has been achieved historically. The equity dimension of the blue economy can be fulfilled by working together to overthrow tyranny; or to create safe working conditions, fair wages and equitable access to the benefits of the sustainable ocean economy, and to exert influence on democratic governance. Social movements may coalesce into representative organisations, such as the International Transport Workers Federation, the World Forum of Fisherpeople and the World Forum of Fishworkers. The Missions to Seamen, which provides spiritual, pastoral and practical care for seafarers, has become particularly important to crews stranded on ships amid the COVID-19 pandemic (Rynd 2020).	A series of connections, formed over centuries of trade among seafaring peoples of the Americas, Europe and Africa, led to loose coalitions of fugitives from state violence and exploitative work. These maritime societies, and the experiences embodied in their stories, existed over 'vast spaces and spans of time' (Linebaugh and Rediker 2000) and were characterised by their mobility and multi-ethnicity—giving rise to the expression 'a motley crew'. They nurtured an Atlantic 'maritime radicalism' characterised by collectivism, anti-authoritarianism and egalitarianism, that connected revolutionary impulses in the United States, France and Haiti (Frykman et al. 2013). These values and the transnational coalitions that spread them are models for today's globalised anti-racist and anti-capitalist protests. Social movements have long begun in seaports, including the Solidarity movement that eventually led to the election of one of its leaders, Lech Walesa, as Polish president. It began among workers in the Gdańsk shipyard in 1980 and, in 1989, succeeded in ending Soviet communism in Poland (Garton Ash 2002).

Table 11.2 (continued)

Contribution to human well-being	Mechanism or rationale	Examples
Group identity and 'belongingness'	Identifying with a nation, ethnic group, community or locality ('belongingness') is associated with well-being (Helne and Hirvilammi 2015). Some societies and cultures identify strongly with the ocean as their 'place' and with fellow ocean users as their people; the well-being of these maritime societies and sea people depends on their access to a healthy ocean, a maritime lifestyle and to relationships with each other.	Many of the Solomoni of Fiji are descended from nineteenth-century indentured labourers. They have acquired and negotiated their sense of belonging through active engagement with their oral history (tukuni), particularly around the notion of tauvu ('springing from the same ancestor') with taukei (Native/Indigenous Fijian). This has helped to break down group stereotypes, overcome initial disadvantage and enable coexistence and intermarriage (Mateiviti-Tulavu 2013). The construction of shared Pacific Islander identity continues at larger scales as the region faces common threats, such as climate change, and as Islanders meet in regional forums and diaspora populations extend across the world—particularly in Australia, New Zealand and the United States. A shared history with the ocean forges an evolving trans-Pacific identity (Hauʻofa 1994).
Cooperation and collective action	Because the ocean is largely governed as a commons, most ocean users cooperate to share access to ocean resources and spaces, and to reduce conflict. This is particularly the case with fishing communities. Building good relationships within and between communities contributes to well-being.	Many coastal fishing societies around the world have at some time developed cooperative ways to manage the marine resources upon which they depend. These social institutions do more than regulate access to resources; they provide the basis for harmonious community life; they perpetuate culture and they provide social security through risk-sharing and asset-sharing mechanisms (Ruddle 1988; McGoodwin 2001). Some of these traditional institutions have been eroded by the switch to state-based fisheries management, but there is revival of traditional management blended with formal government in a range of 'co-management' arrangements, including locally managed marine areas networks in the Pacific (Techera et al. 2009) and territorial use rights for shellfish in Chile (Fernández et al. 2011). Further examples of traditional institutions for marine resource management are given in Sect. 11.4 of this paper.
Intra-household and intra-community relations	In many contemporary cultures, beaches and the seaside have strong associations with family holidays and childhood memories (Marschall 2015), with romance and with togetherness in old age (Huntsman 2001). Within fishing communities, boats crews often have strong kinship and friendship ties. These are all forms of 'social capital' that contribute to relational well-being at more intimate levels, as well as ensuring the intergenerational exchange of knowledge and skills in maritime households.	Australians make or break romances at the beach, they marry and take honeymoons at the beach, they go on holiday with their children at the beach, and in vast numbers retire by the sea. —Robert Drewe, quoted in Huntsman (2001, 2) In the artisanal fishing community of Lobitos, Peru, 'fishermen spend a great deal of time socializing with each other at the harbor, during communal celebrations and activities, on boats and at the usual meeting places, talking about the state of the sea and fishing activity', but they only share fishing secrets among kin. The boats are often crewed by kin: the most common crew combinations are groups of brothers (30.6%) and parents and children (26.5%). Fishing tasks are taught and learned through these family and community relations, with children involved from their pre-teens (Maya-Jariego et al. 2017).

paid to all three dimensions. Different individuals and cultures ascribe different levels of priority to these values, but no society discounts them entirely.

Subjective well-being has entered national economic policy as measures of economic and social performance (Stiglitz et al. 2018), also popularly known as the 'economics of happiness' (Easterlin 2001; Clark 2018).

The material, relational and subjective dimensions of well-being are, however, interconnected or 'co-constitutive' (White 2017), and, like all such classifications, the boundaries between categories are porous. For example, seafood provides for material needs for nutrients, protein, energy, income and profit, particularly in maritime South and Southeast Asia, coastal West Africa and the Pacific islands. But it also contributes to relational and subjective well-being through association with religious observance (e.g. fish at Easter in Catholic societies in South America), status (e.g. seafood banquets in Chinese culture) and feelings of connection to place (e.g. the importance of wild salmon to both Native/First Nation and settler coastal populations in the U.S. and Canadian Pacific Northwest). Note also that most well-being classifications are made at a single scale (e.g. the

Table 11.3 Ocean contributions to subjective dimensions of well-being

Contribution to human well-being	Mechanisms or rationale	Examples
Scientific and scholarly knowledge	The scientific exploration of the ocean has provided the foundations to secure a sustainable and prosperous future for the ocean economy. It allowed the exploration of the ocean in search of the materials that support contemporary human societies. Ocean science has also identified the nature and scale of threats to human well- being posed by ocean ecosystem degradation and has illuminated a number of solution pathways in the form of conservation measures, pollution control and abatement technologies. While ocean sciences provide indirect support to the realisation of relational and subjective well-being, they are not primarily suited for this purpose; additional scholarly disciplines, such as the ones we draw on in this paper, are also required to identify ways to support ocean values and their contributions to well-being. Conceiving of the ocean as a peopled space has been an important first step towards attracting the social sciences and humanities to study the ocean (Steinberg 2001) and how it might be better governed to support human well-being.	Scientific knowledge of the ocean has helped find ways to support sustainable fisheries (Hilborn and Hilborn 2019), ocean-based climate change mitigation solutions (Hoegh-Guldberg et al. 2019), countering pollution threats and conserving biodiversity (Knowlton 2020). Science underpins the search for ways to ensure that material well- being is sustained. Beyond the ocean (natural) sciences, the social sciences, arts, humanities and professional disciplines (e.g. law, finance, management and policy studies) can provide insight into how to support all three dimensions of ocean- related human well-being. Inter- and trans-disciplinary research facilitates knowledge integration and the provision of useful policy advice (Claudet et al. 2020).
Phronetic (practical) wisdom and skills	Knowing how to row a boat, fix an engine, cross the surf or spear a fish are among the many practical skills that imbue a sense of pride in maritime occupations. Skills and practical sea knowledge are useful for sustaining material well-being from the ocean, for gaining admission to maritime society by earning the respect and recognition of other mariners, and as a source of personal pride and of belonging to the ocean. These apply whether you are a navigator, fisher, diver, surfer or marine biologist.	In the highly gendered world of commercial fishing, women in Alaska's Bristol Bay salmon fishery take pride in their seagoing and fishing skills as well as their role in safeguarding and deepening traditional knowledge in their fishing communities. They have earned the right, in their view, to be called 'fishermen' (Lavoie et al. 2019).
Freedom and adventure	A sense of freedom and a sense of adventure both contribute to autonomy, which is an important component of subjective well-being . Freedom evokes a sense of choice and possibility, as well as agency . Adventure involves challenging oneself mentally and physically, learning to calculate and confront risk, and experiencing contrast with everyday life . Exposure to nature is correlated with a sense of autonomy (Passmore and Howell 2014). The search for these subjective mental states has motivated individuals and societies to embark on ocean voyages, to explore the coast and undersea environments and to challenge themselves by big wave surfing, deep-sea exploration or blue ocean sailing.	The sense of freedom and adventure of being on or in the ocean is described by well-known and accomplished participants in marine adventure sports as restorative, connective to nature, and contributing to building their autonomy and resilience (MacIntyre et al. 2019). Fishers often emphasise their need for independence and choose to stay in the fisheries, even when more lucrative work is available, because they value the independence and freedom of working for themselves, or with friends and family, and are unwilling to submit to working indoors, being bound to a timetable and reporting to a boss (Pollnac and Poggie 2008). In contrast, 'adventure' is not one of the reasons listed for the revival of Pacific voyaging, though such voyages through the vast ocean in a small craft would be most people's idea of an adventure. Instead, the 'five values' motivating such voyages are a mixture of the relational and the subjective: knowledge, the pursuit of excellence, the exercise of rights and responsibilities, acting morally and selflessly, and nurturing relationships to the ocean and nature (Herman 2016).
Awe	To land-based people, the ocean inspires a range of emotions, from fear to curiosity. The human psyche flourishes when there is opportunity to confront our anxieties, reflect on our place in the cosmos and experience a feeling of something larger and more permanent than ourselves. The ocean seems to prompt such reflection, due to its vastness and relative unknowability.	Feelings of fear and awe have characterised some of our land-based cultures' views of the ocean, such as Judeo-Christian and Hindu ones (Connery 2006; Andaya 2017), while for those more at home on the waves, the ocean invites awe and respect but is also regarded as a source of comfort and familiarity (King and Robinson 2019). Fear gave way to fascination through the eighteenth- and nineteenth-century notion of the 'sublime' in European culture, where rough seas, ocean depths and rocky coasts are reinvented as sources of aesthetic and sensory pleasure (Gillis 2012).

Table 11.3 (continued)

Contribution to human well-being	Mechanisms or rationale	Examples
Aesthetics	The ocean and coasts have inspired the visual and creative arts, and humans have felt the need for aesthetic expression since at least the time the first cave paintings were created. A continuing cultural relationship with the ocean is important to sustaining this inspiration in future generations.	Marine animals appear in early rock paintings, even in continental interiors in Africa and Australia. Perhaps one of the most recognised marine images comes from Japan: The Great Wave off Kanagawa, an early nineteenth-century woodblock print by Hokusai. Paintings of ships and beach- side scenes are popular in European art. See Annex 2 for sources and further discussion.
Belongingness (subjective elements)	While belongingness has relational components (being part of a group, see Table 11.2), the sense of belonging with the ocean and being 'of the sea' also has subjective elements that contribute to self-actualisation and well-being.	It is often said that the Bajo-Laut people of maritime Southeast Asia feel sick if they spend too much time on land, or away from the ocean. They maintain a rich Indigenous marine cosmology and ritual practice, with belief in supernatural beings—ancestors of the ocean—that live in and control the universe of the ocean, and all the creatures in it (Stacey 2007). See Annex 1 for a more in-depth review. A sense of well-being that comes from feeling at one with the ocean may also be achieved by those who are not of the ocean: 'The term "blue mind" describes the mildly meditative state we fall into when near, in, on or under water. It's the antidote to what we refer to as "red mind," which is the anxious, over-connected and over-stimulated state that defines the new normal of modern life … spending time near the water is essential to achieving an elevated and sustained happiness' (Nichols 2015).
Ocean identity	While the ocean is the place where you go to do your job, it may also be where you feel most free, most in control of your own destiny, most competent and most valued by others. When jobs are evaluated and compared only in terms of returns on investment or labour productivity, they are seen as fully substitutable; they are not (Pollnac and Bavinck 2008). Occupational pride and place attachment are associated with well-being. To know yourself, to be known and respected by others, and to belong to a place are all important to people's subjective well-being. Maritime identities, whether as fisherfolk, fish traders, mariners, islanders or 'waterpersons' contribute to these feelings.	'Fish mammies' are wealthy and respected independent entrepreneurs who finance the fishing operations of men in coastal West Africa, as well as run fish processing and trading operations. It is a title and social position adopted with pride and not one that comes from working as an employee in an industrial fish processing plant. The identity of a person of the ocean or a 'waterman', first associated in wider culture with Hawaiian surfing pioneer Duke Kahanamoku (Davis 2015), has been applied both to those whose work involves physically entering the water (maritime rescuers, commercial divers) and to dedicated practitioners of marine sports, whether they are amateur or professional. It indicates both high levels of competence in and affinity with the ocean.
Symbolism	All human cultures create and value symbols, as material representations of abstract or subjective concepts that are important to us, like love, loyalty, faith, belonging, status and power (Callahan 2013). Many important cultural symbols relate to the ocean and ocean animals. The ocean's power to inspire symbols contributes to our well-being.	Sharks in the Pacific islands were imbued with spiritual powers, considered as ancestor guardians and/or gods who offered protection from the unpredictable forces of the ocean. As symbolic animals, sharks appear to signify both the fear of the unknown vastness and depths of the ocean as well as its bounty to those who respect its ways and powerful creatures. See Annex 3 for sources and further details. At independence, the Caribbean island nation of Barbados adopted an everyday food item of the poor, the flying fish, as symbolic of Bajan identity; it appears on flags, as the name of national sports teams and as the personification of national identity; a person is said to be 'as Bajan as flying fish' if he or she exhibits traditional mores and behaviours (Cumberbatch and Hinds 2013). See Annex 4 for sources and further details.
Spirituality	Spirituality and religiosity are positive predictors of subjective well-being (Villani et al. 2019). The ocean has played an important part in the development of human spirituality—for example, many cultures have 'sea gods', some of which are benign and others which warn of dangers (Andaya 2017). Both benign and danger-warning deities help make sense of fate and provide a psychological means to cope with mortality . Judeo-Christian religious texts are generally hostile to the ocean (Connery 2006), but many non-Western maritime cultures and religions have more complex and affirmative spiritual relationships with it (Andaya 2017; Hauʻofa 2008).	In Nordic mythology, the sea exceeds the land, in power and expanse, and is depicted as 'a treacherous surface to be traversed for fame and gain', its treachery personified by the female sea-deity Rán. A robber of life from men, she personifies death by drowning (Quinn 2014). The lives of peoples reliant on the ocean are fraught with unpredictability; belief in and appeal to sea gods and spirits are means of ensuring both good fortune and protection (Andaya 2017). The ocean people of Southeast Asia believe well-being is assured by seeking protection from benign spirits and gods, and offering propitiation to malign ones. With the advent of long-distance trading and voyaging into the oceanic realm, spirituality has been extended to include the gods of the major religions, notably Islam and Christianity, whose protection is sought in distant reaches of the ocean (Andaya 2017) .

individual, household or nation-state) while here we consider multiple scales. This classification is therefore schematic and each dimension and scale is illustrated by a small number of examples only, due to considerations of space.

The aim here is to establish a new conceptual framework that links ocean services or benefits to human well-being in ways that account for the plurality of human values.

Note that ocean services or benefits described here extend beyond ocean *ecosystem* services. An ecosystem services approach values only some of what the ocean contributes to human well-being. Many of the ocean's contributions are not directly related to its ecology but instead relate to the ocean as a space—both material (having area, volume and fluidity) and non-material (as a place of consciousness and imagination). These distinctions and their importance will become clear through examination of the processes and examples in Tables 11.1–11.3.

> The ocean does not divide us, it connects us.
> Pacific island aphorism that has become a contemporary cultural meme

> When anxious, uneasy and bad thoughts come, I go to the sea, and the sea drowns them out with its great wide sounds, cleanses me with its noise, and imposes a rhythm upon everything in me that is bewildered and confused. Rainer Maria Rilke (1969 [1903])

Tables 11.1–11.3 illustrate the many ways the ocean has and will continue to contribute to human well-being. While many of these contributions, across all three dimensions, rely on maintaining ocean ecosystem health, it is too simple to say that all of them do. Ensuring ocean health is, by itself, not enough to safeguard and improve human well-being. It is also important to continue to maintain and build the kinds of social and cultural connections to the ocean that have improved human knowledge, understanding, cooperation, security, meaning and happiness in the past. If the majority of those who would benefit from an ecologically healthy ocean are excluded from it, this will not lead to improved human well-being for all. Thus, maintaining ocean health *and* maintaining inclusive ocean access should be the dual aims of governing the future ocean.

Although we have separated out the dimensions of well-being in order to explain and explore them, it is important to reinforce that they are interrelated or 'co-constitutive' (i.e. each dimension builds on the others). As Sarah White (2017, 133) notes, 'Rather than dividing "subjective" from "objective", subjective, material and relational dimensions of well-being are revealed as co-constitutive. Wellbeing is emergent, the outcome of accommodation and interaction that happens in and over time through the dynamic interplay of personal, societal and environmental structures and processes, interacting at a range of scales, in ways that are both reinforcing and in tension' (White 2017, 133).

Such reinforcing feedbacks between dimensions of well-being can be found in the ways Pacific Islanders think about their relationship with the ocean. As Epeli Hauʻofa (1994, 153) wrote, the ocean provides material, relational and subjective 'goods' in inseparable and historically constructed ways: '"Oceania" denotes a sea of islands with their inhabitants. The world of our ancestors was a large sea full of places to explore, to make their homes in, to breed generations of seafarers like themselves. People in this environment were at home in the sea.'

Similarly, a sense of being part of a community and a sense of place contribute to the 'social embeddedness' of coastal communities engaged in small-scale fishing (Jentoft 2019). Coastal and sea-dwelling communities have strong social ties and distinct cultures from which they derive well-being. These identities and concepts of embeddedness straddle both the relational and subjective dimensions of well-being—the sense of belonging to a group, such as fishers or a coastal community, of being able to depend on your group during emergencies, times of loss and crisis due to the strength of social relations and networks, but also subjective feelings of pride and self-worth in one's occupation, community or ethnicity.

In Sect. 11.4 of this paper, we will outline some case-study examples of institutions—both contemporary and traditional—that illustrate how the different dimensions of well-being and the multiple spatial scales at which they accrue and are intertwined in the institutions that have evolved to govern human-ocean interactions in practice. First, we consider each set of relationships separately.

Table 11.1 summarises the many ways the ocean contributes to provisioning human needs and regulating the earth's environment to ensure human flourishing and biodiversity conservation. These contributions are linked to the ocean as both a place and as an ecological system.

While the ability to extract minerals or transport goods is largely independent of ocean ecosystem health, these activities certainly impact upon it. The challenge for the future ocean economy is to ensure that governance of provisioning and regulatory goods and services—such as food production and climate mitigation measures—do not threaten ocean health. Future ocean governance also has to ensure that human relational and subjective well-being are supported rather than undermined by the 'blue acceleration'. Most modern, state-based and global ocean governance institutions have formed with the goal of managing access to and use of ocean resources and ocean space for material use and, to a degree, to regulate relationships between private enterprises (e.g. property rights and trade and commercial laws) and between states (e.g. regional seas agreements, freedom of navigation agreements). They seldom consider subjective well-being.

Ocean governance institutions are also mostly designed to regulate commercial activity at sea. However, people do more than extract resources, trade goods or migrate across the ocean, they also interact with the marine environment and the marine species and ecosystems in a multitude of ways that may be rooted in material elements of the ocean, such as seafood, beaches, waves and reefs, but which are enjoyed, both consumptively and non-consumptively, for non-material purposes. These interactions—whether we experience them directly as beachcombers, rock-poolers, snorkelers, divers or recreational fishers, or vicariously through aquarium visits or viewing television series such as David Attenborough's *The Blue Planet*—create sets of relationships with ocean nature that respond to a range of human material, relational, spiritual and emotional needs. As people rise out of poverty globally, such interactions may engage an increasing number of us.

Prior to COVID-19, a burgeoning area of tourism research was devoted to understanding ways to cater to the preferences of China's growing number of newly middle-class beach tourists, both domestically and internationally (e.g. Liu et al. 2019; Jie Li and Carr 2004; Liao and Aguilera 2020). It is encouraging that over 80% of surveyed beach tourists in Qingdao, China, would be willing to pay a tourist tax in order to maintain beach and water quality at their destination (Liu et al. 2019). The global rise of beach and marine tourism, instead of being seen solely as a threat, might be considered an opportunity to bring the well-being benefits of the ocean to a growing proportion of the global population, and to engage ever more people in the cause of sustaining the global ocean.

The ways the ocean contributes to relational well-being (Table 11.2) are more concrete and better understood at smaller scales: the social cohesion of traditional fishing communities and how this contributes to economic, social and cultural life is well-studied, understood and increasingly legally mandated in the form of devolved management and community resource rights. At higher spatial scales, the relationships are more abstract but nevertheless important: for example, the need to share the oceanic realm has fostered certain moral norms that have spread onto land, such as the principles of neutrality, truce and rendering assistance to others in need. These were all codified at sea before they became part of the broader moral and legal framework for inter-state governance, and in some cases (e.g. rendering assistance to others in need) they remain more strongly upheld in oceanic than terrestrial contexts. This became very evident when fishers in the Indian state of Kerala took the lead to rescue thousands of inland folk in the 2018 floods because they felt it was the 'right thing to do' (*OnManorama* 2018).

Of the three main dimensions of well-being, the elements of 'subjective' well-being described in Table 11.3 are the most difficult to ascribe monetary value to and therefore to incorporate into traditional sectoral economic planning, though some of them have been considered in social accounts and happiness and well- being indices (e.g. Stiglitz et al. 2018). We know that these are some of the concepts and emotions that give life meaning, purpose and value beyond the meeting of basic physiological and economic needs and beyond the sociopolitical necessities of cooperating with others. For these reasons, they are worthy of policy consideration.

Because they are difficult to value—and even to articulate—the subjective elements of well-being may be dismissed as unimportant. Yet people have used symbols of belief or identity as a pretext to fight wars or have gone to war driven by socially constructed moral concepts such as honour (O'Neill 2001). Political and legal regimes are built around symbols such as flags (Posner 1998). As this paper is being written, statues that symbolise economic and social progress to some and colonial oppression and enslavement to others are being fought over as the U.S.-initiated Black Lives Matter movement ignites a worldwide reckoning on racism and colonial history (Grovier 2020). The symbolic value of the ocean and its organisms to coastal societies—and the extent to which people from these societies are willing to defend them—should therefore not be dismissed lightly, since it provides opportunity for both conservation and development.

Several policy implications arise from an understanding of the symbolic value of marine organisms. The first is that dominant global sensibilities and relationships to animals may be regarded as an imposition of cultural values if forced upon all people. There are lessons for wider global ocean governance from attempts to implement universal bans on the harvest of whales and other marine mammals, with nation-states and Indigenous Peoples who pursue traditional whaling activity resisting these bans in various ways and maintaining their cultural relationship to whales as food as well as cultural keystone species invested with complex symbolic meaning (Paul 2000). The principle of free prior informed consent (PIC) is relevant here. PIC is a negotiated or treaty-based procedural right for Indigenous Peoples in relation to development or natural resource exploitation proposals and their effect on Indigenous lands, culture and traditions (Rosenthal et al. 2006). PIC relates to the public trust doctrine—the main legal concept for governments' fiduciary obligation to protect and sustainably manage natural places held in common by the public citizenry. It is especially relevant as legal support for citizen participation in official decisions made about the marine space when government trustee obligations are breached.

Subjective well-being is also driven by anxieties, with psychologists identifying six existential ones: identity, happiness, isolation, meaning in life, freedom and death (Passmore and Howell 2014). All these anxieties can be either confronted or relieved (or both) in our relationships with the ocean—and with nature more generally—whether that relationship is professional, residential, consumptive or recreational (Tables 11.1–11.3). We observe that groups whose lives are closely entwined with marine resource use (fisherfolk, mariners, Indigenous Peoples, marine tourism and recreation professionals) have complex, multidimensional relationships with the ocean which are often deeply spiritual (in Southeast Asia; see, e.g., Andaya 2017) and strongly inform social and cultural identities (in the Pacific islands; see, e.g., Hauʻofa 2008).

While separating out the different dimensions of well-being enables them to be identified in any policy context, it is also useful to consider how they relate to and reinforce each other in a sectoral context. Consider, for example, the values embodied in small-scale fisheries (Box 11.2).

Human health also combines all three dimensions of well-being. The physical and mental aspects of people's health is affected positively by a clean ocean, which can be enjoyed by seafood consumption, trips to the seaside, swimming or pleasure cruises on the ocean. It is negatively affected by a polluted ocean (mercury and microplastics in seafood chains, oil spills, coastal industries, etc.). The relational aspect of health has to do with a sense of community, social cohesion, and so on, for example following the disintegration of coastal communities due to loss of fish stocks, as happened with the collapse of the Canadian cod in Newfoundland in the 1990s (Gien 2000). The subjective aspect of health has to do with the emotional state of being, in this case with the kind of feelings towards the ocean that are evoked by relationships to the environment and to marine species. By examining issues from both a sectoral perspective (in this case, health) and a well-being perspective, the ramifications of different policy choices can be examined, and synergies and trade-offs between dimensions of well-being can be identified.

Box 11.2 Ten New Ways to Valorise Small-Scale Fishers

- For their phenomenal vernacular ecological knowledge.
- For their innate contribution to biodiversity conservation through convivial technologies.
- For their largely owner-operated and collegial harvesting which fosters greater equity and comradery in work.
- For their cost effective and energy-efficient operations with lower carbon footprints.
- For their entrepreneurial prowess in providing high private and social returns despite limited means.
- For their greater contribution to food security and wholesome nutrition for local rural consumers at affordable prices.
- For their generation of inclusive livelihoods—particularly among women—along these short value chains.
- For their provision of localised physical protection and security to coastal and riparian territory.
- For their vital contributions to the economy of their countries with minimal subsidies.
- For their protection of balanced life both below and above water.

Source: Kurien (2019).

Finally, it is important to reinforce that cultures, along with their symbols, spirituality, aesthetics and ethics, are not static. Even the ways emotions are elicited and expressed—how we show anger, fear, hope or love—change over time (Zeldin 2012). Governing the ocean to maintain well-being is not, therefore, about preserving the status quo or returning to the past. It is about finding ways to maintain a diverse and inclusive set of relationships with the ocean and among ocean nations and peoples. It is these relationships that have generated—and will continue to generate—curiosity, awe, wonder, spirituality and aesthetic appreciation, as well as food, energy and wealth. Supporting these 'ocean contributions to people' means allowing people to (re)discover and interact with the ocean in ways that build on their own histories and their existing maritime relationships. Such relationships may be highlighted and promoted under existing slogans and campaigns such as those extolling 'ocean pride' (Indonesia Ocean Pride 2020), 'ocean optimism' (Knowlton 2020) and 'ocean literacy' (Schoedinger et al. 2010), though they may need extending to become more inclusive. The aim of such campaigns should be to reconnect people with the ocean, and raise awareness of its importance to our history, our present and our future.

3.3 Addressing Social Difference Within Maritime Societies: Towards a Diverse and Inclusive Future Ocean Economy

Moving towards a more diverse and inclusive future ocean economy, and understanding how plans to develop a sustainable ocean economy might affect people with different identities and circumstances differently, requires that we understand a diversity of people's experiences and relationships with the ocean. Such analyses of the contemporary ocean economy are few, and collating the scattered accounts of diverse people's lives at and with the ocean, upon which such an analysis could be based, is beyond the scope of this study.

Box 11.3 How Are Blue Economy Narratives Gendered?
The 2019 World Oceans Day (June 8) focused on promoting gender equality in all ocean-related activities, linking UN Sustainable Development Goals 5 and 14:

- An inclusive blue economy must, by definition, place fairness and equity at its core. It must consider the different needs and challenges faced by women and men. Research that includes gender data disaggregation or women specific studies, while valuable, is not enough.
- In research and policymaking, gender must be mainstreamed, from project inception and design to implementation, whether talking about fiscal policy and incentive-based management, or natural capital accounting, or impact investment or plastic pollution (Merayo 2019).

There is, for example, no substantive analysis of gender dimensions of the blue economy beyond calls for gender-inclusive development (Box 11.3), though there is a growing historical appreciation of the role of gender relations in shaping the maritime past (e.g. Creighton and Norling 1996) and an evolving historiographic gender research agenda (Stanley 2002). There is an extensive literature on gender and fisheries (e.g. Frangoudes et al. 2019) and an emergent one on gender, ports and shipping, much of it the work of the gender research group at the UN World Maritime University (Kitada et al. 2015). This work could be extended to understand the different relationships men and women (and other gender identities) have with the ocean, how they can inform and enrich governance, and the ways future economic growth and governance reforms could influence those relationships to improve women's social and relational well-being as well as their material economic circumstances.

The idea of maritime work as the domain of men is relatively recent and not present in every culture (Gillis 2012). Prior to the nineteenth century in Europe, women had been very much a part of the coastal world, involved in virtually every aspect of trading and fishing. This was forgotten as the ocean came to perform the metaphorical service of reinforcing and intensifying gender differences that were being eroded on land as women gained access to education, political power, rights to land and professional employment (Steinberg 2001, 191).

Gender inequality is a continuing constraint to improving well-being and meeting the UN Sustainable Development Goals, but it is not the only one. Wealth inequality, after falling in much of the world during the mid-twentieth century, has risen once again, particularly in the 'anglosphere' (the United States, United Kingdom and Australia), as growth has proved not to be the 'rising tide that lifts all boats' (Österblom et al. 2020). The ocean, central to capitalist wealth accumulation through mercantilism, colonialism and globalisation, has not historically offered equal opportunity to improve well-being.

Recent work on equity and inclusion in Washington State's maritime economy (Maritime Blue 2020; Arbow 2019) points to the need to diversify the state's maritime workforce—which is aging, white and male, and faces potential labour shortages that may limit its growth potential. Workplace barriers to greater inclusivity include a climate of discrimination against women and people of colour in the sector and maritime labour unions, with a history of protecting jobs by limiting access to certain ethnic or racial groups. This has led to a pattern familiar throughout the global economy: recent immigrants, people of colour and women are all overrepresented in seafood processing and other low-wage, low-status jobs but underrepresented in senior and middle management positions and skilled or better-remunerated jobs, such as longshoremen in ports. This is likely to be a wider issue in the maritime sector and planning, for a sustainable ocean economy will require specific attention to equity and inclusion in the expanding maritime workforce. The development of new offshore industries provides an opportunity for inclusive maritime vocational training to create a diverse workforce in this emergent maritime economy.

We have so far provided a few illustrative examples of social differences *within* coastal societies and maritime workforces. However, there are also inequalities in ocean-related well-being among geographies. In a sea of exclusive economic zones (EEZs) and nation-states, among the most vulnerable 'ocean citizens' are, ironically, those with the longest histories and closest ties to the ocean. These include Indigenous coastal people around the world (Fig. 11.3) and mobile populations who cross national frontiers or live upon the ocean, like the Sama-Bajau people in Southeast Asia (see Annex 1). Diverse relationships with the ocean in different cultural and geographical settings are explored further in Sect. 11.4.

While we have emphasised sense of freedom, adventure, autonomy and self-actualisation as part of the ocean's contribution to subjective well-being (Sect. 11.3.2, Table 11.3), it is important to recognise that inequalities—and the histories of how these have been produced and reproduced—shape this aspect of our relationship with the ocean. Western literature portrays the ocean as a source of freedom, but in doing

Fig. 11.3 Global map of the location of known indigenous coastal populations, prepared in order to estimate their seafood consumption. *Note: Groups for whom fish catch and population data are known are differentiated from those for whom only location is recorded. Source: Cisneros-Montemayor et al.* (2016)

so it does not represent the experience of the millions of men, women and children who crossed the ocean in shackles, as slaves. For them, and 'for the indentured labourers, convicts and refugees, oceans have never figured as spaces of freedom, exchange and connectedness, but of unfreedom, objectification and a separation from family and homelands' (Bartels et al. 2019, 81).

Discourses about shared ocean values and campaigns for greater ocean literacy should not neglect the legacies of past exploitation and the denial of others' values and knowledges. Nations that built their economies and societies through mercantilism and colonialism, and the nations that were exploited or colonised by them, will have differing perspectives and priorities in governing their ocean estate. Ocean governance futures are likely to be negotiated amid calls for continuing decolonisation (Vásquez-Fernández 2020), strengthening moral and legal arguments for reparations to the descendants of slaves (Araujo 2017) and upholding the rights of formerly colonised states to fully develop resources in their EEZs without hindrance from former colonising powers. Such a 'right to development' (Udombana 2000) is difficult to deny on moral grounds when these nations were denied the right to use their land-based resources for autonomous development, and when that land and those resources were taken by colonisers who also subjugated, displaced or killed the original inhabitants. The legacy of past injustice remains visible in the greater vulnerability of marginalised populations to COVID-19's health and economic impacts (see Sect. 11.3.4), and it drives current global anti-racism protests.

An ocean-based governance reform process that learns from these land-based upheavals will be more successful at addressing the linked problems of inequity and unsustainability than a process that ignores them.

3.4 The Emergent Impact of COVID-19 on Human-Ocean Relationships

On 16 August 2020, confirmed infections with SARS-CoV-2 approached 21.3 million people, resulting in 761,779 deaths (WHO 2020a). As of this date, the pandemic was still growing, in the United States, Latin America, the Middle East, India and parts of sub-Saharan Africa, while much of South and Southeast Asia, Oceania and Europe were seeing control measures decreasing the number of new cases, though with signs of a 'second wave' of infections leading to a return to more stringent social distancing. No vaccine has yet been developed.

Making a rapid assessment of its impacts is complicated by the 'infodemic'—the viral proliferation of information, some of it accurate, some not, that confronts the policy analyst.[2]

As well as the human and economic costs of the public health crisis, the measures to contain the spread of the virus—which have included the closure of businesses, workplaces and schools, and restrictions on travel—have led to mass unemployment, large-scale government expenditures on bailout and stimulus packages, a decrease in trade and economic activity, a fall in the value of financial markets and a global recession (Fernandes 2020). The International Monetary Fund estimates that the global GDP will shrink by 4.9% in 2020 and grow by 5.4% in 2021, to attain a value 6.1% below its pre-COVID 19 projected value (IMF 2020). Low-income households are particularly imperilled, reversing the significant global progress made in reducing extreme poverty since the 1990s (IMF 2020). This makes achieving the SDGs that much harder.

[2]The World Health Organization held its first infoepidemiology conference in June–July 2020 (WHO 2020b).

The crisis has also prompted much thought about what kind of society is to be rebuilt in future, with an exhortation to 'build forward better' and to invest in making our societies more equitable and sustainable and more resilient to future pandemics (van Barneveld et al. 2020).

Table 11.4 summarises documented impacts and responses to the COVID-19 pandemic by the maritime economy.

While impacts by country will vary depending on the role that the maritime economy plays, the three most prominent global impacts are on (1) global trade, where over 80% of the world's goods (by weight; 70% by value) are transported by sea (UNCTAD 2020); (2) the global food system, where 3.3 billion people depend on seafood for at least 20% of their animal protein intake (FAO 2020a, 67); and (3) the world's tourism and leisure industries, 50% of which are coastal and marine-associated. As a whole, worldwide tourism and leisure, pre COVID-19, generated nearly $1.5 trillion in receipts and $250 billion in transportation (totalling around 10% of global GDP in 2008) and employed 319 million people (UNCTAD 2020; TNC 2019). The impacts on each of these sectors, and the societies and economies that depend on them, are complex and take

Table 11.4 Some observed COVID-19 impacts, responses and proposed longer-term outlooks for maritime economic sectors and their governance

Sector or issue	Impacts	Responses	Possible futures
Fisheries and aquaculture	Demand impacts of COVID-19-related lockdowns first hit high-value seafood in the restaurant sector in China and then worldwide. Job losses and supply disruptions affected low-income households' ability to access fish and other nutrient-rich foods, particularly in developing countries. In wealthier countries, demand for tinned and frozen fish has risen. Industrial fishing activity fell by 50% in several European countries in February–April 2020; several epidemics broke out on fishing vessels and in fish-processing factories. (Summarised from Love et al. 2020.)	Governments (e.g. Russia, Canada, South Africa) designated fishers, processors and retailers as 'essential workers' during the pandemic lockdown, allowing many in the sector to keep working. Multilateral organisations (Food and Agriculture Organization of the United Nations, World Bank, etc.) are providing technical, policy and financial support to the sector for adaptation, with a focus on fish-dependent, low-income, food-deficit countries. In the private sector, companies are investing in personal protective equipment for their workers, redesigning workplaces for social distancing and quarantining fishers before they set out for distant waters. Small-scale fisher organisations, marketing cooperatives and local catch schemes have mobilised to support small producers reach local consumers with their produce, to support livelihoods (e.g. in the Indian state of Kerala and the United States). (Summarised from Love et al. 2020.)	Policy emphasis is on building resilience by continuing to address pressures on wild fish stocks (including IUU fishing, subsidies and habitat degradation), building resilience to climate change, investing in mariculture, focusing on small-scale producers most vulnerable to economic shocks, improving traceability of seafood and biosafety protocols, and maintaining diverse product forms in seafood (e.g. by canning, drying, smoking, freezing) as fresh value chains are more vulnerable (e.g. Love et al. 2020; FAO 2020a; Bennett et al. 2020; McCauley et al. 2020). Aquaculture futures depend on whether the post-COVID-19 world is oriented more towards growth or more towards sustainability, and whether trade is globalised or localised (Gephart et al. 2020).

(continued)

Table 11.4 (continued)

Sector or issue	Impacts	Responses	Possible futures
Marine trade and transportation	13–32% downturns in container ship traffic in 2020, relative to 2019, due to slowdowns in both production of and demand for goods. Secondary effects include impacts on the marine insurance industry (Willis Towers Watson 2020). The International Labor Organization (ILO 2020) reports that seafarers face considerable problems joining and leaving their ships in port (each month around 100,000 seafarers are involved in crew changes), due to quarantine and movement restrictions.	Governments have supported continued marine transportation of food, medicines and other essential supplies to land- based populations. Measures have been taken by governments, the private sector and civil society organisations to protect the health and well-being of seafarers and port workers, classified as essential workers (UNCTAD 2020; ILO 2020).	Maritime trade is likely to continue to grow, but the rate at which it does so will depend on demand- recovery as economies reopen. Given its importance, the sector is likely to receive policy attention in areas such as opportunities for decarbonisation, improved crew working conditions and quarantine and sanitary measures on ships and in ports.
Marine tourism and leisure	Cruise tourism slowed dramatically in the first quarter of 2020 and has halted this $40-billion-a-year industry in the second quarter, as early shipboard epidemics drew attention to the vulnerability of cruise ships to epidemic disease outbreaks. Tourism revenue is forecast to decrease by between $300 billion and $2.1 trillion (UNCTAD 2020), with up to half of that value represented by coastal and marine tourism. With 80% of the tourism sector's 319 million employees being seasonal and/or in small and medium enterprises, the welfare impacts of this decline are substantial.	Where tourism is an important source of revenue, states have used stimulus payments to support tourist sector businesses. Airlines, hotel and restaurant groups have moved quickly to monopolise the bailout funds (Renaud 2020). As lockdowns eased in many countries in May and June 2020, businesses reopened while maintaining new distancing and hygiene regulations that restricted their profitability. Populations in lockdown have flocked to beaches when allowed to do so, causing concerns that a second wave of COVID-19 infections would manifest in the Northern Hemisphere summer. Meanwhile, island nations such as Fiji that were virus-free encouraged exclusive 'billionaire tourism' to restart their industries (Doherty 2020).	The need for 'blue space' for health and well-being has been reinforced by lockdowns. Crowding on beaches has exposed the effects of the creeping privatisation of coastal zones around the world, exemplified by the United States (Rao 2020). Investment in improving public access to the foreshore and coast could be part of a strategy to protect public access to natural landscapes for well-being. The COVID-19 crisis has prompted critical examination of 'overtourism', the environmental costs of air travel, and, in the maritime context, the social and ecological impacts of cruise tourism. In addition to overcoming its ships' reputation as 'floating petri dishes', the cruise ship industry will need to examine its impacts on the marine environment, destination ports and their resident populations, and its own labour force, as well as on the safety of passengers (Renaud 2020).
Marine biodiversity conservation	Reports of the return of marine wildlife to heavily used inshore and coastal habitats were widespread, with quieter areas of the ocean being good for whales, too (McVeigh 2020). A reduction in at-sea observers raises the possibility of increased IUU fishing, endangering seabirds and marine mammals. The COVID-19 pandemic has disrupted what was to have been 'a big year for ocean conservation' (Dineen 2020), leading to the postponement of the UN World Ocean Conference, the World Conservation Congress and the Glasgow meeting of the Intergovernmental Panel on Climate Change, at a critical time for the ocean and climate change. Cancellation of in-person meetings, including the 2020 UN Ocean Summit, may have slowed the building of ocean policy constituencies. The COVID-19 pandemic has diverted policy attention away from the ocean at a critical time	The probable origins of the SARS-CoV-2 virus in the wild animal meat trade have drawn global attention to wildlife conservation (Dineen 2020). While seafood is not implicated in SARS-CoV-2 transmission (Bondad-Reantaso et al. 2020), the wider focus on zoonotic disease risks from animal source foods is impacting confidence in seafood safety too, prompting greater investment in food safety procedures. The inability to directly monitor fisheries and conservation is leading to greater use of remote sensing technologies and calls for greater traceability in wildlife meat and seafood sectors. The rise of virtual conferences and meetings, online shared working platforms for routine meetings of regional fishery management agencies, transnational corporations, international agencies and nongovernmental organisations have shown that multilateralism can be pursued with less travel cost. The Virtual Ocean dialogues and related processes have kept the ocean visible in policies for sustainability beyond the current COVID-19 pandemic.	The COVID-19 pandemic seems likely to lead to renewed focus on environmental conservation and the linkages between environmental health and human health. If this is translated into effective policies, it could strengthen the case for investment in ocean health to support human well-being (Franke et al. 2020). It is too early to say how the current crisis will affect multilateral governance. The world's focus on our interconnectedness and the fragilities this brings could either lead to more investment in making multilateral governance and globalised economies work, or to a retreat from both of them. Some analysts have predicted the rise of China in global affairs and the decline of U.S. influence (Campbell and Doshi 2020), which would change the direction of multilateral ocean governance. In the arena of marine biodiversity conservation, 'the potential of multilateral spaces to change the world order for the better is the main reason why we should care about their future after the COVID-19 crisis has passed and find ways to strengthen their legitimacy' (Vadrot 2020).

Fig. 11.4 COVID-19 disruptions and impacts on seafood supply chains. *Note: Disruptions to production, labour, distribution, supply and demand create a range of impacts. The colour gradient indicates the hypothesised relative impacts to different components of, or actors within, seafood supply chains. The ordering of groups is based on multiple data streams collected through May 2020 but is not intended to be a quantitative or absolute ranking. Source: Love et al.* (2020)

place through multiple pathways, as Fig. 11.4 illustrates for the seafood system.

What are impacts of this linked public health and economic crisis on the current and future ocean economy? Who in the ocean economy is most vulnerable? How have governments and ocean economy sector actors responded? How have these impacts and responses affected our future relationships with the ocean? These questions deserve more scrutiny than we can give them here (but see Table 11.4). We therefore recommend, as an opportunity for action (see Sect. 11.5), the application of a social well-being approach to understanding how to build a resilient and equitable set of relationships with the ocean, to complement the more ecological and economic focus of policy advice to date (McCauley et al. 2020; UNCTAD 2020). Bennett et al.'s (2020) proposals for small-scale fisheries address some of the relational and subjective elements of COVID-related impacts on well-being, as does the ILO's (2020) policy briefing for maritime industry employees. The ILO documents mariners' inability to go ashore for medical treatment, to receive medical and safety equipment and to return home. All of these have led to increased fatigue, stress, isolation and social pressures for seafarers and their families.

The COVID-19 pandemic has revealed many things about subjective and relational well-being, as social distancing and travel restrictions have reconfigured our human relationships, our relationships with nature and our sense of what is important for a good and meaningful life. One piece of evidence for the importance of the ocean to our quality of life is that, as COVID-19 lockdowns eased in May 2020, people in Europe, the United States and Australia rushed to beaches (e.g. Wood 2020). The sense of freedom, of tranquillity or sociability, the sense of renewal and new possibility that being by the ocean invokes are powerful and continue to have value. If anything, this highlights that such non-material values are more resilient than the material ones. Much has been made of the monetary value of ocean ecosystem services—estimated at \$2.8 trillion a year (McCauley et al. 2020). And yet the initial economic stimulus package to address short-term economic losses from COVID-19 in the United States alone, was over \$3 trillion (Delevingne and Schneider 2020)—more than the whole of the ocean is apparently worth, in monetary terms, to the whole of humanity. Given this, perhaps the call to calculate ocean ecosystem service values is not the best or only way to draw policy attention to the values of the ocean to humanity.

As thoughts turn to how to rebuild economies and restart social life, the coming months will provide opportunities to reinforce how important 'blue spaces' are to people and to ensure that people have access to them for their well-being.

3.5 Avoiding 'Taboo Trade-Offs' and the Need for Inclusive Ocean Policymaking to Improve Human Well-being

Once a largely coastal species (Gillis 2012), we are once again returning to the littoral. Coastal populations have been growing about twice as fast as national growth rates, and population densities there (ca. 80 persons km^2) are twice the world's average (Steven et al. 2020). Many of the world's megacities are coastal, and seafront land and properties with sea views attract price premiums in real estate markets all over the world (e.g. Jim and Chen 2009). While the majority of the world's people—even the coastal ones—experience the ocean as an alternative to a largely terrestrial existence, there are people who are 'at home on the waves' and for whom 'oceans persistently constitute the principal organizing spaces through which many communities dwell in the world' (King and Robinson 2019, 1). This range of 'ocean citizens' and the rest of humanity, all of us directly or indirectly connected to the ocean though our climate, trade, economic and food systems, derive well-being from very different material, relational and subjective relationships with the ocean.

The examples in Tables 11.1–11.3 represent some of the many ways people interact with and benefit from the ocean. All these interactions have economic dimensions and policy and legislative implications. Governing them needs to go beyond regulating the flow of material goods. Our ocean relationships engage with all the other things that make us human: our need for identity, a sense of social belonging, an attachment to place, our sense of being and doing good in our community or our world, of fulfilling our varying needs for adventure, inspiration, comfort, calm, satisfaction of curiosity and refuge from fear (Schwartz 2012).

Whether they were surfers thousands of years ago in the Hawaiian Islands (Finney and Houston 1996), fishers and coastal traders decorating their canoes in Ghana (Verrips 2002) or Inuit hunters in the Arctic making miniature carvings out of the bones of the marine mammals they caught (Laugrand and Oosten 2008), our forebears had relationships with the ocean that were complex, emotional, spiritual and artistic, as well as material and transactional. We, their descendants, will continue to forge these complex relationships with the ocean, provided we have continuing access to it.

A key planning challenge is to find ways to consider this plurality of ocean-experience and ocean-values in formulating economic development and marine conservation plans. The perspectives of the people most familiar with, most socially and culturally attached to, and most dependent upon the ocean—namely, small-scale fisherfolk, coastal Indigenous Peoples, island peoples and sea-dwelling peoples—must surely feature prominently in marine spatial and economic planning and the formulation of maritime policy and law, both within nation-states and globally. In the interests of legitimacy and equity, this should be so even when utilitarian ethics are applied and the greatest good for the greatest number of people is sought. Recognition of this diversity of interest and incorporation of the knowledge systems and values of this broad 'ocean citizenry' is an important first step towards an equitable and sustainable ocean economy.

In addition to traditional ocean users, the contemporary industrial ocean has its temporary sea-dwellers such as cruise-ship passengers, oil rig workers, merchant and naval seafarers and deep-sea fishers, each of whom may be drawn from less maritime populations and may not share the same set of 'ocean values' as those with longer and more culturally embedded relations. The future ocean may also include blue carbon investors, offshore aquaculturalists, workers in the renewable energy sector and deep-sea miners, each of whom will bring new conceptions of the ocean, new values and new priorities. Ecomodernist visions of the future ocean often incorporate plans for floating cities in coastal and open waters (Riffat et al. 2016), or on insulated ice floes (Bolonkin 2011); these too, have governance implications. While considering how to add new ocean populations and their values to ocean accounting and management, including those who may live or work beyond national exclusive economic zones, there are opportunities to support and learn from the dwindling numbers of historically maritime populations, including those whose extraterritoriality has posed challenges for land-based governments and left them marginalised and sometimes without sovereignty (Stacey and Allison 2019).

The decisions societies make on how to govern the ocean will not be determined entirely by monetary cost-benefit analysis. Power struggles have shaped the ocean governance regime and will continue to do so. Relational and subjective considerations will play their part too: the role of emotion in policy decision- making is often overlooked, but, for example, much of our nation-building seeks to draw on emotional responses to symbols of nationhood (flags, anthems, commemorations and celebrations), and our global stock markets are governed by traders' moods ('behavioural finance'; Nofsinger 2005). Our emotional responses to the ocean are thus also likely to shape our decisions on how to govern it.

While expanding the ocean economy can create new opportunities to improve welfare, it can also lead to unequal endowments, reinforced discrimination, or inequality of status (Satz 2004). Trade-off decisions between use and users will need to be made in an increasingly busy 'blue future'. Ideally, we solve trade-off decisions with the constructive objective of equitable outcomes, where the allocation distribution is envy- free and where no individual would prefer having what another person has (Arrow 1951; Kolm 1972). But even when a socially inclusive and holistic view of a blue future is taken, it is likely to show that trade-offs are pervasive, some are hidden and some are 'taboo' (see Box 11.4). Trade-off analysis has to adequately consider ethical and moral values to prevent individuals and societies from having to make such 'taboo trade-offs'.

Box 11.4 Taboo Trade-Offs at Sea

Taboo trade-offs result when a sacred value is asked to be traded for values that are secular. Sacred values possess infinite or transcendental significance and are inviolable and absolute. Sacred values preclude comparisons with bounded or secular values (Tetlock et al. 2000). Taboo trade-offs are often ignored by managers because the sacred values that people ascribe (whether to possessions or natural assets) are likely to be very different. Not only do the sacred values differ in measure, but the actual values they consider sacred are likely to vary culturally, spatially, and demographically. Generalisation of sacred values is therefore near impossible, and this diversity can breed substantial conflict. Nevertheless, social values and the psychological context within which taboo trade-offs decisions are made must be considered to ensure an equitable, envy- and conflict-free blue future.

When people are asked to trade their sacred values for secular values, they often experience this as deeply offensive. People have an aversion to making taboo trade-offs (Stikvoort et al. 2016), and they are likely to display insensitivity to a strict cost-benefit analysis of the exchange. They are likely to exhibit moral outrage, express anger and disgust, and become increasingly inflexible in negotiations. Examples of taboo trade-offs include being asked to exchange locally held cultural values for something secular like the profit of a fishing or oil exploration company, or, for Indigenous communities, being offered money not to fish or have access to their traditional waters. Contrary to classic economic theory's assumption that financial incentives motivate behaviour, bringing economics into the equation and trading sacred values for money can make people recoil.

Ecosystem management that doesn't acknowledge uncomfortable truths and the taboo nature of some trade-offs is likely to fail. In order to deal better with trade-off decisions, we must be cognisant of how we present and frame decisions and aim to predict decision difficulty and better anticipate resultant behaviour (Daw et al. 2015).

How we feel about the ocean will influence what we choose to do with it, in it and on it. Within and between nation-states, there is heterogeneity in people's emotional response to the ocean, so it follows that there will not be complete agreement within or between countries about what kind of sustainable ocean economy we want. Emotive relationships with the coast and the ocean will influence the 'social license' granted to governments and private sector actors to develop new ocean uses. Understanding people's values (Schwartz 2012)—and the emotional responses elicited when those values are challenged—therefore become a key part of the ocean governance process.

4 Governing Humanity's Relationships with the Ocean: Some National and Regional Perspectives

Governance systems for coastal waters, territorial waters, regional seas and ocean basins have emerged from the turbulent mixing of historic, geographical, sociocultural, legal, political and economic relations. They are based on a rich foundation of traditional or local ecological knowledge and reflect the attempts of different societies to ensure that their relationships with the ocean support their well-being in all dimensions. These governance systems are under threat, but they are part of humanity's social and legal legacy, and they are now being overlaid by governmental and international law. A just and equitable, diverse and inclusive sustainable ocean economy will not allow this legacy to be swept aside but will nurture and support it.

Legal and customary systems in the ocean have also evolved through struggle and litigation. In some cases, modern states have neglected or actively undermined pre-contact and pre-colonial institutions and sovereign systems and attempted to replace them with newer forms of state-based governance. States' capacity to govern their 'marine estates' is limited, particularly in the large ocean states and in low-income, food-deficit countries where ocean governance competes with many other priorities for limited government spending. In these circumstances, instrumental as well as moral reasons may justify encouraging the revival and continued evolution of the traditional institutions of governance that predated modern state-formation.

There is increasing recognition that the knowledges, cosmologies and traditional institutions for environmental governance developed in Indigenous and traditional coastal societies are empirically valid, have contemporary relevance and can be (and have already) been mobilised for current contexts (Eckert et al. 2018; Jentoft et al. 2019). This is complicated by the history of active denigration and suppression of these practices (see, e.g., Maldonado 2014). The current wave of 'decolonisation' of thought systems (as well as territory) responds to this recognition that colonisation has marginalised local and Indigenous people and their knowledge systems and replaced them with human- environment relationships that are less functional and responsive. Other national and international environmental programs have begun to respond to these calls for decolonisation—notably the Intergovernmental Panel on Biodiversity and Ecosystem Services with its shift from talking about ecosystem services to 'nature's contributions to people' (Díaz et al. 2018).

Here we briefly introduce some of the different ways people around the world have built and institutionalised a 'human relationship with the ocean'. We do not present them as blueprints or exemplars of good practice. We merely offer them to illustrate a few of the diverse ways different (non-Western) societies with long histories of living with the ocean have developed ways of life and institutions that could be built upon in the places where they occur. They also illustrate that large economies like China and the African Union have their own plans for the ocean economy; these may differ from a vision that comes from a model of global collaboration and consensus. Finally, we also indicate how contemporary international instruments—in this case the World Heritage process of the UN Educational, Scientific and Cultural Organization (UNESCO)—can support relational and subjective elements of well-being that are embodied in traditional maritime cultures, societies and practices.

We have picked only a few examples to illustrate a diversity of approaches and highlight whether and how (or how not) the institutions of these groups and nations support the relational and subjective dimensions of well-being derived from human-ocean interactions. Space precludes a more comprehensive or globally representative treatment. Every coastal and maritime society will have its own historical and cultural foundations to build upon when it comes to developing an equitable, diverse and inclusive ocean economy that supports human well-being. Whatever those foundations, a guiding principle for 'blue justice' can be that of 'participatory democracy', which implies decision-making devolved to more local scales (communities, municipalities and districts), active roles for a civil society distinct from governmental politics, and a more active engagement of citizens in the political process than is the norm in 'representative democracy' (Barber 2014).

4.1 An Indigenous Perspective: Aboriginal and Torres Strait Island Peoples' Connection to 'Saltwater Country'

Identified as Aboriginal or Torres Strait Island people, Indigenous Peoples in Australia comprise approximately 3% (or about 650,000) of the total population. The majority of coastal Indigenous Peoples live in remote or very remote locations, most of which are part of the Indigenous estate, Aboriginal-owned and managed land and sea, held under some form of Indigenous tenure.

Indigenous Peoples view the ocean, islands and coastal environments as part of their 'sea country' or 'saltwater country' and often refer to themselves as 'saltwater people' (Smyth and Isherwood 2016).[3]

These features relate to ownership of traditional clan estates and marine resources under traditional law, and recognised in some state, territory and commonwealth legislation. The saltwater peoples of the Arnhem Land region continue to rely on coastal and marine environments and resources providing food, cultural identity, health and well-being, and as part of domestic and commercial trade economies. Opportunities for employment are very much determined by good land and sea management and the ability to harvest natural resources. The harvesting of plants and animals for food, ceremonial or celebratory purposes (community feasts), art production or the performance of sacred duties in natural and cultural management, including maintaining social and economic relationships within and between tribal groups, all play an important and central role in Aboriginal livelihoods, belief systems and well-being in Australia's Northern Territories.[4]

There is no overarching legal fisheries management framework for Indigenous customary fishing rights in Australia. Instead, fishing rights have been intricately tied to developments in land and native rights with different local arrangements across states and territories (Schnierer and Egan 2016).[5] This has meant that in most cases Indigenous customary fishing is exempt from fisheries management frameworks and laws. The effect is that Indigenous fishing has not been recognised and consequently engages low numbers of Indigenous people in fisheries and associated businesses (Fleming et al. 2015; Productivity Commission 2016). In most cases,[6] a definition of Indigenous customary fishing does not include fishing for commercial purposes, even though it is recognised that Aboriginal people have fished commercially (i.e. to sell, exchange or barter fish) according to traditional laws and customs. As such, land or Native title-holders who fish commercially have been subject to the same commercial fishing laws and regulations as the rest of the population. In this case, the Australian state's fisheries governance system fails to adequately understand, account for and support the relational and subjective benefits associated with Aboriginal marine resource use.

4.2 A 'Big State' Perspective: China's 'Ocean Dream'

While China's coastlines have historically hosted diverse peoples and cultures (e.g. Anderson 1970; He and Faure 2016), the Chinese state had until recently directed its attentions mainly to the land. In the last four decades, however, state policy has turned increasingly towards the ocean. This recalls

[3] Aboriginal interests also include inland waters and wetlands.

[4] Sacred sites are also registered in these clan estates.

[5] One exception is the Torres Strait Islands, where legal rights for customary and commercial fishing are recognised under Native Title legislation (Lalancette 2017).

[6] Torres Strait is again an exception (Lalancette 2017).

the early fifteenth-century voyages of the great Chinese navigator, diplomat and maritime leader Zheng He, whose seven voyages, with a flotilla of 'treasure ships' and a retinue of 20,000, sought to extend China's trading influence throughout the Indian Ocean and strike awe in all who saw them (Dreyer 2006). Almost a century before Columbus and Vasco da Gama, Zheng He's flotilla sailed throughout the Indo-Malayan archipelago, to India, to the mouth of the Persian Gulf and to the East African coast. As China turns to the ocean once more in the twenty-first century, Heng Ze's exploits are part of a state narrative of a tradition of peaceful trading and knowledge-sharing that China contrasts with European imperial sea voyaging (Holmes 2006). As Western disquiet grows over China's growing modern maritime presence—not least in the disputed territories of the South China Sea—so too does Western historical research that seeks to reinterpret Zheng He's voyages as more overtly imperialistic in intent (Wade 2005).

China's overall domestic strategy aims to mobilise its people to support the 'Chinese Dream': achieving 'national rejuvenation', after what the central authority views as a period of global domination and humiliation by the West, and building a 'moderately prosperous society'. Thus, the national development policy has both relational, subjective and material dimensions. China's 'ocean dream', therefore, is to achieve the 'Chinese Dream' through an ocean-based economy. As such, China's 'blue economy' is state-led, rather than private-sector-driven, and ultimately serves the purposes of the state and bolsters the legitimacy of the Chinese Communist Party.

The Chinese central authority referred to the 'blue economy' in the 13th five-year plan in 2016, but contemporary policy on China's ocean economy dates to the start of the 'opening and reform' period in the late 1970s. Blue economic development in China accelerated around the turn of the twenty-first century. Since China ratified the UN Convention of the Law of the Sea (UNCLOS) in 1996, the state has established numerous exclusive economic zones, called for 'implementing ocean development' and issued various five-year plans for ocean economic development. The focus has culminated with the explicit goal of becoming a 'maritime power' (海洋强国), possessing military defence capabilities, a strong ocean economy and advanced marine science and technology. In 2019, Premier Li Keqiang summarised the state vision of China's blue economy as to 'vigorously develop the blue economy, protect the ocean environment, and construct a great maritime nation' (大力发展蓝色经济, 保护海洋环境, 建设海洋强国) (Li 2019).

Development of China's 'blue economy' has indeed been vigorous: In 2018, it accounted for 9.3% of GDP.

China has focused on transforming its ocean economy from the primary production of raw commodities, such as capture fisheries, to secondary and tertiary production and service industries, such as processing and tourism. The country is also placing increasing emphasis on developing ocean-related technology and innovation; 'blue economic pilot zones', such as the Qingdao Blue Silicon Valley (青岛蓝色硅谷), are built so that demarcated parts of the coast can serve as (industrial or technological) parks for ocean-focused research and development.

The state-led nature of China's blue economy is also apparent in its more ideologically oriented policies.

To bolster blue economic development and China's identity as a maritime power, the state has endeavoured to increase 'ocean consciousness' among the citizenry.

Through outreach and education, the state is working to raise public knowledge about China's ocean nature, economy, culture and politics. Museums dedicated to cultural relics like Mazu, a goddess of the sea, have been newly created. Tourist destinations have likewise been established elsewhere in the country, such as fishing villages and festivals, in an effort to build interest in and understanding of China's maritime heritage. While this might at first sight appear to be directed at building non-material values and recognising tradition, these aims are martialled to support a top-down vision, and their instrumental nature is unlikely to confer the types of well-being that a bottom-up approach to culture and tradition might foster.

China also dreams of achieving marine environmental sustainability. Policy rhetoric certainly emphasises environmental sustainability; 'ecological civilisation' (生態文明), a framework to live in harmony with nature, is highly promoted, even constitutionalised. However, much of 'ecological civilisation' acts as a means to intensify production in some areas while restricting production activities in other, mostly rural, landscapes (e.g. Brown 2014; Hong 2018). This policy better protects some ecologically sensitive areas but also presents social and economic challenges, as it can displace livelihoods (Chen et al. 2017). Challenges in marine environmental governance also remain, including pollution, overfishing, subsidies, implementation and enforcement, and varied levels of government capacity (Zhang et al. 2016; Cao et al. 2017; Mallory 2016).

China's focus on its ocean economy also has international dimensions. The twenty-first-century Maritime Silk Road, a component of China's Belt and Road Initiative, aims to recreate historical international partnerships through investments, trade and aid. China's aspirations to become a maritime power have intensified a range of maritime disputes, such as in the South China Sea. China is also increasingly involved in ocean developments in the global commons, such as in the polar regions and on the high seas (e.g. seabed mining and distant water fishing), where it sees significant security and resource opportunities (Brady 2019; Mallory 2013).

In particular, the increasingly international scope of China's ocean economy means that its vision of becoming a strong maritime power is now interacting with alternative visions for a sustainable ocean economy currently being developed. While elements of relational and subjective well-being are addressed in China's 'Ocean Dream', they are invoked in the service of state power rather than individual or group agency and well-being.

4.3 Japan's Satoumi System: A Socially Negotiated Institution for Sub-national Governance

Satoumi is a Japanese concept describing a mosaic of interacting marine ecosystems and coastal human communities, where the livelihoods of people and the blessings of nature harmoniously co-exist. They are built on traditional ecological knowledge. It therefore addresses several facets of social well-being outlined in Tables 11.1–11.3. It emphasises ecosystem linkages and thus is somewhat incompatible with the species- or stock-based approach of more conventional fisheries management. The delineation of ocean space under *satoumi* is driven not by the need to differentiate ocean space based on user purposes but by the zoning promoted by fishers and other stakeholders to manage and conserve ocean resources and the ocean environment. Thus, there are fundamental differences in both objectives and approaches between spatial management and *satoumi*.

Attempts to characterise *satoumi* as a model of co-governance are inappropriate as they fail to fully appreciate the historic context and social dynamics encapsulated in the decision-making process.

Specifically, unlike the self-governance framework, which limits their scope to collective decision-making by a stakeholder 'community', the scope of *satoumi* extends beyond ocean policymaking, as a greater, regional governance framework. A key feature of *satoumi* is that it is explicitly based on information-sharing among social actors, both administrative and economic. Through a system of information-sharing—including among fishers—*satoumi* facilitates management consensus. It also builds on the belief that fishers must be the stewards and protectors of the ocean; it defines their role and thus the objectives of local coastal governance and marine conservation efforts (Takehiro 2018).

Administratively speaking, Japan's Fisheries Act was the institutionalisation of a historic system of localised fisheries governance and provided rights to local coastal communities. Collective fishing rights are allocated to fishers and fisheries cooperatives, which are responsible for managing their adjacent waters.

Satoumi can, therefore, be considered a social contract between fishers and local communities founded upon the awareness of complex interactions between ocean and humans. Nevertheless, *satoumi* is not a concept that is universally recognised or defined but rather one that is dynamically applied on a case-by-case basis. Ocean management that is described as *satoumi* does not implement a specific set of measures. While *satoumi*'s key functions are described as 'productivity enhancement', 'conservation of environment', 'promotion of communication' and 'cultural succession', it is not necessary for all these functions to be explicitly identified in a system described as *satoumi*. Under the *satoumi* model, conservation is a means to improve fisheries productivity and mobilise social networks for conservation effort, with the understanding that such effort supports fisheries. If *satoumi* is to be considered a form of social contract that transcends conservation and fisheries aspirations, it is critical that further discussions focus on the ocean as an integral part of the coastal community, rather than on the environment that the coastal community occupies and utilises.

4.4 Indonesia: Diverse Marine Ecosystems Support Diverse Maritime Cultures and Societies

Indonesia, a centre of global marine biodiversity and at the heart of the Coral Triangle, has five main maritime populations: Bajo, Bugis, Butonese, Makassarese and Madurese (from the Raas and Tondok islands in west Java), plus a number of smaller populations (Stacey 2007). Since before the earliest European presence in Indonesia, these populations have engaged in migratory behaviour as part of artisanal commercial fisheries for local (e.g. dried and fresh reef fish) and international trade (e.g. trepang, shark fin, live reef fish), the latter strongly driven by demand from China and other Southeast Asian countries for highly prized marine products. Since the seventeenth century, fishing, sailing, fishing and trading strategies have permeated as far south as northern Australia, throughout eastern Indonesia to the north to Malaysia and Singapore, and even as far east as the island of Palau in the northwest Pacific (Stacey 2007). Over the last three centuries, these groups have adapted diverse sailing, fishing and trading livelihood strategies in response to the island environment, political processes and alliances, and commercial trading networks.

Mobility and adaptability underlie the social and economic life of these maritime populations and are key features of these communities. People move regularly and frequently between home villages and transient or semi-permanent settlements across the archipelago, staying for short or extended periods in settlements. Mobility is facilitated by kinship, economic ties (patron-client) and historical antecedents (Stacey 2007). The most mobile and specialised of all seafaring groups are the Sama-Bajau (commonly referred to in the academic and popular literature as 'sea nomads'). They are also the most vulnerable and marginalised due to lack of secure sea tenure, landlessness and their status as a minority Indigenous group (ILO Convention no. 169 [1989]; see Annex 1).

Mobility among Indonesian fishers does not mean an absence of resource governing institutions, however, and these provide the basis for both fisheries management and marine conservation and economic development, including the traditional community-based coastal resource management sasi system of the Maluku archipelago. Sasi, which means 'to prohibit', regulates the harvesting of certain biological resources in the estuarine and nearshore coastal areas, in an effort to protect their quality and population. Sasi also operates to maintain patterns of social life, through the equal distribution among all local citizens of the benefits from the surrounding natural resources (Kissya 1995). As an institution it has never been static, changing with the coming of state and church organisational structures into the islands and varying from village to village. The governing and enforcing authorities may be traditional, church, local government or private individuals holding the harvest rights to coastal land and aquatic resources. In certain areas sasi has evolved to accommodate significant commercial transactions involving the natural resources and a spectrum of claimants.

Consequently, the rules that define how the players in sasi work together are a mixture of tradition and modern innovations and demonstrates attention to relational and subjective issues that make it more than a technical means to manage fishing effort. This has been important to the resilience of the institution and its continued relevance to culture and well-being.

The modern state apparatus in Indonesia was keen to make marine fisheries an important source of foreign-exchange earnings. Extending state control over the coastal waters of the archipelago was a prerequisite for this. State patronage of modern fishing technologies (such as the bottom trawl), with investors from the Chinese communities taking the lead in the mid-1960s, resulted in the gradual and extensive spread of bitter conflict with coastal fishermen using small- scale, artisanal techniques. Institutions like sasi were initially deemed irrelevant to handling these new forms of conflict. State-supported legislation and zoning arrangements were introduced to contain the conflict, but these centrally administered regulatory regimes were costly to implement and largely ineffective in enforcement given the geographic spread of the islands of Indonesia. Moreover, they had no legitimacy in coastal communities that were marginalised from their traditional fishing grounds. This led to a revival of interest in the coastal villages for more community- oriented arrangements for protection and nurturing of the natural assets of the coastal waters. The sasi system takes on new meaning in this context.

Sasi does not cover the entire fishery. It is applied only in small inshore areas and to a few species. However, these areas and species can be considered to be keystones for the health of the ecosystem. This important ecological fact, together with the sociocultural foundations of sasi in Maluku, provides a robust rationale for supporting sasi where it continues to be vibrant, and for efforts to revive it where it faces extinction. Since collaboration, trust and legitimacy are the pillars of the sasi system, these are also crucial elements of any new institutional arrangements (Novaczek et al. 2001).

4.5 South India: Sea Courts and Legal Pluralism

Two case studies from South India illustrate the strong institutional 'interplay, fit and scale-relevance that characterise effective and resilient institutions' (Young and Gasser 2002). They also illustrate that the processes by which decisions on natural resource governance are made affect social well-being; having a voice, belonging to a group and exercising local autonomy are key values that support these institutions.

4.5.1 Kadakkodi: The Court of the Sea

Among the Hindu fishing communities scattered in the predominantly Muslim districts of Kozhikode, Kannur and Kasargode, in the Indian state of Kerala, the age-old traditional community institution called the *kadakkodi*, or 'sea court', is closely associated with the temples located on the beach. The fishery of the region exhibits great seasonality and is marked by bumper harvests. Confusion and conflicts among fishing units are inherent to the very nature of the fishery. The 'court' consists of the 'elders' and certain number of 'functionaries' who implement the decisions. The court meets openly. All fishers participate in the discussions on issues that relate to access, conservation and conflict resolution, thus nurturing senses of status and belonging and fairness.

The elders make the decisions, which are considered final. The implementation and the sanctions against offenders are the responsibility of the whole community. The *kadakkodi* has more recently been subjected to considerable pressure by rapid technological changes, new organisational forms promoted by the government, new political divisions among fishing communities and the greater involvement of formally educated youth in fishing operations. Yet its basic scaffolding is still in place. With the government emphasising decentralised resource management and governance, there is latent interest in reviving and strengthening the institution, albeit in a new form. In this context, communities with a history of traditional institutions will have an important edge in the negotiation of any new stewardship contract between state and community (Kurien 2001).

4.5.2 Uur Panchayats and Legal Pluralism

The Coromandel Coast of southeastern India has a long history of settlement and particularly strong expressions of customary law (Bavinck 2001a). The fishing communities belonging to the Pattinavar caste had established village councils (*uur panchayats*) for formulating and implementing a broad spectrum of customary laws. Along this coastline fishers law often prevails, with civil servants having to walk on tiptoe.

Uur panchayats' prime responsibility is social and territorial in nature and ultimately anchored in control over people as well as territory (Bavinck and Vivekanandan 2017). All adult men are considered members of the community and are considered equal—a fact mirrored not only in the structure of village meetings (members seated in a circle at the same level) but in the consensus approach to decision-making (Bavinck 2001b). All members contribute taxes to the village and not only follow the rules that are collectively adopted but also enforce them. The position of the elders used to be hereditary. But today most councils organise regular elections to fill these positions.

The *uur panchayat* controls adjacent waters, regulating the kinds of fishing practiced and also taxing outsiders who wish to land their catches locally. Residential lands and common lands are in principle still held collectively under the jurisdiction of the *uur panchayat*. Beaches adjoining fishing settlements are also controlled by the village councils. All tenure rights are held under community common property regime, with rights flowing to members of the village population as a whole. These rights are not transferable and so protect the group against unwanted encroachment and infiltration.

According to India's constitution, the use of marine waters is regulated by the state alone. In the case of fishing, the clash between the state and the customary legal systems such as the *uur panchayat* has been pronounced and sometimes violent. The introduction of semi-industrial fishing by the state caused uproar in the *uur panchayats*, since this new category of fishers was blatantly infringing upon village fishing territories, causing significant damage and indignation. Recently *co-management* has become a buzz word in government circles, but though the *uur panchayats* are not considered legal and held in suspicion as a relic of the past, on an informal basis, government representatives have been shown to negotiate regularly with *uur panchayats*, recognising the need to come to terms with the legal plurality for the sake of maintaining peace, equity and better management of fishery resources.

4.6 African Maritime Economies: Historical Foundations and Contemporary Visions

African nations, under the leadership of High Level Panel member states Kenya, Ghana and Namibia, together with South Africa, are leading the global charge to embrace the growth possibilities of the 'blue economy'. The Seychelles has pioneered the use of 'blue bonds': an innovative financial instrument to support the conservation of its ocean estate and its associated ecosystem goods and services, building on debt-for-nature swaps (Schutter and Hicks 2019). While conservation benefits are a primary motivation for some of their development partners (such as The Nature Conservancy), African nations are looking at the blue economy largely in the context of an imperative to industrialise, grow their economies and provide employment opportunities and food for their citizens.

African nations' success at lifting their citizens out of poverty is crucial to meeting SDGs. But the ocean around Africa is not empty, and it has a history. That history—and the human relationships with the ocean that have persisted through or been shaped by the mercantile and colonial periods—provide a basis to build on. The Swahili, for example, are regarded as a coastal or maritime culture (Fleisher et al. 2015). While their languages, religion, customs and sailing technologies have reached the heart of the African continent, they are originally a cosmopolitan maritime trading society, whose East African port cities of Lamu (Kenya) and Stone Town Zanzibar (Tanzania) are listed as UNESCO World Heritage sites (see Annex 5), attracting international tourism in the past 50 years. Plans to develop a new port near Lamu may make trans-oceanic trade once again its most important economic activity (Lesutis 2019). Whether Africa's future ocean economy is to be built on expanding ports and transportation infrastructure (much of it funded by China's Maritime Silk Road initiative; Lim 2015) or whether it will be built on 'blue bonds' and rationalised fisheries remains to be seen. What is clear, however, is that Africa's citizens will benefit most if any such development is also built on Africa's existing maritime cultures and institutions. Here we introduce the Yoruba littoral in Nigeria to illustrate that new ocean economy initiatives will be layered upon a rich tradition of maritime trade and interactions with and dependencies on the ocean, even in societies usually associated with land-based activities.

4.6.1 West Africa and the Atlantic: The Yoruba Littoral

The Yoruba are found mainly in the western part of Nigeria, but also with substantial numbers in the neighbouring republics of Benin and Togo. Descendants of Yoruba slaves exported to the Americas between the seventeenth and nineteenth centuries live in Brazil, Cuba and several Caribbean and Latin American nations. With an estimated population today of around 56 million in Nigeria, the Yoruba have lived in large settlements for centuries—they were the most urbanised African ethnic nationality before European colonisation in the nineteenth century. The bulk of the Yoruba population lives in the hinterland, while a much smaller percentage lives on the Atlantic coast.

The Yoruba littoral is not exclusively Yoruba. Other Nigerian and non-Nigerian coastal peoples also live, fish and trade in the zone. Among these are the Ijo (Izon) and Egun of Nigeria, the Ewe (Keta) of Togo and Ghana, and the Fante of western Ghana. It is claimed that migrant fishermen from Gold Coast/Ghana have been in the Lagos section of the Yoruba littoral since the late eighteenth century (Adewusi 2017, 165). The diversity of people speaks to the multicultural character of the Yoruba littoral and the range of criss-crossing migrations, over hundreds of kilometres across the Gulf of Guinea— westwards to Côte d'Ivoire and eastwards to Cameroon, Gabon and Angola. Fishing techniques and methods of fish processing have been borrowed or transferred by migrants as they fished and traded beyond their homelands. Migrations, economic enterprise, war and peace, and cultural exchanges have defined identity and inter-group relations in the Yoruba littoral. The zone was the site of power relations between proximate and distant neighbours, commercial enterprise, oracular and religious activities, all of which are critical to the daily lives of the people. There were hierarchies of power relationships, especially between political and economic nodes, on the one hand, and their satellites, on the other.

The sea (*okun*), lagoon (*osa*), lake (*adagun-odo*) and river (*odo*) are connected in Yoruba cosmology. The sea features in Yoruba legends of migrations and festivals. All over the coast, festivals dedicated to sea goddesses are commemorated either to celebrate fish harvests or to placate hostile natural forces so that the environment may be conducive to fishing. The association of the Yoruba with the ocean is embodied by the deity Olokun (Lord of the Sea) and Yemoja (the sea goddess). Rituals and festivals are performed by the Yoruba and non-Yoruba ethnic groups in Nigeria in honour of this deity. The iconic Ori Olokun mask—adopted as symbol of the global Festival of Black and African Arts and Culture in 1977—represents the Yoruba, though Olokun is not exclusive to the Yoruba. The deity is represented in the pantheon of the religious and cultural systems of the neighbouring non-Yoruba Edo, Itsekiri and Western Igbo communities in midwestern Nigeria. The multi-ethnic character of the Yoruba littoral has led to extensive mutual cultural borrowings and overlaps in language registers, broad similarities in songs and festivals, dress styles, family, personal and place names (though the same words might have different contextual meanings) and inter-ethnic marriages. Festivals for Olokun are celebrated across ethnic and social divides. Okosi, an annual festival of rowing and sailing, is a boat regatta to appease Olokun and thereby ensure a greater catch, as well as safety for fishermen on the lagoons and the ocean (Adeyeri 2012).

Ayelala, strongly entrenched among the Ilaje and their Ikale (fellow Yoruba) neighbours, is another sea-themed deity that cuts across the Yoruba littoral. Ayelala is 'not only worshipped with pomp and pageantry but also highly revered and respected by its worshippers [It] is linked to conflict resolution and retribution against societal impropriety' (Raheem and Famiyesin 2017, 233). It has a fearsome reputation among the Ikale, Ilaje and Ijaw-Apoi for dispensing swift justice in cases of sexual infidelity or murder. Its religious and oracular network extends far beyond the cultural and geographical boundaries of the Yoruba littoral The deity thus plays a role in fostering peaceful inter-group relations among communities across the zone. 'Seeing the efficacy of Ayelala's powers,' it has been noted, 'other neighboring and distant communities such as Ikaleland were quickly attracted to the goddess and infused it as part of their traditional deity' (Raheem and Famiyesin 2017, 244).

An overview of the economic activities of the Yoruba coast, with an emphasis on fishing, is given in Annex 6 fishing has been the driving force behind the lateral movements along the coast It remains the centre of littoral social and economic life Fishing is the impetus behind Ilaje, Izon, Ogu and Keta migrations and settlement across the Gulf of Guinea and beyond The fishing industry has witnessed significant innovations, while remaining largely artisanal, since the 1890s Both Indigenous religion and Christianity have contributed to the political, economic and social development of the Yoruba littoral.

The key lesson from the way the Yoruba have institutionalised their relationship to the ocean is that coastal trading societies need ways to foster cohesion, cooperation and mutual understanding among distinct but regularly interacting groups if they are to benefit from trade relationships Their cosmology is built on fostering and maintaining these interactions and attending to relational, spiritual and practical needs.

4.7 Island Communities' Leadership in Governing the Ocean Locally and Globally

Island nations in the Pacific, Caribbean, North Atlantic and Indian Ocean have featured prominently both in the redevelopment of local conservation and resource management institutions and in ensuring that the ocean is prominent in global governance mechanisms and policy discourses around 'greening' the economy and reaching agreement on global greenhouse gas emissions.

The nations of the Pacific Community have been at the forefront of campaigns for local autonomy in marine and coastal natural resource management and for local and Indigenous knowledges as the basis for systems of governance. The 'New Song', or Nouméa Strategy (SPC 2015), calls for an enhanced focus on coastal fisheries management and related development activities in the Pacific region. It is a community-driven approach built upon traditional Melanesian, Micronesian and Polynesian institutions, supported by national governments and all other stakeholders, to provide direction and encourage coordination, cooperation and an effective use of regional and other support services to develop management of coastal fisheries. At the regional level it coordinates initiatives and stakeholders with a shared vision of coastal fisheries management. At the national and subnational level, it seeks political recognition of the value of coastal fisheries to food security and rural development. It thus addresses what have been seen as key limitations of local governance initiatives: coordination and scalability.

Pacific island nations, such as Solomon Islands, have worked to include locally managed marine areas and other forms of customary marine tenure in their legal systems, which are based on state laws, themselves a mix of English law dating from the colonial era and post-independence legal development (Schwarz et al. 2020). This pluralistic legal system is itself also nested within regional treaties and agreements of the Pacific Community and international law, including the law of the sea. The 'New Song' supporting local coastal fisheries is mostly compatible with the FAO Voluntary Guidelines for Securing Sustainable Small-Scale Fisheries (SSF Guidelines) (FAO 2015), with areas of divergence occurring around gender relations and human rights (Song et al. 2019), illustrating both the strengths and weaknesses of global policy harmonisation: it fosters coordination but potentially undermines cultural autonomy. The governance regime for the Pacific is thus both polycentric and plural, with the complex legal and policy environment responding to evolving relationships between people and the ocean at multiple jurisdictional levels.

At the level of global environmental governance, the Alliance of Small Island States (AOSIS) has been prominent in four ocean-related arenas: global climate change agreements, evolving high seas fisheries governance, agreements governing deep-sea mining and the conceptual roots of the blue economy. In all these cases, the negotiating and diplomatic tactics employed by AOSIS have relied extensively on appeal to subjective and relational values, as we briefly discuss here with respect to climate change and the blue economy.

In the climate change arena, AOSIS, building on the work of many civil society advocacy groups and regional and international nongovernmental organisations (NGOs), built a narrative around islands as vulnerable to sea level rise and other ocean-related climate change but not responsible for climate change. This narrative also rejected victimhood and stressed resilience, equity, rights and justice as values embodied in their calls for industrialised nations to commit to curbing carbon emissions and funding adaptation. In doing so, they influenced the outcome of the UN Framework Convention on Climate Change's 21st Conference of the Parties, resulting in the Paris Agreement (McGregor and Yerbury 2019).

The blue economy was originally an appeal by the 'large ocean states' (as SIDS now prefer to be called) of the Pacific Community and the Caribbean for investment and policy attention around greening the economy to move beyond the land. AOSIS argued that most of the technologies, policy measures, investments and attention around greening the economy—through energy efficiency and decarbonisation, improved land-use and recycling materials—were focused on terrestrial technologies (Voyer et al. 2018). The blue economy narrative has since shifted and broadened to encompass a range of views (see Sect. 11.3.1), but it was originally conceived around ways small island states, with their small-scale community customary fisheries and large ocean territories, might participate actively and equitably in the greening of the global economy. Thus, the blue economy concept was originally built on island nations' concerns for equity and participation as well as the growth potential and environmental sustainability of the ocean.

4.8 Maritime Examples of UNESCO's 'Intangible Cultural Heritage' Designations

While many traditional systems of ocean governance and some more recent state-driven ones demonstrate how ocean resources and the ocean economy are governed with relational and subjective elements of well-being in mind, the contemporary global governance instrument that most explicitly seeks to consider these non-material dimensions of ocean-related contributions to people is UNESCO's 1972 Convention Concerning the Protection of the World's Cultural and Natural Heritage.

UNESCO (2020a) defines heritage as 'our legacy from the past, what we live with today, and what we pass on to future generations. Our cultural and natural heritage are both irreplaceable sources of life and inspiration'.

UNESCO evaluates, designates and maintains lists of natural and built-environmental sites as well as intangible (i.e. non-material) cultural heritage. While nation-states invest in protecting their own heritage, what makes the concept of World Heritage exceptional is its universal application. 'World Heritage sites belong to all the peoples of the world, irrespective of the territory on which they are located'

(UNESCO 2020a). The process of identifying and designating such sites draws attention and resources to their conservation and to support their continued contribution to humanity as 'irreplaceable sources of life and inspiration'. These listings are supported by legislative protection derived from the Convention Concerning the Protection of the World Cultural and Natural Heritage, including the 2003 UNESCO Convention on Intangible Cultural Heritage.

Sites and cultural systems may receive multiple UNESCO World Heritage designations due to their landscape or biodiversity significance, their historical and material significance or their contributions to less tangible elements of heritage such as ritual, belief, language, skills, identity and social organisation—many of which this paper has discussed.

The Marine program within the UNESCO World Heritage program (UNESCO 2020b), under which a number of marine and coastal sites have been designated, is helping to raise the profile of World Heritage designations in ocean and coastal governance. Although much of the program's work is focused on natural heritage, several designations of coastal and marine sites include either historical and archaeological heritage or living human cultural practices and meanings as criteria for listing. These include Papahānaumokuākea (United States), an isolated linear cluster of small, low-lying islands and atolls, with their surrounding ocean, roughly 250 km to the northwest of the main Hawaiian archipelago and extending over some 1931 km^2. The area has deep cosmological and traditional significance for living Native Hawaiian culture, as an ancestral environment, an embodiment of the Hawaiian concept of kinship between people and the natural world, and the place where it is believed that life originates and to which the spirits return after death. On two of the islands, Nihoa and Makumanamana, archaeological remains testify to pre-European settlement and use. Much of the monument is made up of pelagic and deep-water habitats, with notable features such as seamounts and submerged banks, extensive coral reefs and lagoons. It is one of the largest marine protected areas in the world.

An overview of the application of UNESCO World Heritage designations to oceanic and coastal sites is given in Annex 5, with examples of maritime- and ocean-associated inscriptions under the 2003 UNESCO Convention on Intangible Cultural Heritage.

5 Opportunities for Action to Support Pluralistic and Inclusive Ocean Values

There have been calls from scientific leaders for a new narrative about the ocean that replaces indifference or despair at the state of the ocean with optimism and innovation, to 'reset expectations and liberate ingenuity' (Lubchenco and Gaines 2019, 911). Calls for new narratives also come from the grass roots, with small-scale fishers' representatives calling for a more positive story about the role of small-scale fisheries in contemporary and future society (FAO 2020b). We suggest that both these narratives are calls for recognition of the many and diverse contributions the ocean makes to human well-being.

5.1 Synthesis and Conclusions

People have multiple economic, political, social, cultural, spiritual and emotional relationships with the ocean. These 'blue relationships' are a product of geography, history and human diversity—including diversity of economic circumstances. Because there is unprecedented attention to ocean policy at present, and because—amid a health and economic crisis—there is a wider global reflection on human values and trajectories and a rising tide of protest against economic and racial injustice, the present moment offers great opportunity to take the bold political actions needed to develop a sustainable ocean economy built on diverse relationships, in ways that encourage equity and inclusion and that recognise the non-material aspects of well-being.

The human relationship with the ocean tends to change with distance from land. More of humanity is acquainted with the coast than with the high seas. Our relationships with shorelines, estuaries and tidal waters are intimate, while our relationships with blue waters may be warier and more transactional. This gradation of relationships also requires a gradation in the scale of legal and policy frameworks. Local and traditional systems are prevalent in inshore waters and could provide a basis for building governing institutions with legitimacy and in ways that sustain both the material and non-material contributions the ocean makes to well-being. The legal regime governing EEZs and the high seas is largely in place and supported by UNCLOS, but it requires strengthening and dialogue to accommodate new ocean uses as countries make ocean economic plans and engage in marine spatial planning. It also requires recognition that all peoples and nations should have a say in how this 'common heritage of humanity' is *governed*. This principle—and the right to participate in decision-making about areas beyond national jurisdiction—is increasingly exercised by landlocked states, local coastal communities and Indigenous Peoples (Vierros et al. 2020).

A sustainable economy will be accessed through the land-water interface. How we govern coasts will determine who accesses and benefits from blue space. A heavily privatised, zoned and securitised coast will exacerbate the separation of humanity and the ocean and risk alienating and reducing access for lower-income visitors and residents, as well as long-term ocean resource users and stewards, such as fisherfolk and Indigenous Peoples. An accessible coastal commons, built upon existing institutional foundations and providing livelihood and well-being benefits to all citizens, is likely to foster a more constructive long-term engagement with the ocean.

Our overarching conclusions from our review of the myriad human relations with the ocean, across time and space, are threefold:

- First, there is no simple human relationship with the ocean with which all people will identify. Fishers inshore and offshore, refugees attempting to cross the Mediterranean, beach and adventure tourists, seaside condominium buyers, oil rig workers, Ghanaian fish mammies and the oceanographers all have different interests, experiences, economic stakes, emotional investments and cultural and social ties to different aspects of the coast and ocean. Building on this plurality of values to forge a diverse and inclusive sustainable ocean economy provides opportunities for increasing the ocean's contribution to both material and non-material well-being on a planetary scale. Doing this in practice is likely to require a participative style of democracy with the active engagement of ocean and coastal citizens.
- Second, ocean economic development plans that specifically address equity and inclusion will help reduce existing gender, class, ethnic, North-South and racial inequalities. While the ocean's regulatory and support services benefit all humanity, it is particularly important to address the concerns and interests of the majority of those working on the ocean or stewarding the ocean, such as Indigenous Peoples using diverse natural resources, municipal authorities maintaining clean water and beaches, and those working in and managing fishery resources and conservation areas. Collectively, small-scale fisherfolk, sea nomads and coastal Indigenous Peoples are 'too big to ignore' (Chuenpagdee 2011).
- Third, in the industrialising ocean, maintaining open and natural spaces such as coastal beaches and seas contributes to citizens' access to opportunities to gaze at, walk, swim or play near, in or on the ocean. These access rights and resources should be preserved as far as possible and extended where they have been eroded or unjustly encroached upon. Losing this access to 'blue nature' will result in an incalculable loss to human well-being.

This is therefore a once-in-a-generation opportunity to pause and carefully consider our complex relationship with the ocean, and to rethink it and remake it to meet the challenges future generations will face. The Sustainable Development Goals themselves represent more than a reduction in the incidence and prevalence of the material dimensions of poverty—important as these are. They represent a set of pathways to human well-being and a transition to planetary sustainability. Achieving them will require humanity to have a rich, diverse, engaged and evolving relationship with our ocean planet.

5.2 Opportunities for Action

We present action opportunities as linked steps, starting from a reframing of the human-ocean relationship, progressing through an engagement with a wider ocean constituency, and finally supporting that constituency to establish diversity and inclusion as core elements of a sustainable ocean economy.

5.2.1 Humanise the Ocean Narrative

Narratives motivate and inform political action (Lubchenco and Gaines 2019). Narratives that celebrate the rich diversity of human social, cultural, cognitive and emotional relationships with the ocean and emphasise the relationship between human well-being and ocean ecosystem flourishing could help broaden the political consensus around a sustainable ocean economy. We therefore suggest several ways that such narratives can be developed, progressing from short- to longer-term action.

Shifting Language and Frames of Reference

Three shifts in frames can help create a context for more inclusive actions in support of positive human-ocean relationships:

- *Reclaim the idea of the blue economy*. It has energised governments, NGOs and the private sector but alienated some in civil society. Originally developed as a means to bring the principles of equitable 'green growth' to small island developing states, it has been co-opted by many different interests. Its 'greenness' and its commitment to equity need to be reasserted, while the growth imperative itself requires critical scrutiny.
- *Reframe ocean ecosystem services as 'nature's contributions to people'* (NCPs), following the IPBES (Díaz et al. 2015, 2018). The emphasis on converting all of nature's goods, services and gifts to humans to their equivalent in monetary values (even if only conceptually) is both politically polarising and problematic for many outside of Judeo- Christian cultural influences, particularly Indigenous Peoples. NCPs constitute a more inclusive frame that recognises a diversity of knowledges and value systems (Pascual et al. 2017).
- *Emphasise the ocean's contributions to meeting all SDGs.* Here it is particularly useful to move beyond the achieve-

ment of SDG 14 to consider potential ocean economy contributions not only to food security and poverty reduction but also to gender equity, youth employment and development partnerships. Tools for mapping ocean economy plans against potential contributions to SDGs are being developed and could be applied to sustainable ocean economy development plans at the national and subnational levels (e.g. Obura 2020).

Broadening the Knowledge Base: Informing Blue Futures

Local and Indigenous knowledges and the environmental humanities can, along with natural and social sciences, inform the sustainable ocean economy and reflect the diversity of human-ocean relationships. Here are tangible ways to achieve this representation:

- Ensure that historians, anthropologists and local and Indigenous knowledge-holders are part of national ocean economy planning teams.
- Allocate marine research funding to the arts and humanities as well as the natural and social sciences.
- Encourage institutions such as maritime museums to consider broader representations of the ocean sector.[7]
- Work with communities, municipalities and private sector sponsors to support cultural festivals that celebrate coastal and sea life, or arts, theatre and film festivals[8] with ocean themes.
- Identify coastal and maritime candidates for UNESCO World Heritage listing. Such listings not only help preserve and reproduce cultural and social values but also attract investment in tourism and renewal of coastal towns' housing stock and regeneration of waterfronts.
- Document fishers' knowledge to broaden the knowledge base. *The IUCN Guidelines: Gathering of Fishers' Knowledge for Policy Development and Applied Use* (to be published shortly) sets out protocols for doing this.

All these activities draw attention to both positive and contentious human relationships with the ocean and complement the more widely known public presentations of the ocean that focus on ocean wildlife or present the ocean as despoiled wilderness.

5.2.2 Engage Key Constituencies in the Development of Future Ocean Visions and Planning Processes at National and International Levels

After some 40 years of global consensus on globalised and liberalised economies, vulnerabilities in that system revealed by the COVID-19 pandemic, concerns for rising inequalities and inadequate action on climate change are leading to radical calls for transformative economic and social policy. There are a diversity of visions and values for both the global economy and the global ocean being developed ('blue justice', 'blue degrowth') but these are largely outside the UN process. The proponents of these visions, which include small-scale fisher representative organisations, could be included in dialogues and planning for the sustainable ocean economy. Specific actions may include the following:

- *Set up intergenerational dialogues on ocean futures at the national level*. Youth are taking a lead on global climate action and could bring that leadership to the ocean policy arena, in dialogue with elders who, in many Indigenous and traditional societies, are keepers of stories, knowledge and authority.
- *Engage with organisations proposing alternative visions for human-ocean relationships*. Civil society organisations representing some 'ocean citizen' interests have expressed concerns about the process and vision of developing the sustainable ocean economy. They have watched what has happened to their fellow citizens in previous agrarian and industrial revolutions and fear what follows from the 'blue acceleration'. Their concerns are legitimate, and their institutions, knowledge and policy advice could help prevent such outcomes in the future ocean economy. Indigenous Peoples are key constituents here in many ocean states; so too are trade unions and NGOs in the human rights, community development and environment and conservation arenas.
- *Choose between commons or private ocean*. This should include holding national-level dialogues on the institutional and financial means to achieve a diverse, equitable and sustainable ocean economy that delivers well-being to the greatest number of people. The debate centres principally on the use of communitarian, public sector or privatisation approaches to governance. Balancing local and global responsibilities is the critical challenge.
- *Support small-scale fisherfolk*. Small-scale fishers are currently the largest population group directly economi-

---

[7] Stories of the past are integral to shaping values and world views—as the current challenges to ethnocentric histories and cultural symbols are showing. Exhibitions on slavery, immigration and maritime labour unions are increasingly found in the maritime museums of former colonial powers (e.g. in Liverpool and Amsterdam), to balance the more traditional tales of heroic exploration and naval victories. These attract more diverse visitors and, through a better understanding of the past, allow a reimagined future.

[8] Community theatre, dance, song and poetry are widely popular globally (e.g. Buck and Rowe 2017) and used to both celebrate and explore contentious issues. Pêcheurs du Monde (Fishers of the World) is a film festival held biannually in Lorient, Brittany, France. The 2019 British film *Bait*, about gentrification in a Cornish fishing village, has won a number of festival awards; see https://en.wikipedia.org/wiki/Bait_(2019_film).

cally dependent on the ocean and are part of the private sector. They feel squeezed out of coastal zones that they have occupied, used and stewarded, in some cases for centuries. They could be powerful allies for ocean stewardship.

- *Engage port cities and coastal local governments in inclusive ocean governance.* Port cities have played major roles in shaping the human relationship with the ocean, often both driving economic growth and leading social change movements. Leaders of major cities are already key actors in global policy arenas such as climate action, sustainable food systems and equity and justice (Pearson et al. 2014), so they are well positioned to play a greater role in ocean governance. Ports, waterfronts and ocean tourism are key elements of many coastal city economies, which increasingly look to a 'blue urbanism' to improve their citizens' quality of life (Beatley 2014). Coastal local governments may also be better than national marine spatial planning processes at accommodating diverse local interests.

The dialogues with small-scale fishers and with coastal Indigenous people could be brokered through FAO's civil society platforms, through which they have been able to develop the SSF Guidelines (FAO 2015)—a voluntary global governance instrument with significant buy-in from the world's fishing communities and, increasingly, governments, coastal Indigenous Peoples and environmental NGOs (Jentoft et al. 2017). This process of engagement could begin with the 2021 meeting of the FAO Committee on Fisheries. An equally important mission is to ensure that the democratic and human rights–based guiding principles and provisions of the SSF Guidelines are mainstreamed and embedded in fisheries large and small, and in the numerous blue economy programs at the national and international levels.

Table 11.5 summarises the rationale for developing the knowledge base, narratives and engagement strategies described above.

5.2.3 Create Policies and Mobilise Finance for Actions in Support of an Inclusive Ocean-Society Relationship

Inclusive governance is best supported by participatory democracy, which requires an active and capable civil society. We propose three actions to safeguard and facilitate engagement of, and action by, a wide spectrum of ocean interests, including those who have been historically or recently marginalised by the economic development process. This entails support for such communities and populations to enable them to participate fully in the sustainable ocean economy and to retain and expand their historical rights and responsibilities in the ocean. The effort will require the development of adaptive leadership in both the public and private sectors.

Table 11.5 Synthesis of means to foster narratives, dialogues and knowledge to mobilise key constituents to support inclusive, pluralistic ocean governance

Areas of benefit Goal for action	Discourse	Knowledge	Value	Alignment
Enrich the diversity of ocean policy actions by humanising ocean narratives.	Reclaim the original meanings of the 'blue economy', centred on equity and sustainability.	Broaden the knowledge base informing 'blue futures' to include indigenous and local knowledge, the arts and humanities.	Shift from valuing ocean ecosystem services to valuing the ocean's contributions to society.	Emphasise the contributions of the ocean to meeting all SDGs, not just SDG 14.
	Stress the relational and subjective elements of ocean contributions to societal well-being.	Ensure equity of access to information by marginalised and/or vulnerable groups.		
Ensure Ocean inclusivity by engaging key constituencies.	Set up intergenerational dialogues on ocean futures.	Engage overlooked or marginalised constituencies for the ocean.	Engage with religions and spiritual beliefs about the oceans	Develop dialogues with small-scale organisations representing fisheries.
			Recognise the sovereign claims of indigenous peoples.	Engage with leadership of the governance bodies of major coastal cities.
	Dialogue and facilitation		Mainstreaming and policy alignment	

1. **Create a publicly funded community-based knowledge depository for use in dialogue with new ocean economy interests**. In order to safeguard their own knowledge and perspectives that connect intergenerational interests and communities' needs for a sustainable ocean economy, we need to *build on traditional institutions, values and narratives of the ocean in different regions and nation-states and support communities* **to continue to evolve their ocean relationships**. Public funds to support these relationships could include support for scientific monitoring and data collection, maintenance of social institutional knowledge and practices, and support for civil society organisations and Indigenous governments as they chart their own courses in the future ocean.

   ACTION: Establish long-term public funding streams dedicated to the creation and maintenance of national-level knowledge repositories in which community-level experiences of disasters, toxic exposures and development in general can be archived. Build institutionalised connections between such repositories and communities or their legitimate representatives in order to increase community-level access to salient information and prior experience, and level the playing field for communities negotiating with external interests.[9]

2. **Provide statutory protection to prevent private equity from undermining community capacity and interests**. Powerful corporate interests have the capital and political influence to shape community-government relationships in their favour. Governments have a duty of care to ensure that their citizens' interests are fairly considered in future ocean economic development. Governments need to create legal and expert support aid for ocean-dependent communities and civil society organisations to facilitate their capacity (including their internal decision-making process and legal base) to negotiate with external interests in order to represent their cultural world views in formal negotiation processes. Current ocean-related funding reflects global conservation and development values but leaves little space for local voices and values. The funding will prevent powerful actors from buying their 'social licence to operate'.

   ACTION: In recognition of clear conflicts of interest, and in order to improve social license for development as well as development outcomes and impacts, disallow industry and development interests from funding the negotiators representing the communities and decision-makers whose interests they seek to influence. Instead, establish institutionalised, national-level sources of expert legal support that may be freely accessed by communities approached by development interests. Ensure that legal support is fluent in and supportive of the diverse priorities and cultural world views of the range of represented community groups.

3. **Re-evaluate development funding structures and mechanisms to support meso-level institutions**.

   In reformist agendas such as those explored by the Ocean Panel, there is a tendency to look to either high-level processes and powerful actors (technological change, global laws, standards and conventions, intergovernmental organisations, national governments, national policy instruments, market forces, large corporations or industry associations, international conservation NGOs) or shifts in individual behaviour (diversifying out of fishing, eliminating single-use plastics). These are the two extreme levels in multi-level governance. In between are devolved, municipal and local government, Indigenous sovereignty, community, civil society organisations, trade unions, pluralistic legal systems, public institutions, small and medium enterprises, and the trade and cooperative organisations that bind them together.

   ACTION: Invest in the capacity of socially and culturally embedded meso-level institutions to govern both traditional and emergent ocean industries, in partnership with government and intergovernmental and international NGO actors where appropriate. This includes support for institutions that enable legal protection of sea tenure, uphold existing human rights (gender, labour, rights to food, rights to livelihood, etc.) and facilitate access to new opportunities in the ocean economy by marginalised groups in society.

4. **Ensure that responses to COVID-19 are based on an understanding of well-being in all its dimensions:** COVID-19 impacts are linked to many other issues, including building resilient economies and food systems and adapting to and mitigating climate change. This nexus of responses needs to build on an understanding of what is required to support subjective and relational well-being as well as material needs.

   ACTION: Invest funding in social well-being assessments as part of COVID-19 recovery planning. Support inclusion of ocean-dependent communities in recovery planning in other sectors, principally transportation, tourism and fisheries.

Finally, the Ocean Panel has the opportunity to reassert a commitment to multilateralism as part of any attempt to bring greater order to the ocean and to use the members' diplomatic channels to engage other states in this endeavour: The 14 countries' call for harmonised ocean governance comes at a time of resurgent nationalism, when many of the world's largest economies are either turning away from multilateral treaties and institutions or seeking to control and influence them in their

[9]Namati, who 'put the power of law in people's hands' around the world, is an example of such a group: https://namati.org.

own interests. There is a delicate balance between recognising countries' rights to use their ocean assets for their national priorities, on the one hand, and representing the 'common good of humanity' and the rights of non-human nature, on the other. It will take bold political and social leadership to develop such a governance architecture.

6 Conclusion

The Yoruba littoral has experienced the profound impact of waves of human migrations over the centuries.

Migrations took place along two axes: north-south, dominated by fellow Yoruba-speaking peoples; and east- west, dominated by the Ilaje, Izon, Ogu and Keta (Ewe).

The littoral is, therefore, 'Yoruba' only in the sense of the overwhelming dominance of Yoruba-speaking people in the zone. Most Yoruba littoral communities share social and cultural institutions and practices. These include the insignia of chieftaincy and traditional institutions; divination by individuals and communities; the Olokun, Malokun and Okosi festivals; and the pervasive presence of Ayelala. Nevertheless, non-Yoruba elements have contributed substantially to the zone's socioeconomic development. Hence, the region is a linguistic and cultural continuum, a pan-Yoruba commonwealth, which includes Yoruboid (Itsekiri and Edo) and non-Yoruba peoples as indigenes at both ends of the zone and as residents all over it.

Fishing has been the driving force behind the lateral movements along the coast. It remains the centre of littoral social and economic life. Fishing is the impetus behind Ilaje, Izon, Ogu and Keta migrations and settlement across the Gulf of Guinea and beyond. The fishing industry has witnessed significant innovations, while remaining largely artisanal, since the 1890s. Both Indigenous religion and Christianity have contributed to the political, economic and social development of the Yoruba littoral.

The Yoruba, with the exception of the Ilaje and Awori subgroups, are largely riparian landlubbers, but the ocean has shaped their world view (Olukoju 2000, 2017). The Ilaje are the only truly maritime community among the Yoruba, followed in importance by the waterside Ijebu and Awori. Ilaje colonies all over the Yoruba littoral, and far beyond, testify to their unique status in the zone.

The littoral has not been a dominant force in the geopolitical and economic systems of the Yoruba of western Nigeria. It has been marginal in terms of political influence and state formation. In pre-modern times, Indigenous communities in littoral Yorubaland were subject to political and cultural domination from hinterland power centres, such as Ife, Ijebu and Benin. Such control or influence varied over time. It was minimal in post-1800 Lagos but pronounced in the case of Ejinrin and other lagoon communities vis-à-vis the Ijebu Kingdom. Badagry and Epe were havens or rear bases for political fugitives from Lagos before 1862.

Inter-group relations between indigenes and residents of the Yoruba littoral are complex and dynamic. In general, ethnic affinity between host communities (Awori and Ijebu) and fellow Yoruba immigrants (especially the Ilaje) has mitigated potential conflict and produced generally cordial relationships. In contrast, ethnic diversity has compounded ordinarily tense relations centred on competition over land, fishing and other economic rights. This is illustrated by the Ilaje-Izon conflict in southern Ondo State in the late 1990s, and clashes between the Yoruba and Ogu in the Ajah axis of metropolitan Lagos in 2016.

Multifaceted relationships characterise the Yoruba littoral. These have been underpinned and moderated by homogenising forces of religious affinity, cultural exchanges, commercial relations, intermarriage and the linguistic and cultural accommodation of immigrant elements in local communities.

[a] Lead author or contributing author of Blue Paper 11

Jonathan Barton, Janice Cumberbatch, Christina Hicks, Moeniba Isaacs and Kimberley Peters contributed ideas and support to early drafts of this paper. The work also benefited from having co-authors in common with other Blue Papers related to human relationships with the ocean. Allison and Fabinyi were also involved in BP13, on equity, and Allison was involved in BP12, on governance transformations. We thank the author teams on those papers for support and cross- fertilisation of ideas. The work was completed while Allison was a visiting fellow at the Australian National Centre for Ocean Resources and Security, University of Wollongong.

The authors thank the paper's technical reviewers, Olanike Adeyemo, Tekau Frere, Hugh Govan, Danika Kleiber, Ghislaine Llewelyn, Jorge Torre and Joeli Veitayaki, as well its arbiter, Jane Lubchenco, who all provided helpful technical comments. The authors also thank World Resources Institute for providing support as the Ocean Panel Secretariat, its insights, support and patience during the preparation of this paper.

While our colleagues were very generous with their time and input, this report reflects the views of the authors alone. The authors thank Alex Martin for copyediting and Carni Klirs for design.

Annex 1. Social Well-being and Values of Sama-Bajau

Scattered throughout island Southeast Asia are three groupings of specialist maritime populations commonly referred to in academic and popular literature as 'sea nomads' and 'sea gypsies', 'a designation at once romantic and derogatory' (Gaynor 2005, 90). These ethno-linguistic groups are the Moken, Orang-Laut and the Sama-Bajau. Each of these groups is geographically, linguistically and culturally distinct and has developed its own modes of adaptation and livelihoods on Southeast Asia's highly biodiverse island, coral reef and ocean environments to support its livelihoods. The Sama-Bajau are the most widely dispersed ethno-linguistic group indigenous to insular Southeast Asia, scattered over a maritime zone 3.25 million square kilometres in extent, stretching from the Philippines to Indonesia. Between 750,000 and 1.1 million Sama-Bajau speakers are estimated to live in Southeast Asia (Stacey and Allison 2019). Generally landless, the Sama-Bajau spend their entire lives in the vicinity of the ocean, in a marine environment that constitutes 'culturally defined living spaces' (Chou 1997). It is often said by Sama, and by other Indigenous groups with whom they reside, that Sama feel sick if they spend too much time on land, or away from the ocean. They maintain a rich Indigenous marine cosmology and ritual practice, with belief in supernatural beings—ancestors of the ocean—that live in and control the universe of the ocean and all the creatures in it for Sama-Bajau people (Stacey 2007).

Sama-Bajau culture is intimately connected to marine environments on which they depend for subsistence and cash income, as well as their cultural identity.

Culturally defined patterns of fishing activity (including migratory expeditions) unite all sectors of Sama-Bajau communities through catching, consuming, processing and trading of marine resources. Fishing and gathering of shellfish and other strand resources provide the focus for individual and communal relations within villages and across extensive kin and trading networks. The maintenance and transmission of Indigenous language and knowledge from one generation to the next occurs through socialisation into livelihoods and related social and cultural activities. As such, customary beliefs and practices in relation to boats and sea spirits endure among the Sama-Bajau, and are primarily oriented to ensuring return on fishing effort (Stacey et al. 2018).

The perception of the ocean as an open space of living and trading, as well as the Sama-Bajau's notion of freely moving through that space as performing their identity and generating their world (Pauwelussen 2015), stands in contrast to the politically fragmented seascapes we see on maps. As Cynthia Chou (2006, 1) notes, 'Whichever translation one is inclined toward, the heart of the matter is that the space which others have named "Southeast Asia", comprising a number of bordered nation-states, is, in contrast, a space of deep emotional and personal meaning for the sea nomads'. The islands and sea which they occupy constitute 'living spaces' (Chou 1997, 613) for the generally landless Sama-Bajau. The movement of Sama-Bajau is entirely over water, whether commuting in dugouts between neighbouring households, visiting the 'mainland' or going fishing. Extensive pressures undermine Sama-Bajau fishing practices and their way of life, which in turn erode values of social well-being. The majority of Sama-Bajau in Southeast Asia are marginalised Indigenous groups, and in many instances their contributions as fishing peoples are not recognised by the region's governments. In many cases, they remain on the outskirts of mainstream societies in the countries they inhabit and are often stigmatised as being unruly, lazy and backward aliens. It is unlikely, then, that mainstream societies will recognise the societal loss associated with the erosion of the Sama-Bajau access to fisheries and the consequent transformations in Indigenous knowledge, cultural practices and diversity. However, loss of the fundamental values that underpin Sama-Bajau culture and social well-being will have significant impact beyond obvious implications for the Sama-Bajau themselves. In a country like Indonesia, for example, which prides itself on the national motto *Bhinneka Tunggal Ika* ('Unity in Diversity') and the concept of *Nusantara* as an archipelago where seas connect society, the loss of a unique maritime way of life such as that of the Sama-Bajau is an erosion of the very principle that constitutes the nation's desired identity. Moreover, at a local level, many rural fish markets in areas where Sama-Bajau reside are largely stocked by fishing activities from these Sama-Bajau groups and provide land-based ethnic groups with important sources of nutrition. Furthermore, marine conservation and sustainable fisheries management initiatives across the region increasingly recognise that effective and locally relevant measures need to flow from increased ground-level co-production of knowledge and practices drawing from Western technical management principles and local traditional knowledge. The presence of the Sama-Bajau at sea and their knowledge of the ocean should be acknowledged as a significant asset not only for any marine resource management initiative but also for the national identities of the region's states.

Annex 2. The Arts and the Ocean

The sea, the ships that navigate it and the fish and mammals that inhabit the marine space are a limitless source of artistic inspiration. Artistic representations of the ocean can create similar emotions that we experience from seeing, hearing, smelling and interacting with the ocean. Art can simply be a record of a place, time or event, but its purpose is usually to create an emotional response. Contemplating marine art can 'enrich … us, help us see how precious all our lives are' (Krupinski 2019, 9).

Marine (or maritime) art has a prominent place in European history (and much has been written on this topic) but equally so in other parts of the globe. Perhaps one of the most recognised marine images comes from Japan: an early nineteenth-century woodblock print by the Japanese artist Hokusai, *The Great Wave off Kanagawa*. Marine art in Europe initially focused on harbours (e.g. *A Calm* [1654], by Dutch artist Jan van de Cappelle) and sea battles but gradually progressed to works where the ocean and the shores were depicted as playgrounds for recreation, bathing and sailing Later a fascination with heavy industry and shipbuilding became a focus. The last century saw more depiction of things below the surface, as these have become more known and accessible.

Marine art is not only produced near the ocean. Prehistoric rock paintings in the interior of Africa depict marine mammals and fish (van Riet Lowe 1947). In Australia, Indigenous art has historically been influenced by the *ocean, and it still is today*. *Indigenous Australian marine art has recorded many events in time*. For instance, in the Northern Territory rare Indigenous rock art may depict the first seafarers to reach Australian shores (Middleton 2013). Marine art can change history. It has played an important role in self-determination and gaining sea rights for a group of Australian Indigenous people. The success of the Yolŋu community's native sea title claim was underpinned by bark paintings that evidenced a long relationship with the ocean (https://hyperallergic.com/412659/sea-rights-bark-paintings-australia/).

Annex 3. Sharks as Symbolic Animals

Shark binders and charmers in the Gulf of Mannar linking South India and Sri Lanka are believed to have operated for six centuries to protect pearl divers from shark attacks. In 1885 the then colonial administration forced them to discontinue what it saw as a superstitious practice linked to payments that exacted an undue toll on the pearl industry (Cordiner 1807; Kunz and Stevenson 2001 [1908]).

Sharks in the Pacific islands were believed to have spiritual powers, as ancestor guardians and/or gods offering protection from the unpredictable forces of the ocean, or as malevolent spirits in the form of shape- shifting 'shark men', who needed to be appeased so they would not devour human beings venturing into their domain (Beckwith 1970; Grimble 1972; Hviding 1996; Barry 2002; Montgomery 2006; Hilmi et al. 2016).

As symbolic animals, sharks appear to signify both the fear of the ocean's vast unknown depths and the bounty available to those who respect the ocean's ways and its powerful creatures.

Annex 4. Flying Fish as Symbol of Barbadian Identity

As Bajan as a flying fish
—Local Saying

To Barbados the flying fish (*Hirundichthys affinis* and other species) is a quintessential aspect of intangible heritage: a symbol of Bajan 'pride and industry' (the country's motto). It adorns the silver dollar coin and the logo of the Barbados Tourism Authority, as well as being the mascot for some national sports teams.

Bajan cuisine has its own unique ways of preparing and cooking the flying fish. It is also a tangible part of Bajan culture, as a source of livelihoods and nutrition in an important fishery. Long a mainstay of local fisheries and diets (its bones have been found in archaeological digs of Indigenous people's middens), the flying fish was officially recognised as one of Barbados's icons after the island gained independence in 1966 and the government began looking for symbols that generated a sense of pride among the populace, something of which islanders could say, 'This belongs to us and nobody else'.

But the availability of flying fish is at risk, as are its associated traditions, and there is no regulatory framework to protect this icon of national heritage. Threatened by a maritime boundary and fisheries dispute, it struggles under the legacy of price controls that hamper the profitability of the fishing industry. It is uncertain whether 50 years from now there will still be people to harvest the species, or people who know how to de-bone it in the traditional way. Significant variability in abundance could affect Barbadians' access to flying fish, and climate change could even lead to the species' local extinction.

A small survey (100 people) of Barbadians' cultural attachment to flying fish showed that as a symbol of national identity it lags behind the broken trident on the national flag, is a close second (34 vs. 35 respondents) to the much larger dolphinfish (*Coryphaena hippurus*) as the preferred fish to eat and as a staple food is challenged by the rising consumption of chicken throughout the Caribbean.

Annex 5. The Use of UNESCO World Heritage Instruments to Support the Conservation of Plurality of Values Humans Derive from Interactions with the Ocean

Marine and coastal world heritage sites that are UNESCO-listed also include St. Kilda and surrounding islands (Scotland, UK), Ibiza (Spain), the Trang An Landscape complex in the Red River Delta (Vietnam) and the Rock Islands Southern Lagoon (Palau). Some sites that could perhaps be listed as mixed cultural and natural heritage, such as the Sundarbans in Bangladesh or the Great Barrier Reef in Australia, are currently designated as Natural Heritage only.

Africa is generally underrepresented in the designation of World Heritage sites (Breen 2007). Its coastal and marine representation includes the port cities and island trading centres of Lamu Old Town (Kenya); Stone Town Zanzibar (Tanzania); the Island of Mozambique; Robben Island (South Africa); and the islands of Gorée and Saint-Louis (Senegal). Many of these are listed partly or mostly because of their historical role in the Indian Ocean and transatlantic slave trades or, in the case of Robben Island, because it is where Nelson Mandela, was held for much of his 27 years as a political prisoner of South Africa's apartheid-era government. More positive representation of cultural and maritime heritage is an unrealised (and so far, little-discussed) opportunity within the 'blue economy' movement in Africa (Table 11.6).

Table 11.6 Examples of maritime and ocean-associated inscriptions under the 2003 UNESCO convention on intangible cultural heritage

Country, year listed, list category	Maritime, coastal or ocean-related cultural heritage
China, 2009	**Mazu belief and customs**. As the most influential goddess of the sea in China, Mazu is at the Centre of a host of beliefs and customs, including oral traditions, religious ceremonies and folk practices, throughout the country's coastal areas. Deeply integrated into the lives of coastal Chinese and their descendants, belief in and commemoration of Mazu is an important cultural bond that promotes family harmony, social concord and the social identity of these communities.
South Korea, 2016 (1)	**Culture of *Jeju haenyeo*** (women divers). In Jeju Island, there is a community of women, some in their 80 s, who go diving 10 meters under the surface to gather shellfish, such as abalone or sea urchins, for a living without the help of oxygen masks. With knowledge of the ocean and marine life, they harvest for up to 7 h a day, 90 days a year, holding their breath for just 1 min for every dive and making a unique verbal sound when resurfacing. Before a dive, prayers are said to the Jamsugut, goddess of the sea, to ask for protection and an abundant catch. Knowledge is passed down to younger generations in families, schools, local fishery cooperatives which have the area's fishing rights, *haenyeo* associations, a school and a museum. The culture of *Jeju haenyeo* has also contributed to the advancement of women's status in the community and promoted environmental sustainability with its eco-friendly methods and community involvement in management of fishing practices.
Indonesia, 2017	**Art of Pinisi boatbuilding, South Sulawesi**. *Pinisi* refers to the rig and sail of the famed 'Sulawesi schooner'. The construction and deployment of such vessels are part of the millennia-long tradition of Austronesian boatbuilding and navigation that has brought forth a broad variety of sophisticated watercraft. Shipbuilding and sailing are not only the communities' economic mainstay but also the focus of daily life and identity. The reciprocal cooperation between the communities of shipwrights and their relations with their customers strengthen mutual understanding among the parties involved.

(continued)

Table 11.6 (continued)

Country, year listed, list category	Maritime, coastal or ocean-related cultural heritage
Islamic Republic of Iran, 2011 (2)	**Traditional skills of building and sailing Lenj boats in the Gulf of Iran**. Lenj vessels are hand-built and used by inhabitants of the northern coast of the Persian Gulf for sea journeys, trading, fishing and pearl diving. The traditional knowledge surrounding Lenjes includes oral literature, performing arts and festivals, in addition to the navigation techniques and terminology and the weather forecasting closely associated with sailing, as well as the skills of wooden boat-building itself. The philosophy, ritualistic background, culture and traditional knowledge of sailing in the Persian Gulf are gradually fading.
Belgium, 2013	**Shrimp fishing on horseback in Oostduinkerke**. Brabant horses walk breast-deep in the surf, parallel to the coastline, pulling funnel-shaped nets held open by two wooden boards. A chain dragged over the sand creates vibrations, causing the shrimp to jump into the net. Shrimpers place the catch in baskets hanging at the horses' sides. A good knowledge of the ocean and the sand strip, coupled with a high level of trust and respect for one's horses, are the shrimpers' essential attributes. The tradition gives the community a strong sense of collective identity and plays a central role in social and cultural events. The shrimp fishers function on principles of shared cultural values and mutual dependence. Experienced shrimpers demonstrate techniques and share their knowledge of nets, tides and currents with beginners and the up to 10,000 visitors who attend the annual shrimp festival.
Cyprus, Croatia, Spain, Greece, Italy, Morocco and Portugal, 2013 (1)	**The Mediterranean diet** involves a set of skills, knowledge, rituals, symbols and traditions concerning crops, harvesting, fishing, animal husbandry, conservation, processing, cooking and particularly the sharing and consumption of food. Eating together is the foundation of the cultural identity and continuity of communities throughout the Mediterranean basin. It is a moment of social exchange and communication, an affirmation and renewal of family, group or community identity. The Mediterranean diet emphasises values of hospitality, neighbourliness, intercultural dialogue and creativity, and a way of life guided by respect for diversity. It plays a vital role in cultural spaces, festivals and celebrations, bringing together people of all ages, conditions and social classes. Women play an important role in transmitting knowledge of the Mediterranean diet: They safeguard its techniques, respect seasonal rhythms and festive events, and transmit the diet's values to new generations. Markets also play

Note: Three types of designation are included on these lists: (1) representative heritage sites and practices, (2) those in need of urgent safeguarding and (3) those representing good safeguarding practices

Annex 6. Economic Activities of the Yoruba Coast

Commercial Activities in Coastal Yorubaland

Trade across the Yoruba littoral was anchored in the lagoon ports of Badagry, Lagos (well before modern port development began in the late 1890s), Epe, Ejinrin and Atijere. While slave trafficking dominated the external trade with the Americas up to the mid-nineteenth century, forest produce, which accompanied the slave exports, became dominant in the second half of the century with British colonial rule. The lagoon ports were melting pots of culture, as epitomised by the history and peopling of Lagos, Epe and Ejinrin during the nineteenth and twentieth centuries. In its formative years, Epe drew migrant hunters, fishermen and political adventurers from the Yoruba towns of Ile-Ife, Ilara, Ibeju and other outlying settlements in the Epe region, and from Benin, a non-Yoruba kingdom. The Ilaje from the waterside of Okitipupa Division and the non-Yoruba Ijo [Izon] were also represented in the population before 1900. Izon men caught fish, while their wives produced a local staple, *garri*, from cassava flour, and manufactured local gin, *ogogoro*, from palm wine.

Though Epe people engaged in other economic activities—cassava, rice and maize farming; boat- building (for deep-sea fishing and water transportation); and commerce—fishing has been their defining economic activity. This earned them the nickname 'Epe Eleja', meaning, 'Epe, community of fishermen'.

Ejinrin, the port of the Ijebu (a Yoruba kingdom) was 'a strategic link between Lagos and the rest of the southeastern Yoruba hinterland' (Olubomehin 1990: 128). It was also a point of convergence for traders from other lagoon settlements, such as Epe and Atijere, and from as far in the hinterland as Ode Ondo. The hinterland of Ejinrin expanded after the defeat of the Ijebu by the British in 1892: it received an influx of traders from the Yoruba hinterland towns of Ife, Oyo, Ilesha, Gbongan, Ado-Ekiti, Owo and Ilorin (Olubomehin 1990, 132). This made it an important feeder for the port of Lagos, which, until 1914, relied on the lagoon network for produce for local consumption and export, in which Ejinrin was a lynchpin.

Fishing and Other Economic Activities in Littoral Yorubaland: Focus on the Ilaje

Coastal Yoruba exhibit occupational specialisation in accordance with variations in ecological setting and resource endowments. The people engage in seafaring, fishing, saltmaking and boat-making, though on an artisanal scale.

However, fishing is the dominant activity in the zone. It is characterised by large-scale migrations of fisherfolk across the Gulf of Guinea, which have facilitated exchange of technology of fishing and fish processing. These migrations have been classified into six types: internal, short-term, seasonal, long-term, permanent and contractual. These have been further grouped into two broad categories: internal (within a country) and trans-border or international (Adewusi 2017, 165). Human migrations, especially seasonal ones, tend to follow the migration of fish species.

Fishing and commercial activities across the Yoruba littoral have generally been peaceful. The ecological context has promoted economic symbiosis between the upland areas conducive for arable farming and the littoral that is dominated by fishing. Foodstuffs, especially yams and cassava tubers, and palm oil produced outside of the coastal mangrove swamp, are exchanged for fish and salt produced in the latter zone. The range of migrations and commercial exchanges is indicated as follows: the 'agriculturally poor but fish-rich eastern Delta [homeland of the Ilaje] exchanged fish for agricultural products from the adjoining communities, including the Ijebu in the west, the Ijaw in the north and the Ikale in the east, which supply most of the food items like cassava (gari), yam, plantain, and palm oil' (Onipede 2017, 181). These and other commodities of the lagoon trade, such as prawns, coconuts and cassava flour, are conveyed over a wide area beyond the coastal zone.

The spatial spread of these activities runs hundreds of kilometres, reaching places as distant as Port Harcourt, Onitsha and Enugu in eastern Nigeria, and Lagos, Ibadan, Ondo, Oyo, Ode-Aye (Ikale) and several Ijebu and Ekiti towns (Onipede 2017, 182). A major item of trade during the twentieth century, second only to fish in importance, is local gin (*ogogoro*). Once declared illicit by the British colonial government and the successor nationalist government, it is now widely consumed in the coastal and upland areas of southern Nigeria, for both social and religious purposes (Oluwapayimo 2017).

The positive impact of non-Indigenous migrants on the domestic economy is indicated by claims that the arrival of the Fante 'boosted fishing' in Ijebu Waterside, while the arrival of the Keta (Ewe) and Ilaje had the same effect on Badagry (Olukoju 2000, 72). The Orimedu community east of Lagos also benefited from the settlement of Gold Coast/Ghanaian fishermen, from whom they adopted the seine 'drag net' fishing technique the Ghanaians introduced on their arrival in the 1890s. It is claimed that while the Yoruba hosts have continued to practice subsistence fishing for family consumption, the Ghanaians run theirs as a business. The Yoruba continue to fish in small canoes, unlike the Ghanaians, who employ 'boats fitted with outboard engines, synthetic nettings such as beach seiners, set nets, gill nets and long lines' (Adewusi 2017, 166–67).

However, occasional conflict interrupts peaceful commercial and social exchanges on the Yoruba littoral. The most protracted and catastrophic was the Ilaje-Ijo war of 1998–1999, fought over claims to a territory rich in hydrocarbon deposits. The war proved ruinous to both parties, who suffered heavy human and material losses (Ehinmore 2014). Analysis has shown that conflicts are more intense in inter-group relations between Yoruba and non-Yoruba, and rarely between two Yoruba groups (Olukoju 2000).

The Ilaje are the most dominant fishing and migrant Yoruba subgroup in the zone. Outside of their homeland on the eastern edge of the Yoruba littoral, they have established colonies all over the Yoruba littoral and the entire Gulf of Guinea. Ilaje migrant fishermen and their families overlap with Indigenous communities as well as Izon and Ogu migrant fishing groups. In the port city of Lagos, the Ilaje occupy lagoon-side neighbourhoods, especially at Bariga, where a common Yoruba identity has ensured cordial relations with their Awori hosts. Ilaje have intermarried with the Awori and now bury their dead in Lagos, contrary to age-old practice.

Ilaje fishing enterprise and extensive migrations eastwards of their homeland towards the Congo, westwards to Senegal and southwards to Angola have been described as 'perhaps "the greatest inter-regional movement in the modern history of the Yorubas"'. It has been stated that they are 'always on the move … in search of fish' (Olukoju 2000, 70). Ilaje fishing enterprise is complex, comprising artisanal fishery, local aquaculture and industrial fishing (Ikuejube 2005). Artisanal fishing remains dominant, carried out in local canoes with traditional fishing instruments: *awo* (nets with hooks laced with bait of earthworms), *akase* or *eporo* (bamboo spears) and *iyanma* (baskets used in shallow streams and creeks) (Onipede 2017, 183). But Ilaje fishing has also incorporated innovations from external sources. The Ilaje learned the *dogbo* method of trawling from the Ijebu in the 1930s and borrowed the *itahun*, 'a new method of fishing net floatation,' from Gabon in the early 1970s (Ehinmore 1998, 31, 37). A turning point in Ilaje fishing enterprise was the 1960s expansion from freshwater to coastal fishing. This necessitated the use of larger watercraft, with carrying capacities varying with the distances covered and the quantity of merchandise carried. Engine-powered boats are now deployed in high-sea fishing, thus extending Ilaje fishing enterprise beyond the lagoon. In addition, the Ilaje in metropolitan Lagos have, since their initial settlement in the 1930s, expanded their fishing enterprise and diversified into other business ventures—quarrying sand from the lagoon, lumbering and water transportation (Olukoju 2000; Onipede 2017, 184).

About the Authors

Lead Authors

Edward H. Allison is Research Director of the Nippon Foundation Ocean Nexus Center, and Research Chair for Equity and Justice in the Blue Economy at WorldFish, Penang, Malaysia.

John Kurien is a founding member of the International Collective in Support of Fishworkers, a Visiting Professor at the Azim Premji University in Bengaluru, India and Honorary Fellow at WorldFish, Penang, Malaysia.

Yoshitaka Ota is Director of the Nippon Foundation Ocean Nexus Center and Research Assistant Professor at the School of Marine and Environmental Affairs, University of Washington, Seattle, USA.

Contributing Authors

Dedi S. Adhuri is coordinator of the Maritime Study Group at the Indonesian Institute of Sciences, Jakarta, Indonesia.

J. Maarten Bavinck is Professor of Maritime Studies at the University of Amsterdam, the Netherlands.

Andrés Cisneros-Montemayor is Deputy Director of the Nippon Foundation Ocean Nexus Program at the University of British Columbia, Vancouver, British Columbia, Canada.

Michael Fabinyi is Associate Professor of Anthropology in the School of Communications, University of Technology, Sydney, Australia.

Svein Jentoft is Professor of Sociology at the University of Tromsø, Norwegian College of Fisheries Science, Tromsø, Norway.

Sallie Lau is a recent graduate of the Masters in Marine Affairs program at the School of Marine and Environmental Affairs, University of Washington, Seattle, USA.

Tabatha Grace Mallory is founder and Chief Executive Officer of China Ocean Institute, Seattle, Washington, USA.

Ayodeji Olukoju, is Professor of History at the University of Lagos, Nigeria.

Natasha Stacey is Associate Professor at the Research Institute for the Environment and Livelihoods, College of Engineering, IT and Environment, Charles Darwin University, Darwin, Northern Territories, Australia.

Ingrid van Putten is an Environmental Economist with the Commonwealth Scientific and Industrial Research Organisation in Hobart, Tasmania, Australia.

Michelle Voyer is a Research Fellow at the Australian National Centre for Ocean Resources and Security, University of Wollongong, Australia.

Nireka Weeratunge is an anthropologist and independent scholar, affiliated as Research Fellow to the International Centre for Ethnic Studies in Colombo, Sri Lanka.

Highlights

- The ocean is a global commons on which the prosperity and well-being of humanity rests. Business as usual will result in the collapse of key biophysical ocean functions, which will have significant implications for the global economy, societies and people.
- Science has demonstrated that ecosystems on land, rivers, deltas, estuaries and the ocean are intrinsically linked. Therefore, to transition to a sustainable ocean economy that protects the ocean and provides for humanity, a more holistic approach to ocean governance is needed. In short, humanity needs to redefine its relationship with the ocean.
- Ocean governance currently consists of different forms of plural and multilevel institutions responsible for designing solutions for common resources in the ocean. However, the nature of these institutions limits their ability to consider outcomes at different scales, and the ability of resource users to devise livelihood strategies within integrated systems. These weaknesses in the current system generate significant problems for the conservation, sustainable use and equitable sharing of the ocean.
- Major efforts to better manage the ocean as a common resource are needed. These efforts will require greater willingness and cooperation, from local communities to national and international action. Stronger accountability, transparency and participation mechanisms will be required to resolve conflicts and enable equitable sharing among different users, particularly in areas beyond national jurisdiction.
- This paper considers what governance configurations would facilitate the better management of the ocean as a global commons. To do so, it considers the conditions that have facilitated societal transitions in the past, from the information and communications technology revolution in the 1970s to the more recent Paris Agreement of the UN Framework Convention on Climate Change, and the governance arrangements that have enabled them. The paper's authors are optimistic about these shifts, pointing to system transitions that are already occurring at the local level through 'niche innovations' that communities, governments and business are implementing, to governments negotiating new agreements at the global level.
- This paper proposes four key opportunities for action to strengthen ocean governance: support current UN ocean processes (e.g. ratification of UNCLOS); reconfigure nation-state authority as it relates to the ocean (e.g., establish a global 'ocean agency' that supports polycentric, 'bottom up' governance innovations); support civil society's ability to play a more significant role (e.g. by recognising access to a healthy environment as a human right and establishing a new 'wiki-type' interactive ocean knowledge commons for co-creating solutions); and integrate property rights with stewardship responsibilities (e.g. establish local user rights programs).
- A balance of civil society rights and stronger government leadership from the state is crucial to avoid overburdening citizens with securing their future in the ocean system, or with inequitable access opportunities and benefit distribution resulting from policy interventions that fail to consider their implications.

1 Introduction

The ocean is the ultimate commons. Sustainability narratives now recognise what science continues to demonstrate—that ecosystems on land, rivers, deltas, estuaries and the ocean are intrinsically linked (Mathews et al. 2019). There is a growing consensus that the prosperity and well-being of

humanity depends on the health of the ocean environment, including the ocean-climate nexus (OECD 2016; IPCC 2019). Critical indicators reveal that business as usual is going to result in the collapse of key biophysical ocean functions, with major implications for the global economy and societies (IPCC 2019). Science has demonstrated that these close systemic interlinkages in and among ecological, economic and social systems require solutions which are responsive and flexible, robust yet elastic (SDG 2019).

It is also evident that time is of the essence (Steffen et al. 2018; IPCC 2019). A new relationship between humanity and the ocean is thus required. It follows that the transition to a new and effective governance system for the ocean should ensure that it 'does justice to humanity's obligations to itself, and to the planet which is its home' (International Court of Justice judge C.G. Weeramantry in Gabčíkovo-Nagymaros Project (Hungary v Slovakia) 1997).

This paper proceeds from the assumption that the ocean is a commons. The problem this paper seeks to address is the complex challenge of governing the ocean as a commons. Governance systems since the dawn of modernity have evolved to govern city-states, nation-states and international relations. But the transformations to sustainability require governing interlinkages and interactions that have not previously existed across sectors, and scales with multiple actors. Sustainable development is not only a laboratory for governance innovation (How will goals be achieved?) but also for policy innovation (Which concrete goals need to be set in a specific situation?) (Meuleman 2019). Governance configurations to craft the required policies that are appropriate for a global commons like the ocean are nascent at best. It follows, therefore, that this paper must address this key question: In response to the threats to the ocean's biophysical functions and life-support services, what transition dynamics are emerging at different levels (local, regional and global) that suggest appropriate governance configurations for the future?

What governance configurations could be established to govern the ocean as a commons?

The scale of the contemporary transition that is required now can be compared to that of the transition from hunter-gatherers to agrarian societies, and from agrarian societies to industrial societies (Haberl et al. 2011). Over the past 500 years, societal transitions of this scale have typically resulted in a change in governance with respect to socio-political arrangements, territorial authority, representation, rights, regulatory authority and accountability (Jessop 2016). In addition, since the beginning of human civilisation, people have collaborated to secure and protect common natural resources they have depended on for their survival (Ostrom 1990). During the modern industrial era, the commons has gradually been replaced by private ownership, on the one hand, and the public goods owned or controlled by states, on the other. The sustainability- oriented transitions that characterise the twenty-first century have once again brought into focus the crucial importance of the commons (Dasgupta et al. 2019). This has been made most clear with respect to the global scientific consensus about climate change, which is, arguably, about protecting the most important commons of all.

Societal transitions are not random events. Following the well-known 'multilevel perspective' on sustainability transitions, they emerge from a specific constellation of conditions that interact in complex ways (Geels and Schot 2007; Geels 2010; Grin 2010; Geels et al. 2017; Schot and Kanger 2018). Transitions come about when landscape pressures (e.g. population growth, technological change, climate change) result in a realisation that existing socio-technical regimes (e.g. fossil fuel-based energy systems, mobility systems based on the private car, industrial fishing) are inappropriate to address potentially destructive pressures or achieve a set of broader goals that previously did not exist (e.g. mitigating climate change, degradation of the ocean). For example, overfishing may be allowed by a legalised fishing regime, incentivised by an economic system and promoted by a political system. Yet in too many cases, the governance system as a whole does not resolve the problem of the ultimate collapse of the fish stocks as predicted by scientific research on wider landscape-level system dynamics (Cullinan 2014). At the same time, 'niche innovations' can open up as key networks of innovators respond to changing conditions by designing systems that aim to respond to the emerging landscape pressures (e.g. sustainable fishing regimes in the ocean context, or renewable energy in the context of climate change). Sometimes existing governance regimes engage with and absorb the niche innovations as their way of responding to the landscape pressures (e.g. the decision of large coal-based energy companies like Italy's Enel to become major renewable energy providers; Swilling 2019). At other times, regimes resist change, thus creating space for niches to coalesce and emerge as an alternative regime (e.g. the emergence of the organic food movement in response to the persistent dominance of the conventional global food system) (Smith et al. 2005). Sometimes niches are too weak and alternative regimes refuse to reform, resulting in landscape pressures causing social-ecological system breakdowns (as is emerging in water systems in many city-regions; Smith et al. 2005).

If, however, the dynamics of change are such that a societal transition becomes possible (e.g. the commitment by 57 countries to meet 100% of their energy needs with renewables, led by countries like Costa Rica and Uruguay; REN21 2018), much will depend on the emergence of governance configurations that are fit for purpose.

Incumbent governance arrangements can often prevent the implementation of known solutions (e.g. despite the rapid growth in renewables worldwide, there is no significant decline in the use of fossil fuels, largely because of path dependencies that existing tax and subsidy regimes reinforce; Geels 2014). Given the focus on a new set of global environmental goods such as the climate, the ocean and water, new governance arrangements appropriate for managing a commons will better enable the necessary transitions to occur in these sectors.

The approach to sustainability transitions used in this paper draws on complex adaptive systems theory (Levin 1998; Norberg et al. 2008; Preiser et al. 2018), many aspects of which are relevant to ocean systems (Lubchenco et al. 2016). The ocean system, from this perspective, is portrayed not as deterministic, predictable and mechanistic but as a diverse range of complex processes underway at multiple scales (global, regional, local). These processes catalyse self-organising dynamics that produce a new set of emergent and adaptive patterns. Ex post facto, data- intensive modelling may track past patterns, but future predictions cannot capture many critical drivers and responses. Scenario analysis and other forms of modelling may be useful for certain purposes, such as exploring global pathways to mitigate coastal risk through nature-based solutions (Chaplin-Kramer et al. 2019) or quantifying a subset of interacting ecosystem components for coordinated sectoral management, such as coastal habitat-fishery and disaster reduction linkages (Mumby et al. 2004; Arkema et al. 2015; Guannel et al. 2017; Rogers and Mumby 2019), but such approaches are unlikely to help us fully understand the highly complex dynamics of the ocean transition (Levin et al. 2012).

By identifying landscape, regime and niche dynamics, sustainability transition theory instead uses narrative analyses to help create useful categories for describing different kinds of transition dynamics, how they intersect and probable future pathways.

In order to describe what a transition to a more sustainable ocean system might look like, we first characterise the system through a brief outline of the current governance regime (Sect. 2) for the ocean. Establishing a governance baseline is required in order to build a narrative which can be used to understand ocean dynamics, and assist in identifying the nature of the changes that are needed for the transition to a sustainable ocean economy. Next, we define the stakeholders for several key sectors and describe the dynamics at play at multiple scales in the various sectors comprising the ocean economy (Sect. 3). We then demonstrate how regimes can respond to landscape pressures by diagnosing the principal drivers of change, including global and local scales (Sect. 4). Thereafter we demonstrate how the ocean system has evolved as a result of these drivers of change.

Hundreds of niche innovations have emerged, some of which we detail for illustrative purposes (Sect. 5). We propose theories of change which are suggestive of future trajectories, which in turn highlight the benefits of protecting and regenerating the ocean commons (Sect. 6). We offer paths forward, with examples of actions taken at local, national, regional and global levels which demonstrate successful transitions (Sect. 7). We conclude with opportunities for nation-states and other stakeholders in the ocean economy to contribute to a purposive transition to a thriving and vibrant relationship between humans and the ocean founded on a clear vision of the changes required, and an agreed future pathway for bringing about those changes (Sect. 8).

2 Current Governance Baseline

Governance is recognised as one of the key enablers of sustainable transformation (SDG 2019; TWI2050 2018; Pretlove and Blasiak 2018). The United Nations' 2030 Agenda represents a new mode of governance, one defined not through binding legal agreements but through the Sustainable Development Goals (SDG 2019). Current governance models and arrangements, whether global, regional, national or institutional, are ill-suited to develop, oversee or implement truly integrated, multidimensional sustainable development agendas such as the SDGs (Vidas 2011; Kotzé 2017, 2019; TWI2050 2018). Ocean governance is currently too fragmented across administrative boundaries and sectors to provide integrated responses (IPCC 2019; IPBES 2019).

An analysis of ocean governance includes institutions with mandates related to land use (urban, rural, coastal), freshwater management (surface and groundwater; quantity and quality), natural resource use (agriculture, horticulture, silviculture, mining, fisheries), environmental protection (including protected areas in terrestrial, freshwater and marine environments), development policies (e.g. economic, energy, transportation), human-environment interactions and the policies, procedures and regulations within and across segments of the source-to-sea ocean continuum (Mathews et al. 2019).

2.1 Ocean Governance

The current regime for ocean governance is complex (WCED 1987). As with international environmental law in general, governance internationally is comprised of two branches: customary law (judicial precedent, government policy and practice) and conventional law (international conventions).

The UN Convention on the Law of the Sea (UNCLOS) is at the centre of ocean governance. A key provision in UNCLOS is the distinction between various maritime zones of coastal states in contradistinction with the high seas (UNCLOS 1982). Maritime zones endow coastal states with either full sovereign jurisdiction or more limited sovereign rights (depending on the zone), in contradistinction to the principles of freedom of navigation and freedom of fishing which operate in the high seas, otherwise known as areas beyond national jurisdiction (ABNJs).

ABNJs generally are subject to weaker governance and poorer management. These waters are home to some of the rarest and most charismatic species on the planet—but all countries have the right to navigate, fly over, carry out scientific research and fish on the high seas with limited restriction (High Seas Alliance Treaty Tracker 2019). This, by definition, is why the high seas are a global commons. However, unlike the natural commons that is the focus of extensive work on commons governance today (influenced by Ostrom's research), the high seas as commons lack integrated commons governance.

In ABNJs, no nation-state is vested with jurisdiction, nor is any single international body vested with a strong mandate or effective means to secure a holistic, sustainable approach to managing the high seas (Pretlove and Blasiak 2018). In addition, human activities, water conditions and migratory species in nations' exclusive economic zones (EEZs) and territorial waters affect, and are affected by, activities in ABNJs. Ocean currents and species do not heed governance boundaries; and economic sectors commonly overlap in ocean spaces and share inputs to production (Klinger et al. 2018). Even the significant bodies such as the International Seabed Authority (ISA) or the various regional fisheries management organisations (RFMOs) are not mandated to implement the holistic comprehensive approach that is required to secure sustainable management of humankind's most important global commons. Peggy Kalas from the High Seas Alliance argues, 'The current high seas governance system is weak, fragmented and unfit to address the threats we now face in the twenty-first century from climate change, illegal and overfishing, plastic pollution and habitat loss' (High Seas Alliance Treaty Tracker 2019).

A promising development is the new agreement being negotiated under the provisions of UNCLOS, known as the internationally legally binding instrument for conservation and sustainable use of biological diversity in areas beyond national jurisdiction (the BBNJ).

A working draft of the BBNJ, released in September 2019, addresses a package of four topics, namely, the conservation and sustainable use of marine biological diversity of areas beyond national jurisdiction; marine genetic resources, including benefit-sharing; area- based management tools, including marine protected areas, environmental impact assessments and capacity building; and the transfer of marine technology (A/CONF.232/2019/6). During the first Marine Regions Forum, held in October 2019, participants emphasised the potential of universal participation in the BBNJ (Tsioumani et al. 2019). Proposals included listed mandatory environmental impact assessments; innovative options for the management of high seas biodiversity; improved coordination and cooperation among key stakeholders; and ongoing inter-regional exchange (Tsioumani et al. 2019). Concerns remain, however, as to whether the final agreement will be sufficiently robust to overcome the tension in a process characterised by individuated state and (institutional) interests. It will need to do so in order to solve a collective problem—the protection of ocean biodiversity in ABNJs. Several challenges may compromise a meaningful agreement. First, the agreement will require some inherent flexibility in its design in order to provide a useful framework for regulating decision- making in circumstances characterised by uncertainty; second, in an already crowded ocean governance space, existing institutions need to be rationalised in ways that increase coherence and effectiveness; and, finally, the new agreement needs to respond to the complex set of multiple, multilevel and systemic threats to marine biodiversity in areas beyond national jurisdiction (including, among other things, overfishing, plastic pollution and climate change) (De Santo et al. 2019) (see Appendix A1 for a more detailed discussion of the BBNJ).

2.2 Coastal Governance

Coastal regions naturally fall within the sovereign jurisdiction of coastal states. The interface between humans and the ocean is keenly experienced at the coast. More than 1.9 billion people lived in coastal areas in 2010, mostly in developing countries (Kummu et al. 2016). Coastal ecosystems provide services to humanity which are not easily included in monetary-based decisions, such as coastal stabilisation, regulation of coastal water quality, biodiversity, spawning habitats, carbon sinks, buffering and livelihood resources (Baker et al. 2019). The ocean is also an integral part of the global climate system (IPCC (Intergovernmental Panel on Climate Change) 2013; IPCC 2019).

From a governance perspective, integrated coastal management (ICM) is an approach developed to manage, in an integrated way, the complex and dynamic system encompassing the many interactions between people and ecosystems (Bremer and Glavovic 2013). The underlying key principle in ICM is the recognition that the traditional sectoral approach to managing human activities in the coastal zone, characterised by competing needs and overlapping mandates, has significant negative impacts on the environment. The aim of ICM is then to provide integrated governance for guiding coastal area development in an ecologically sustainable fashion (FAO 2019a). ICM has been applied in regional applications with marine ecosystem programs and regional seas programs, for example the EU Integrated Maritime Policy, and in a growing number of nations (see Winther et al. 2020).

However, regulatory challenges for effective ICM arise as a result of institutional and sectoral inertia, lack of flexible decision frameworks to manage the complexity, uncertainty and difficulties managing the trade-offs inherent in ICM (Vierros and Buonomo 2017).

Figure 12.1 illustrates the complexity of overlapping and competing interests and mandates which exist in the ocean economy.

Ngeta (2014, p. 28) confirms this by stating that ‘the complexity of the actor constellation tends to increase as one moves up the governance ladder from the local to the global’. Complexity of this nature in coastal governance has implications for resource and livelihood sustainability (Agrawal and Perrin 2009). For this reason, implementing ICM has proven to be a challenge in different parts of the world (Ngoran et al. 2016; Cantasano et al. 2017; Warnken and Mosadeghi 2018).

Figure 12.1 demonstrates that, from a national perspective, overlapping mandates in the ocean economy arise primarily within coastal states’ exclusive economic zones, but they can also occur on the high seas. An integrated ocean management (IOM) approach to policymaking is designed to address challenges for ocean management in EEZs that can include conflicts between sectors (e.g. tourism versus hydrocarbon extraction), across different scales of organisations (such as local, municipal, regional) and biophysical features (local water bodies, shared watercourses, regional seas, global ocean) and across time (current and future uses) (Klinger et al. 2018; Winther et al. 2020). Another obstacle to integrated management is a lack of information on how sectors interact, and how changes in one affect incentives and actions in others (Klinger et al. 2018). Anticipated economic growth from the blue economy is likely to lead to additional cross-sector conflicts and could bring environmental degradation, inefficient natural resource use and other socially undesirable outcomes (McCauley et al. 2015; Winther et al. 2020). A FAO study on the application of IOM in a number of countries including Norway, Indonesia and Angola found that multi-sectoral coordination, created through a grouping of marine ministries, was very effective in Indonesia (Torrie 2016). Information- gathering through a decentralised power structure and incorporating stakeholder engagement through a network approach (see Sect. 7.1.2)

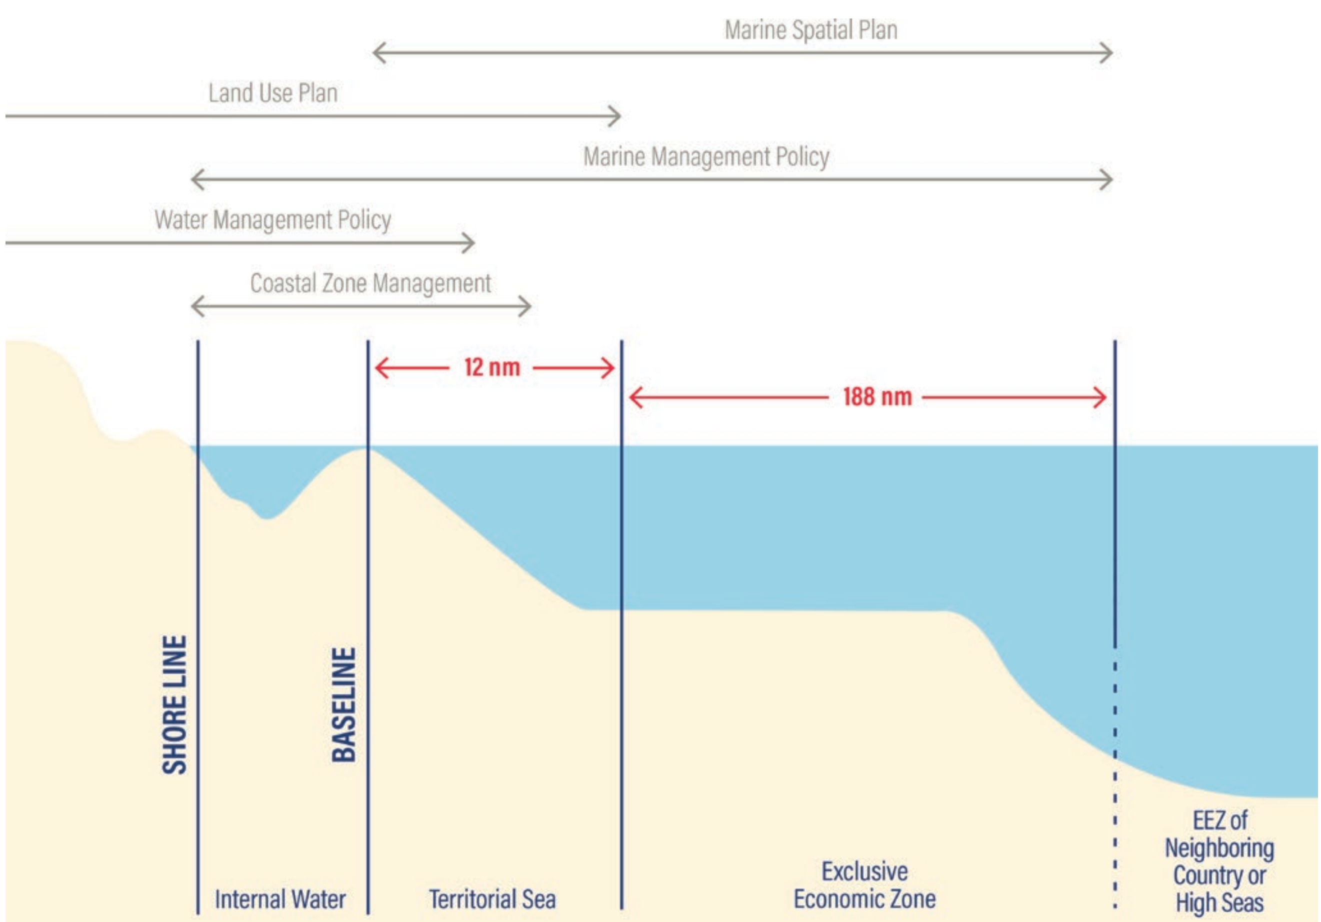

Fig. 12.1 Independent and overlapping management frameworks in the source-to-sea system in Sweden

provided highly valuable information (Torrie 2016). An advantage in Norway has been the relative speed and flexibility with which the government is able to draft, pass and enforce laws, which has contributed to effective ocean governance focused on the health of fish stocks and ecosystems (Torrie 2016).

Many of these principles will be echoed throughout this paper. In addition, the knowledge commons for sharing information and establishing transparency (discussed in Sect. 7.2.2) will facilitate policy development in the national context. Polycentric governance processes within the boundaries of national laws and policies will facilitate coordination, the sharing of knowledge and information and the identification of possible solutions for trade-offs.

Enhancing understanding about the governance interactions, as well as the manner in which governance outcomes may influence resource and livelihood sustainability, is needed in order to elucidate understanding about how different forms of commons governance produce different outcomes for livelihoods and well-being of marginalised communities (Brockington and Wilkie 2015). South Africa's first UN Educational, Scientific and Cultural Organization (UNESCO) World Heritage Site, Simangaliso, provides an example of the governance challenges which arise as a result of the co-existence of plural and multilevel governance systems and institutions governing the coast (see Appendix A2 for this case study).

Sectoral institutions still dominate in national governments and in the UN system. This gap presents one important opportunity for future policy development—a UN or another version of a supranational body could, through access to a knowledge commons platform (discussed later in this paper), analyse the functioning of existing laws and institutions, articulate a flexible framework (which can provide for diverse region-specific conditions) on agreed ICM principles, as well as provide monitoring and oversight to achieve greater coherence. To that end, sectorally focused management regimes would benefit from greater integration, such as integrating marine spatial planning with efforts aimed at regulating land-based activities such as food production and the resulting nutrient runoff, tourism-based livelihoods and small-scale fisheries (Sale et al. 2014; Lubchenco et al. 2016). The functions of ICM are more fully developed in the Blue Papers "*Coastal Development* and *Integrated Ocean Management*".

2.3 Shared Resource Governance

Governance of shared resources has matured over the past several decades. The lucrative global fisheries for migratory and straddling fish stocks in the high seas, such as tuna, are managed through several measures. Regional fisheries management organisations (RFMOs) were set up under the UN Fish Stocks Agreement (UNFSA), and sector-specific measures were taken by the UN Food and Agriculture Organization (FAO), including the FAO Code of Conduct for Responsible Fisheries, the International Plan of Action to combat illegal, unreported and unregulated (IUU) fishing, and the Agreement on Port State Measures to Prevent, Deter and Eliminate IUU Fishing. While some RFMOs have been effective, severe challenges result from a lack of cooperation among states, conflicting interests in resource utilisation and conservation, fragmented responsibilities, lack of political will, lack of effective monitoring and enforcement and perverse economic incentives for 'free riders' to cheat the system (Figueres et al. 2014).

River-basin management of shared transboundary waterbasins provides useful lessons for joint stewardship of the ocean. In circumstances of shared international watercourses, states have been required to share sovereignty in a kind of 'joint ownership' of the water body (Rieu-Clarke and Spray 2013). For example, the Mekong River Basin, a 4909 km river system which flows through six countries, is collaboratively managed by the Mekong River Commission. The UN Watercourse Convention 1997 (UNWC), is widely recognised as a pivotal document in international water law (Litke and Rieu-Clarke 2014). It codifies and clarifies existing norms and develops emerging principles of customary international water law. It constitutes a model that can guide the interpretation of other treaties and the negotiation and drafting of future ones; and it has informed the judgements of international and regional courts (Litke and Rieu-Clarke 2014). Some of the unique procedural provisions in the UNWC offer lessons for future regulatory frameworks for regional or international management of shared estuaries or seas. In addition, the principles of shared water management through regional organisations set up under the UNWC could be adapted for regional fisheries management by adapting or expanding RFMOs into regional ocean management organisations (ROMOs). ROMOs would be responsible for the preservation and productivity of the entire ecosystem, rather than only shared fish resources or specific species (Figueres et al. 2014).

3 Sectoral Regime Dynamics and Stakeholders

Having briefly outlined a high-level overview of current ocean governance, the next step in determining potential pathways to a purposive ocean transition requires understanding some of the regime dynamics at play in the ocean and identifying the key stakeholders in those dynamics. Regimes are understood in the sustainability transitions literature to be a tightly knit combination of regulations; key operators that produce products or services; consumers who depend on those products or services; the revenues that governments, agencies and regulators extract in the form of levies or taxes and so on; the financial institutions that have provided debt or equity; plus a substantial infrastructure operated by people who have been trained over decades to understand and operate the system in certain ways.

This combination of interlocking interests creates an alignment of purpose that reproduces path dependency.

Path dependency can be described as a constraint on decisions or processes due to a combination of interlocking interests that creates an alignment of purpose and resistance to change. The tightly interdependent set of interests limits possible decisions for any given circumstance due to past decisions or because of inexperience with new conditions, even when past circumstances may no longer be relevant or appropriate (e.g. reliance on fossil fuel energy). Generally, path dependencies arise because of the tendency of institutions to act (and react) as a result of their historical structural properties or beliefs. For changes in a regime to occur, the reprogramming of a vast array of system components will be necessary. This is why regime change is challenging, and why often regimes resist change. Regimes will change in response to landscape pressures if they have the internal capacity to manage change and access to new external knowledge about alternatives. Without these conditions, niche innovations will emerge outside the regimes and can eventually coalesce into alternative regimes that are more responsive to landscape pressures than are the incumbent regimes (Smith et al. 2005).

In order to propose a theory of change, it is necessary to view the ocean system in its full complexity. The key ocean-relevant regimes that directly and indirectly affect the future resilience of the world's ocean are summarised in Appendix B. The regimes we outline are shipping, ocean-based food extraction, offshore oil and gas, ports, marine and coastal tourism, marine and seabed mining, marine biotechnology, cabling and maritime equipment, and offshore and renewable energy. The regimes we sketch in Appendix B are sectoral in nature, with distinct governance and operational dimensions. Regimes often interact at multiple scales, and shifts that seem unimportant at the local or regional scale, when aggregated, could actually precipitate major changes in other regimes (e.g. aquaculture and coastal development; Rocha 2010).

Several regime responses illustrate shifts in existing ocean systems towards sustainability. For example, institutions such as the International Maritime Organization (IMO) and some industries have contributed to significant regime responses in the shipping sector.

Green ship recycling is one example. This involves environmentally friendly ways of managing end-of-life ships (OECD (Organisation for Economic Co-operation and Development) 2010; IMO Guidelines for Shipbreaking; the Hong Kong Convention; NatCap (Natural Capital Project) 2019; EU Directive on Ship Breaking). Also in the shipping sector, the GloFouling Partnership project was formed under the auspices of the IMO to support anti-fouling measures. These measures are designed to guard against the significant risks to marine biodiversity created by ship's discharges contaminated with alien invasive species. The move towards the decarbonisation of the shipping industry, initiated by the *Initial IMO Strategy on the Reduction of GHG Emissions from Ships* (IMO 2018), is underway. A target has been set to decarbonise the shipping industry by 2035, which would equate to a reduction in shipping's carbon dioxide (CO_2) emissions of between 82 and 95% below the current level (OECD International Transport Forum 2018). Some ports around the world (Los Angeles, Auckland, Valencia, Guayaquil, Baku and Rotterdam) are working towards becoming carbon-neutral. Several transparency initiatives are also unfolding across numerous regimes. For example, in the maritime transport sector, the Open Simulation Platform, founded by industry in 2018, facilitates collaborative open platforms for the design, operation and building of ships. Fisheries certification schemes such as the Marine Stewardship Council (MSC) are supported by new information products such as Global Fishing Watch. These information products track and analyse global fishing activity using publicly available automatic identification system transmissions from boats and satellite images. Traceability programs of this nature allow full tracking of harvested species along the entire production chain (Costello et al. 2019). Such monitoring information is critical to building trust that fishery management interventions are having the desired effects, or if not, to encouraging action and adaptation throughout the seafood value chain, and enabling monitoring and compliance through these systems. The suite of sustainable fishery management approaches that have been implemented in the ocean and food extraction regime, such as rights-based fisheries management (RBFM), marine protected areas (MPAs) and integrated coastal management regulations, indicate that fish stocks, marine habitats, fisher communities and ocean food–based supply chains can recover if management objectives are clear and monitoring and scientifically based assessments inform open discussion of trade-offs and adaptation over time (Costello et al. 2019). New synergies are being investigated in the cabling and maritime equipment sector, which could lead to the use of private sector submarine telecommunications infrastructure for climate monitoring and disaster warning (Submarine Telecoms Industry Report 2019). Other responses are emerging; for example, a submarine cable in the Olympic Coast National Marine Sanctuary in the U.S. Pacific Northwest was re-buried and then systematically monitored to reduce concerns about entanglement of fishing gear and species disruptions (Antrim et al. 2018).

3.1 Inter-regime Dynamics

Although the regimes described above and in Appendix B are conceptually distinct, in practice they overlap in highly complex ways that are both mutually reinforcing and potentially contradictory. A growing global consensus and plethora of scientific reports are contributing to an awareness that these regime and inter-regime dynamics have unintended consequences that could irrevocably harm the ocean's biophysical systems in ways that subvert ocean-dependent regimes (Winther et al. 2020).

4 Drivers of Change

Now that we have outlined the existing framework of ocean governance, and identified the dynamics of the ocean system, we turn to a diagnosis of the landscape-level pressures or 'drivers of change' which are destabilising the system. Establishing an understanding of the issues and practises which have led to the landscape pressures now facing the ocean will help identify pathways that will allow change to occur. Landscape pressures are broad, long-term emergent cumulative shifts that are not caused by single current actions in present time.

4.1 Greenhouse Gas Emissions

Anthropogenic greenhouse gas emissions, and CO_2 specifically, are widely recognised as the biggest long- term threat to a functional ocean (Rogers and Laffoley 2013; Gaines et al. 2019). Climate change is altering the ocean's impact on climate, its chemistry, temperature, circulation, sea level and ice distribution. Collectively, these system changes are affecting the habitats, biological productivities and species assemblages that support ocean-based economies and cultures. Ocean circulation changes also are predicted to lead to increased intensity and frequency of tropical cyclones and extreme sea level events, including storm surges and flooding and precipitation (Gaines et al. 2019).

Increasing ocean acidity is influencing large swathes of ocean ecosystems in a range of ways (Suggett et al. 2012; Kroeker et al. 2013) and is most acutely felt in shallow water systems such as the subarctic Pacific and western Arctic Ocean (IPBES 2019). The ocean has absorbed over 90% of the excess heat from global warming, with consequences for organisms that are adapted to specific temperature ranges in terms of both latitude and depth (IPCC (Intergovernmental Panel on Climate Change) 2013). Oxygen content is in decline, dramatically observed in increasingly extreme hypoxic events (Stramma et al. 2010). Other primary stressors on ocean systems include habitat destruction, overfishing and pollution from land and coastal sources (Bailey and van der Grient 2020). Impacts of climate change on biodiversity and ecosystems are well documented, including shifts in species ranges and the socio-ecological ramifications of this (Cheung et al. 2010; Pecl et al. 2017; Costello et al. 2019; Gaines et al. 2019).

4.2 Overfishing

Direct exploitation of fish and seafood has the largest relative near-term impact among drivers of ocean status (IPBES 2019). Currently, 33% of fish stocks are classified as over-exploited and greater than 55% of the ocean area is subject to industrial fishing (IPBES 2019). Since 1950 the percentage of fish stocks that are 'developing' (i.e. still increasing in output) has declined dramatically, while stocks that are exploited, over-exploited or collapsed has escalated dramatically since the 1980s (FAO 2018; Costello et al. 2019; Widjaja et al. 2020). Severe impacts on ocean ecosystems can occur through direct harvest of target and bycatch species, and, indirectly, through degradation or destruction of benthic habitats (e.g. through dredging in soft-bottom regions or dynamite fishing in coral reef areas) or through the ramifications of predator-prey and other food web dynamics (Costello et al. 2019).

Small-scale fisheries catches have been increasing, from about 8 MT per year in the early 1950s to 22 MT per year in 2010, and continue to grow at the global scale, while industrial catches at larger scales decline (Pauly and Zeller 2016). Small-scale fisheries suffer from highly variable regulation and enforcement, even where catch, area or gear limits do occur. Such fisheries are characterised by very limited information on stock status and fisher behaviour, exacerbating socioeconomic pressures on vulnerable fishing communities dependent on local seafood for nutrition and livelihood support (FAO 2015). Additional detail on drivers in the current fishing regime is provided in Sect. 3 and Appendix C.

4.3 Seabed and Land Use

Another direct driver with a high relative impact on the ocean is the many changes in the uses of the sea and coastal land (IPBES 2019; Addo et al. forthcoming). Nearshore regions of the world are straining to support exploding demand from oil and gas development, shipping and port activities, fisheries and aquaculture, tourism and the protection of people, property and infrastructure from increasing storm intensity and sea level rise (Fig. 12.2). Much of the planet's population growth over the next decades will occur along coastlines, where development pressures already are destroying nearshore marine ecosystems (e.g. mangroves,

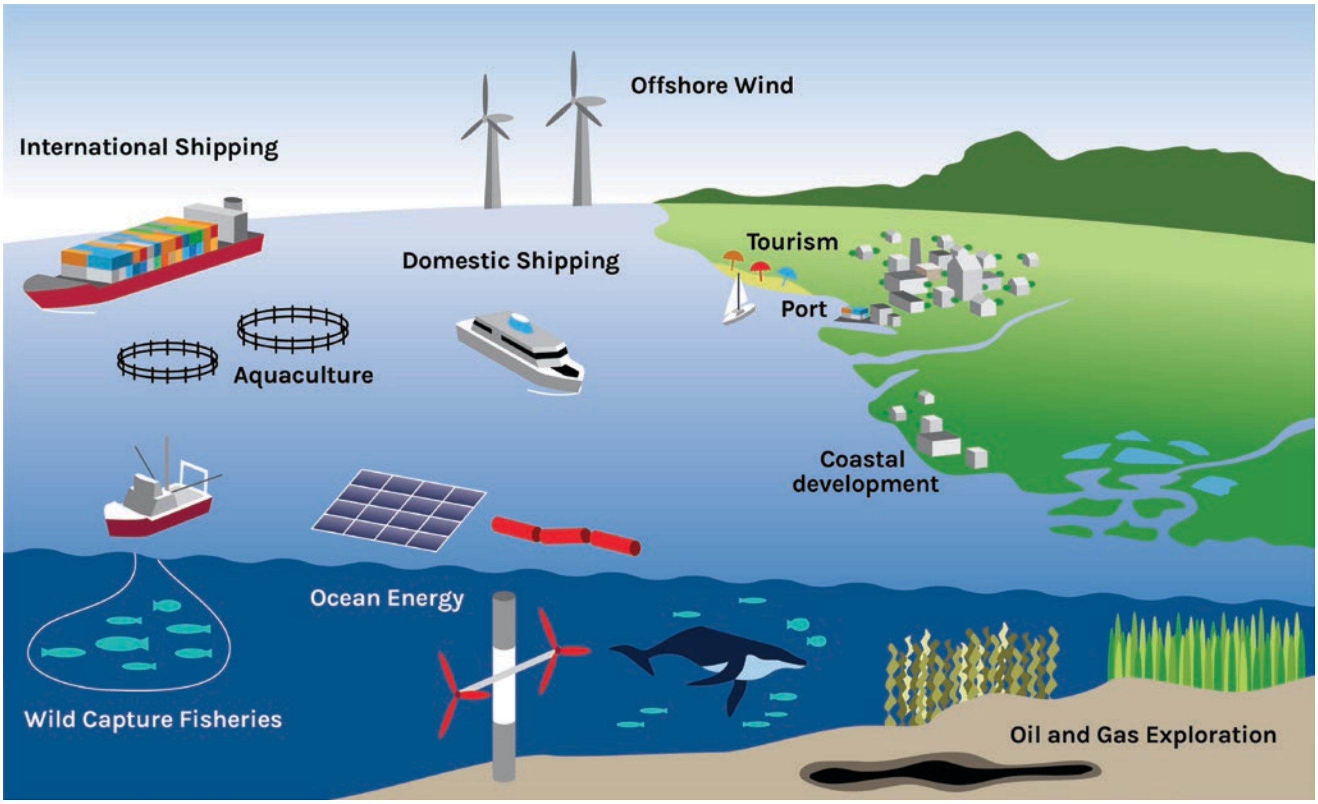

Fig. 12.2 A sampling of human activities in the coastal ocean

coral reefs, wetlands, seagrasses, kelp forests) that provide many of the benefits on which people rely (Costello et al. 2019; Aburto-Oropeza et al. 2020). Coastal habitats, including estuaries and deltas critical for marine biota and regional economies, have been severely affected by sea-use changes (coastal development, offshore aquaculture, mariculture and bottom trawling) and land-use changes (land clearance, urban development along coastlines, pollution of rivers). Ocean drilling, while relatively small in scope, has expanded since 1981 to roughly 6500 offshore oil and gas installations worldwide in 53 countries (60% in the Gulf of Mexico by 2003) and likely will expand into the Arctic and Antarctic regions as the ice melts. Plastic microparticles and nanoparticles are entering food webs in poorly understood ways (Jambeck et al. 2020). High levels of metals, nutrients and persistent organic pollutants from industrial discharges and agricultural runoff damage fish species and seabed biota. The dynamics of ocean and airborne transport of pollutants mean that the harm from inputs of plastics, persistent organic pollutants, heavy metals and ocean acidification is felt worldwide, including with consequences for human health (IPBES 2019).

4.4 Fragmented Governance

As we have already indicated, governance arrangements are too fragmented across administrative boundaries and sectors to provide the integrated responses that are required to meet the increasing and cascading risks of negative environmental impacts on the ocean (IPCC 2019). Existing governance is inadequate to stem unsustainable ocean uses in some coastal regions, where often a full constellation of resource demands and human activities are degrading ecosystems, and where regulatory contexts lack mechanisms to integrate management across sectors (IPCC 2019). Bigagli (2016) argues that more resilient ocean management systems incorporate learning-based management strategies that are supported by science-based advice to policy. He reviewed over 500 existing international agreements for environmental protection and regulation of human activities in the world's ocean and found them woefully inadequate. At global scales, agreements largely focus on single-sector objectives—fisheries, pollution, nature protection and transportation primarily—governing human use and management of the ocean. Regional agreements tend to include multiple sectors, but inclusion of ecological resilience considerations is mixed at best (see Winther et al. 2020). Integration and coordination of ocean governance is required to address these issues. In the absence of this, a very real risk arises: if a governing system becomes too complex, diverse or dynamic, it may become ungovernable in itself (Jentoft 2007; see also Winther et al. 2020).

It is clear from this and previous sections that a wide range of increasingly significant landscape pressures are already starting to harm the functional effectiveness and resilience of the ocean's complex social-ecological systems. Although pre-existing governance regimes are no longer adequate, as indicated earlier, significant shifts are already underway. These shifts are reflected in the ways regimes are responding to landscape pressures, and how niche innovations (instigated often at the local level by new actor networks) are emerging with a focus on the protection and regeneration of the commons.

5 Niche Innovations

In order for transitions to occur in response to landscape-level drivers of change, two dynamics must be at play: either existing regime actors (i.e. key individuals located within a particular regime, which could include decision-makers, consumers, regulators or funders) respond to these drivers, and/or networks of innovators come together to instigate so-called niche-level innovations. When path dependencies persist because regime actors resist change, niche innovations can emerge that demonstrate through trial and error that alternatives are possible. Niche innovations tend to be geographical and/or sectoral spaces where coalitions of innovators coalesce in response to perceived landscape pressures. Often, these niche innovations are protected from market dynamics (via subsidies or soft money) or political interference (via regulation or location in the non-profit sector).

For example, groups of anti-nuclear activists initiated wind-power experiments in Denmark in the 1980s and 1990s. Government policy banned businesses from owning windmills located within communities, thus protecting these niches from competitive pressures, and regulations resulted in rewards for—and subsidies of—innovations. Denmark has subsequently become a world leader in wind-power generation through its global company Vestas (Mey and Diesendorf 2018). The same applies to organic food production. In the United States, for example, the Whole Foods supermarket chain has transformed previously limited-impact organic food niches (farming and retail) into a mainstream food retail regime. In this case, niches were 'protected' by the evolution of a particular set of consumer values and organic certification schemes. Niches can coalesce into an alternative regime (e.g. wind power), or existing regimes can change course and absorb niche innovations (e.g. the way Italy's energy utility Enel has decided to close down half of its coal-fired power business and enter the renewable energy market as a mainstream global player).

These niche innovations reveal how regulatory interventions (if any), stakeholder engagement/organisation, institution-building, and ongoing monitoring and evaluation have worked in ways that counteract the negative landscape pressures. We offer four examples here to illustrate the diversity of niche innovations emerging in the ocean: coastal zone development planning in Belize (Box 12.1); the Chilean territorial user rights fisheries (TURFs) as an example of rights-based fishery management (Box 12.2); shared stewardship in business in SeaBOS fishery companies (Box 12.3) and responses to plastic pollution in the ocean (Box 12.4). There are literally hundreds of niche innovations, some disconnected, others are starting to coalesce into potential alternatives. To illustrate the breadth of niche innovations in the ocean system, we highlight four additional examples in Appendix C to reveal their breadth and dynamics: integrated coastal development, fisheries and disaster risk planning in Belize; rights-based fishery management; illegal, unreported and unregulated (IUU) fisheries monitoring innovations; and justice in marine sustainability, including the Pacific Islands' Parties to the Nauru Agreement (PNA Tuna 2010).

Box 12.1. Coastal Zone Development Planning in Belize

The Government of Belize's Coastal Zone Act of 2000 recognises the value of multi-sectoral, integrated spatial planning to guide policy and investment for more sustainable use of the coastal zone. The government approved a national Integrated Coastal Zone Management Plan (ICZMP) in 2016, led by a new ministry inspired by integrated development planning, connecting in one department Agriculture, Fisheries, Forestry, the Environment and Sustainable Development (CZMAI (Coastal Zone Management Authority and Institute) 2016). The government led an interactive stakeholder engagement process to co-develop the plan, beginning with identifying shared objectives for artisanal and commercial lobster and conch fisheries; reducing the risk to coastal infrastructure, property and people from sea level rise and storms; and sustainable tourism benefits, the largest sector of the Belizean economy. The iterative science-policy process engaged all relevant stakeholders from government ministries, non-governmental organisations, business, and community leaders (Arkema and Ruckelshaus 2017). The final plan is projected to improve coastal protection from storms and sea level rise, and increase revenue from fisheries and tourism, more than alternative plans emphasising either conservation or development alone (Arkema et al. 2015, 2019; CZMAI (Coastal Zone Management Authority and Institute) 2016). At the same time, the plan improves protection for mangroves, coral reefs and seagrass beds—the natural capital upon which coastal populations' safety and livelihoods depend.

The final ICZMP highlights the importance of coordinating the management of, and investment in, a diverse set of activities and actors implicated in sustainable outcomes for the nation, ranging from those engaging in or affecting coastal pollution, dredging, fisheries, aquaculture and tourism development, to education, social resilience to climate change, and preservation of cultural heritage. The plan led the Belizean government to enact a permanent ban on all oil exploitation within the second-largest coral reef in the world. The ICZMP actions and new zoning-based management are being implemented with funding from the government, the Inter-American Development Bank and other sources. The Belize plan has been hailed by UNESCO as 'one of the most forward-thinking ocean management plans in the world' (Douvere 2016). In 2017, the Belize Barrier Reef was removed from the UNESCO List of World Heritage in Danger because of the protections provided in the government ICZMP.

The key innovations in the Belize ICZMP process include a legal government mandate, in the Coastal Zone Management Act of 2000, requiring a cross-sectoral, multi-objective and spatial planning process. In and of themselves, such laws do not necessarily lead to transformation of ocean management. An important institution in Belize, the Coastal Zone Management Authority and Institute (CZMAI), played a key role in designing the co-development process for the ICZMP, and continues to lead its ongoing implementation and adaptation. The science-policy process to envision, debate, and select the final ICZMP approved by the government also included training of Belizeans on the scientific and policy aspects of ecosystem-based management, increasing the chances that the process will be internalised in government and civil society activities (Arkema and Ruckelshaus 2017). Appendix C details efforts in fisheries and disaster risk sectors to integrate more fully with coastal zone development planning in Belize.

Box 12.2. Chilean Territorial Use Rights Fisheries

In 1991, after an overfishing crisis led to critical closures of the Chilean abalone ('Loco') fishery in the late 1980s, Chile enacted the first step in a governance transformation—a Territorial Use Rights in Fisheries (TURF) policy (Gelcich et al. 2010). As of 2013, there are over 450 TURFs in full operation, making up more than 1100 km^2 of subtidal habitat decreed to fisher organisations throughout the Chilean coast (Gelcich et al. 2017). This network of TURF areas has been established by numerous associations of fishers, along a wide geographic range, under one policy instrument, Chile's National Fisheries and Aquaculture Law (Marín et al. 2012). As a result of the TURFs, Chile's artisanal sector has increased in importance, with landings consistently surpassing the industrial catch since 2008. Artisanal fisheries are a significant source of employment for coastal communities in Chile, and their harvests represent a key source of nutritional food for many rural communities. Increases in biomass and size of individuals from species within properly managed TURFs also are demonstrating the potential of this rights-based management approach to sustain ecosystems and fishery benefits (Gelcich et al. 2019a, b).

The national enabling legislation, combined with the presence of scientific knowledge signalling alternative ways to manage stocks, and the capacity and political leverage of fisher associations that facilitated the cross-scale and the cross-organisational interactions for change, each were key in institutionalising the new governance regime.

Any registered fishing association in Chile can register as a TURF under the national law, thus encouraging volitional participation in the program, a key component of adaptive governance for a more resilient system. The TURF network has improved the knowledge of fishers and their access to learning, especially as it relates to harvest management practices, biological aspects of the resource and the interactions of the target species with other elements of the ecosystem. This increased understanding has served to develop a sense of resource stewardship on the part of fishers.

While the 25-year-old Chilean TURF model has proven its potential to improve the sustainability of fisher communities and fisheries, its governance must continue to evolve as information on social and ecological barriers to further scaling emerges (Gelcich et al. 2010). TURFs convey rights to fishers and allow them a greater, collective voice in the long-term management of the resource, a key component of their adaptability and responsiveness to changing social-ecological conditions. Currently there is room for improvement with respect to enforcement, profitability, socioeconomic impacts on resource users and the adaptability of the policy to local realities. Science, both social and natural, is key to informing ways to maintain the policy, enabling adaptation of TURFs and identifying new conditions that must be improved to build the resilience of TURFs or enable further transformations.

Box 12.3. Seafood Business for Ocean Stewardship

The Seafood Business for Ocean Stewardship (SeaBOS) initiative is an innovative collaboration among 10 of the largest global seafood companies that is transforming business operations for more sustainable wild capture fisheries and aquaculture production. Collectively, the companies in the SeaBOS initiative influence the strategic direction of more than 639 subsidiaries along the seafood value chain, with operations in at least 93 different countries, and participation in fisheries and aquaculture decision-making institutions such as regional fisheries management organisations. Under the SeaBOS platform, the world's leading seafood businesses are managing seafood cooperatively, monitoring their practices and impacts, and charting a new path for their sector. They have pledged to address illegal, unreported and unregulated fishing; work towards full traceability and transparency throughout their supply chains; make efficient use of aquaculture feeds and use fish feed resources from sustainably harvested stocks; apply existing certification standards; eradicate labour abuses and human rights violations from their supply chains; reduce the use of plastics in seafood operations; work towards reducing the use of antibiotics in aquaculture; and prevent harmful discharges and habitat destruction. The participating businesses also have pledged to work with governments to improve existing regulations concerning aquaculture and fisheries (Österblom et al. 2017). The scope of the undertaking spans every continent and all segments of seafood production. The collaborative nature of the SeaBOS project also helps companies share information to develop best practices, which in turn has helped to build trust and common purpose. An on-deck species-detecting camera and facial-image recognition software pilot is aimed at identifying illegal catch and undocumented fishermen onboard vessels. SeaBOS has recognised the crucial role of scientists in framing the urgency of problems and potential solutions. The initiative is an ongoing experiment that is being closely monitored to understand the significance of the changes over time. Such initiatives engaging with the private sector are best considered a complementary approach to existing processes, such as government regulations. This initiative is improving the prospects for transformative change by providing novel links between science and business, between wild-capture fisheries and aquaculture industries, and across geographical space (Österblom et al. 2015). SeaBOS is best described as a co-production initiative between science and business, in which companies can develop their agency (Westley et al. 2013) and ability to influence change across subsystems, thereby contributing to amplifying new norms of ocean stewardship.

Box 12.4. Global Response to Plastic Pollution in the Ocean

Over the past several years, awareness of marine plastic pollution has skyrocketed around the world. Stories of marine turtles and mammals dying from ingested plastic and plastic pollution washing up on beaches have inspired hundreds of commitments from government, businesses and non-governmental organisations, dozens of innovation challenges, hundreds of start-up companies seeking to create solutions and millions of citizens eager to take action (Jambeck et al. 2020). Global plastic production has indeed exploded, from 1.7 million metric tonnes/year in 1950 to 422 million metric tonnes/year in 2018 (Geyer et al. 2017; Plastics Europe 2019), with a concomitant increase in plastic in the waste stream (in the United States, plastic was 0.4% of the waste stream by mass in 1960 and 13.2% in 2017 (U.S. EPA 2014, 2019)). Both micro- and macro-plastics can enter the ocean through direct discharge, discharge into rivers that then flow into the ocean, runoff from land or deposit from air into waterways. Impacts of this increased load on biodiversity include negative effects on growth, reproduction and survival of marine species (Jambeck et al. 2020).

Strategies to address ocean plastics include enhancements to wastewater, stormwater and coastal zone management, development of alternative materials, greater resource efficiency, recovery and recycling (Jambeck et al. 2020). The plastic challenge is systemic, spanning product-specialised value chains and geographic heterogeneity in plastic generation, use and recycling capabilities (Jambeck et al. 2020). The specific solutions to plastic pollution in the ocean are likely to be many, crossing sectors and spatial scales, from changing individual choices to company sourcing decisions to enforcement of existing and new regulation. Efforts to address the ocean plastic challenge are acknowledging the need both for a systems approach and for understanding the ocean as a commons. For example, ocean plastic is a growing problem in Africa, where waste volumes within coastal countries are relatively low but waste streams from other nations are overwhelming limited environmental regulation (Jambeck et al. 2018, 2020).

Leaders from governments, businesses and civil society are focusing on changing perceptions and behaviour along the entire supply chain, from design, production and use through to disposal and further use. Heightened public concern about plastic in the ocean is currently an effective catalyst for action on solutions; and this urgent attention is beginning to activate broader strategies to reduce the flow of other pollutants into the ocean. For example, a number of social innovations emerging in Africa are aimed at waste problems generally, such as community-driven collection systems and financial reward for recyclables, such as Wecyclers in Nigeria and Packa-ching in South Africa (Jambeck et al. 2020). At the regional scale, the Lower Mekong Initiative, a multinational partnership to integrate the policies of Cambodia, Laos, Myanmar, Thailand, Vietnam and the United States, is now addressing plastic contamination upstream before it gets to the ocean (Jambeck et al. 2020). The system-level collaboration emerging to address plastic pollution is a promising start to what needs to be a worldwide response. Collaborative efforts such as the Ellen MacArthur Foundation's New Plastics Economy Global Commitment, which requires signatories to align on a shared vision and targets, and the World Economic Forum's Global Plastic Action Partnership, which is a public-private collaboration platform helping to translate commitments into action, are also providing forums where many stakeholders can work together at the system level.

The system-level collaboration emerging to address plastic pollution is a promising start to what will most effectively be a worldwide response.

6 Transition Dynamics: Theories of Change

To transform socio-ecological systems, the elements below are needed to enable articulation of future aspirations, as well as a generative dialogue so that learning and adaptation can occur.

6.1 Knowledge for Transitions

Up until this point we have described the key regime dynamics (with overviews in Appendix B of shipping, ocean-based food extraction, offshore oil and gas, ports, marine and coastal tourism, marine and seabed mining, marine biotechnology, cabling and maritime equipment and offshore renewable energy), the various relevant landscape pressures and a sample of niche innovations (see Sect. 5 and Appendix C). In summary, it is clear that there are a set of landscape pressures that could result in the collapse of the ocean's key ecosystem functions, with negative implications for humanity and, specifically, the global economy. Despite the strong governance framework provided by the UNCLOS system, the existing regimes are institutionally misconfigured for this challenge. They are locked into path dependencies at odds with what is required to face the landscape pressures. However, some regime dynamics respond positively to these landscape pressures.

These sustainability-oriented regime dynamics are suggestive of future trajectories. Similarly, there is a mushrooming of niche innovations as constellations of actors (primarily, but not exclusively, at the local level) respond to landscape pressures and the inadequacy of current regimes. What is distinctive about these niche innovations is that they entail forms of stakeholder collaboration that are driven by an overriding concern to protect and regenerate the commons. As Nobel Prize winner Eleanor Ostrom (1990, 2000) has argued, humans have collaborated for millennia to protect the commons that they recognise they are dependent on. The niche innovations, therefore, suggest future trajectories that valorise the commons. They also provide signposts for the 'anticipatory thinking' (Poli 2018) that is needed in order to chart a course for the future. Transdisciplinary research methodologies will be required to conduct research on the constantly changing interactions between landscape pressures, regime dynamics and niche innovations in order to grasp the emergent properties of the sustainability-oriented ocean transition (van Breda and Swilling 2018; van Breda 2019).

6.2 Capacity and Incentives for Transitions

Transition dynamics are dependent on three key factors: whether or not existing regimes access new knowledge from external sources; whether or not they have the capacity to integrate new knowledge in order to facilitate substantive change processes; and whether or not there are incentives, initiatives or other enabling conditions that activate change. In simple terms, if within a given regime (e.g. a car-based fossil fuel–dependent transport system in a given country) there is sufficient capacity to manage change (among, in this transport case, the policymakers, regulators, transport company managers, etc.) coupled to rapid learning about alternatives (derived from experimental examples), the chances are high that a transition will occur over time (in this example, to a decarbonised transport system). However, actual changes will only take place if some catalytic event instigates the need to activate the capacity for managing change. This could be anything from price hikes to protest movements to an electoral shift that brings a new party to power with an anti-car agenda.

Following Smith et al. (2005), there are four possible transition pathways, depending on how these knowledge, capacity and catalytic factors combine. When a particular regime can access new external knowledge, when it has the capacity to manage change and when enabling conditions are present, a 'purposive transition' can occur. Such transitions can be quite radical, including the transcendence of the mainstream regime itself in the process (e.g. the renewable energy transition in Germany). A purposive transition, however, is not inevitable. If the capacity to manage change exists but only 'internal knowledge' is relied on to envision alternatives, the result will be a reform of the regime rather than its replacement (i.e. an 'endogenous renewal'). Conversely, if there is limited capacity to manage change and external knowledge is sourced, the result will be an 'emergent transformation', that is, the internal breakdown of the regime followed by the mushrooming of alternatives with limited capacity for implementation. Where there is both limited capacity for change and a reliance on internalised knowledge sources, the result will be a 're-orientation of trajectories' as the old regime becomes dysfunctional but viable alternatives fail to emerge.

The above analysis is more appropriate for understanding transitions in particular sectors, such as the transition to renewable energy or to organic food. Ocean governance is an amalgam of sectoral and spatial regimes, loosely assembled within—and beyond—the UNCLOS framework. However, as revealed in the sections above (and in Appendix C), as our understanding of regime dynamics and niche innovations improves, emergent change is unfolding. In brief, there is evidence in the ocean system that all four of these transitions are underway. A system-wide 'purposive transition' that builds on emergent regime responses to landscape pressures and transformative niche innovations is the most effective pathway to ocean sustainability. These Blue Papers have instigated the process of sourcing external knowledge that helps stakeholders to reimagine the future of the ocean. Key governments, business and civil society can now lead the way in developing the coordination capacity to manage a 'purposive transition' based on the accelerated learning emerging from the Blue Papers.

What follows is a framework for how a 'purposive transition' to a global ocean governance system can be imagined. A purposive transition suggests there is clear vision of the changes required and an agreed future pathway for bringing about these changes. It draws from the principles emerging from the above selected regime responses and niche innovations. Together, they provide the framework for ensuring that the key elements of a successful transition are put in place. A combination of a new legal framework, an 'ocean agency' and an ocean knowledge commons would bring into focus (1) the need to remove perverse incentives and promote incentives that reinforce the regime shifts and niche innovations that can catalyse a purposive transition; (2) knowledge-sharing that will be a precondition for nudging along the transition dynamics; (3) dialogues that inspire a new vision and compelling narrative; (4) the importance of a clear set of guiding principles that become the basis for new institutional configurations; and (5) the need to reinforce and empower early adopters and amplify best practices and niche innovations that reveal the alternative pathways towards a purposive transition.

7 Framing Transitions: Regulatory Lessons

The sustainable development of the ocean's economic potential will require a balance between, on the one hand, sufficient flexibility to meet constantly changing conditions and, on the other, regulatory structures that are sufficiently vigorous, strong and transparent to protect the planet for current and future generations (Pretlove and Blasiak 2018). Effective responses require international coordination and cooperation at unprecedented levels (TWI2050 2019). Multifaceted, integrated solutions can lead to new modes of stewardship (protecting, caring or responsibly using the environment) and social practices for managing the ocean as a commons. The World in 2050 report (TWI2050 2019) states that 'it is even more important now to integrate social and economic goals with climate, water, oceans, biodiversity and other Earth-systems so that sustainable development is not threatened in the long term'. Drawing on our understanding of the landscape pressures, regime dynamics and niche innovations, we propose a way of thinking about such a fundamental shift. In particular, we imagine a global governance transition that is more faithful to commons-oriented niche innovations.

Jessop (2002) argues that governing complexity means breaking away from linear modes of policymaking whereby problem analysis leads to policy solutions.

Instead, as our world becomes more complex, it helps to accept that 'governance failure is routine'. An adaptive, iterative process (i.e. learning and evolving through repetition) which reimagines a transition from the current, top-down nation-state structure towards a law for the commons will be more adaptable and sustainable (Bollier 2016). There is no one-size-fits-all solution.

Governance approaches that are diverse, tailored, innovative and adaptive, using science to support decision-making and develop early warning systems, are likely to be more sustainable (SDG 2019). Global collaboration is therefore essential, but on what terms?

Jessop (2011) recommends that governance reflect the context and align with stakeholders' concerns.

Social learning is crucial in order to understand drivers, attribute responsibility appropriately, understand the capacity for action and coordination in a changing, turbulent environment, and to activate change in decisions and activities. Finally, a common worldview is best for guiding action, and a system of meta-governance will help establish rules of conduct, as well as stakeholder orientations and expectations (Jessop 2011).

Meta-governance can be described as the governance of governance among interacting groups (Jessop 2011). These mechanisms could coalesce into a commons governance system which is based neither solely on the incremental logic of market forces, nor on top-down planning, but builds on these existing processes and interactive learning among a plurality of operationally autonomous but interacting agencies (Jessop 2011).

Bollier (2016) proposes that such a new sustainable system encompass three radical shifts in the current established system: (1) reconfiguring nation-state authority (along the lines suggested by Jessop)—as multiple governing bodies at different scales interact within a system of *networked governance*, they voluntarily learn and adapt followed by repetition (*adaptive voluntary governance*) in ways that that can eventually consolidate into new modes of *meta- governance*; (2) making communities sovereign by empowering the commons through rights and institutional capabilities for collectively managing knowledge and material resources; and (3) making ownership generative by integrating property rights (ownership or use) with stewardship responsibilities to ensure that the exercise of such rights incorporates environmental responsibility (Fig. 12.3). We have elected to use Bollier's conceptualisation for the purposes of this paper, although these shifts also are echoed in slightly different terms as necessary governance reforms in The World in 2050 report (TWI2050 2019).

While these shifts may seem far-fetched, in reality all three of these transitions are already underway in the ocean system. A closer look at an example of each in global governance will demonstrate the viability of these pathways to achieving sustainability in ocean governance, and illuminate the possible pathways into the future.

7.1 Reconfiguring Governance and Authority

7.1.1 Governance as Voluntary and Adaptive Learning

The traditional concept of governing through nation-state authority has begun to shift in several ways. One pathway is through voluntary commitments aimed at delivering outcome-oriented activities. Voluntary commitments have become a well-recognised mechanism in international sustainability policy (Neumann and Unger 2019). The UNFCCC Paris Agreement (UNFCCC 1992, 2015) demonstrates the possibility of a new model of international governance through a shift to a *volitional reflexive* approach (Box 12.5). This type of governance involves two aspects: (1) volitional or voluntary commitments aimed at delivering outcome-oriented activities and (2) reflexive governance where governance (the concepts, practices and institutions by which societal development is overseen) has the flexibility to adapt and adjust to include more appropriate alternatives over time, as a result of social learning. The Paris Agreement reflects this shift through two complementary mechanisms. First, state parties are legally obliged to comply with procedural commitments such as transparency reporting, but these commitments are combined with an element of volitional, non-binding obligations, allowing state parties to determine their own goals (or 'nationally determined contributions' [NDCs]) for measuring progress on meeting global climate targets (Pickering et al. 2018).

The obligations create a long-term framework for cooperation that aims to add momentum to the global response to climate change. At the same time, the volitional, softer layer underneath (the substance of NDCs) provides the flexibility needed to minimise barriers to universal participation (ones that would arise through rigid requirements) and to adjust contributions in the light of changes in scientific knowledge and shifts in complex social-ecological systems (i.e. in a reflexive manner as a result of learning over time) (Pickering et al. 2018). This style of governance therefore allows for dynamic real-time adjustments and flexible ecosystem-based responses. See also the example of the voluntary national review process under the UN SDGs (Appendix A3).

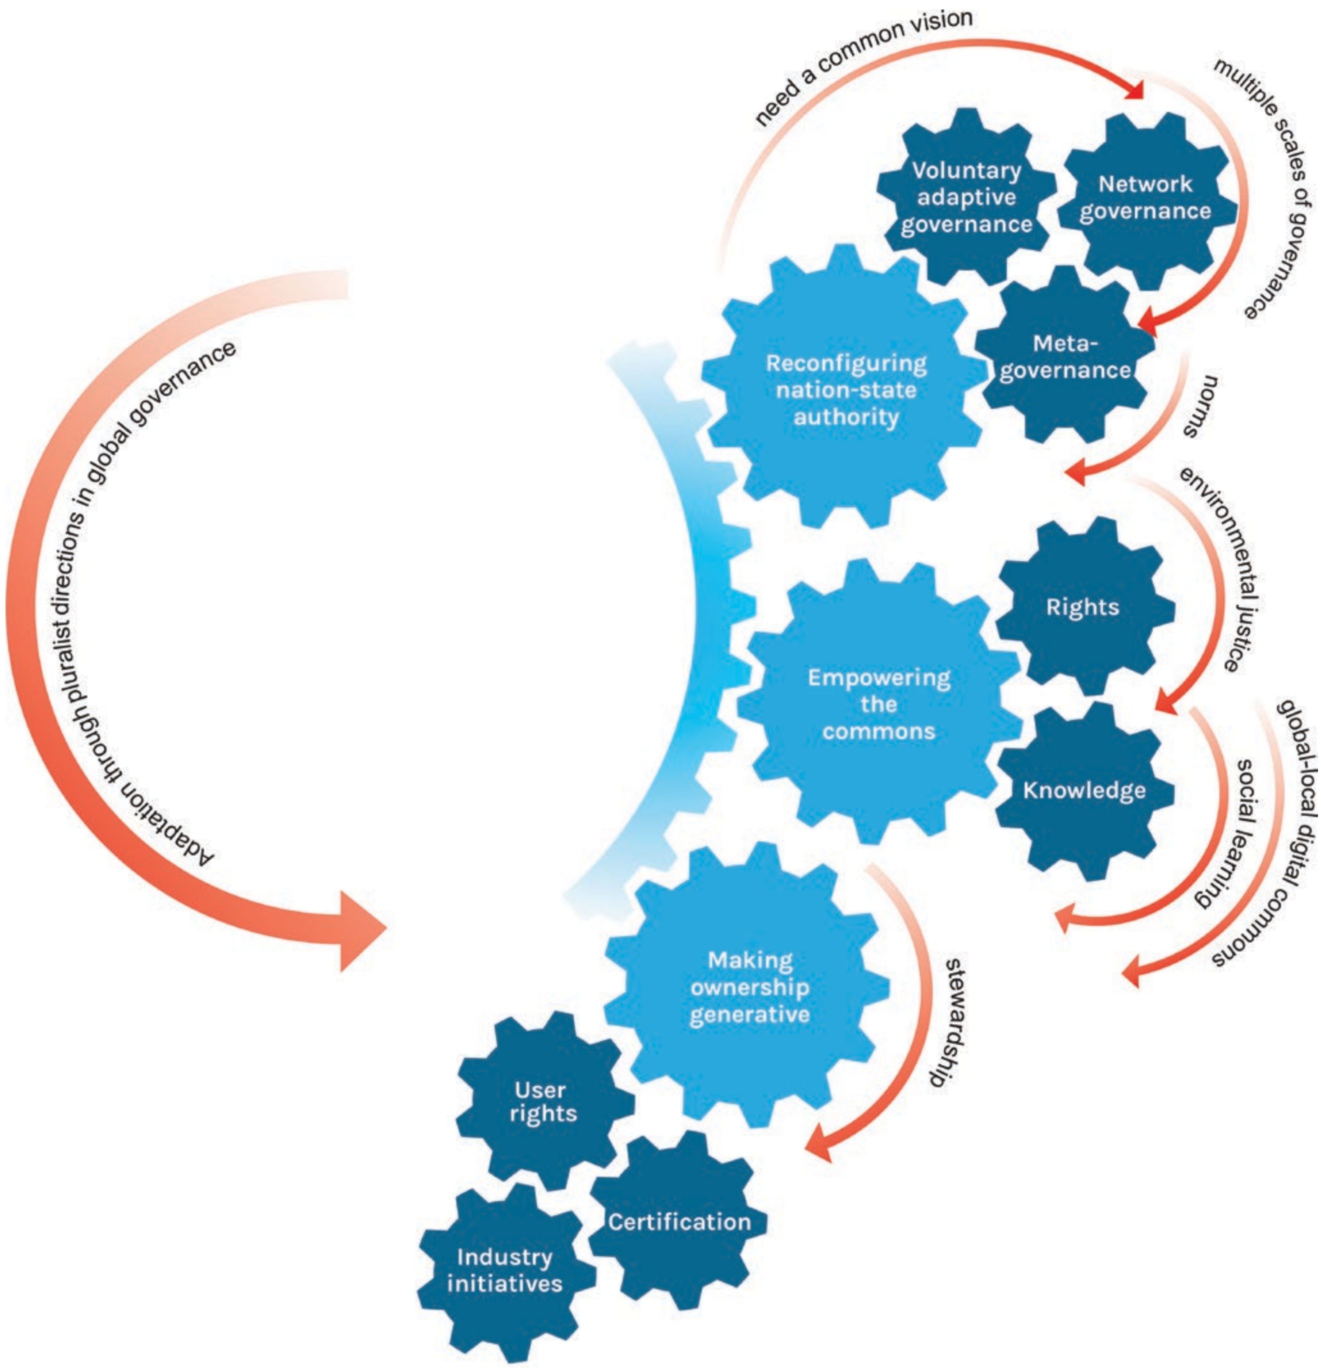

Fig. 12.3 Elements informing a transition to effective global ocean governance. Source: Authors. Conceptual elements drawn from Bollier (2016)

In ocean governance, two major international processes presently harness voluntary contributions. Voluntary commitments made under the banner of the Our Ocean Conference (OOC) series and the UN Ocean Conference provide opportunities to raise awareness, promote engagement and catalyse political will for action by states as well as the public and private sectors (Neumann and Unger 2019). In evaluating verifiable outcomes of voluntary commitments made at the OOC from 2014 to 2017, Grorud-Colvert et al. (2019) found that one-third of the announcements focused on marine protected areas (MPAs), and that almost half of the promised MPA actions were completed at the time of publication.

These voluntary commitments cumulatively amounted to over 5 million km^2 of protected area, encompassing 1.4% of the ocean, almost doubling the quantity of implemented MPAs worldwide (Grorud-Colvert et al. 2019).

During October 2019 at the sixth Our Ocean Conference, 370 commitments worth $63 billion were made to marine health and productivity (Evans 2019). The research conducted by Grorud-Colvert et al. (2019) has demonstrated the potency of these voluntary commitments. However, a uniform global process is still required to register and assess commitments, including consistent reporting and monitoring systems with clear targets, baselines and review systems (Neumann and Unger 2019).

7.1.2 Interacting, Multiple Centres of Governance at Different Scales

Another pathway to reconfiguring nation-state authority is through polycentric or network governance models (Ostrom 2010). Network-based modes of governance rely on the involvement of public, private and societal actors, and thus change the traditional top-down structure of political leadership (Sørensen 2006). This type of governance occurs across multiple scales, from transnational agreements, regional and national agreements and policies, down through individual municipalities, to the operations of public and private institutions and individuals (TWI2050 2018). Multiple centres of authority and distributions of power, which operate in complementary combinations, can address complexity more effectively than a single mode of governance (Pahl-Wostl 2017; Ostrom 1990; Dietz et al. 2003). The presence of these various forms of interacting decision-making bodies in a network governance structure is a core characteristic and requirement for sustainability transitions (Ottens and Edelenbos 2019). This type of network governance of the commons enables adaptation and mitigation through open, inclusive, pluralist directions in global governance (SDG 2019).

Box 12.5 Lessons from the Paris Agreement

Several innovative aspects of the Paris Agreement offer signposts for a new direction for global governance of the ocean, even though the resources and complex ecosystem services offered by the ocean commons are not as easily quantifiable as the carbon budget:

- The recognition that governments are only one set of the players in solving global commons problems. The Paris Agreement is a cooperative effort across sectors, including civil society, the private sector, financial institutions, cities and other sub-national authorities, local communities and indigenous peoples (Macy 2017).
- Instead of a top-down or bottom-up focus on narrow issue-based objectives, global goals inform policy directions. (This is also reflected in the UN 2030 Agenda.)
- Effective transparency mechanisms for reporting and verifying performance can replace or complement the need for compliance mechanisms and sanctions.
- Volitional reflexive commitments can provide the flexibility for evolution, for ‘ratcheting up’ commitments to reflect more ambitious targets, without requiring extensive time-consuming negotiations and trade-offs between state parties.
- Legal instruments for coordination of global action for commons problems need not be limited to treaties between states defining rights and obligations but can provide frameworks to facilitate and support action between governments and non-state actors (Macy 2017).

Network models, where multiple governing bodies interact to make and enforce rules within a specific policy arena or location, allow decision-makers to ‘experiment with different governance solutions tailored to particular scales and socio-ecological contexts’ (SDG 2019). They allow social learning, and importantly often include the involvement of directly affected local communities. Network governance may reinforce a system’s ability to adapt structural elements and alter processes in response to current or anticipated changes in the social or natural environment (Pahl-Wostl 2017; Dietz et al. 2003; TWI2050 2019). Network governance structures have proliferated, the Chilean TURFs being a well-documented development in ocean governance (Box 12.2; see also description of U.S. Fishery Management

Councils in Hanna 1995). Many existing network arrangements for the ocean include elements of the second shift (i.e. making communities sovereign by empowering the commons) and third shift (i.e. making ownership generative by integrating property rights with stewardship commitment) underway as discussed below.

7.1.3 Meta-governance

The final piece of the transition in reconfiguring nation-state authority is the concept of meta-governance, or supranational governance. The Arctic Council and the Antarctic Treaty System are demonstrably important examples of supranational management (IPCC 2019). In some instances, multilateral agreements between states have successfully addressed commons issues.

The Montreal Protocol has, for example, successfully protected the ozone layer (the hole in Earth's ozone layer is the smallest in recorded history (Helfenstein et al. 2019) and is widely recognised as an example of effective protection of the global commons (Dietz et al. 2003). Regional cooperative agreements, implemented between states (such as the UN Shared Watercourse Agreement of 1997), have successfully created effective new modes of governance of shared water resources. Despite some successes, however, the nation-state political system is too fragmented, slow and rigid to manage the profound normative, societal, political and institutional changes that are required to implement integrated, multidimensional sustainable development agendas (TWI2050 2019).

A culture of global cooperation is required to develop multiple sustainable development pathways across scales (TWI2050 2019). A common worldview coupled with supranational standards could provide framework conditions for addressing issues at different scales, in response to changing needs, capacity and context (Jessop 2011; TWI2050 2019). Governing the trade-offs between different policy objectives which arise in multi-scalar, polycentric, adaptive governance models will be easier if meta-governance principles, such as transparency, accountability and inclusiveness, are in place (Weitz et al. 2017; UN ECOSOC 2018; TWI2050 2019). Some examples of ocean-related meta- governance instruments include the FAO 'Step-wise Guide for the Implementation of International Legal and Policy Instruments Related to Deep-Sea Fisheries and Biodiversity Conservation in Areas beyond National Jurisdiction' (FAO 2019b); the *Voluntary Guidelines for Securing Sustainable Small-Scale Fisheries in the Context of Food Security and Poverty Eradication* (FAO 2015); UNESCO's Man and the Biosphere programme (Bridgewater 2016); and several IMO guidelines, for example, the *Post-2015 Development Agenda* (IMO 2015) for the maritime transport sector, the *Guidelines for Safe and Environmentally Sound Ship Recycling* (IMO 2012), and the *Guidelines on Places of Refuge for Ships in Need of Assistance* (IMO (International Maritime Association) 2003).

7.2 Empowering the Commons

The second shift suggested by Bollier (2016) and the TWI report (and implicit in our assessment of the niche innovations) towards a new ecological order is making communities sovereign by empowering the commons. It is important to remember that the commons is both the resource of a defined community and the protocols, values and norms devised by the community to manage its resources (Bollier and Burns 2011). A commons in this sense is characterised by bottom-up participation, subjective responsibility, transparency and self-policing accountability (Bollier and Burns 2011). One way to achieve this is through the creation and protection of rights to the commons.

7.2.1 Rights to the Commons

Environmental obligations generally are resolved at an interstate level (Boyle 2012), but if one considers the ocean as a global commons that is part of the global ecological system (IPCC 2019), then in legal terminology, the obligations inherent in concepts such as the sustainable use of natural resources, intergenerational equity and the common concern of humankind can be considered obligations owed to the international community as a whole (Boyle 2012; Weston and Bollier 2013a, b; Kotzé 2019). While commons have traditionally been held in trust by sovereign nations, or collaboratively managed through inter-state relationships, this has proved insufficient to protect the ocean commons (Dietz et al. 2003). A third way is now needed.

A human rights perspective provides a useful basis to ensure transnational environmental fairness and justice, because human rights are understood to permeate traditional sovereign boundaries (Robinson 2016; Weston and Bollier 2013b). The development of the human right to a decent or sound environment is a basis from which to empower the commons. Risks posed to human rights by climate change are significant (Robinson and Shine 2018). Global warming of 2 °C would, for example, impact the right to food and the right to an adequate standard of living. This raises a question of ethics (Robinson and Shine 2018): 'If the international community accepts that climate change is happening, understands its causes and knows what needs to be done to change course—how can it justify its continued delays to act on the scale, and with the urgency required?' Robinson and Shine (2018) suggest in response that rights-informed climate action can maximise benefits for people and the planet (Box 12.6).

The link between the environment and human rights has long been recognised (UN General Assembly 1972; OHCHR (Office of the High Commissioner for Human Rights) 1994;

OHCHR 1995, 1996; IUCN (International Union for the Conservation of Nature) 1995). Although the International Union for Conservation of Nature (IUCN) covenant was presented as a means of strengthening momentum for global action to implement the 2030 Agenda for Sustainable Development, it has not gained universal support or momentum. Despite this, in the 50 years which have passed since the Stockholm Declaration (UN General Assembly 1972), the human right to a healthy environment has been refined to include procedural rights (such as in the Convention on Access to Information, Participation in Decision-Making and Access to Justice (UNECE 1998)). Substantive elements have also been clarified in some constitutions (e.g. the right to clean air, safe water, adequate sanitation, healthy and sustainably produced food, healthy biodiversity and ecosystems, and a safe climate; see Boyd 2019, by the UN special rapporteur on human rights). In 2019, 130 states were party to regional treaties which incorporate a right to a healthy environment, and in over 110 states this right is constitutionally protected. In total at least 155 states recognise, in law, the right to a healthy environment (Boyd 2019).

The human right to a sound environment was once again brought to the fore by an initiative of the French legal think tank Club des Juristes, which in 2017 called for a Global Pact for the Environment; in May 2018, the UN General Assembly adopted a resolution opening negotiations to create the treaty (Club des Juristes 2018). The Global Pact codifies a human right to an ecologically sound environment and is designed to consolidate and integrate generally accepted but fragmented environmental norms and principles into one overarching, binding text. This way of thinking informs the work of the Ad Hoc Open-Ended UN Working Group towards a Global Pact for the Environment, which held its third session in May 2019.

Box 12.6 South African West Coast Rock Lobster

An example of rights-based environmental action demonstrates the utility of a human rights perspective for ocean resources. In terms of Section 24 of the Bill of Rights in the South African constitution, the environmental right comprises two parts: first, 'everyone has the right to an environment that is not harmful to their health or well-being' and, second, everyone has the right 'to have the environment protected, for present and future generations, through reasonable legislative and other measures that … secure ecologically sustainable development and use of natural resources while promoting justifiable economic and social development' (Republic of South Africa 1996, Chap. 2, Sec. 24). This right is mirrored in the South African environmental legislative framework.

On the basis of the foundation provided by this constitutional right, a landmark decision was handed down by the Western Cape High Court in 2018 in *WWF South Africa v. Minister of Agriculture, Forestry and Fisheries and Others* [2018], 4 All SA 889 (WCC). The West Coast rock lobster fishery is one of South Africa's oldest formal commercial fisheries, dating back to the late nineteenth century. It has also been a mainstay of poorer subsistence fisher communities. Catch peaked in the 1950s at around 18,000 tonnes but has declined sharply over the past few decades to an all-time low of 1500 tonnes in the 1995–1996 season. A scientific working group convened by the Department of Agriculture, Forestry and Fisheries called in 2016 for a total suspension of lobster fishing until a sustainable path for the resource was established (with compensation for stakeholders). The same working group recommended a total allowable catch (TAC) of less than 800 tonnes for the 2017–2018 season. Instead, the TAC for the 2017–2018 season was set at 1934 tonnes. The WWF sought to have this decision set aside, arguing that, given the depleted state of the resource, its harvest above prudent levels posed a threat of serious or irreversible environmental damage. The court set the TAC determination aside on the basis that it was unlawful, in contravention of the constitutional right, the subordinate legislation and South Africa's obligations in international law under UNCLOS. (Other principles were also relevant, including the precautionary principle and critical role of scientific analysis in the determination of the sustainability of a marine resource (Glazewski 2018)).

The constitutional environmental right in this matter made it possible for civil society (in this case, WWF) to ensure that the government department upheld the principles of sustainable development.

Despite some criticisms (Biniaz 2017), the reintroduction of the groundbreaking universal, justiciable individual human right to the environment opens the possibility of using the existing legal human rights framework for enforcement of the right to a decent environment. The Global Pact (or another similar agreement) could, if adopted, generate a shift in the collective understanding of legal norms and environmental rights in a similar fashion to what occurred in the human rights body of law as a result of the Universal Declaration of Human Rights (1948). This type of agreement provides a possible paradigm shift away from the conventional justification of social and economic development at the cost of the environment and embodies the potential for a new holistic environmental stewardship for the planet, based on human rights.

The relevance of adopting a human rights approach in the context of the environment was affirmed by the explicit recognition of human rights in the Paris Agreement (Robinson and Shine 2018). In 2015 the Dutch court in the Urgenda case[1] was prepared to venture into the uncertain territory of separation of powers in order to enforce a duty of care to meet greenhouse gas emission targets by the Dutch government. In June 2019 the Danish Institute for Human Rights launched strategic web-based tools it developed to operationalise the synergies between SDGs and human rights, namely, the Human Rights Guide to the SDGs and the SDG Human Rights Explorer (2020). The younger generation has been particularly vocal in asserting the right to intergenerational equity (UN News 2019; *La Rose et al. v. Her Majesty the Queen*, T-1750-19, Federal Court of Canada).

These developments illustrate that the nature of human rights is not fixed or static—human rights are changeable and relate to particular historical moments and social contexts. The right to a healthy environment could form a baseline 'net' for governance of the commons to address and redress the grave inequities suffered by individuals and communities exposed to environmental degradation and the unsustainable extraction of natural resources.[2] Human Rights Watch, in its World Report (Orellana 2018), stated that global recognition of the right to a sustainable environment is long overdue, as has Boyd (2019), the UN special rapporteur for human rights.

7.2.2 Knowledge Commons

Traditional economics was premised on the assumption that resources were unlimited and information scarce—the reverse is now true. The digital revolution has resulted in open information platforms otherwise known as the 'digital knowledge commons' or 'platform co-operativism'. This is a rapidly unfolding phenomenon that could be harnessed for the benefit of the ocean. A growing body of literature proposes that these new technologies provide the most powerful way to accelerate the empowerment of the commons by creating a new generation of trans- sovereign institutions that facilitate 'many-to-many' communications, including the reconfiguration of nation-state authority over shared commons that transcend national boundaries (see Bauwens et al. 2019). (The term *digital revolution* includes virtual and augmented reality, additive manufacturing (e.g. 3D printing), artificial intelligence, deep learning through open platforms, robotics, big data, the Internet of Things, and automated decision-making systems including crowd-sourced tracking and monitoring (TWI2050 2019; Leape et al. 2020)). Digitalisation hardly featured in the Paris Agreement or UN Agenda 2030, but it is increasingly clear that digital changes are becoming a key enabler of societal transformation (Domingos 2015; Schwab 2016; Tegmark 2017; Craglia et al. 2018; TWI2050 2019). It is predicted that by 2020 data generation will increase annually by 4300% (Sunderji 2016).

Bollier (2016) argues that there is enormous practical potential in developing a digital knowledge commons sector as a quasi-independent source of production and governance—a kind of 'fifth estate'. The World in 2050 (TWI2050 2019) states that 'digitalization is not only an "instrument" for resolving sustainability challenges, it is also a fundamental driver of disruptive, multiscalar change'.

The information and communication technology (ICT) revolution that emerged in the 1970s introduced the 'network' as an alternative to market- and hierarchical modes of organisation. Vast swathes of contemporary organisational and economic life are now organised in networks that have been hardwired into massive global 'many-to-many' platforms. ICTs made possible 'self-managed mass communication' as a new mode of sharing knowledge that was never before technically feasible (Castells 2009). Over the past two decades, these two modes of organisation and communication—networks and self-managed mass communication—have fused, resulting in increasingly complex, global interactive networks. Using the new ICTs for direct 'many-to-many' communications without transacting through a regulator or a market operator, a new 'peer-to-peer' (P2P) economy has emerged that can be configured in a wide variety of ways. The result is the rapid expansion of an information and knowledge commons, whether this is for private profit, as with Facebook, Uber and Airbnb, or for the public good, as with Wikipedia, GNU and Mozilla Firefox.

For Bauwens et al. (2019), the peer-to-peer mode of production becomes the basis for what they call a 'commons-centric society' or what others have called 'platform economies'. Bauwens et al. (2019) connect three aspects of this emergent alternative: (1) it creates conditions for a new mode of social relationships for learning, innovating and producing on a global scale; (2) it develops a technological infrastructure that makes scaling up possible through mutual coordination; and (3) it creates new property relations that mix shared ownership of the commons with private use for commercial gain.

The core of numerous types of for-profit and non-profit platform economies is clear: designs/data are loaded up in real time for collaborative co-production and optimisation, while users download applications from the knowledge com-

[1]Urgenda Foundation v. The State of the Netherlands. 2015 HAZA C/09/00456689 (June 24, 2015); aff'd (Oct. 9, 2018) (District Court of the Hague, and The Hague Court of Appeal (on appeal).

[2]The Oganiland case (Social and Economic Rights Action Centre v. Nigeria, 2001, AHRLR 60) demonstrates this point. The applicant would have had the additional armory of founding liability in a duty of care owed by the multinational corporations involved in the despoliation of the Niger delta. This extended duty of care would have been owed to the people of the region in addition to the state's duty to ensure its citizens' right to a satisfactory environment.

mons for use in their local or sectoral environments. Until now, this has never been possible before at scale (Bauwens et al. 2019; Leape et al. 2020).

Bauwens et al. (2019) show that each of these major global initiatives have three exemplary features (that are relevant for the purpose of imagining an ocean commons): (1) a 'productive community' of people who voluntarily create new and improve existing understanding in the commons; (2) an 'entrepreneurial coalition' that is licensed to exploit the understanding in the commons in the wider market, but with controls over the distribution of surplus; and (3) a 'for-benefit association' supported from the revenues generated to reinvest in the capabilities of the productive community and wider environment. These three become the potential organisational template for building up from below the ocean commons–based peer production.

Components of such a knowledge commons for the ocean exist, but there is much more work to do (Box 12.7; Leape et al. 2020).

An 'Ocean Knowledge Commons' would comprise its own 'productive community' (including scientists and a wide variety of other people who share a common interest in the future of the ocean); an 'entrepreneurial coalition' to manage the distribution of and access to knowledge—perhaps a Global Ocean Commons Institute (GOCI); and a 'for-benefit foundation' that raises funds to actively support and develop the 'productive community' and GOCI. To make it happen, 'transvestments' from the traditional grant-making, for-profit and public sectors will be required until the Ocean Commons Community (the ocean 'commoners', GOCI and for-benefit foundation) has its own autonomous capital base.

The most appropriate architecture for an Ocean Knowledge Commons could be a fusion of a global commons (e.g. Wikipedia) and a localised commons (e.g. the decentralised slow-food movement) in what Jose Ramos calls 'cosmo localism' (Fig. 12.4; Ramos 2019). In this model as adapted to the ocean, a 'wiki-type' global commons would be created for pooling (at least) two types of information: (1) crowd-sourced data (from, e.g., sensors on ships of various types) plus satellite data; and (2) alternative processes and arrangements (e.g. locally relevant approaches for restoring damaged mangroves or building sustainable fishing systems) that 'commoners' can collaboratively work on together, drawing from a range of local case experiences.

However, the localised commons would also be created as decentralised platforms for commoners from particular subregions to collaborate, both using designs downloaded from the global commons and generating new designs and monitoring data fed upwards into the global commons. The result would be an 'ocean cosmo localism' supported by the relevant generic institutional forms that have emerged at the global commons level, that is, what we referred to above as the GOCI and the for-benefit foundation, plus equivalents where necessary at the local level (that could be either local partners or local branches of the GOCI and the for-benefit foundation).

Box 12.7 Open-Source Data and Analytical Platforms for Ocean Decision-Making

Open-source data and analytical platforms envisioned under a knowledge commons already exist for components of the ocean system. These platforms are being used to design and improve content in a peer-to-peer sense, and also at multiple scales by decision-making communities such as those for small-scale fisheries and integrated coastal management (Costello et al. 2019). They also help collect global satellite remote-sensing data from the U.S. National Oceanic and Atmospheric Administration and the U.S. Geological Service (Leape et al. 2020). At the global scale, the Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services (IPBES) harnessed an open-source global data and software platform (InVEST; see Sharp et al. 2020) and a networked community of scientists to model for the first time global changes in biodiversity, ecosystem services and the values to people under UN future scenarios, including in the ocean realm (Chaplin-Kramer et al. 2019). Open source data, models and interactive viewers for the IPBES global modelling platform (NatCap (Natural Capital Project) 2019) are catalysing discussions with multilateral institutions, governments and civil society leaders about how to standardise and improve data, analytics, and communication to diverse audiences such as those tracking SDG progress and impacts of nationally determined contributions under the UNFCCC. The same InVEST data and analytical platform are being used to drive integrated, multi-sectoral coastal development and disaster risk planning at national (e.g. see Box 12.1) and regional scales around the world (e.g. Arkema et al. 2015, 2019; Mandle et al. 2017; Silver et al. 2019; Wyatt et al. 2017) and China's national zoning for development (Ouyang et al. 2016). Progress towards integrative frameworks to connect these existing open data platforms is ongoing, mostly from the producer communities (e.g. Selig et al. 2018). Clear signals for priority policy needs, and engagement between global- and local-scale actors, can accelerate these nascent efforts.

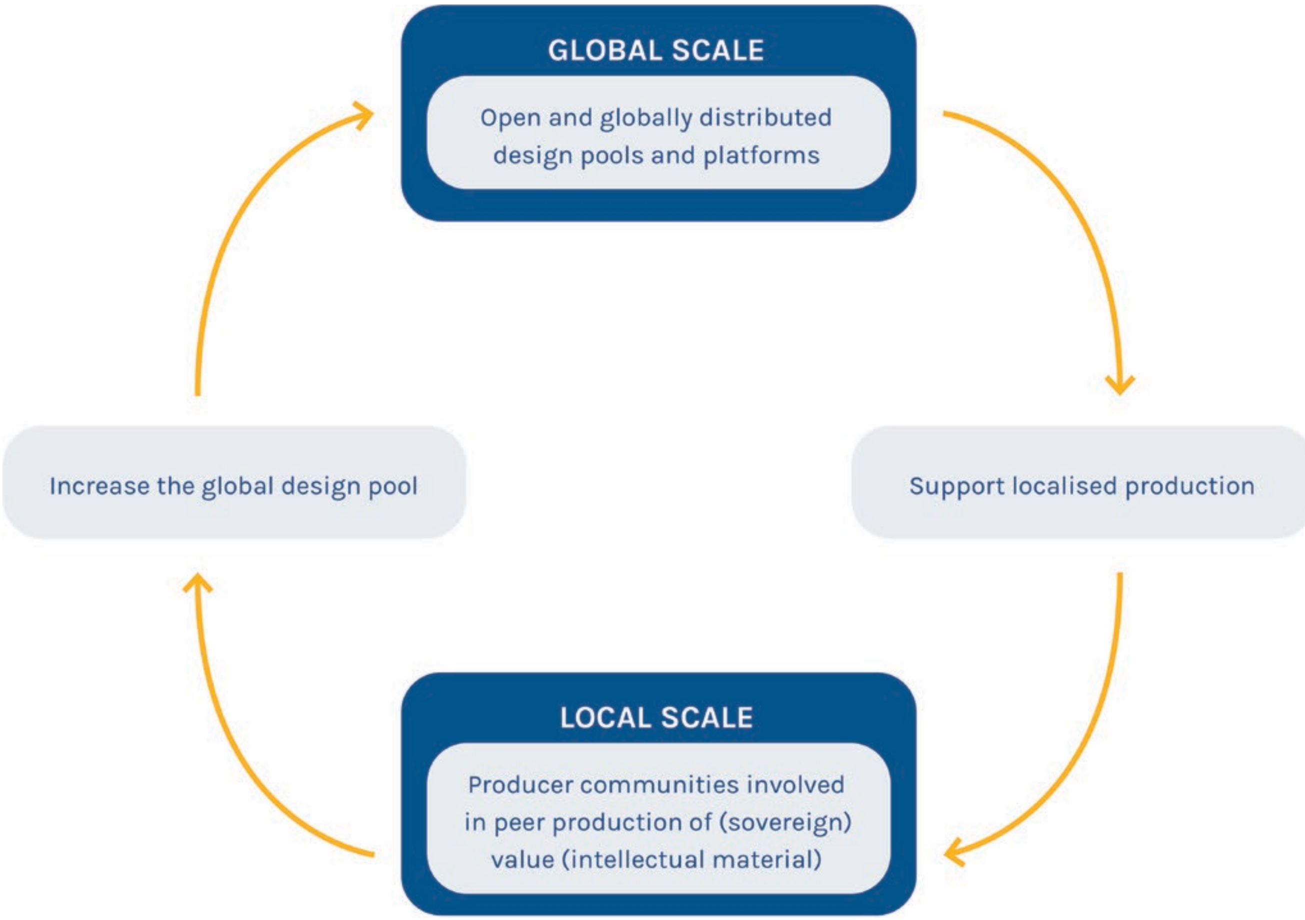

Fig. 12.4 Cosmo localism. Source: Derived from Ramos (2019)

7.3 Making Ownership Generative (Integrating Property Rights with Stewardship Commitment)

The third and final building block of a new ecological order as suggested by Bollier (2016) is to make ownership generative by integrating property rights with stewardship commitment. Bennett et al. (2018) see an urgent need and propose a framework to promote improved human-environment interactions through stewardship, defined as 'the suite of approaches, activities, behaviours, and technologies that are applied to protect, restore or sustainably use the environment'. The concept of integrating property rights with stewardship, embedded in this transition pathway, is already evident in the ocean economy. Fisheries management, for example, has seen a growing emphasis on the role, rights and responsibilities of small-scale fishers in stewarding local resources (Bennett et al. 2018). As discussed in Sect. 5, the integration of property rights with stewardship is happening currently, as exemplified in the case of SeaBOS (Box 12.3) and Chilean TURFs (Box 12.2; Appendix C).

In summary, the current governance regime, structured around nation-states and international treaty systems, is facing serious new pressures. The internet and digital technology have increased the velocity of transborder flows, not only in commerce but also in the exchange of ideas, values, projects, policy initiatives and visions for humanity, and these are catalysing revolutionary pressures from below (Bollier 2019). A new global polity activated and adapted by 'commoners' can light a pathway to transformational change (Bollier 2019).

The elemental components of the commons pathway (reconfiguring nation-state authority, empowering the commons, making ownership generative) are not talismans to preserve us from the pressures we are facing, but they do provide a means for us to rediscover the ancient wisdom that sovereignty ultimately resides not in the state or market but within ourselves, together (Bollier 2019).

8 The Ocean in a Transformed World: Towards a Governance Framework

Sustainability transitions are inherently political (Ottens and Edelenbos 2019). 'Precisely because politics plays a potentially powerful role (defining the landscape, propping up or destabilizing regimes, protecting or exposing niches), it requires explicit attention from those interested in understanding sustainability transitions' (Meadowcroft 2011). There is broad consensus that governmental steering solely through top-down decision-making or markets is not sufficient to address sustainability transitions (Meuleman 2020; Ottens and Edelenbos 2019; Meadowcroft 2011; Loorbach 2010).

The next step, therefore, is for the international community to recognise how a purposive transition can encompass a shared vision for a future pathway. As we have already argued, the transition to a thriving, vibrant and reciprocally rewarding relationship between humanity and ocean requires three fundamental elements that characterise any successful transition: (1) new knowledge drawn from beyond the current regimes; (2) the capacity to manage change in the context of rapid, unpredictable circumstances; and (3) incentives or other enabling conditions that activate the change. With regard to the first element, we have proposed a knowledge commons (a 'cosmo local digital commons', as discussed in Sect. 7.2.2). For the second, we propose the consolidation of a system of polycentric governance anchored by a new supranational ocean agency of some kind. The third element represents the Ocean Panel's catalytic role in the face of increasingly serious landscape pressures.

A key challenge woven into the substrate of ocean governance is that commons 'are either situated outside national jurisdiction or their conservation and sustainable use conflicts with national sovereignty and regulation' (Dasgupta et al. 2019). One of the methods which has evolved in the international arena to achieve this is the adaptive, flexible approach adopted in the Paris Agreement (Rajamani 2016). This approach provided a means to successfully negotiate a path through the sovereignty maze and secure broad agreement on comprehensive rules to address climate change. The BBNJ will, in a similar fashion, rely on volitional state responsibility for commitments, for example in relation to funding and transfer of technology. However, on its own, this is not likely to be sufficient.

We have also shown that in the ocean, local and regional realms are functionally connected with global and transnational scales (Bollier 2016). Thus, cross-sector coordination and multilevel network governance will facilitate a sustainable transition (Pahl-Wostl 2017; Tosun and Leininger 2017; Weitz et al. 2017; Leck et al. 2015; TWI2050 2019; SDG 2019). A purposive transition in ocean governance requires an evolving system of polycentric governance, including supranational policy and normative guidelines, flexible, adaptive governance and bottom-up stewardship.

To facilitate the workings of this system of top-down and bottom-up polycentric governance, we recommend two new institutional architectures that remain autonomous from one another. The first we have already proposed: a 'cosmo local ocean commons' to facilitate information-sharing and accelerated learning. Initiated by a coalition of knowledge institutions, this 'cosmo local commons' will require its own well-funded and dedicated set of autonomous institutions. The second is an ocean agency that will establish the norms, principles, 'rules of the game' and arbitration mechanisms for conflict resolution. What follows is a more detailed discussion of the latter.

Despite some successes in the international arena (e.g. the Montreal Protocol, the 1997 UN Shared Watercourse Agreement), the nation-state political system has not been able to manage the profound societal, political and institutional changes required for implementing an integrated ocean governance system to support the SDGs and other shared goals at the scale and with the urgency required. Building on some of the precedents and examples of experiments and regime shifts underway in many regions, it is clear that a polycentric system of governance for the ocean will be required that is neither centralised and top- down nor purely about the flourishing of bottom-up initiatives. Without a shared set of norms, values and operating rules, the bottom-up flourishing of commons initiatives will not lead to systemic impact. In order to create common future narratives, provide normative guardrails and negotiate the maze of trade-offs that will be required between different policy objectives, a supranational ocean agency of some kind (a form of meta-governance or transnational structure) could be considered. Similar to the way UNESCO's Man and the Biosphere programme works (but also learning the lessons from this experiment; Bridgewater 2016), this meta-governance institution could be mandated to establish 'rules of the game' for a polycentric system that empowers local actors to collaborate, with the goal of protecting and regenerating ocean commons at regional levels. This ocean agency could provide frameworks for addressing ocean-related challenges at different scales, in response to changing needs, capacity and context.

Furthermore, governing the trade-offs between different policy objectives which will arise in polycentric, adaptive governance models will be easier if meta-governance principles and structures, such as transparency, accountability and inclusivity, are in place.

The ocean agency could be created by UN resolution, or it could be created by a founding group of nations that invite others to participate. Its establishment should ensure legitimacy and safeguards against capture by special interests.

The ocean agency on its own will not be adequate. Its effectiveness will depend on the viability and vibrancy of the 'cosmo local' knowledge commons. Open and free entry into an ocean-oriented knowledge system would result in continuous, real-time information flows within a public space that cannot be controlled by a few dominant actors. Using satellite and other remotely observed metadata, crowd-sourced micro-data from ship-based sensors and uploaded modelling and design information, it will be possible to create wiki-type open databases that give regulatory watchdogs, research institutes, civil society organisations and industry bodies access to unprecedented levels of quality data that can be used to ensure and maintain maximum transparency (Leape et al. 2020). This, in turn, will encourage an entirely new generation of (potentially interlinked) observatories motivated by a desire to protect and regenerate the ocean commons. Given that most states lack the resources to build traditional closed information agencies to back up their regulatory functions, an open- source wiki-type global knowledge commons for the ocean would be the cheapest and most effective way of accessing design solutions that could catalyse local action.

9 Conclusion and Opportunities for Action

> *On the one hand, I believe it is vital to accept uncertainty, not-knowing, and unpredictability fully to the point of deep humility. On the other hand, I also believe that we need to choose to act from the conviction that we can design for positive emergence in complex systems even if it is not an exact science and we cannot know with certainty how our efforts will turn out to affect transformative change.*
> —Daniel Wahl, *A Brief History of Systems Science, Chaos and Complexity* (2019)

SDG 14 provides the global community with an opportunity to consider how to strengthen governance of the ocean. We have demonstrated that a range of transition dynamics are underway as existing regimes (fisheries, shipping, etc.) and niche innovations (mainly local level initiatives) respond to changing landscape pressures (climate change, depletion of fish stocks, pollution, etc.). Transition dynamics can be messy, and their legitimacy requires well-functioning science-policy engagement processes built on diverse stakeholder participation, trust and open discourse at multiple, interacting scales.

New insights into the complex interconnections among different ecosystems—on land and in rivers, deltas, estuaries, nearshore and in the ocean—have contributed to a growing realisation that a more holistic approach is needed to inform the design of policies and institutions across sectors and nations (Mathews et al. 2019).

Governance solutions for common pool resources such as the ocean that prioritise resource users' ability to devise livelihood strategies that restore rather than deplete ocean ecosystems (Ostrom 1990; Bavinck and Gupta 2014) can enable transition to a sustainable system.

Our conclusion is clear: national governments, the private sector and civil society have an opportunity to collaborate at the regional and international level to harness and give direction to the emergent regime shifts and niche innovations already contributing to a 'purposive transition'. Such a transition requires access to shared transdisciplinary knowledge, the build-up of capacity to implement changes and initiatives that activate change. This anticipatory perspective is supported by the evidence we have presented regarding regime and niche responses to increasingly serious land- and seascape pressures. Ours is neither a predictive approach based on a model nor a narrative approach that constructs scenarios. We have interpreted transitional dynamics at regime and niche levels as discerned from particular directions. Our approach is similar to one articulated eloquently in 1987 by the World Commission on Environment and Development, which in the conclusion of its Our Common Future report states, 'We have tried to point out some pathways to the future. But there is no substitute for the journey itself, and there is no alternative to the process by which we retain a capacity to respond to the experience it provides' (WCED 1987).

Leaders in public and private sectors can catalyse a transition to a more sustainable ocean system by harnessing and directing emerging niche innovations and regime shifts. Governance approaches that facilitate transformation and guide societal change in the face of uncertainty, and that are legitimate and fair, can lead to a transition in the ocean system when the overarching principles below are followed:

- Guide governance decisions by the ocean sustainability imperative.
- Integrate policies across sectors and spatial zones (addressing complexity).
  - Increase regulatory coordination across sectors and mandates.
  - Increase regulatory coordination among governing bodies.
- Use science to support decisions.

  - Adopt a precautionary approach in light of uncertainty, thereby shifting the burden of proof to the person or party who wishes to carry out the activity (rather than the person alleging damage to the environment).
  - Include explicit mechanisms and processes to base decisions on science and expert knowledge.
  - Consistently monitor and evaluate policies, actions and system responses.
- Create flexible frameworks for policymaking and governance decisions to facilitate responsiveness (including efficiency and reflexivity).
  - Include the expectation of change and surprise by building in provisions for periodic review and adaptive management.
  - Incorporate climate change adaptation exemptions into existing standards to avoid inefficient inflexibility.
- Establish a network approach to governance.
  - Widen the scope of participation (ensure transparent and authentic inclusivity of local and all stakeholder participation.
  - Establish networks of leadership and governance at different scales which allow for a distribution of power and decision-making capacity across scales of governance (legitimacy, inclusivity).
- Share information through an accessible knowledge commons available to everyone (transparency, accountability, social learning).
- Reinforce stringent monitoring and evaluation mechanisms, including transparency through compliance requirements (accountability).
- Foster equality and equity.
  - Incorporate environmental responsibility with property rights.
  - Protect human rights.
  - Examine the incentives that might help drive sustainable behaviours, and stop perverse incentives for maladaptive behaviours.
  - Balance long-term goals with short-term perspectives.

Based on these principles, we propose the following set of opportunities for action:

National governments, businesses and civil society have opportunities to support current UN ocean transition processes.

Examples of such opportunities include the following:

- Advocate for the ratification by non-party states of the UNCLOS agreement (especially the United States).
- Encourage the ratification, implementation and operationalisation, at the national level, of the BBNJ as soon as possible but by no later than 2025.
- Lobby for the ratification, implementation and localisation of the Global Pact for the Environment (or similar UN convention) as soon as possible, but no later than 2025.
- Support other UN initiatives such as the UN Environment Programme, Communities of Ocean Action, Ocean Conference Voluntary Commitments and so on.

Should there be agreement that a more sustainable ocean system is required, then national governments, businesses and civil society can consider the following opportunities for action to encourage the reconfiguration of nation- state authority vis-à-vis the ocean:

- Establish a new supranational 'ocean agency' of some kind to support polycentric governance, including transition processes and dynamics, the development of norms to guide the transition process and the design of flexible and adaptive frameworks which take account of local contextual issues. (Working task forces could provide pro forma frameworks for the different elements of a transition which draw from successful local niche innovations and regime responses, and all the lessons learnt from the Ocean Panel process; see Appendix D.)
- Strengthen voluntary learning and adaptation by improving coordination, monitoring and reporting on national voluntary commitments.
- Encourage nation-states to facilitate new modes of inclusive governance that are framed by an agreed- upon, general set of top-down principles but powered by bottom-up decision-making on resource use. This could include supporting multilateral, local area– based and regional governance innovations through legislative frameworks and negotiated agreements which establish shared rules of engagement but are flexible and can accommodate rapid change.

If there is agreement that civil society and communities should play a more significant role in promoting the restoration and sustainability of the ocean commons, then we propose the following opportunities for action:

- Promote the global recognition of a human right to a sound environment (as per the global pact for the environment or similar instrument mentioned above).
- Invest in various capacity-building initiatives and incentives that help increase the involvement of a diversity of leaders in niche innovations at the local, regional and global scales, so they learn to develop and hold their visions and aspirations, and also develop the ability for generative dialogue.
- Use the advances in informational technologies now available to encourage creation of an ocean knowledge commons through mobilising the funds required to build a new open-source, 'wiki-type' ocean knowledge commons that collates crowd-sourced and satellite data, and creates a clearing house for shared strategies that amplify best practices and viable working alternatives;
  - ensuring that a global network emerges of research institutes, universities and knowledge organisations across the world's regions, all actively participating in the open-source knowledge commons; and
  - ensuring that the transparent open data-sharing platform consolidates all relevant knowledge and research as a basis for creating a system which pools and transmits information, and can facilitate the design of solutions capable of responding to changing landscape pressures and new transitional dynamics through diverse scales and institutions.

Should there be a shared commitment to a new form of ocean stewardship that explicitly prioritises the restoration and sustainability of the ocean ecosystem, then a key opportunity for action would be the integration of property rights with stewardship responsibilities through initiatives such as local user rights programs, certification of exemplary practices, and recognition of industry initiatives.

Acknowledgements The paper's technical reviewers, Jessica Blythe, Douglas Rader, Alejandro Robles Gonzalez and Niels Vestergaard, as well as its arbiter, Adrien Vincent, all provided helpful technical comments. Mary Ruckelshaus's time was supported in part by generous gifts from Peter and Helen Bing and Roger and Vicki Sant.

The authors also thank World Resources Institute for providing support as the Ocean Panel Secretariat.

While our colleagues were very generous with their time and input, this report reflects the views of the authors alone.

The authors thank Alex Martin for copyediting and Billie Kanfer for design. The authors are grateful for the artistic talents of Keith Atkin, who helped in the development of Fig. 12.3.

About the Authors

Lead Authors

Mark Swilling is Distinguished Professor of Sustainable Development and Co-director of the Centre for Complex Systems in Transition, Stellenbosch University. Email: swilling@sun.ac.za.

Mary Ruckelshaus is Managing Director of the Natural Capital Project and a Senior Research Scientist at Stanford University. Email: mary.ruckelshaus@stanford.edu.

Tanya Brodie Rudolph is a Research Fellow at the Centre for Complex Systems in Transition, Stellenbosch University, and Founder of Enviromer. Email: tanya@enviromer.co.za.

Contributing Authors

Edward H. Allison is Research Director of the Nippon Foundation Ocean Nexus, an Honorary Fellow at WorldFish, Penang, Malaysia; and an Honorary, Adjunct and Visiting Professor at, respectively, the Universities of Lancaster (UK), Washington (USA) and Wollongong (Australia).

Stefan Gelcich is an Associate Professor in the Ecology Department at the Center of Applied Ecology and Sustainability and the Centro para el Impacto Socio-económico de las Políticas Ambientales at Pontificia Universidad Católica de Chile. He is also an advisor and member of the board of directors of Global Green Grants Fund.

Philile Mbatha is a Lecturer in the Environmental and Geographical Science Department at the University of Cape Town.

Henrik Österblom is Professor and Science Director at the Stockholm Resilience Centre, Stockholm University.

Appendix A. Governance

UNCLOS Implementation Agreement: Biodiversity Beyond National Jurisdiction—Challenges and Opportunities

One of the risks facing the international instrument on biodiversity in areas beyond national jurisdiction (the BBNJ) is that the 'best' credible science may fail to foster ambitious progress because major stakeholders may question whether the science reflects their interests and concerns (legitimacy) and is presented at a time and in ways compatible with their policymaking context and constraints (salience) (de Santo et al. 2019). This problem could be addressed by ensuring that the scientific and technical body created by Article 49 of the draft BBNJ (A/CONF.232/2019/6) is an independent autonomous body, informed by a diversity of perspectives, including transnational science and citizen networks, with sufficient resources and an effective mandate.

There is some debate that a risk of fragmentation arises as a result of Article 4, according to which the BBNJ 'should not undermine the existing regime' (Mendenhall et al. 2019). Some states (and institutions) may have vested interests in maintaining the status quo fragmentation of governance in areas beyond national jurisdiction (ABNJs). However, institutional fragmentation could be reduced through harmonisation processes such as the Kobe Process, which was used to harmonise and increase efficiencies between five tuna-related regional fisheries agreements (de Santo et al. 2019). The nesting of the BBNJ within the architecture of the UN Convention on the Law of the Sea (UNCLOS) provides opportunities for harmonisation and synergy without increasing fragmentation and competition through wide participation and shared norms.

Given the high levels of attention to systemic issues, a shift in the framing of the BBNJ could better reflect UNCLOS's obligations on coastal states to prevent, reduce and control pollution, moving the focus from resource allocation to an agreement which expands the existing law of the sea framework to better ensure conservation and sustainable management of biodiversity beyond national jurisdiction.

This may be difficult to achieve, but it would overcome the fact that the suite of management measures currently on the table (e.g. marine protected areas, environmental impact assessments, benefit-sharing and technology transfer) do not integrate systemic issues (Mendenhall et al. 2019). Leary et al. (2019) state that even though this may prove difficult, reframing the agreement to include threats to biodiversity like climate change and marine plastics could increase the potential for issue linkages and help to counteract vested interests in fisheries, mining and commercial use of marine genetic resources (de Santo et al. 2019).

Case Study of Coastal Governance: Kosi Bay, South Africa

The sustainability of livelihood strategies that marginalised peoples have developed over the years largely depends on the nature of governance systems, institutions and policies that exist to govern land and resources (Agrawal and Perrin 2009). The same holds true for the governance of marine resources and coastal zones. South Africa's first UN Educational, Scientific and Cultural Organization (UNESCO) World Heritage Site, Simangaliso, was declared in 1999, within a context of coastal communities' historically marginalised access to the coast during apartheid. The site's planners had hoped for a more inclusive decision-making processes with respect to marine and coastal governance following apartheid. However, the injection of multilevel coastal conservation through the creation of the world heritage site in 1999 entrenched a plural system of governance embedded at international, national, provincial and local scales. In addition, Kosi Bay people have a long-standing customary fisheries governance system that predates colonial times. Although it is largely overlooked by statutory structures, this customary system plays a significant role in regulating small-scale fisheries governance at the local level.

Despite this, governance processes in Simangaliso were and still are driven by UNESCO and by the state at the national level, and these are communicated poorly to actors at the local level, including wider communities (Mbatha 2018). A gap exists between stated policy objectives of sustainability, good governance and inclusiveness, on the one hand, and the lived realities of the people on the ground, on the other. This gap is widened by the fact that the institutional design that drives coastal conservation within

Simangaliso from the international to the local level allows little room for livelihood considerations to be a focus of governance practices within the Simangaliso site. Mechanisms to ensure effective interaction between higher-level governance actors and communities are not in place because of the lack of representation of communities in decision-making platforms.

It is unclear whether UNESCO was aware of the socioeconomic and political challenges created by establishment of the site, and the negative livelihood impacts that ensued. Ongoing debates in Kosi Bay have centred on whether the community was effectively consulted about the declaration of the Simangaliso World Heritage Site; 95% of communities have stated that they were not consulted in the process for establishing the site (Mbatha 2018). The design of plural and multilevel institutions governing common pool resources (e.g. coastal and marine) influences the ability of resource users to devise livelihood strategies, as well as governance outcomes (Ostrom 1990; Ostrom and Janssen 2004; Cinner et al. 2012). This is because pluralism tends to exacerbate uncertainty, and ‘in many countries, state laws are largely unknown in villages, and sometimes when new laws are promulgated, not only villagers but also government officials at the district or village levels are ignorant of the new laws’ (Meinzen-Dick and Pradhan 2002, p. 13).

Governance Examples

Another form of volitional reflexive governance is the voluntary national review process (VNR), which lies at the heart of the global SDGs’ follow-up and review mechanism set by the UN 2030 Agenda. Since 2016, 142 VNRs have been submitted to the UN High-Level Political Forum on Sustainable Development (HLPF), and 50 new reports are expected to be presented at its 2020 session (SDG Knowledge Hub, https://sdg.iisd.org/). The reports have given the international community a broad perspective on the status of the advance towards the SDGs at the national level. A Latin American think tank, Cepei (which provides analysis of global development agendas), has shown in recent research that current reporting is too static. Second-round VNRs should answer more reflexive questions like, ‘How have we progressed since our previous report?‘ ‘What worked well and what failed since then?‘ ‘What have we learned on our way towards the SDGs at the national level?‘ and ‘Where do we predict we will be in the short- and medium-term?‘ (SDG Knowledge Hub).

Cepei also suggested that second-round VNRs focus on integrating ministerial and sectoral silos, share successes and failures to facilitate learning, be democratised to encourage input from local voices and be more rigorously verified through the review process (SDG Knowledge Hub).

Appendix B. Regimes

	Shipping
Description	By 2017, 11.7 billion tonnes of cargo shipped across the ocean (UNCTAD 2018) More than 80% of global trade (IMO 2019) transported via this industry An increase of almost 40% in most trade segments (apart from crude oil and oil products) expected between 2016 and 2030, with a 2% annual rise for the period 2030–2050 (Gjølberg et al. 2017)
Stakeholders	Private sector governments Non-governmental organisations
Applicable governance/ institutions/mechanisms	UN Convention on the Law of the Sea (UNCLOS) and all supporting conventions and institutions (Pretlove and Blasiak 2018) including (but not limited to) • International Maritime Organization (IMO) • Agreement on Port State Measures, 1982 • International Convention for the Prevention of Pollution from Ships (MARPOL) • Liability conventions • Certification and classification schemes
Challenges	Energy consumption and emissions Recycling end-of-life ships Biofouling Pollution and discharges Flags of convenience Ports of convenience Accidents and damage to ecosystems
	Ocean-based food extraction
Description	Pillar of global nutrition (Pretlove and Blasiak 2018; Costello et al. 2019; FAO 2018) Capture fisheries and plant and animal mariculture provide nearly 80 mmt of edible food, people with 20% of their animal protein and critical micronutrients not found in land-based foods (long-chain omega-3 fatty acids) (Costello et al. 2019; FAO 2018) Global mariculture production expanded significantly; marine production now around 30 million tonnes annually (Pretlove and Blasiak 2018) Significant further expansion in aquaculture and mariculture is expected
Stakeholders	Food security for humanity Parties to UNCLOS and subordinate conventions regional fisheries management organisations (RFMOs) private sector Small fisheries Coastal communities
Applicable governance/ institutions/mechanisms	Both sovereign and commons space (in areas beyond national jurisdiction [ABNJs]) from a spatial/zonal perspective, and a species perspective, given the nature of fish stock UNCLOS and all supporting conventions and institutions (see Pretlove and Blasiak 2018) including (but not limited to) the following: • UN Fish Stocks Agreement 2001 • National legislation • FAO (Codes of Conduct, Guidelines for Small-Scale Fisheries, Guidelines for Fisheries in ABNJs) • Mariculture regulation is complex; involves interlinking regulatory bodies (e.g. spatial planning, regional planning, environmental agencies, food safety)
Challenges	A sustainable and efficient system is required to maintain food security (given the anticipated population increase by 2050) Over-harvesting Indirect impacts from bycatch Illegal, unreported and unregulated (IUU) fishing: $23.5 billion each year; up to 30% of total catch, and for one in five fish transacted in markets (FAO 2018; Global Fishing Watch 2018; Widjaja et al. 2020) Monitoring and enforcement (Costello et al. 2019; Aburto-Oropeza et al. 2020; Widjaja et al. 2020) conservation of biodiversity and ecosystem services while increasing production Social justice: uneven distribution of the fishing enterprise impacts on small-scale fisheries (Costello et al. 2019; Österblom et al. 2020) Management and monitoring of RFMOs Appropriate regulatory frameworks needed to address competing interests and overlapping man-dates in mariculture
	Offshore oil and gas
Description	Extraction of fossil fuels increasingly moving to deeper waters of exclusive economic zones (EEZs); under state authority Beginning to see exploration in ABNJs
Stakeholders	Private sector governments Financial system investors

	Offshore oil and gas
Applicable governance/ institutions/mechanisms	Activities take place on the continental shelves of coastal states under domestic legislation If exploration and production moves into the area, activities would be regulated by the International Seabed Authority (ISA) Private sector regulations and best practices (e.g. global oil and gas industry association IPIECA (http://www.ipieca.org/))
Challenges	Cross-border jurisdictional issues such as baseline data collection and monitoring, transboundary oil spill response/planning Weak ISA regulation and authority in ABNJs High ecological and climate risks in deeper, pristine ocean habitats (OECD 2016) Global disinvestment campaign targeting the $5 trillion subsidy to oil industry Decarbonisation commitments by financial investors could increase risk of stranded assets (McGlade and Ekins 2015)
	Ports
Description	Port expansion is increasing globally (number and size of ships) Increasingly crowded ocean makes shipping lane designations critical
Stakeholders	Private sector governments regions Consumers
Applicable governance/ institutions/mechanisms	UNCLOS and supporting conventions, including (but not limited to) the following: • Agreement on port state measures, 1982 • MARPOL • Merchant shipping (minimum standards) convention, 1976 (ILO Convention No. 147) • Regional efforts such as European Commission (2007, 2011) • Regional port state memoranda of agreement • IMO code of good practice for port state control (for more detail, see Addo et al. forthcoming)
Challenges	Pollution of environment by ships, port activities Shipping lanes stress species, habitats Ports of convenience give rise to compliance and enforcement issues in IUU fishing and other illegal activities
	Marine and coastal tourism
Description	Second-fastest growing sector of ocean economy (OECD 2016) relies on ocean resources which it often depletes or impacts
Stakeholders	Private sector governments consumers
Applicable governance/ institutions/mechanisms	Emerging financial instruments (see Sumaila et al. forthcoming) to address vulnerabilities integrated ocean management (IOM) approaches (Widjaja et al. 2020; Winther et al. 2020) civil society advocacy
Challenges	Balancing need for tourism infrastructure and risk to species and ecosystem services Generally not monitored or regulated via internationally accepted certifications
	Marine and seabed mining
Description	Retrieval of mineral resources, either on continental shelves or on the deep sea bed, e.g. polymetallic nodules, polymetallic sulphides or seafloor massive sulphides (Aldred 2019) Exploration zones comprising 1.5 million km^2 are mainly in the Pacific, mid-Atlantic and Indian Oceans, in the ABNJs Rich deposits of rare earth minerals in deep ocean being discovered (e.g. samples extracted 500 km from the Canary Islands revealed deposits of the scarce substance tellurium—used in solar panels—in concentrations 50,000 times higher than in deposits on land)
Stakeholders	Private sector governments civil society
Applicable governance/ institutions/mechanisms	In ABNJs governed by the ISA (under UNCLOS) ISA Council in 2019 addressed regulations for financial models for mining of polymetallic nodules ISA regulations adding an additional scoping stage to the environmental assessment process and providing financial incentives for companies to participate in environment assessment and reporting
Challenges	Depleting terrestrial deposits of rare earth metals, coupled with rising demand for metals for smartphones and green technologies, has resulted in a surge of interest in deep sea mining (Cuyvers et al. 2018) Biophysical impacts of deep sea mining can be significant (IUCN (International Union for the Conservation of Nature) 1995) Many countries lack regulations or capacity to enforce regulations in their EEZs (Pretlove and Blasiak 2018) United States have not ratified UNCLOS
	Maritime biotechnology
Description	The creation of products and processes from marine organisms in these ecosystems, through the application of tools in biotechnology, molecular and cell biology, and bioinformatics Potential for new pharmaceutical drugs, chemical products, enzymes, advancement of aquaculture and seafood safety, bioremediation, biofuels, etc.
Stakeholders	Private sector governments civil society
Applicable governance/ institutions/mechanisms	Developments in governance underway to address some of the legal challenges which arise (see Blasiak et al. 2020; Sect. 3.1 and Appendix A1 above in relation to the international instrument on biodiversity in areas beyond national jurisdiction [BBNJ])
Challenges	Legal challenges for ownership of material derived from ABNJs (see notes on BBNJ) Technological, ecological and other knowledge barriers

	Cabling and maritime equipment
Description	Submarine cable network provides over 95% of international telecommunications and is the 'backbone' of the internet (Davenport 2015) Numbers and extent of submarine cables will increase drastically in coming decades as more islands and archipelagos are connected and renewable energy projects such as offshore wind farms, tidal and wave turbines are developed
Stakeholders	Private sector governments civil society
Applicable governance/ institutions/mechanisms	UNCLOS (rights and obligations of states for protection of submarine cables and the freedom to lay, repair and maintain such cables)
Challenges	Current gaps in legal regime around cybersecurity, counterintelligence and environmental impacts Environmental impacts include noise, pollution, physical disturbance, electromagnetic fields, heat, entanglement risk, pollution and threats to benthic reefs and reserves (Taormina et al. 2018)
	Offshore renewable energy (ORE)
Description	Wave, tidal and offshore wind energy generation—stationary installations in EEZs New technologies in development produce ORE through other processes, including by salinity gradients and thermal gradients
Stakeholders	Private sector governments intergovernmental bodies civil society Institutions (e.g. International Renewable Energy Agency, International Energy Agency, WindEurope, Ocean Energy Europe)
Applicable governance/ institutions/mechanisms	Domestic legislation Private sector standards, certification schemes, guidelines
Challenges	Growing scale and deployment expansion will push the technology into areas of both scientific and engineering uncertainty Environmental impacts Need for data and information streamlining to meet demand (Veers et al. 2019)

Appendix C. Case Studies of Niche Innovations

Integrated Ocean Management for Development Planning, Fisheries Management and Disaster Risk Management in Belize

Sustainability transformations call for cross-sectoral thinking and approaches. Sectoral policies and measures can be effective in particular contexts but often fail to account for indirect, distant and cumulative impacts, which can have adverse effects, including exacerbating inequalities. Cross-sectoral approaches, including ecosystem-based management approaches, integrated watershed and coastal zone management, and area- based and marine spatial planning, offer opportunities to reconcile multiple interests, values and forms of resource use, provided that these cross-sectoral approaches recognise trade-offs and uneven power relations among stakeholders (from IPBES 2019; Winther et al. 2020).

The final Integrated Coastal Zone Management Plan (ICZMP) approved by the Belizean government (Box 12.1) coordinates the management of, and investment in, a diverse set of activities and actors implicated in sustainable outcomes for the nation, ranging from those engaging in or affecting coastal pollution, dredging, fisheries, aquaculture and tourism development, to education, social resilience to climate change and preservation of cultural heritage.

The fishery sector in Belize has in parallel adopted a combination of secure fishing rights and a locally controlled 'managed access' approach through which small-scale fishers are given licenses to fish in and manage specific geographic areas through a territorial use right for fishing (TURF). The managed access fishery approach in Belize transitioned from a few pilots with positive fishery returns to a national scale in 2016 (Fujita et al. 2017), so the full economic and ecological impacts are not yet clear (Fujita et al. 2018). Surveys of fishers participating in the new Belizean managed access program emphasise the importance of government enforcement and response, which will encourage fishers to comply with required surveillance, which comes at a cost with as yet unproven economic returns (Wade et al. 2019). Furthermore, integrating fishery TURF locations with the coastal development planning zones and protected areas identified through the Integrated Coastal Zone Management Authority and Institute (CZMAI) could improve fishery returns and thus livelihood security, providing positive feedbacks to small-scale fishing communities (Arkema et al. 2019).

The institutional, legal and science-policy engagement innovations exemplified in the Belize case are transferable to anywhere in the world. Promoting co-existence and synergies among ocean uses is a key issue for spatial management. Area-based and 'ridge-to-reef' management approaches for managing social- ecological systems in an integrated way have shown the value and broad relevance of cross-sectoral spatial planning in marine coastal zones, ranging from the Great Barrier Reef Marine Park in Australia (e.g. Day 2002; Fernandes et al. 2005; Olsson et al. 2008; Day 2017) to the *ahupua'a* (ridge-to-reef) system in Hawai'i and the concept of *vanua* in Fiji (Minerbi 1999; Johannes 2002; McGregor et al. 2003; IPBES 2019), to spatial planning under the European Union's Maritime Spatial Planning Directive (e.g. EU (European Union) 2014; de Grunt et al. 2018). Sale et al. (2014) suggest that expanded use of marine spatial planning could provide a framework for 'more effective, pragmatic management based on ocean zones to accommodate conflicting uses'. Establishing boundaries for resources and those allowed to use them could enable the separation of incompatible uses and give rise to governance systems that effectively address the commons dilemma (Sale et al. 2014).

Aware of the rising costs of disaster risk management and recovery under changing climate regimes, governments, multilateral development banks and businesses are beginning to turn their attention to nature-based solutions that provide greater resilience to impacts from sea level rise and increasingly intense coastal storms. The UN Global Assessment on Disaster Risk Reduction (UNDRR 2019) is tracking country commitments to integrate DRR in development planning and budgeting. Encouraging examples are emerging in Indonesia, Vietnam, Fiji and the Philippines, where DRR is being actively integrated with development planning policies, programs, capacity building and financial resources. More broadly, as in Belize, the growing number of ministries of marine affairs (e.g. Indonesia) or of the 'blue economy' (Barbados, Kenya, Seychelles) points to cross-sectoral integration.

Food production sectors, through fisheries and aquaculture, put major demands on marine and coastal regions. Although aquaculture could address the gap between aquatic food demand and supply, realising this potential will depend in part on the availability of suitable space. Integrated spatial planning for aquaculture and other uses is fundamental to the sustainable development of aquaculture in a way that accommodates the needs of competing economic sectors, minimises conflict and integrates social, economic and environmental objectives (FAO 2018).

Similarly, for fishery management, global guidance is available to ensure that area-based management, including the consideration of marine protected areas, is integrated within broader fisheries management frameworks and follows good practices with regard to participatory approaches, especially for small-scale fisheries. Both the *Voluntary Guidelines for Securing Sustainable Small-Scale Fisheries in the Context of Food Security and Poverty Eradication* (FAO 2015) and the *Voluntary Guidelines on Responsible Governance of Tenure of Land, Fisheries and Forests in the Context of National Food Security* (FAO (Food and Agriculture Organization of the United Nations) 2012) describe such practices and outline, among other things, the need to respect customary and informal tenure rights.

Rights-Based Fisheries Management

Rights-based fisheries management (RBFM) can represent a significant regime shift as institutions, regulations and community engagement adapt over time (see Costello et al. 2019 for a more detailed treatment). The territorial user rights fisheries (TURFs) of Chile, described in Box 12.2, are a well-studied example of RBFM that has been able to adapt over time. Successful local governance supported by recognition of local rights has often incorporated knowledge of how nature contributes to human well-being to motivate such behaviours (IPBES 2019). Recent studies have shown a positive relationship between leadership, social capital and sustainable fisheries outcomes (Gutiérrez et al. 2012). Results demonstrate the critical importance of prominent community leaders and robust social capital, combined with clear incentives through catch shares or other rights-based mechanisms, and conservation benefits derived from protected areas, to successfully managing aquatic resources and securing the livelihoods of communities depending on them (Gutiérrez et al. 2012). The Belize TURF/CZMAI example (discussed above), U.S. fishery reforms (Lubchenco et al. 2016) and a number of other cases provide compelling examples of how RBFM, in combination with other management and social capital elements, can lead to improved ecosystem conditions and livelihood support. Modelled fisheries using data from nearly 5000 stocks worldwide indicate that RBFM can lead to catch, biomass and profit increases for diverse fisheries (Costello et al. 2016). Co-management is considered by Gutiérrez et al. (2012) to be the only realistic solution for the majority of the world's fisheries, one that can solve many of the problems they face. Yet in some cases, RBFM interventions alone will not be sufficient.

For example, economic incentives for stewardship and asking fishers to join participatory processes are unlikely to work if economic insecurity is high and government or community capacity to enforce or respond is low. If more fundamental social and political development interventions are implemented first, based on key incentives that will motivate fishing people, then RBFM approaches are more likely to succeed (Allison et al. 2012; Wade et al. 2019).

In order to enhance governability to benefit small-scale fisheries, governance designs and interactions must be sensitive to the needs and contexts of small-scale fishing people. In a review of alternative governing modes for small-scale fisheries, Jentoft and Chuenpagdee (2015) find that small-scale fisheries globally will benefit from more constructive interaction, collective action, policy and market innovation, and empowerment but that generalised governance principles are not likely. The transition of governing modes observed in many cases illustrates how governance actors try to cope with system dynamics. Often, the combination of different modes into one coherent but hybrid approach is warranted.

To support these commitments to sustainable small- scale fisheries development, it is crucial to better develop the understanding and knowledge base about small-scale fishing enterprises. Several initiatives are underway to improve and expand existing empirical information and to quantify the importance of the marine and inland small-scale fisheries sector (e.g. World Bank 2012). Bennett et al. (2018) identify additional fisheries examples, such as the rise of community supported fisheries programs globally (Brinson et al. 2011; McClenachan et al. 2014), the release of the global *Voluntary Guidelines for Securing Sustainable Small- Scale Fisheries* (FAO 2015) and increased funding of non-governmental organisation programs that focus on small-scale fisheries (e.g. the Fish Forever Program (Barner et al. 2015; Bennett et al. 2018)).

Monitoring Innovations for Illegal, Unreported and Unregulated Fisheries

One of the key challenges in countering illegal, unreported and unregulated (IUU) fishing historically has been the limited capacity of coastal states to monitor the vast swathes of ocean comprising their EEZs, as well as areas of the high seas. The modus operandi of IUU fishing has been to fish inside or hover at the edge of EEZs (where the majority of fish stocks are found) with smaller vessels, which then drop their catches into larger ‘mother ship‘ refrigeration vessels waiting in the high seas, beyond the reach of national jurisdiction. The rapid development of vessel monitoring systems and automatic identification systems over the past several years provides new possibilities for the reduction of IUU fishing given that many open platforms now exist which provide real-time tracking of vessels (Widjaja et al. 2020). The ability to identify locations allows enforcement responses to be accurately and effectively focused.

Justice in Marine Sustainability

Several developments indicate a move towards social justice in marine sustainability thinking. Eco-labelling, certification schemes and supply chain transparency have, for example, given rise to the concept of socially responsible seafood, evident in the common use of mobile apps which show the full supply chain (such as Monterey Bay Aquarium’s Seafood Watch app).

Cooperative fishing arrangements such as the Parties to the Nauru Agreement (PNA) in the Pacific islands are being developed to equitably share fishing benefits.

The PNA governs the annual fishing effort of skip-jack tuna. This highly migratory species moves between the EEZs of the island countries and also in response to climate (Lehodey et al. 1997). The PNA’s ‘vessel day scheme‘ facilitates cooperative management of these species within the combined EEZs of the PNA members (Aqorau et al. 2018). A capped fishing effort of vessel days is shared among members, allowing a trading scheme which enables responses to extreme weather events and migratory patterns. As a result, all members receive revenue regardless of where fish are caught, and stock has remained robust under this cooperative management arrangement (Aqorau et al. 2018). An example of this in the South African context is Abalobi—an innovative information and communication technology tool (mobile app) that is playing a significant role in improving small-scale fisheries governance in South Africa. It does this by addressing social justice and access issues faced by small-scale fishers within the sector, while assisting the government in improving catch data monitoring by accessing catch data of small- scale fishermen. Abalobi (2019) promotes traceable and ‘storied’ seafood that encourages ecological sustainability as well as social justice.

Appendix D. Potential Governance Functions of a Supranational Ocean Agency

1. Draft the flexible frameworks for policymakers and lawmakers, animated by commons norms discussed above and building on existing mandates and initiatives (UNESCO, UNEP, FAO, ILO, UNFCCC, etc.). Frameworks could be designed in such a way that law and policy can be applied at local levels and adapted according to rapidly changing needs, capacity and context, as well as guide the negotiation of trade-offs and realisation of co-benefits. This could result in appropriate combinations of decision analysis, land and ocean use planning, public participation and a science- policy process, diverse knowledge systems and conflict resolution approaches (IPCC 2019, C3.3). In turn, this would help reduce short-term risks, build long-term resilience and sustainability, and facilitate capacity building. Framework policy guidelines could be crafted with temporal awareness. Many coastal and ocean decisions now being made have time horizons of decades to over a century, far longer than the lifespan of the governance arrangements facilitating them (IPCC 2019, C3.4).

2.	Coordinate measurable volitional commitments by stakeholders, such as commitments to marine protected areas and biodiversity targets in the international instrument on biodiversity in areas beyond national jurisdiction (BBNJ), aspects of the voluntary national review process related to Sustainable Development Goal 14, voluntary commitments under the Our Ocean Conference series and the UN Ocean Conference
3.	Provide a monitoring function to ensure transparency, compliance and accountability of ocean commitments made in international processes. Without some form of agreed transnational accountability, voluntary governance based on volitional commitments lacks gravity and certainty (SDG 16: Develop effective, accountable and transparent institutions at all levels). A shared knowledge commons (see Sect. 7.2.2) will facilitate this accountability
4.	Facilitate social learning, social innovation and reflexive, adaptive governance responses through the creation of an overarching legal architecture for the ocean transition sufficiently flexible to allow it to respond to rapid change but sufficiently robust to provide a cohesive framework for the implementation of selected transition pathways. This is the type of governance that can create conditions for mutual learning and coordination
5.	Provide a venue for co-construction of sustainable ocean narratives that includes existing agencies and institutions (SDG Target 16.7: Ensure responsive, inclusive, participatory and representative decision-making at all levels; SDG 17: Strengthen the means of implementation and revitalise the global partnership for sustainable development)

Highlights

- The ocean is important for everyone—it produces oxygen and food, stores carbon and heat, offers space for economic activities and recreation, and continues to inspire and support culture and well-being.
- Access to ocean resources and sectors is rarely equitably distributed. Many of their benefits are accumulated by a few, while most harms from development are borne by the most vulnerable.
- Inequity is a systemic feature of the current ocean economy. It is embedded in existing political and economic systems, the result of historical legacies and prevailing norms. This has brought global environmental challenges and negative effects on human well-being.
- Legal frameworks to support equity exist but are not sufficiently developed. In practice, ocean policies are largely equity-blind, poorly implemented and fail to address inequity.
- Inequity manifests, for example, in unfair distribution of commercial fish catches; limited political power of small-scale fishers, particularly women and other minority groups; limited engagement of developing nations in high-seas activities and associated decision-making; and consolidated interests of global supply chains in a few transnational corporations, with evidence of poor transparency and human rights abuses.
- Climate change will create and worsen challenges of fairness and equity faced by developing countries, regions and communities reliant on marine livelihoods.
- Discussions on environmental sustainability have largely overshadowed concerns about social equity. Addressing inequalities and preventing the widening of ocean inequities are integral to a sustainable ocean economy; and promoting equity is essential for securing fair development, the legitimacy of policies, social stability and sustainability.
- A sustainable ocean economy should protect human rights, improve human well-being, stimulate inclusion and gender equity, and prioritise recognition, diversity and equal access to resources to provide fair opportunities consistent with sustainable development. It should also address corruption and tax evasion, demand responsible and transparent business practices and create a shared economy that facilitates a fair redistribution of wealth and benefits. A sustainable ocean economy should be aware of environmental and social limits on growth and consider degrowth where appropriate.
- Shifting a historical trajectory of persistent and increasing inequities will require strong leadership, inclusive governance and long-term planning that starts with a commitment to equity as integral to a sustainable ocean economy and relationships within and across nations.

1 Introduction

1.1 Overview

The blue economy is being promoted as capable of achieving sustainability and prosperity, fair use of the ocean and the UN Sustainable Development Goals (SDGs). Ensuring a more equitable distribution of goods and services provided by the ocean represents a major challenge. There is overwhelming evidence that current access to ocean benefits and resources, as well as exposure to harms, is distributed inequitably. This results in negative effects on the environment and human health, loss of livelihoods, limited financial opportunities

for vulnerable groups and challenges to nutritional and food security. Powerful interests (including states, communities and economic entities) benefit from existing arrangements. Challenging inequality represents a direct threat to such interests. Inequality is increasingly influencing economic development and political stability. Current and recent examples of social unrest are closely associated with concerns about inequality, climate change, corruption and related societal problems perceived as having an unfair impact. Increased scientific attention to inequality is starting to shape debates associated with the ocean. We argue that there is a general policy blindness to instruments and practices that maintain the unfair status quo, but that there are remedies to such blindness. The purpose of this Blue Paper is to explore ocean inequities and suggest approaches for the just inclusion of diverse actors in the blue economy agenda and the equitable distribution of ocean benefits. First, we define inequity terms and their drivers, as well as how they affect sustainability. Second, we explore policies and practices that have (or have not) worked in favour of equity, while also promoting ecological sustainability. Finally, we provide opportunities for action for policymakers, funding and research institutions, international and non-governmental organisations, business leadership as well as civil society to address systemic aspects of inequities along a spectrum of ambitions, from basic to transformative. These opportunities for action are not intended as alternatives. They constitute complementary and reinforcing action to support and inform pathways to a sustainable and just ocean economy.

1.2 Context

The ocean plays a critical role in securing human well-being, but marine ecosystems have a long history of overexploitation, habitat destruction and pollution (Jackson 2001; Roberts 2010; Halpern et al. 2008; Nash 2013; Reusch et al. 2018). The scale and impacts of these pressures, which now also include climate change, are critically undermining the function and role that the ocean plays.

Despite increasing knowledge of these pressures and their effects, the ocean continues to be perceived as an economic frontier: a resource with substantial potential to stimulate economic growth, employment opportunities and innovation (European Commission 2012; United Nations 2014; OECD 2016). Notions such as ‘the blue economy’ or ‘blue growth’ facilitate such perceptions. These concepts are used to legitimise and generate support for ocean-based economic development opportunities—including aquaculture, bio-prospecting, marine tourism, shipping, oil and gas, renewable energy and deep-sea mining (OECD 2016; Lloyd’s 2014; Economist 2015) and are often linked to the idea of environmental stewardship (Biermann et al. 2017; Brent et al. 2018).

Despite substantial differences in how ocean development concepts are presented and what they imply for economic and social development (Silver et al. 2015; Voyer et al. 2018; Bennett et al. 2019a, b), they are increasingly central to national and international ocean policies (European Commission 2017; OECD 2016; World Bank and United Nations 2017; Childs and Hicks 2019). They have also gained broad levels of support across diverse actors, including small-island and developing states (Michel 2016; van Wyk 2015). A historical asymmetry between the capacity to grow the ocean economy and the capacity to regulate it raises questions about whether promoting growth in ocean use can be made compatible with sustainable use of marine resources and the protection of ecosystems (Ehlers 2016; Llewellyn et al. 2016; Golden et al. 2017; Niner et al. 2018; Laffoley et al. 2019).

The controversy and debate around the sustainable ocean economy illustrate the disparities among visions of the way humanity should relate to the ocean— arguably the greatest common global resource. Some believe that economic growth based on the ocean is critical to development—the foundation of human well-being—and can be made sustainable through technological innovation and regulations. Others are more sceptical and contend that current economic paradigms and power structures are the very reason for unsustainable development and inequities, that the potential for further expansion of ocean-based sectors is limited at best, and that achieving sustainability can only be accomplished by transitioning towards a collaborative economy, which would include limiting, or ‘degrowing’, economic ocean-based activities (Kostakis and Bauwens 2014; Hadjmichael 2018).

Concerns about environmental sustainability have overshadowed concerns about social equity (Stanton 2012; Halpern et al. 2013; Boonstra et al. 2015; Bennett et al. 2019b). Yet there is increased recognition that equity is necessary, if not sufficient, for sustainability (UN 2015; Raworth 2017a; Hamann et al. 2018; Leach et al. 2018; Cohen et al. 2019); that fairness and sustainability are ‘two sides of the same coin’ (Berg et al. 2012; Piketty 2014) and that any sustainable ocean economy investments predicated on fostering sustained economic growth must also pay attention to reducing inequality. These are arguments for explicitly considering inequality in national ocean economy plans, rather than addressing it through global blueprints. The shortcomings and failures of some of the International Monetary Fund (IMF) and World Bank structural adjustment programs of the 1980s and 1990s constitute warnings against the adoption of universal macro-economic recipes for economic management (Dollar and Svensson 2001).

Social equity (Box 13.1) in relation to the sustainable ocean economy includes a focus on the provision of social, cultural and economic benefits. A sustainable ocean economy should respect human rights and provide fair opportunities for employment. It should also improve wages, address workplace discrimination, stimulate gender equity and affirm the right to a healthy and safe work environment. A sustainable ocean economy should include aspects of recognition, equal access to resources and inclusivity, and should also support fair distribution of benefits and insulation for the most vulnerable from risks of harm, and where harm is done, assign liability and responsibility for remedy (Klain et al. 2014; Klein et al. 2015; WWF 2018). This is generally not how ocean policies are designed or implemented.

Box 13.1: Definitions: Equality, Equity and Fairness

Social equality and *social equity* are closely related terms that merit clarification. *Social equality* refers to the level to which all members of a society are assigned the same status based on recognition, opportunity and outcomes. For example, different groups (such as genders, classes and ethnicities) could have the same status in terms of legal rights, economic opportunities or access to goods and services (Sen 1992; ISSC et al. 2016). Equality of recognition and protection under the law is a basic tenet of legal systems and constitutions in most countries, though application of this premise varies significantly. Under the 'capability approach', equality is recognised in terms of people's assets, capitals or abilities to take advantage of development and livelihood opportunities (Sen 1992; Nussbaum 2011). Equality of access to assets is thus assumed to lead to improvements in equality of opportunities (Leach et al. 2010). Equality of outcomes refers to an objective comparison of the level of parity in terms of distribution of measures such as income, assets or wealth either within or across societies.

The term *social equity* goes further and combines a concern for equal treatment, with an assessment of what constitutes fair treatment across both substantive outcomes and procedural concerns. Fairness is most often addressed in terms of distributive equity, in other words the distribution of 'goods' and 'bads' across different individual and groups in society (McDermott et al. 2013; Tyler 2015; Bennett et al. 2019a). Achieving social equity may require redressing existing social inequalities so that members of disadvantaged social groups receive a fairer share of the benefits than they did in the past. What constitutes 'fair distribution' is subjective and needs to be understood in relation to the social beliefs, values, practices and institutions of different cultures and societies (e.g., Sandel 1990). Distributive equity may also be influenced by the level of procedural equity, which refers to the recognition of rights and stakeholders, inclusion and participation, as well as political power to influence decisions regarding management and distribution of goods and services (Pascual et al. 2014; Tyler 2015). True procedural equity requires that all actors have adequate capacity to participate, and benefit from information transparency and processes that ensure all voices are heard and can influence decisions (Bennett et al. 2019a).

1.3 Why Is Equity Important?

Inequity is most visible when there is great income disparity within and between countries. The challenges associated to wealth inequality have repeatedly been voiced by social justice non-governmental organisations (NGOs), with a particular focus on extreme differences in wealth between the super-rich and the 'bottom billions' of the world (Oxfam 2019). Concerns about wealth inequalities, their causes, possible solutions and consequences for economic growth and social well-being are also voiced by organisations commonly associated with growth-focused economic policies, such as the Organisation for Economic Co-operation and Development (OECD) (Cingano 2014), the International Monetary Fund (IMF) (Dabla-Norris et al. 2015), the *Economist* magazine (Economist 2015) and various banks (e.g., Camposi 2017). A recent survey among private corporations illustrates that 88% of chief executives believe our economic system needs to refocus on equitable growth (IPBES 2019). These concerns arise because income and wealth inequality, having largely fallen from the 1920s until the early 1980s, have been rising since that time (Alvaredo et al. 2018).

Rises in inequality are associated with rapid economic growth in transitional countries (China, India, Indonesia and Brazil), economic liberalisation in Russia and, in some developed nations (particularly English-speaking ones), the adoption of 'neoliberal' economic policies (Kotz 2015). These policies include large-scale transfer of public goods to the private sector through the sale of previously state-owned companies, public lands, health and education services; the lowering of corporate taxes and tax rates on top earners; deregulation of financial markets; and liberalisation of trade. All are intended to boost growth, which under this development approach is supposed to reduce poverty through trickle-down effects. While there has undoubtedly been success in reducing global poverty, inequalities have widened both nationally and globally (Alvaredo et al. 2018) and include the emergence of highly consolidated industries (Blasiak et al. 2018b; Monacelli 2018; Folke et al. 2019).

The social democrat countries of Europe, conversely, have the lowest levels of wealth inequality (Alvaredo et al. 2018). These high-wage, high-taxation economies are effective in providing accessible public services and are funded by redistributive, or progressive, taxation schemes. In these countries, the sustainable ocean economy may well develop to deliver hoped-for gains in human welfare, as the institutions and practices are in place and operational. However, the use of tax havens by private corporations and citizens, and other mechanisms aimed to avoid or reduce taxation (see Galaz et al. 2018), represent a challenge also for countries with functional taxation schemes.

The Sustainable Development Goals (SDGs) cannot be achieved when a billion or more people remain in poverty and inequality is systemic. However, there is no simple, universal relationship between inequality and economic growth. The empirical literature is converging on a tentative consensus that inequality is generally harmful for the pace and sustainability of economic growth over the medium run (Berg et al. 2018). In their study Berg et al. (2018) reach the following conclusions:

First, lower net inequality is strongly and robustly correlated with faster and more durable growth, controlling for the effect of redistribution. Second, redistribution appears generally benign in terms of its impact on growth; only when redistribution is very large is there some evidence that it may have direct negative effects on the durability of growth. Third, we find preliminary evidence that inequality's impact on growth works through lower education and life expectancy, and higher fertility.

Beyond negative impacts on national economies, for example through limited participation in formal markets, evidence is also accumulating that links inequality with social 'bads', such as increases in child mortality, increasing crime rates, declines in social trust, mental health problems and rising rates of incarceration (Wilkinson and Pickett 2009, Fig. 13.1). Inequality is also associated with social conflict and political instability (Scheffer et al. 2017), both within and between nations. Signals of such conflict and instability have become increasingly evident in recent years (Østby 2008; Cederman et al. 2011; Dabla-Norris et al. 2015).

Within the more general concerns about inequality and its effects on society and growth, there is a particular focus on the impacts of gender inequities. A review of studies focusing on the correlation between gender equality and economic growth (Nallari and Griffith 2011) suggests that gender equality, measured in terms of education and employment (Kabeer and Natali 2013), is positively linked to economic growth. The contrast between women in poor and rich countries is striking, with women in poorer countries faring much worse on indicators of gender equality such as education, health, economic rights, marriage rights and participation in parliament. The International Finance Corporation (IFC 2017, p. 3) concludes that gender equality is 'a key contributor to growing and strength-

Fig. 13.1 Health and social problems are worse in more unequal countries. Note: Inequality has negative societal consequences for both rich and poor nations. (Sources: Wilkinson and Pickett 2009 and www.equalitytrust.org.uk)

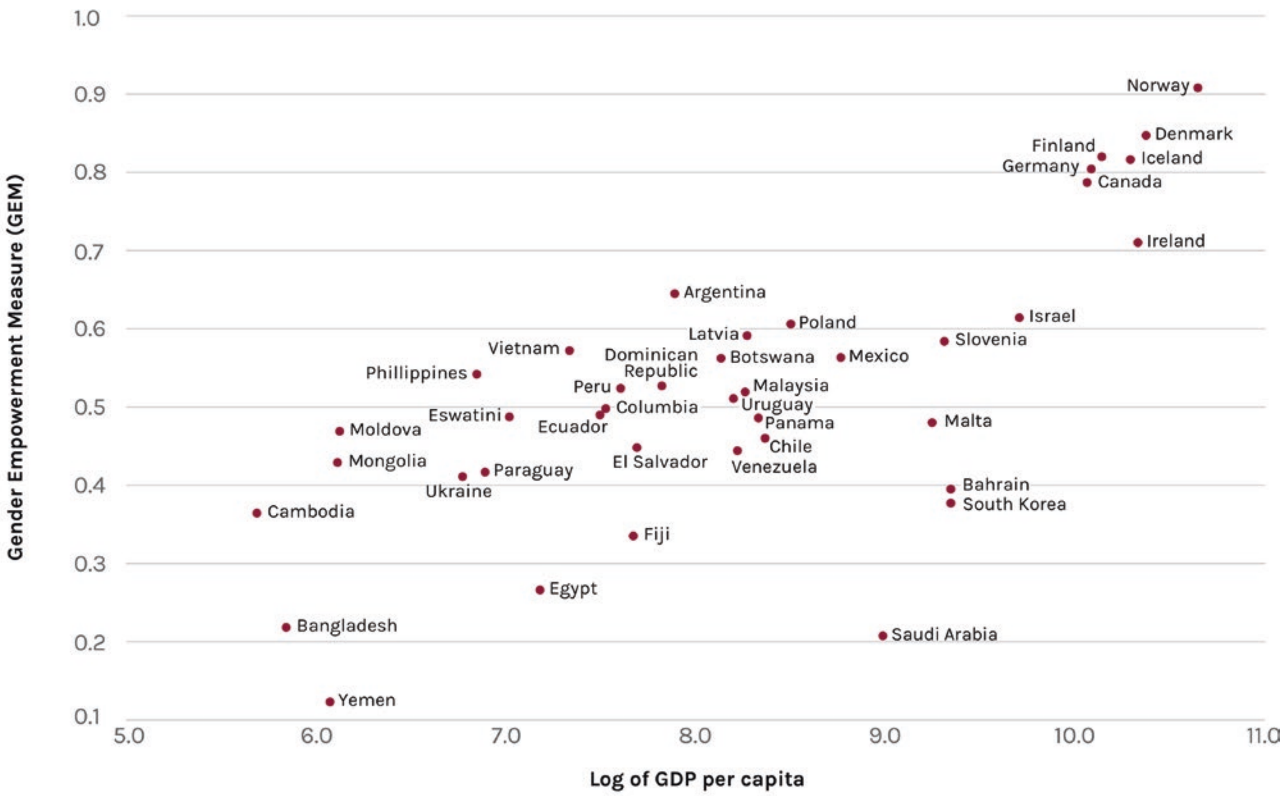

Fig. 13.2 Relationship between Gender Empowerment Index (GEM) and Gross Domestic Product (GDP). Relationship between Gender Empowerment (GEM) index and gross domestic product (GDP), from data for every third country in the IMF database (ordered alphabetically). If data were missing, the next country on the list was chosen. (Source: Stotsky 2006, pp. 23–24)

ening national, regional, and global economies'. While correlations between gender equality and growth are strong (Fig. 13.2), they appear to be asymmetrical. Gender equality contributes to growth, but findings are much less consistent when it comes to growth redressing critical dimensions of gender equality (Kabeer and Natali 2013; Kabeer 2016). Investments and processes of growth consequently need to be accompanied by specific gender equality–oriented public and private sector measures (Kabeer 2012; IFC 2017).

Any future sustainable ocean economy strategy should include means of reducing existing inequalities as well as preventing the widening of ocean inequities, both within and among countries. A sustainable ocean economy should ensure that the potential gains in wealth from the development of new ocean industries are distributed to address social problems seen in more unequal societies. The development approaches and policy strategies designed within a sustainable ocean economy must also shape existing ocean sectors (e.g., fisheries, maritime transport, aquaculture) so that they too recognise and include social equity concerns (Bennett et al. 2019a, b).

Extreme inequality is a social 'bad', for both moral and instrumental reasons. Addressing inequalities should include addressing issues of governance, social norms, gender, global inequalities (e.g., between North and South), inequalities at national scales and intergenerational inequities. Borrowing from the definition of the 'green economy', a sustainable ocean economy should thus include opportunities for economic development that result in 'improved human well-being and social equity, while significantly reducing environmental risks and ecological scarcities' (UNEP 2011, p. 16; UNCTAD 2014, p. 2).

1.4 Equity in an Ocean Context

The inequitable distribution of benefits is not consistent with a global policy agenda advocating for sustainable ocean use for the benefit of all (UN 2015). In short, concerns associated with social equity and an ocean economy are related to (1) the way benefits are shared and (2) the distribution of harms, both of which include the level to which different groups are included in or excluded from decision-making.

In this Blue Paper, we assess the fairness of the current global ocean economy and explore what can be done to facilitate fair sharing of the benefits from ocean use, with an aim to align concerns for social equity with concerns about environmental sustainability. The fairness issues we address exist at and across multiple scales (from global and national levels to those of communities and subgroups) and involve relationships (bilateral or otherwise) among multiple types of actors (governments, civil society, international agencies, and private corporations) with different levels of power, capacities and incentives to address ocean equity. Where actors have the power to disregard equity concerns, there has to be some mechanism to bring fairness issues to bear; for example, through multilateral agreements and/or regulatory approaches. Without an active championing of equity, inequality will be the default outcome.

This Blue Paper addresses the following central questions:

- What types of inequity are prevalent in the use of marine resources? How can differences in fairness be explained?
- How are sustainable and fair use of marine resources interrelated? Why is it important to strive for both simultaneously?
- What can be done in terms of policy and practice to improve social equity in relation to people's use of the ocean?

In the following sections, we explore different types of equity, describe why inequity is a challenge in relation to sustainability and conclude with opportunities for action aimed to foster just ocean sustainability.

2 Key Findings

2.1 How Are Ocean Benefits and Harms Distributed?

The ocean produces oxygen, stores carbon and heat, produces food, offers space for economic activities and facilitates international trade and the transport of goods (White et al. 2012; Resplandy et al. 2018). It also provides non-monetary benefits in the form of advances in scientific knowledge, opportunities for collaboration, sense of place, feelings of wonder and worship, and a free place to play or gather with family and friends (Fraser and Spencer 1998; Whitehead et al. 2008; Garcia Rodrigues et al. 2017). The ocean and all its benefits should be enjoyed by all.

The potential benefits from ocean-based economic activities, include taxation and rents for governments, payments for access agreements, financial and employment benefits for national economies, as well as livelihood opportunities and social benefits for local communities and tourists visiting coastal and marine environments. Globally, the value of key ocean assets has been estimated at US $24 trillion and the value of derived services at between $1.5 trillion and $6 trillion per year (Hoegh-Guldberg 2015; Lillebø et al. 2017; Cicin-Sain 2015; OECD 2016).

Generally, however, the distribution of benefits from ocean use flows disproportionally to some actors (Klain et al. 2014; Wynberg and Hauck 2014). Focusing on fisheries as a sectoral example, between 2004 and 2014, 25 countries were responsible for roughly 82% of global catches (FAO 2018). The concentration of national actors is substantially higher on the high seas, beyond exclusive economic zones (EEZs) (Tickler et al. 2018), where five high-income countries are responsible for 86% of total fishing effort (McCauley et al. 2018). In the corporate sphere, some companies are becoming more powerful than countries, and industry consolidation is prevalent. In seafood production, for instance, 13 companies control 11–16% of global catches (Österblom et al. 2015). A similar analysis for genetic resources shows that 1 company has registered 47% of all known marine genetic sequences, thereby exceeding the share of 220 other companies (Blasiak et al. 2018b). Consolidation is also prevalent in the seed industry, agriculture, forestry, mining and other sectors influencing the planet and its people (Folke et al. 2019). Ongoing analysis of ocean industries indicates substantial consolidation in maritime transport, cruise industries, offshore wind, ports, shipbuilding and repair, as well as offshore oil and gas, with the majority of companies headquartered in a small number of countries (Monacelli 2018; John Virdin, Duke University, unpublished data). Such patterns highlight the unequal control of access to and distribution of benefits arising from ecosystems all over the world (Wynberg and Hauck 2014).

The ocean economy can produce a number of social harms, undermine the productivity and abundance of marine resources that local communities rely on, and pollute the marine environment, thereby compromising the safety of food resources and local people's health, recreation and well-being (Stonich et al. 1997; Stonich 1998; Page 2007). Development activities can also undermine people's rights or displace them from areas they have historically and/or traditionally used (Zalik 2009; Bennett et al. 2015; Barbesgaard 2018).

Inequity arises from a number of social factors. These include not only the different stakeholders involved and the power they can wield but also the social institutions and structures through which the economy operates (Ciplet et al. 2015; Crona and Bodin 2010; Felipe-Lucia et al. 2015). Mechanisms that can uphold inequities from the ocean economy include historical and colonial legacies, lack of access to and allocation of resources, insecure territorial and tenure rights, financial resources and technological capacity (Abdullah et al. 2017; Bourguignon 2015).

Value chains, market policies and investments similarly shape equity in terms of access, benefits and costs, and working conditions. Not taking the full value chain of the ocean economy into account hides inequitable opportunities and impacts on women, for instance, who tend to be less involved in the extractive part of the value chain but are engaged in processing and marketing (Harper et al. 2013; Kruijssen et al. 2016). Invisible value chains, based on unreported catches and illegal activities, can mask labour trafficking, peonage systems, unsustainable resource use or health and sanitary issues while simultaneously detracting from wider economic benefits and avoiding taxation (Lopes et al. 2017; Moreto et al. 2019).

Insufficient consideration or inclusion of developing states or local populations in decision-making processes related to ocean development is a substantial concern. Representatives from coastal communities and groups often marginalised (e.g., women, indigenous groups, individuals with disabilities and poor people) are frequently not, or not adequately, included in decisions related to development (e.g., site selection of ports, energy and oil development, aquaculture) that will impact them (Kerr et al. 2015; Flannery et al. 2018). Fisheries agreements have, for instance, been described as primarily commercial deals negotiated by governments behind closed doors, with few benefits accruing to local economies (Kaczynski and Fluharty 2002; Le Manach et al. 2012). See, however, Almeida et al. (2009) for an example of fair and participatory fisheries agreements.

2.2 Why Is Social Equity Important in a Sustainable Ocean Economy?

The idea of fairness in relation to use of natural environments can be explained by the concepts of 'environmental justice' (Schlosberg 2009) and 'ecological justice' (Baxter 2004). Environmental justice bridges key goals of environmental protection and social justice by focusing on correcting maldistribution, or how less powerful groups in societies derive fewer environmental benefits and are exposed to more environmental harms (Schlosberg 2009) (see Box 13.1). In essence, 'Environmental justice is defined as the fair treatment and meaningful involvement of all people regardless of race, color, national origin, or income, with respect to the development, implementation and enforcement of environmental laws, regulations, and policies' (EPA 2017). Ecological justice, in contrast, focuses on preventing, mitigating or repairing environmental harm brought about by human activities and the granting of fundamental rights to non-humans. This Blue Paper is concerned with the former only, in other words—equity and fairness in relation to the access to and control over ecosystem benefits (Leach and Mearns 1998; Ribot and Peluso 2003).

A number of academic fields have focused explicitly on environmental justice. Central to this literature is the idea that people and groups appropriate ecosystem services and benefits through claims, underpinned by various abilities, or power bundles (Ribot and Peluso 2003; Boonstra 2016) sanctioned by law, custom or convention. These powers, in turn, are ultimately rooted in people's ability to influence the behaviour of others and the social and ecological conditions in which others operate (Boonstra 2016).

We suggest that social equity provides an all-encompassing framework and define two specific sub-categories of social equity: procedural equity and distributional equity (Franck 1995; McDermott et al. 2013; Pascual et al. 2014; Zafra-Calvo et al. 2017) (see also Box 13.1). These two sub-categories can be defined as follows:

1. **Procedural equity** refers to the recognition of rights and needs of all groups and the level of inclusion and participation in decision-making related to ocean development.
2. **Distributional equity** refers to fairness in the sharing of benefits and the minimisation of harms across all groups from ocean development.

There are two broad reasons why pursuing equity should be a central concern for a sustainable ocean economy (Bennett 2018). The first is a normative argument: extremes of inequality challenge universal notions of fairness. Including people in decision-making as well as improving how benefits are distributed is simply the right thing to do. Indeed, these are global norms contained in many guiding policy documents and international commitments related to human rights, sustainability and development (see Sect. 2.3). The second is an instrumental argument: equitable procedures and outcomes can be important for supporting the achievement of sustainability objectives.

Equity is an increasingly critical component of ensuring that ocean-based economic and other activities have a social license to operate (Mather and Fanning 2019; Voyer and van Leeuwen 2019). Taking social equity considerations into account will lead to a fairer distribution of benefits to different segments of society and maintain the legitimacy of the ocean economy. What is considered fair and what levels of inequality a society tolerates vary from place to place (Box 13.1). This is a decision for individual societies to make, however, as part of their commitments to achieving the SDGs, and in line with existing legal frameworks.

2.3 What Rules and Principles Exist to Support Equity?

The international community increasingly recognises equity as central to achieving the SDGs. A number of the global goals spell this out explicitly, including SDG 1 (Ending Poverty), SDG4 (Education), SDG5 (Gender Equality) and

SDG 10 (Reduced Inequalities). SDG 14 (Life under Water), also has a number of equity-related targets, such as Targets 14.6 and 14.7. The desire to address inequality is most clearly spelled out in the overall ambition of the UN Agenda 2030 to 'leave no-one behind'. Despite the recognition of the importance of equity in international law (Franck 1995), equity is not, as such, a general rule. Rules and principles to achieve equity may, however, be established through law-making processes such as treaties and customary international law. Soft-law instruments can contribute to both the making of a treaty, as standard setting, and to customary international law, as state practice.

Guiding principles of equity are relevant in addressing two categories of ocean equity. The first, *intergenerational* equity (Sect. 2.3.1), relates to the conservation and sustainable use of the marine environment in a manner that ensures the ability of future generations to reap its benefits also (Brown-Weiss 1990; Tladi 2007). The second, *intragenerational* equity (Sect. 2.3.2) is more immediate and concerned with ensuring equitable distribution of benefits and resources within the current generation (Okereke 2006; Tladi 2007). It calls for solidarity in uplifting those who are marginalised and underprivileged. The sentiment is expressed in, for example, the call by the Conference of the Parties of the Convention on Biological Diversity that 'ecosystems should be managed for their intrinsic value and for the tangible or intangible benefits for humans, in a fair and equitable way' (CBD 2000).

2.3.1 Intergenerational Equity: Protection of the Marine Environment

Three key principles have been designed to enhance *intergenerational* equity. First and foremost, the precautionary principle (Freestone and Hey 1996, p. 3; Tladi 2014, p. 108) stipulates that scientific uncertainty should not be used as a reason not to adopt measures to protect the environment. It represents a central element of the Fish Stocks Agreement (UNGA 1995, Arts. 5 and 6) and the 2012 Rio Plus 20 outcome document, *The Future We Want* (para. 58).

Second, the duty to prevent transboundary harm to common areas, including the ocean, is clearly spelled out in Article 3 of the Convention on Biological Diversity: '[States have] the responsibility to ensure that activities within their jurisdiction or control do not cause damage to the environment of other States or of areas beyond the limits of national jurisdiction' (ICJ 2010; Murase 2015, paras. 55–59).

Third, the duty to perform environmental impact assessments for activities that may cause harm to the marine environment (ICJ 2010; ILC 2018), and may therefore negatively impact future generations, is also firmly rooted in laws and policies relevant to the management of the ocean (ITLOS 2011; UNGA 2018, Art, 206; ICJ 2010).

The UN Convention on the Law of the Sea (UNCLOS 1982) contains general provisions on the duty to protect the marine environment (UNCLOS Part XII). The convention also contains particular rules applicable to the different maritime zones. Even with the numerous provisions on environmental protection, the environmental regulations in the convention are seen as insufficient (Gjerde 2006). Other regulatory tools exist that can complement the legal framework established by UNCLOS. For example, although the Convention on Biological Diversity in principle only applies to areas within national jurisdiction (CBD Art. 4[a]), its provisions can be applied to the ocean, including areas beyond national jurisdiction, with respect to 'processes and activities' (CBD Art. 4[b]).

Relevant CBD processes include, for example, the criteria for the establishment of Ecologically or Biologically Significant Marine Areas (EBSAs) (CBD 2008). The annual General Assembly resolutions on oceans and the law is another avenue relevant for the interpretation of obligations under UNCLOS. They contain provisions addressing the marine environment, including the call for an ecosystem approach (UNGA 2018, para. 187). A number of other environmental rules, such as several International Maritime Organisation conventions and rules under the Regional Seas Program can complement UNCLOS. Overall, however, these rules are fragmented and there is insufficient coordination in their application, resulting in uneven protection of the marine environment, thus undermining intergenerational equity.

Intergenerational rights to a healthy environment are also specifically considered in the constitutions of 74% of the world's nations—in theory therefore offering the best hope to protect future citizens as constitutions supersede other laws in a jurisdiction by establishing sovereignty (Treves et al. 2018). If these frameworks were to be enforced by decision-makers and courts, they would sustainably protect the biosphere and substantially contribute to equity in a sustainable ocean economy. 'Enforcing constitutional and public trust frameworks for intergenerational equity will be more feasible in jurisdictions that grant legal standing to youths and the legitimate representatives of future generations' (Treves et al. 2018).

2.3.2 Intragenerational Equity: Promoting Economic Equity

The *intragenerational* dimension of equity requires that efforts to protect the environment account for the needs of the most vulnerable in society (Brundtland 1987). However, this sentiment is not well developed in international environmental law, policy and practice. Nevertheless, policy options for addressing intragenerational equity, which may be collectively referred to as common-but-differentiated responsibilities, include the idea of differentiation of obligations, transfer of technology and funds, as well as capacity-building. In relation to ocean governance, all of these options are possible.

The principle of the common heritage of mankind, which has been described as a norm that combines the intragenerational with the intergenerational dimensions of equity (Tladi 2015), is the principle most synonymous with equity under UNCLOS. Through the application of Part XI of UNCLOS, this principle requires that activities in the deep seabed (the 'Area') 'be carried out for the benefit of mankind as a whole, irrespective of the geographical location of the States, whether coastal or landlocked'. While application of this principle beyond the 'Area' is not accepted by all, one of its central tenets, benefit-sharing, remains an important policy option to ensure a more equitable allocation of benefits from the ocean (Morgera 2016). Other provisions geared towards intragenerational equity include capacity-building and technology transfer provisions (UNCLOS, part XIV).

Technology and fund transfer to developing countries will be key to protecting marine biodiversity in areas within and beyond national jurisdiction (IGC 2018; Voigt-Hansen 2019), to enable developing countries to meaningfully participate at international fora and meet their international obligations. However, while UNCLOS and the Convention on Biological Diversity include absolute obligations to transfer technology (Morgera and Ntona 2018; CBD 2004, Annex, para. 11), the meaning of 'transfer of technology' is very broad and all-encompassing, with those obligations couched with qualifiers such as 'in accordance with capabilities' or 'endeavour to promote' and closely tied with scientific knowledge. This leaves much open to interpretation and makes it difficult to evaluate how international cooperation is to work in practice (Harden-Davies 2017). While capacity-building and transfer of technology obligations in UNCLOS and other instruments are qualified, the commitments to 'increase scientific knowledge, develop research capacity and transfer marine technology' under the SDGs are not (SDG14a). Even if these commitments are not legally binding, they do provide a political springboard for the elaboration of unqualified, legally binding commitments in new instruments and legal frameworks.

The 2001 International Treaty on Plant Genetic Resources for Food and Agriculture provides a useful model regarding the sharing of benefits from genetic resources beyond national jurisdiction. Articles 10 to 13 provide for a multilateral access and benefit-sharing regime based on four pillars: (a) exchange of information; (b) access to and transfer of technology; (c) capacity-building and (d) sharing of benefits arising from commercialisation. A similar framework forms the basis of the access and benefit-sharing regime for genetic resources established by the 2010 Nagoya Protocol, to ensure that states in whose territories—including in maritime areas—genetic materials are sourced are able to enjoy the benefits arising from the use of those resources (Voigt-Hansen 2019; Harden-Davies and Gjerde 2019; however, see Blasiak et al. 2018b for some of the protocol's limitations). Beyond benefit-sharing alone, capacity-building and technology transfer are key to fostering distributive and procedural equity (see also Leape, Abbott, Sakaguchi et al. Blue Paper: 'Technology, Data and New Models for Sustainably Managing Ocean Resources').

A striking example of the challenge of achieving both procedural and distributive equity concerns landlocked states, which are without physical access to the sea and almost by definition excluded from enjoying ocean benefits. To remedy this inequity, UNCLOS creates rules to facilitate the rights of landlocked states 'to participate, on equitable basis, in the exploitation…of the surplus of the living resources of the exclusive economic zone of coastal states' in the same region (UNCLOS, Art. 69). However, the right to participate is limited to 'an appropriate part of the surplus'; if a coastal state was to claim that it does not have a surplus, then arguably the right cannot be claimed, and the right to participate is subject to agreement between states. Provisions, therefore, while present, tend to be filled with many caveats making their implementation difficult.

2.3.3 Human Rights

While international human rights are not typically seen as directly applicable in ocean governance, they should be included and applied in the search for equity in a sustainable ocean economy. Human rights obligations apply not only within the territories of states, but also over an activity under the control or jurisdiction of states, including vessels flying the flag of a state and activities in the high seas or the Area under the control of states (Wenzel 2008).

A number of rights may be particularly relevant in the pursuit of ocean equity. First, the right to development, which calls for solidarity and uplifting the poor and marginalised, is directly related to the intragenerational equity described above. It is contained in, among other instruments, the African Charter on Human and Peoples' Rights (Art. 22), the 1993 Vienna Declaration and Programme of Action (para. 10) and the 2000 Millennium Declaration (para. III). It can also be inferred from other instruments such as the International Covenant on Economic, Social and Cultural Rights and the Rio Declaration on the Environment and Development. Second, the right to equality and non-discrimination can further support fairness in an ocean governance context (Universal Declaration of Human Rights Art. 2, International Covenant on Economic, Social and Cultural Rights, Art. 2, International Covenant on Civil and Political Rights, Arts. 2 and 26).

Some prohibited grounds of discrimination have also been the subject of specific treaties, such as the Convention on the Elimination of All Forms of Racial Discrimination and the Convention on the Elimination of All Forms of Discrimination against Women. These rights could potentially be made applicable to, for example, fishing permits. While regional fisheries management organisations do not, typically, consider race and gender when establishing allowable catch requirements, national authorities should, in keeping with human rights standards, account for the needs of the most disadvantaged and marginalised.

Labour rights is one area in which the protection of human rights has been directly applied in ocean governance. Labour or employment rights are contained in, for example, the International Covenant on Economic, Social and Cultural Rights, including the right of 'just and favourable conditions of work' (Art. 7). The Maritime Labour Convention (Arts. III and IV) includes requirements for regular payment and processes to ensure fair wages (e.g., Regulation 2.2). The Work in Fishing Convention C188, adopted in 2007, aims to ensure that all fishers have decent working conditions on board fishing vessels.

One area with much room for improvement is the role of business in enhancing equity. While human rights obligations are binding on states, business entities have the greatest potential to impact human rights and the environment (Ratner 2007; Oyewande 2008). Business entities, including those fishing and mining in the ocean, do not have direct obligations under international law. This creates difficulties where business entities act in the territories of third states and areas beyond national jurisdiction (Duruigbo 2003; Muchlinski 2007). To address this issue, the obligations of states in human rights treaties to 'protect, respect and fulfil' have been interpreted as establishing a duty on the state to ensure that rights are protected in private relationships, including between corporations and other persons (Ruggie 2008), thus creating an indirect duty of 'non harm' on the corporations. Moreover, the United Nations is currently considering the possibility of a treaty to regulate the activities of multinational corporations that impact on the environment and the enjoyment of human rights (Meyer 2017).

2.4 Case Studies of Hope and False Hope

The following sections focus on concerns for ocean equity across a variety of ocean-related sectors and equity dimensions, including the distribution of burdens and benefits on the high seas, inequalities associated with infrastructure development and the role of transnational corporations in a sustainable ocean economy (see Table 13.1 for an overview). Although much of the scientific work to date has revolved around gender equity and the rights of small-scale fisheries and coastal communities (Tables 13.1 and 13.2 and Appendix 1), there is increasing interest in engaging with inequalities in other areas.

Table 13.1 Key points from case studies

Case study	Summary
Equity and sustainable fisheries	Substantial attention has been devoted to addressing ecological sustainability in fisheries, and the FAO Code of Conduct for Responsible Fisheries is an important example. Endorsement of the Voluntary Guidelines for Securing Sustainable Small-Scale Fisheries (SSF) in the Context of Food Security and Poverty Eradication may contribute to improvements in the equitable distribution of benefits by giving a voice to, as well as representing the interests and respecting the human rights of small-scale fishers. However, implementation of existing international guiding policies remains a challenge
Gender-transformative approaches	Existing training opportunities, targeting only women in 'accommodating' ways, have had limited impact because they have failed to address underlying harmful power structures and norms restricting women from equitably engaging in and benefitting from ocean-based activities. Gender-transformative approaches encourage men and women to shift these barriers and catalyse fair development outcomes
Ocean-based infrastructure and coastal community equality	Coupling of offshore activities with a regular compensation mechanism to coastal communities in the United Kingdom is an example of how to support the fair distribution of benefits from ocean-based industry. While this is an example from a wealthy state where institutions are prepared to set up and control such a system, it illustrates a possible framework through which vulnerable coastal communities can be associated with offshore activities
Equity in areas beyond national jurisdiction	Pelagic fish stocks and marine genetic resources (MGRs) are two examples of transboundary resources often shared at one stage or the other (of their life cycle or migration routes) between exclusive economic zones (EEZs) and areas beyond national jurisdiction (ABNJs). Fisheries on and conservation of highly migratory stocks may disproportionately affect developing states. In the case of MGRs, an imbalance in patent ownership is problematic from an equity perspective. Ongoing negotiations on an international legally binding instrument under the United Nations Convention on the Law of the Sea on the conservation and sustainable use of marine biological diversity of areas beyond national jurisdiction are attempting to redress these inequities by developing strong and sustained mechanisms for capacity-building and technology transfer at global, regional and national scales
Can corporate actors promote equity?	While corporate bodies operate within legislative and other norm-based frameworks, they also shape expectations as to what constitutes appropriate behaviour as well as aspirational desires for future relationships. Although several ocean-based sectors have paid substantial attention to ocean sustainability, equity concerns remain poorly addressed. Prioritisation of equity by major actors has the potential to influence entire sectors

Table 13.2 Scientific documentation of inequities in small-scale fisheries, undermining sustainable livelihoods and contributing to loss of well-being

	Outcomes	Examples
Inequity of benefits		Canada, Kenya, Indonesia, Philippines
Structural inequalities in value chains	Unequal trading relationships and inability to obtain fair value of catch. Limited capacity to compete with more powerful actors	Wamukota (2009), Cinner et al. (2012), Knudsen (2016), Fabinyi (2012), Trinidad et al. (2014), Crona et al. (2016), Rosales et al. (2017), Purcell et al. (2017), Hicks et al. (2019)
Vulnerability to degradation of resources	Loss of food security, cultural practices and well-being. Compelled by subsistence needs, may also increase destructive behaviour, resource use or non-compliance	Cinner (2009), Cinner et al. (2009), Crona et al. (2015), Sadovy de Mitcheson et al. (2018), Yamazaki et al. (2018), Frid et al. (2016), Baker-Médard (2017)
Invisible inequities		Multiple locations
Gendered invisibilities	Women are often invisible, and hence marginalised in the management of marine resources (e.g., due to gender-blind policies, focus on formal and paid fishing activities, or the production segment of fisheries value chains) Difficult to know how women are affected as the fisheries sector develops	Yodanis (2000), Bennett (2005), Williams (2008), De Silva (2011), World Bank (2012), Harper et al. (2013), Daw et al. (2015), Lentisco and Lee (2015), Schwerdtner Máñez and Pauwelussen (2016), Kleiber et al. (2017), Harper et al. (2017), Fortnam et al. (2019)
Inequity in access		Bangladesh, Brazil, Canada, Ghana, Kenya, Madagascar, Norway, Philippines, Zambia
Gendered access barriers	Barriers to profitable segments of supply chains, and/or access to fishing grounds, boats, fishing gear, financial capital, credit, education, alternative livelihoods	Yater (1982), O'Neill and Crona (2017), Walker (2001), Eder (2005), Matsue et al. (2014), Wamukota (2009), Cole et al. (2015), Kruijssen et al. (2016), Baker-Médard (2017), Cole et al. (2018), Kleiber et al. (2017), Gerrard and Kleiber (2019)
Decision-making and governance		Bangladesh, Brazil, Canada, Tanzania, Indonesia, Solomon Islands
Access to governance	Women and minority groups—such as indigenous groups, disabled and poor people—face access barriers to governing institutions (e.g., as a result of customary rules and norms) and are not accounted for in fisheries management, leading to policy interventions that undermine sustainable livelihoods	Bennett et al. (2018), Thorburn (2000), Fröcklin et al. (2013), Kleiber et al. (2017), Ban et al. (2018), Bennett (2005), Daw et al. (2015), Baker-Médard (2017)

Note: The countries specified in the table represent examples of places where inequities have been scientifically studied. Some of these countries have recently invested in human, financial and/or technical capacity to address challenges identified, but, at the time of publication of this blue paper, no peer-reviewed scientific documentation was available that had assessed the effectiveness of such recent efforts.
Details in Appendix 1

2.4.1 Equity and Sustainable (Small-Scale) Fisheries

Small-scale fisheries support the majority of the world's fisherfolk (47 million women and men in developing countries alone) and utilise the least capital, fuel and technology (World Bank 2008, 2012; Schuhbauer et al. 2017; Zeller and Pauly 2019). While landing the bulk of catches for human consumption, large-scale industrialised fleets, in contrast, are highly subsidised, employ relatively few fisherfolk and have high discard rates (World Bank 2008; Carvalho et al. 2011; Sumaila et al. 2016; Zeller and Pauly 2019). Large-scale industrial fisheries and associated value chains can undermine the catches, livelihoods and food security of small-scale fishers and coastal communities (De Schutter 2012; Gagern and van den Bergh 2013; Pauly et al. 2014). There is a risk that intensification of economic use of the ocean and coasts for mining, logging, infrastructure development, coastal tourism and aquaculture can reinforce the weak position and vulnerability of small-scale fishers (Bavinck et al. 2017, 2018; Carver 2019; Cohen et al. 2019).

Small-scale fishing communities, particularly indigenous and women subgroups, often have relatively limited political power compared to large-scale fisheries actors (Table 13.2). Small-scale fishers are at times depicted by policymakers as ignorant, inefficient or environmentally destructive, leading to policies that target them with negative livelihood effects (Lowe 2013; Cohen et al. 2019). Blaming small-scale fisheries for problems often misses systemic inequalities that can be driving far more significant environmental degradation, including illegal fishing and corruption (Eder 2005; Fabinyi 2012; Li 2007; Segi 2014; Finkbeiner et al. 2017; Sumaila et al. 2017).

Inequities are apparent also within small-scale fish-producing communities. These are often structured along intersecting social categories such as wealth, gender, age, religion, migrant-status and ethnicity. Inequities in ocean resource benefits may reinforce existing inequities experienced by particular groups in access to healthcare, education and rights over land (Béné and Friend 2011; Jentoft and Eide 2011; Mills et al. 2011; Allison et al. 2012).

The Food and Agriculture Organization of the United Nations (FAO) Code of Conduct for Responsible Fisheries (CCRF), adopted in 1995, is an important tool for fisheries sustainability and has advanced equity through development of the Voluntary Guidelines for Securing Sustainable Small-Scale Fisheries (SSF) in the Context of Food Security and Poverty Eradication (FAO 2015). These guidelines are closely related to the Voluntary Guidelines for the Responsible Governance of Tenure of Land, Fisheries and Forestry in the Context of National Food Security (VGGTs). Both instruments are grounded in a human rights-based approach and specifically include equity and equality among their guiding principles.

The SSF guidelines have been embraced by several regional organisations (TNI 2016): the Central America Fisheries and Aquaculture Organization, the Fishery Committee for the Eastern Central Atlantic, the Southeast Asian Fisheries Development Center, the African Union and the General Fisheries Commission for the Mediterranean. The General Fisheries Commission's 10-year Regional Plan of Action for Small-Scale Fisheries is expected to increase social equity within the fisheries sector in that region. A draft law in Costa Rica, aiming to overcome the voluntary nature of the SSF guidelines, will likely contribute to improvements in the equitable distribution of benefits.

More generally, the CCRF has also been integrated into national regulatory frameworks with technical guidance and voluntary guidelines aimed to facilitate its operationalisation. Examples of particular relevance to social equity include the Ecosystem Approach to Fisheries in the FAO Technical Guidelines for Responsible Fisheries, which specifically encompasses improving human well-being and equity (FAO 2003). The FAO Technical Guidelines for Responsible Fisheries on the management of marine protected areas and fisheries aim at balancing environmental and social outcomes in a domain often dominated by conservation goals (Westlund et al. 2017).

Although an international framework of guidance is in place to support social equity in the fisheries sector, implementation often remains a challenge. Scientists, civil society organisations and social movements are analysing threats posed by ocean economy developments in terms of justice and equality (TBTI 2016) to understand how implementation can be accelerated.

2.4.2 Gender-Transformative Approaches

Significant efforts have been made to mainstream gender in fisheries policy and investments. These have mainly focused on visible gender gaps, such as gender imbalances in who accesses and participates in extension programs (Kleiber et al. 2017) and typically have consisted of 'accommodating' and 'gap-filling' approaches. For instance, in Bangladesh, women are targeted for capacity-building activities in ways that accommodate their practical needs (Choudhury et al. 2017; Behailu et al. 2019). Trainings may be held close to women's homes, at a time convenient for them, and the skill or technology transferred may feed into a livelihood option that can be performed at home. While socially acceptable, interventions that only build women's capacity, target women or deploy gender-responsive technologies at women have limited impact (Morgan et al. 2015; Farnworth et al. 2015; Behailu et al. 2018; Choudhury et al. 2017). Indeed, they fail to address underlying barriers that perpetuate gender inequities, including stereotypes, non-recognition of women as fishers or contributors along the value chain, and harmful norms restricting men and women from engaging in and benefitting from activities equitably (Kantor et al. 2015; McDougall et al. 2015; Choudhury and McDougall 2019).

Gender-transformative approaches in natural resource management are meant to address these underlying normative barriers (Wong et al. 2019; Cole et al. 2018), yet their implementation in developing countries remains limited. In Indonesia, for example, despite women being reached by many project activities since 1998, only two projects (10%) applied a gender-transformative approach (Stacey et al. 2019). A case from Bangladesh (see Box 13.2) illustrates the potential of transformative approaches to catalyse greater development and gender outcomes. While focused on a freshwater context, the framework is likely also relevant for marine resources (see Promundo-AAS 2016; Cole et al. 2018). More generally, advancing public discussion of gender equality in fisheries and making progress in women's empowerment requires effective messaging and awareness, political and social will, and support from the government, NGOs and the private sector.

Box 13.2: Transforming Underlying Gender Barriers in Bangladesh

Introducing innovations, such as more intensive homestead-based pond polyculture that can provide nutrient-dense small fish to low-income and coastal communities often struggling with nutrient deficiencies, is a priority for Bangladesh's government, NGOs and international research for development. Interventions have commonly targeted and trained women, but because the latter were not given control over ponds, and because investments in ponds have largely depended on the support of male household members, women were not able to implement and optimise innovations (Morgan et al. 2015). Women were also reluctant to get into ponds for practical reasons (because their wet clothing is difficult to dry).

The development of an affordable small-mesh gillnet that women could use from the pond banks did not resolve the problem, because women's use of such nets was constrained by gendered roles that see 'fishing' as a men's domain. Women therefore faced social repercussions for harvesting (Kruijssen et al. 2016), despite the strong nutritional need for fish for families and children in this area (Bogard et al. 2015).

Building on pre-pilots (Farnworth et al. 2015; Kantor et al. 2015; McDougall et al. 2015), the gillnet intervention was redesigned to build commitments for family support for women as fishers (aquaculturalists) and innovators. The transformative measures involved spouses and more powerful household members in critical reflection and dialogue (Promundo-AAS 2016) around gender dynamics ranging from intra-household gender power hierarchies to food distribution. Interventions also sought to discuss how current norms limited individual and family well-being and what steps could be taken collaboratively to shift gender relations. Women were also coached in self-confidence, negotiating skills and assertiveness. Results showed changed attitudes amongst men and women, enhanced collaboration among family members and greater acceptance of technology use by women.

Despite repression, by drawing strength and inspiration from their traditional identities and power within their society, women themselves can be agents of change. In British Columbia, First Nations Heiltsuk women drew on their traditional and contemporary roles as mothers, teachers, organisers and political leaders to oppose a controversial commercial herring (*Clupea pallasii pallasii*) sac-roe fishery. By taking on leadership roles, increasing social cohesion, facilitating information flow and engaging in critical negotiations, women demanded care over traditional marine resources for their children, culture and future generations and helped transform governance of herring on British Columbia's Central Coast (Harper et al. 2018). This example illustrates the importance of social equity and the potential strength of (indigenous) women as agents of change in fisheries governance. However, in many socio-political contexts gender dynamics limit women from exerting this level of leadership, voice and agency.

2.4.3 Ocean-Based Infrastructure and Coastal Community Equality

Activities in the ocean raise questions about how their costs and benefits are distributed among coastal communities. The onshore pollution effects of offshore accidents are well documented, including the Gulf of Mexico Deepwater Horizon accident (Hayworth et al. 2011; Michel et al. 2013), the Erika disaster (Čović et al. 2013) and the recent Brazilian oil spill (Reuters 2019). Yet more enduring relationships between ocean industries, such as oil and gas and offshore renewable energy, and coastal communities also exist. In the United Kingdom, for example, a number of coastal communities have long-standing experience interacting with the offshore oil and gas industry, with new questions being asked about ocean-coastal connections as the number of offshore renewable energy developments increases.

Exploitation of oil and gas in the United Kingdom began in the 1970s and included the construction of onshore facilities to receive crude oil via pipeline, ahead of onward transportation by tankers at the Sullom Voe Terminal in the Shetland Islands. The project remains one of the largest construction sites in Europe and the largest oil terminal ever built at once (Carr and Williamson 1982). At its peak, it processed over 1.5 million barrels of oil a day (Sullom Voe terminal 2018). At the time the terminal was being proposed, the local authority negotiated a compensatory agreement to account for the terminal's negative impacts on Shetland during the course of activities. Compensation was not a one-off payment but a disbursement placed into a trust and linked to activity levels until 2000, after which the money was invested on the stock exchange and in local subsidiary companies (Morgan 2009). The funds are governed by the Shetland Charitable Trust. Financial flows have been substantial and have supported onshore benefits through important investments in community assets, such as sports and cultural venues as well as a district heating scheme. In 2018, closing reserves topped £300 million (Sullom Voe terminal 2018). In this case, local and national governance processes support a third-sector organisation (the charity) to mediate the impact of corporate activity. The beneficiaries of this activity are local community members.

There are also examples of approaches where the potential for unequal experiences of the costs and benefits of development are addressed through formal sharing of benefits (rather than compensation for negative impacts). The idea of 'community benefit' payments first emerged in the onshore renewable energy sector, whereby communities located near renewable assets receive annual payments, often linked to energy production capacity or performance, as part of sharing the benefits of the energy scheme (Kerr et al. 2017; Rudolph et al. 2014; SSE 2019). Community benefit payments are in addition to any positive supply chain effects. Although not mandated by law, on-land community benefit packages have developed through the dynamic interplay between energy developers and communities, under the watchful eyes of governments. The rationale behind community benefit payments is 'driven by a desire to equitably share the benefits gained by harnessing a national natural resource' (Scottish Government 2018, 7). In the United Kingdom, if and how such principles might apply to offshore energy developments is a matter of ongoing consultation.

Arrangements therefore exist that consider the distribution of costs and benefits of ocean-based developments affecting coastal communities. There is also an opportunity to transfer learning from experiences of land-based developments, especially in the context of renewable energy, to ocean-based settings. The particular set of arrangements made will vary depending on the location of developments, the governance context and the power that communities have in their interactions with corporations. Coastal communities are often economically vulnerable and financially subject to fluctuations in the resources they depend upon. Addressing this vulnerability will enhance the equalities profile of the sustainable ocean economy. The two examples above focus on a country with institutional capacity to ensure that development is equitable; regions and countries exposed to ocean-related developments where this may be lacking will need support to avoid inequitable outcomes.

2.4.4 Equity in Areas Beyond National Jurisdiction

Discussions of equity frequently centre on communities, local resource users, traditional knowledge and associated governance and regulatory regimes. The majority of the ocean, however, is more than 200 nautical miles (370 km) from national coastlines, and thus remarkably remote from the daily lives of most people. Indeed, marine 'areas beyond national jurisdiction' (ABNJs) account for some 64% of the ocean. A growing body of research underscores the degree of ecological connectivity between ABNJs and coastal communities, and their importance for the functioning of the biosphere (Popova et al. 2019; Ramesh et al. 2019; Cheung et al. 2019). The life cycles of whales, sharks, seabirds, turtles and tuna species, as well as microorganisms and all species with a pelagic larval development or adult stage, crisscross ABNJs and national jurisdictions (Block et al. 2011; Bierne et al. 2016).

Among the industries active in ABNJs, the fishing industry draws a substantial proportion of the questions about justice, fairness and equity. Fisheries in ABNJs are heavily subsidised, and an estimated 54% of current high-seas fishing grounds would be unprofitable if these subsidies were removed (Sala et al. 2018). Three species account for 42% of the fish caught in ABNJs: skipjack (*Katsuwonus pelamis*), yellowfin (*Thunnus albacares*) and bigeye tuna (*Thunnus obesus*) (Schiller et al. 2018). All three move across vast ocean territories and in and out of national jurisdictions. Several Pacific atoll countries and territories (Kiribati, Tuvalu, Marshall Islands and Tokelau) are extraordinarily dependent on the access fees that they receive from distant water-fishing nations (DWFNs) who fish for tuna in their EEZs. These fees contributed 60–98% of all (non-aid) government revenue in 2016 (FFA 2017). In a number of countries, tuna caught within their EEZs also play a crucial nutritional role (Bell et al. 2018, 2019; Yadav et al. 2019). In many low-income, food-deficit countries, fish is a key source of micronutrients crucial for human health, and nutritionally rich alternatives are not readily available (Golden et al. 2016; Hicks et al. 2019). Poor governance on the high seas and mismanagement of fisheries can therefore result in not only economic losses for global seafood operations but also negative health outcomes and loss of livelihoods in coastal communities.

While the UN Fish Stocks Agreement requires that conservation and management measures for fisheries targeting highly migratory species such as tuna not disproportionately penalise developing states, fulfilling this obligation has been difficult (Hanich et al. 2015). Addressing these governance challenges requires encouraging the development of, for instance, applied research methodologies that can contribute to practical governance solutions that resolve or mitigate conservation burden obstacles and concerns in transboundary fisheries (see FERN 2019; Hanich et al. 2015).

Scientific exploration of ABNJs has yielded deeper insights into life in extreme environments of the deep and open ocean, including hydrothermal vent systems. New techniques have resulted in a rapid fall in the cost of genetic sequencing of collected organisms, supporting the exponential growth of public repositories of genetic sequence data (Laird and Wynberg 2018; see also Blasiak et al. Blue Paper: 'The Ocean Genome: Conservation and the Fair, Equitable and Sustainable Use of Marine Genetic Resources'). While the number of commercial applications is clearly accelerating (Arrieta et al. 2010; Blasiak et al. 2018b), the marine biotechnology industry is highly concentrated in a handful of countries. In 2011, ten countries owned 90% of patent claims; 7 years later the same countries own 98% of patent claims (Arnaud-Haond et al. 2011; Blasiak et al. 2018b). Absence of requirements for sample origin data, or even of taxonomic information in patent filings, makes it virtually impossible to determine which of these are associated with genes collected in ABNJs (Arnaud-Haond et al. 2011; Blasiak et al. 2019).

Scientific advances in the biotechnology and data analytics sector have consistently and dramatically outpaced the development of appropriate regulatory policy (Wynberg and Laird 2018). Publicly accessible open-access databases are one of the cornerstones of capacity-building and should result in a more equitable system of access to and sharing of knowledge. By themselves, however, they do not solve the problem of limited scientific capacity to access and use genetic resources from ABNJs (UNESCO 2017; Salpin et al. 2018), or to use (digital sequence) information. Hence, many developing states cannot explore commercially valuable potential benefits from open access information on the sole basis of information-sharing through open access databases.

In fact, by itself, this needed step does not obviate the need for capacity-building in scientific disciplines (e.g., molecular biology), and research infrastructure– the main drivers of inequalities (Arnaud-Haond et al. 2011).

Operationalising equity commitments in the SDGs with regard to ABNJs has proven challenging. In the context of the ongoing negotiations for an international legally binding instrument under UNCLOS on the conservation and sustainable use of marine biological diversity of ABNJs, states have an opportunity to reshape activity in these areas [1]. However, least developed countries (LDCs) and small island developing states (SIDS) have been underrepresented in the negotiations around biodiversity in areas beyond national jurisdiction (BBNJ) and face technical and legal capacity constraints (Blasiak et al. 2016, 2017a), raising questions about equity in the context of the negotiations. Capacity-building has been seen as one vehicle to move towards greater equity. A voluntary fund was established by the UN Division for Ocean Affaires and the Law of the Sea (UNDOALOS) to help LDCs, SIDS and landlocked developing countries participate in the BBNJ negotiations. If the BBNJ agreement is to be implemented and equitable outcomes achieved, strong and sustained mechanisms for capacity-building and technology transfer at global, regional and national scales will be crucial (Minas 2018). Building on the unqualified capacity-building and technology transfer commitments in the SDGs, negotiators should consider developing a capacity-building and technology transfer regime without the qualifiers contained in UNCLOS. One possibility to consider, among others, is a capacity-building and technology-transfer fund resourced from assessed contributions.

2.4.5 Can corporate Actors Promote Equity?

The increasing power and influence of transnational corporations has attracted scientific attention to their activities and agency (Dauvergne and Lister 2012; Griffin 2017). Historical analysis of corporate engagement in policy development suggests that businesses rarely play a progressive and ambitious role in sustainability efforts; in fact, the opposite is true (Clapp and Fuchs 2009; Oreskes and Conway 2011; Murphy et al. 2012). Where regulations exist, particularly in places with limited capacity, companies can incentivise compliance, through voluntary reporting, naming and shaming, or enforcement activities themselves (e.g., as observed in efforts to reduce illegal fishing in the Southern Ocean: Österblom and Bodin 2012).

Corporate engagement in, and reporting of, sustainability has generated mixed results, ranging from 'greenwashing' to substantial reductions in environmental impacts (Folke et al. 2019). A wide range of voluntary environmental programs (Appendix 2) have engaged multiple ocean-based industries in sustainability. These programs vary in their membership standards, compliance mechanisms, focus and effectiveness. While most focus on environmental and legal concerns rather than equity, these initiatives indicate that platforms exist for engaging corporations in equity. The UN Global Compact (n.d.) represents an important platform for corporate sustainability, with its 10 principles focusing on human rights, labour, environment and anti-corruption.

Whereas ecosystem sustainability is evidently important for corporations whose activities depend on a functioning planet, the case for equity is not as straightforward. What would the incentives be for corporations to share, or give up, some of their powers? Why would a corporation want to pay more taxes or engage in other forms of benefit-sharing mechanisms? Increased attention to global inequalities, in science, among policymakers, and within established, mainstream economic institutions indicates that addressing inequality is likely to be an important aspect of major corporations' future legitimacy and their continued license to operate.

Identifying the relevant companies, where they are operating and what their associated impacts are is a foundation for action. Companies can demonstrate leadership through both better practice and reporting, as well as through active engagement with policymakers for an improved focus on equity. Greater attention to both human rights and the environment by legislators, combined with improved corporate reporting and increased transparency in global supply chains, is incentivising corporations to operate responsibly (Folke et al. 2019). Recent engagement with representatives from 10 of the largest seafood sector companies through the Seafood Business for Ocean Stewardship (SeaBOS) initiative is an example of science-business collaboration in this domain (Österblom et al. 2017). The exposure of slavery and human rights abuses in seafood production (Mendoza et al. 2016; Kittinger et al. 2017) is one reason for increased corporate engagement in sustainability associated with seafood, as reputational risks are incentivising companies to 'do the right thing' (Lubchenco et al. 2016).

Owners, banks, investors and shareholders are able to influence companies to take on a larger responsibility for sustainability and equity. Improved legislation and consumer demands, combined with economic incentives, can stimulate corporations to adopt and integrate environmental and social responsibility (Folke et al. 2019; Jouffray et al. 2019).

[1] The "negotiations shall address the topics identified in the package agreed in 2011, namely, the conservation and sustainable use of marine biological diversity of areas beyond national jurisdiction, in particular, together and as a whole, marine genetic resources, including questions on the sharing of benefits, measures such as area-based management tools, including marine protected areas, environmental impact assessments and capacity- building and the transfer of marine technology" (UNGA 2017).

2.5 Equity and Climate Change

The above case studies showcase the possibilities and barriers associated with promoting more equal distribution of access to, and benefits from, goods and services in a sustainable ocean economy. Current trajectories of global change (IPCC 2019) and associated risks of conflict among resource users (Pinsky et al. 2018; Spijkers et al. 2019) under future conditions further suggest that shifting towards more equitable and inclusive resource use and access will be difficult. Equity approaches are supported in the Paris Agreement. Yet national targets are currently insufficient to meet the 2 °C warming target, with additional commitments needed by the G8 and China.

Climate change is projected to disproportionally affect ecosystems and communities in some of the least developed countries, particularly SIDS (Campbell and Barnett 2010; Sovacool et al. 2015; Hallegatte et al. 2016; Burke et al. 2015; Diffenbaugh and Burke 2019), with the potential to reverse significant development gains. Climate change in the poorest countries is more than 90% likely to have resulted in decreased economic output, whereas the effect is less pronounced in developed nations (Diffenbaugh and Burke 2019). Inequality will cause disadvantaged groups, especially women, girls and indigenous communities, to suffer disproportionately from the adverse effects of climate change, deepening existing social inequalities (Althor et al. 2016; Islam and Winkel 2017), possibly leading to unrest and severe social disruption (see Gaines et al. Blue Paper: 'The Expected Impacts of Climate Change on the Ocean Economy').

The rise in developing nations' inequality is due not only to projected climatological changes but also to the sensitivity of coastal communities to shifts in the distribution and abundance of fish stocks, crucial for livelihoods and nutrition (Blasiak et al. 2017b). This accentuated sensitivity is coupled with comparatively low levels of adaptive capacity, as remote coastal communities often lack the connectivity to urban and peri-urban areas where greater access to education, health services and alternative livelihoods could buffer negative impacts (Cinner et al. 2018).

Some researchers are suggesting that support be provided to countries projected to experience high levels of impact and greater financial cost in terms of lost benefits and opportunities as well as more extensive adaptation measures (Wolff et al. 2015). Specifically, international adaptation funds, such as the Green Climate Fund, could be determined and disbursed to be commensurate with impacts to the country's ecosystem, and a metric of equity could be included within a vulnerability framework (Wolff et al. 2015). Further analyses and mechanisms that systematically consider 'equity' to understand the impact of climate policies are needed to inform efforts to achieve adequate and fair climate action for present and future generations (Klinsky et al. 2017). Addressing equity is increasingly recognised as an important mechanism to develop more effective solutions, support buy-in to climate change policies, and improve adaptive capacity and wholesale system transformation to create climate resilience (see Gaines et al. Blue Paper: 'The Expected Impacts of Climate Change on the Ocean Economy').

Climate scientists, economists and energy systems modellers have developed a range of storylines that examine how society, demographics and economics might change over the next century. These descriptive storylines are collectively known as shared socioeconomic pathways (SSPs) (Riahi et al. 2017) and explore five trajectories that the world could take based on contrasting societal choices—including economic growth, education, urbanisation and the rate of technological development (Table 13.3).

From an equity perspective, SSP1 (Sustainability) and SSP4 (Inequality) represent two extremes. In one possible future (SSP1), an emphasis is placed on improving management of the global commons and investing in health services and education. Consequently, SSP1 leads to a world in which inequality declines both across and within countries and where greater emphasis is placed on human well-being than on economic growth (O'Neill et al. 2017). By contrast, SSP4 is characterised by large, unequal investments in human capital, which together with increasing disparities in economic opportunity and political power increase stratification within and across countries, as a growing majority of the world's resources and trade are controlled by a small group of global elites (O'Neill et al. 2017). In this 'Fortress World', societies grow increasingly fragmented and investments in social and environmental policies are focused on the richest areas (Calvin et al. 2017). Recent years have seen politicians in some of the world's most powerful economies adopting increasingly protectionist or even xenophobic attitudes that align with the narrative of the 'Fortress World' of SSP4.

The narrative of a burgeoning ocean economy suggests an opportunity to align more closely with an equitable future development trajectory (SSP1). Such a scenario is consistent with promoting and supporting international cooperation on climate change mitigation, shown to be critical to lowering emissions. Indeed, recent modelling work found that in scenarios in which individual nations undertake self-serving policies, global cumulative CO_2 emissions are twice those of more cooperative scenarios (Mi et al. 2019). Being able to participate competitively in emerging ocean-based industries requires adequate capacity and research that follows the Findable, Accessible, Interoperable and Reusable (FAIR) data principles (Wilkinson et al. 2016). Researchers and entrepreneurs in low- and middle-income countries are still likely to face an uphill battle to secure financing, market access and highly trained collaborators. Capacity-building and provision of funds remains a ubiquitous target and prior-

Table 13.3 Summary of SSP narratives

Scenario	Scenario name	Outcome and key characteristics
SSP1	Sustainability—Taking the Green Road	A world focused on sustainable growth and equality *'The world shifts toward a more sustainable path, emphasizing more inclusive development that respects perceived environmental boundaries. Management of the global commons slowly improves, educational and health investments accelerate the demographic transition, and the emphasis on economic growth shifts toward a broader emphasis on human well-being. Driven by an increasing commitment to achieving development goals, inequality is reduced both across and within countries. Consumption is oriented toward low material growth and lower resource and energy intensity'*
SSP2	Middle of the Road	A world where trends broadly follow current and historical patterns *'The world follows a path in which social, economic, and technological trends do not shift markedly from historical patterns. Development and income growth proceeds unevenly. Global and national institutions work toward but make slow progress in achieving sustainable development goals. Environmental systems experience degradation, although there are some improvements and overall the intensity of resource and energy use declines… Income inequality persists or improves only slowly and challenges to reducing vulnerability to societal and environmental changes remain'*
SSP3	Regional Rivalry—A Rocky Road	A fragmented world *'Resurgent nationalism, concerns about competitiveness and security, and regional conflicts push countries to increasingly focus on domestic or, at most, regional issues. Policies shift to become increasingly oriented toward national and regional security issues… Investments in education and technological development decline. Economic development is slow, consumption is material-intensive, and inequalities persist or worsen over time… A low international priority for addressing environmental concerns leads to strong environmental degradation in some regions'*
SSP3	Inequality—A Road Divided	A world of ever-increasing inequality *'Highly unequal investments in human capital, combined with increasing disparities in economic opportunity and political power, lead to increasing inequalities and stratification both across and within countries. Over time, a gap widens between an internationally-connected society that contributes to knowledge- and capital-intensive sectors of the global economy, and a fragmented collection of lower-income, poorly educated societies that work in a labor intensive, low-tech economy. Social cohesion degrades and conflict and unrest become increasingly common… Environmental policies focus on local issues around middle and high income areas'*
SSP5	Fossil-Fueled Development—Taking the Highway	A world of rapid technological progress and development *'This world places increasing faith in competitive markets, innovation and participatory societies to produce rapid technological progress and development of human capital as the path to sustainable development. Global markets are increasingly integrated. There are also strong investments in health, education, and institutions to enhance human and social capital. The push for economic and social development is coupled with the exploitation of abundant fossil fuel resources and the adoption of resource and energy intensive lifestyles around the world… There is faith in the ability to effectively manage social and ecological systems, including by geo-engineering if necessary'*

ity in international agendas and frameworks, with a continuous lineage from Part XIV of UNCLOS on the development and transfer of marine technology to the 2030 Agenda and 17 Sustainable Development Goals.

2.6 Summary of Findings

Inequity is a systemic feature of the ocean economy. Lack of fairness is embedded in existing political and economic systems, and is the result of historical legacies and existing norms. There are, however, multiple ways to promote and advance equity—inequity can be addressed with directed policies and practices that explicitly reflect on and address existing approaches. An increased understanding of the intertwined dynamics of sustainability and equity shows that addressing equity is good for economic growth, policy legitimacy, social stability and sustainability. A failure to address equity risks accelerating social tension and eroding credibility in blue growth agendas, while also increasing reputational risks for corporations and trust in existing development approaches. Inequity is also increasing vulnerabilities to climate change. Although legal frameworks partially exist to support equity, they are not sufficiently developed. In practice, ocean policies are largely equity-blind, contributing to current patterns of inequity (Fig. 13.3). The presented case studies identify current barriers to the implementation of equitable principles across ocean-based sectors as well as illustrate successful measures in and developments towards achieving greater fairness.

People will increasingly turn to the ocean to meet their food, nutrition, livelihood and energy needs. Shifting the current trajectory of persistent and increasing inequities will require strong leadership and intentional and long-term planning that starts with a clear commitment to equity. Achieving true equity will only be possible if inclusive consideration is given to all uses and value systems and if destructive or degrading activities are halted (Agardy 2016). Climate

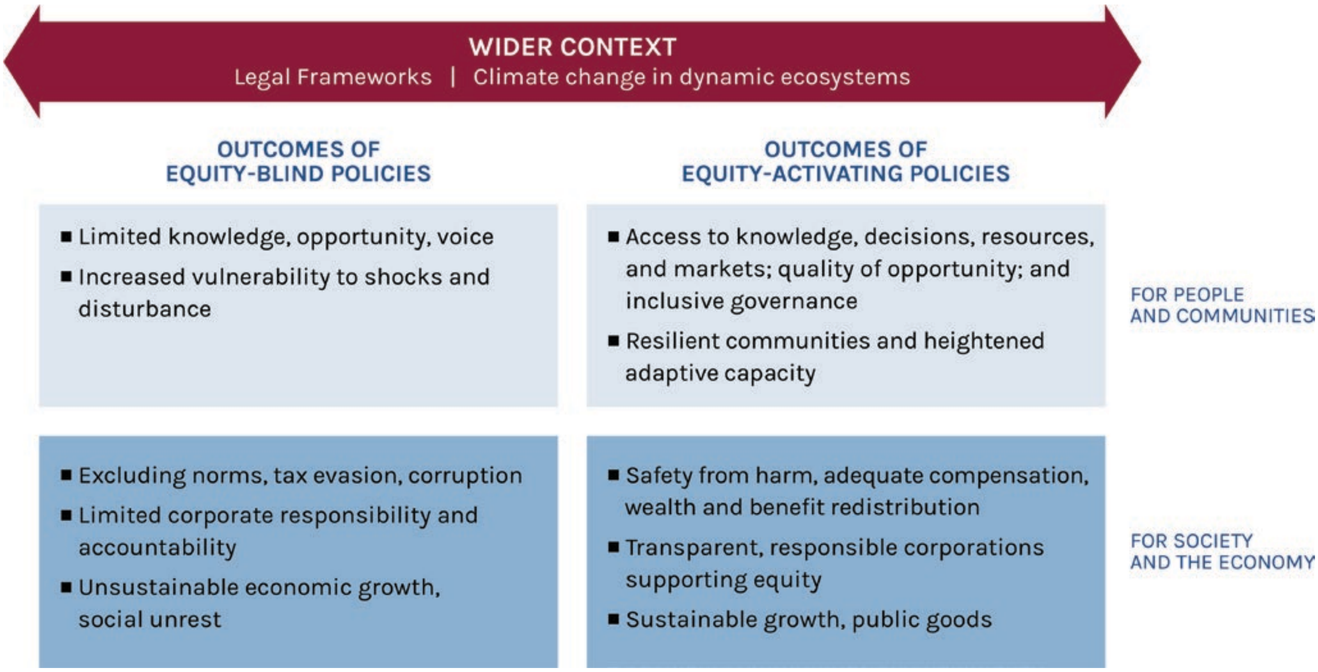

Fig. 13.3 Differences between equity-blind and equity-activating policies and practice

change projections indicate increasing impacts on already vulnerable nations and urgently demand that justice be considered in all sectors, at all political levels, and that policies to increase equity be urgently implemented.

3 Opportunities for Action

We outline opportunities for action, for policy development, business leadership and civil society. These range from the essentials (safeguards, or no-regrets, policies), to the more ambitious (mainstreaming approaches), to transformative approaches (see also Swilling et al. Blue Paper: 'The Transformation to a Sustainable Ocean: A Systems Transition Perspective') aimed at ensuring a fair, equitable, inclusive and sustainable approach to ocean-based development and protection (Table 13.4). These opportunities for action represent reinforcing levels of ambition that acknowledge 'the unique vulnerability and capacity challenges faced particularly by least developed, small coastal and island states, and landlocked states, and therefore the importance of [international] cooperation' (Commonwealth Secretariat 2018, p. 5).

Critical to achieving equity is access to information, promotion of environmental literacy, and engagement, coordination and collaboration across diverse actors, with different skills, capacities and powers. Building local capacity is fundamental to achieving equity and includes human (e.g., skills, education), social (e.g., connections, organisations), financial (e.g., access to capital) and physical (e.g., infra-

Table 13.4 Overview of opportunities for action for achieving equity in a sustainable ocean economy

Category	Opportunities for action
Safeguards—No regrets	1. In development activities and conservation initiatives, engage and include developing states and local populations in decision-making processes 2. Recognise the rights and needs of women, individuals with disabilities, small-scale fishers, indigenous and other minority groups and lift existing access barriers 3. Protect human rights and the rights of indigenous groups 4. Address corruption and tax evasion
Mainstreaming equity— Doing what's right	5. Recognise, protect and operationalise equity and access rights 6. Build local capacity—including access to low-cost and accessible technologies—to establish equality of opportunity 7. Understand social-ecological causality in ocean environments to assign responsibility and liability, and secure an equitable distribution of social gains 8. Demand, require and stimulate transparent, responsible business practices
Transformative approaches—The bold policies	9. Create a shared ocean economy that facilitates redistribution of wealth and benefits 10. Democratise ocean knowledge 11. Create inclusive governance processes by incorporating local voices and visions into plans for the ocean economy, at all scales 12. Be aware of environmental and social limits on growth and consider degrowth

structure, transportation) assets (Sen 1992; Nussbaum 2011; Bennett et al. 2018).

3.1 Safeguards: No Regrets

When governments and agencies engage in development activities, such as foreign direct investment, offshore energy and allocating of access programs, equity should be a cross-cutting concern. This is equally true for conservation initiatives, such as the identification of marine protected areas' location, or protecting individual species. Governments should invest in dialogue, capacity-building, education and training programs for women, girls, boys and men, combined with data collection and monitoring of equity. Tackling corruption and tax evasion is important to advancing ocean equity. Corporations, scientists and science funders also have a role to play in advancing equity safeguards.

3.1.1 Consider the Social Context and Engage Diverse Actors in Decision-Making

Development activities and conservation initiatives should engage and include developing states and local populations in decision-making processes. Women, indigenous groups, individuals with disabilities, and other minorities are key in these processes even when they are not harvesting resources themselves or part of the market chain. Context, values and cultures influence the adoption rate and effectiveness of implemented measures. Thus, activities that work in one community or country may not work in another. Failure to consider context (socioeconomic, political, cultural or ecological) often represents a missed opportunity, is inefficient, and can be counterproductive (see also Gaines et al. Blue Paper: 'The Expected Impacts of Climate Change on the Ocean Economy').

	Opportunities for action	Main target actors	Barriers	Overcoming barriers
a	*Recognise* that people are part of the ocean, and ensure recognition of rights, needs and priorities of developing nations, local people and marginalised groups in development and conservation.	Governments, international organisations, NGOs, funding agencies, private corporations	Equity-blind policies and practice, established norms	Teaching, training and main-streaming knowledge about equity
b	*Develop* policies and planning processes that mandate consideration of local people and communities in development.	Governments	Equity-blind policies and practice, established norms	Training and mainstreaming knowledge about equity
c	*Develop* and *employ* social and economic science to guide decision-making (development policies, marine spatial planning and economic development initiatives). *Document* pre-existing rights, livelihoods and socioeconomic status of relevant communities and consider the implications for producing equitable development.	Research institutions, NGOs, funding agencies	Established practices; limited focus on inter- and transdisciplinary science	Establishing funding mechanisms, piloting and mainstreaming of practice

3.1.2 Recognise the Rights and Needs of Women, Individuals with Disabilities, Small-Scale Fishers, Indigenous and Other Minority Groups

Many groups are marginalised from decision-making processes but rely on ocean resources and play a critical, but overlooked, role in the ocean economy. Recognising their roles, strengths, interests and responsibilities and lifting existing access barriers will engage new groups of leaders, negotiators, decision-makers and entrepreneurs. This will alleviate poverty, strengthen food security, reinforce adaptive capacities and increase development opportunities, in addition to stimulating new mind-sets and innovation. Steps taken towards implementing gender equality considerations, for example, need to be taken in conjunction with action (e.g., education) to address systemic hurdles limiting vulnerable groups from accessing and benefitting from the ocean equitably. A 'gender lens' in all sustainable ocean economy development programs will generate economic opportunities for women, empower them and provide opportunities to engage in decision-making and leadership (Williams et al. 2012; see also USAID 2019 and Barclay et al. 2019 for how to effectively integrate gender considerations in a fishery policy context).

	Opportunities for action	Main target actors	Barriers	Overcoming barriers
a	*Integrate* and *implement* gender equality considerations as part of policymaking, data collection, stakeholder engagement and education	Governments, international organisations, NGOs, research institutions, corporations, funding agencies	Outdated practices, established norms	Education, targeted training, empowerment, critical reflection and championing of minority leaders

	Opportunities for action	Main target actors	Barriers	Overcoming barriers
b	*Recognise* and *respect* pre-existing property rights, tenure and adjacency of coastal communities and indigenous populations to areas of the ocean and marine resources. *Consider* how the above factors need to be accounted for in development planning	Governments, corporations	Equity-blind policies and practice	Establishing practice through learning by doing
c	*Foreground* the needs and rights of small-scale fishers in resource management and development decisions (e.g., in accordance with the FAO Small-Scale Fisheries Guidelines)	Governments	Vested interests	Actively acknowledging the needs and rights of small-scale fishers and enforcing supportive policies

3.1.3 Protect Human Rights and the Rights of Indigenous Groups

At the very least, sustainable ocean development must 'do no harm'. Development activities must protect fundamental human rights, paying particular attention to indigenous rights and workers' rights, and ensuring that supply chains are free from unsafe working conditions, child labour and slavery (Kittinger et al. 2017; Teh et al. 2019).

	Opportunities for action	Main target actors	Barriers	Overcoming barriers
a	*Adhere* to international legally binding treaties, such as the UN Declaration on Human Rights and the UN Declaration on the Rights of Indigenous Peoples *Ratify* relevant legal conventions and ensure relevant complaint and compliance mechanisms are implemented by national governments	Governments, corporations	Limited capacity and knowledge, vested interests	Investment in capacity-building and knowledge development

3.1.4 Address Corruption and Tax Evasion

Corruption, environmental crime and tax evasion represent severe threats to the effectiveness of resource management and perpetuate as well as accentuate inequities in access to resources and benefits derived from them (Le Billon 2014). Corruption can be so ingrained that resource users will practice it without realizing it. Understanding and addressing corruption and other crimes requires education, regulations and enforcement. Systemic corruption is best seen as a collective action problem (Ostrom 1998; Le Billon 2014). Ending it may require transformational change in institutions (see Diamond 2008; and Swilling et al. Blue Paper: 'The Transformation to a Sustainable Ocean: A Systems Transition Perspective'). Identifying who engages in corruption and for what reasons first requires identifying how to incentivise compliance (Sundström 2012; Williams and Le Billon 2017). Leaders in policy, business and practice should lead by example and be role models (Persson et al. 2013).

	Opportunities for action	Main target actors	Barriers	Overcoming barriers
a	*Ensure* that mechanisms are in place to pay greater attention to systemic corruption or tax evasion, by *monitoring* the extent of corruption, *identifying* who engages in corruption or tax evasion and *examining* for what reason	Governments, NGOs, research institutions, corporations	Lack of knowledge, vested interests, dangerous to investigate	Education, regulations, monitoring, enforcement, promoting reciprocity and trust, championing of leaders and role models
b	*Implement* and *enforce* sanctions for corruption and tax evasion	Governments, international organisations	Established norms and legal grey zones	Obtaining convictions and sentences, active leadership in changing corporate practice
c	Increase *monitoring* and *reporting* of social and environmental impacts to ensure accountability and transparency	Governments, funding agencies, international organisations	Limited monitoring	Independent follow-up of development programs

3.2 Mainstreaming Equity: Doing What's Right

Systematically addressing issues of inequity needs to be mainstreamed into development, management and conservation interventions at all scales, from local marine protected areas to global treaty negotiations on ocean governance. As new treaties are being negotiated, active steps need to be taken to ensure that all states and international organisations have the necessary capacity and sense of responsibility to safeguard equity, irrespective of policy positions or financial resources. In addition, analyses and estimates of the economic consequences of unmanaged development in the ocean need to be improved upon and communicated.

3.2.1 Recognise, Protect and Operationalise Equity and Access Rights

The provision of access to local resources is imperative for the establishment of equality and equity at community levels (WRI et al. 2005). Equity and access rights are already enshrined in conventions, international agreements and policies, but they are insufficiently operationalised (see Sect. 2.3). Restricted and unequal access to local ecosystems and resources constitutes a barrier that makes it more difficult for vulnerable groups, such as the poor, to improve their conditions (Bennett et al. 2018; Cisneros-Montemayor et al. 2016; Haider et al. 2018). Access to local ecosystems has to be informed by customs and traditions, grounded in both formal and informal institutions, but it needs to also reflect current scientific knowledge.

	Opportunities for action	Main target actors	Barriers	Overcoming barriers
a	*Implement* policies that require consideration of historical and pre-existing access to natural resources, how these will be impacted by development, what mitigation can minimise impacts on access and how compensation mechanisms might be employed when impacts cannot be avoided	Governments, international organisations, research institutions, NGOs, corporations	Established practice and limited knowledge	Recognition of indigenous or cooperative governance and effective implementation of existing commitments (i.e., legitimising decentralised governance) Promoting co-management and building capacity and skills of all actors

3.2.2 Build Local Capacity to Establish Equality of Opportunity

The ability of coastal populations and coastal island and developing nations to benefit from ocean resources and development depends on their capacity to do so—in other words, equality of benefit requires equality of opportunity. Capacity is provided by human (e.g., skills, education), social (e.g., connections, organisations), financial (e.g., access to capital) and physical (e.g., infrastructure, transportation) assets (Sen 1992; Nussbaum 2011; Bennett et al. 2018). Enhancing the commitment to capacity-building and the transfer of marine technology, including through strengthening existing legal frameworks, constitutes an important priority. Access to low-cost and accessible technologies that support the SDGs represents a significant and increasingly relevant mechanism for developing adequate capacity (Meikle and Sugden 2015; see also Leap et al. Blue Paper, 'Technology, Data and New Models for Sustainably Managing Ocean Resources', on, for instance, the risk of widening the gap if equitable development and access are not considered). Local ownership of businesses that harvest ocean resources and of businesses that provide labour, services, goods or supplies can increase local benefit from economic development (Bennett et al. 2019b).

	Opportunities for action	Main target actors	Barriers	Overcoming barriers
a	*Develop* policy mechanisms and programs that provide opportunities by *bolstering* physical assets and *building* human skills and capabilities among local constituents prior to and during development	Governments	Established practice, lack of knowledge	Adjusting policies, targeting funding, piloting of practice, strong leaders
b	*Strengthen* legal obligations on capacity-building and transfer of technology	Governments	Priorities, limited funding, intellectual property concerns	Political will
c	*Create* low-cost and accessible technology	Governments, corporations, venture capital investors, funding agencies	Limited access to markets, funds and information	Establishing targeted funding schemes, supporting creative solutions and innovation

	Opportunities for action	Main target actors	Barriers	Overcoming barriers
d	*Support* local ownership of ocean businesses *Set up* entrepreneurship training programs and create credit schemes *Facilitate* connections to markets	Governments, corporations	Limited experience, knowledge and capacity	Effectively communicating existing knowledge and practice, investing in teachers and trainers, developing effective collaboration
e	*Create* user-friendly information-sharing mechanisms to monitor and communicate capacity needs and impacts of capacity-building efforts on local communities	Research institutions, governments, international organisations, NGOs	Limited information availability and infra-structure	Collaborating with UN Decade of Ocean Science

3.2.3 Understand Social-Ecological Causality, Assign Responsibility and Secure Equitable Distribution of Benefits

Development opportunities in ocean environments can entail social gains and harms. Some progress has been made in understanding and monitoring ecological harms, such as overfishing or eutrophication, and how these impact people. However, more knowledge needs to be gained about how ocean-based economic development can produce both direct and indirect social benefits and harms. Understanding causality in ocean environments is important to assigning responsibility and liability and securing an equitable distribution of social gains and avoidance of harms. Economic instruments such as taxes and fees need to be leveraged to internalise environmental and social benefits, costs and risks to society (WWF 2018).

	Opportunities for action	Main target actors	Barriers	Overcoming barriers
a	*Document, project, forecast* and *report social* benefits and harms, both those that occur indirectly via environmental impacts and those that impact humans directly *Assign responsibility* and *implement* mechanisms to equitably redress socioeconomic and ecological impacts of development activities	Governments, NGOs, research institutions, international organisations	Limited information and practice	Developing knowledge and practice
b	*Develop* compensation, remediation and redress mechanisms for past or future impacts. *Eliminate* harmful subsidies. *Regulate* harmful industries *Enforce* existing laws and principles[a] *Strengthen* instruments and introduce social impact bonds or environmental taxes	Governments	Limited practice and capacity	Mentoring of strong leadership, piloting of practice; sharing of experiences; coaching and support for active participation in the international policy arena
c	*Develop* means to ensure equitable distribution of benefits derived from ocean services	Governments, corporations	Limited practice and capacity, vested interests	Supporting active participation in international policy; promoting multilateral benefit sharing mechanisms

a. Such as by applying the polluter-pays principle, through the International Convention on Liability and Compensation for Damage in Connection with the Carriage of Hazardous and Noxious Substances by Sea.

3.2.4 Demand, Require and Stimulate Responsible Business Practices

Ocean industries derive substantial wealth and income from ocean environments. However, like most industries, they operate with limited transparency, which hinders the monitoring of their impact on society and ecological well-being, and thus the granting of a social license to operate. Incentives that shape a positive competitive environment can encourage industry to adopt corporate social responsibility practices to preserve their social license to operate (McGee 2013; Aguilera et al. 2007). Increased transparency will stimulate the private sector to respect and advance ocean equity and stewardship, while also encouraging learning across corporations.

	Opportunities for action	Main target actors	Barriers	Overcoming barriers
a	*Demand* full transparency of ongoing and planned activities and acceptance of liability and social responsibility, as well as limits on growth (within environmental capacities), as preconditions for engagement in ocean-based industries	Governments	Limited corporate reporting; limited monitoring, control and enforcement capacity; corruption	Developing practice and capacity, active leadership

	Opportunities for action	Main target actors	Barriers	Overcoming barriers
b	*Amend* legal duties and corporate laws to account for negative externalities *Encourage* companies to include 'social responsibility' provisions in articles of incorporation to support and promote equitable choices	Governments, corporations	Limited legislation; lack of monitoring, control and enforcement; limited capacity	Developing practice and capacity, providing incentives to 'do the right thing'
c	*Require* companies to submit strategic plans, along with reporting and auditing reports, detailing how their activities support smallscale fishers, local communities and ocean stewardship	Governments, international organisations	Limited legislation; lack of monitoring, control and enforcement; limited capacity	Developing practice and capacity
d	*Showcase, incentivise* and *stimulate* positive leadership	Governments, research institutions, corporations	Limited history of collaboration, fragmented knowledge	Synthesising knowledge and critically reflecting on progress made

3.3 Transformative Approaches: The Bold Policies

Discussions of systemic change to the global economy are no longer unusual (Jackson 2009; Hickel and Kallis 2019; Hadjmichael 2018; IPBES 2019). An acceleration of the ocean economy, along current trajectories, will continue to deliver the greatest benefits to a small subset of high-income countries, corporations and individuals. The scientific literature is increasingly exploring purposeful and meaningful steps to change course. Allocation of rights (including property rights for fisheries, offshore wind and aquaculture) and development of new knowledge and technologies are often regarded as necessary to facilitate environmental sustainability and economic viability, but they also risk reinforcing existing power structures and limiting the development of low- to middle-income regions. Given the global nature of the ocean, the scale of the challenges and the slow pace of international policy development, immediate and concrete steps are needed to develop and evaluate alternative approaches to economic growth and allocation of social, economic and technological capital (Raworth 2017b). Transformative approaches require redistribution of power and resources to improve longer-term equity perceptions and outcomes. Limits on growth, and even degrowth, of some sectors may need to be considered. Changes to the status quo will not be easy, but—as this Blue Paper has illustrated—they could substantially advance progress towards the SDGs.

3.3.1 Create a Shared Ocean Economy that Facilitates Redistribution of Wealth and Benefits

The ocean's global nature and the current unequitable distribution of access, benefits and negative impacts from ocean sectors requires bolder approaches. If such approaches are not taken, there is a real risk that the legitimacy of the current ocean policy agenda will be substantially eroded. Current ocean-related fund allocations from high-income countries to middle- and low-income ones are primarily handled through bilateral and multilateral official development aid (ODA) financial flows. While the source of many positive impacts, these allocations are dwarfed by the size of the ocean economy. Just 1% of the global ocean economy represents US $15 billion per year generated from the world's ocean and coasts (OECD 2016). New ways of thinking, creative policies and accounting mechanisms that internalise externalities and include long-term economic and environmental considerations, and the use of progressive and affordable technologies are needed to facilitate a redistribution of wealth and benefits from the ocean economy.

	Opportunities for action	Main target actors	Barriers	Overcoming barriers
a	*Develop* and *implement* a global ocean tax to reallocate parts of profits to places where environmental resources are harvested and where management actions, capacity-building, conservation or restoration are required	Governments, international organisations	Politically charged questions, vested interest in the status quo	Collaboratively investigating ideas and potential effects
b	*Apply* scenarios to understand how future benefits and harms might or should be distributed to different local groups and to current and future generations (see Bennett et al. 2019a, Box 13.1) *Incorporate* intergenerational accounting (Sumaila and Walters 2005) and climate change impacts into projection models and planning	Governments, researchers, development planners, investors, loan officers, funding agencies	Powerful interest groups, practice of discounting future harms in favour of present gains	Developing capacity to build on existing models, developing collaboration to model distribution of impacts
c	*Centralise* human well-being as both a proximate and ultimate goal of ocean economy development (Cisneros-Montemayor et al. 2019), within the capacity of the biosphere	Governments	Focus on economic profits	Managing for long-term local livelihood and food security objectives, ensuring that new developments support human well-being
d	*Develop* and *stimulate* access to low-cost, low-tech, long-term transformative solutions for equity and sustainability (aiming to increase access for communities, improve monitoring and enforcement, report on corruption and promote knowledge exchange)	Governments, funding agencies, international organisations	Many technologies primarily focused on generating capital and facilitating control over resources, lack of capacity to use technologies among key groups	Issuing global call (or challenge fund) and deploying sustainable and equitable technologies; building visibility and capacity to develop and utilise these technologies
e	*Develop* and *implement* mechanisms to redistribute wealth *Reallocate* shares to local communities and workers *Contribute percentage* of profits to local government or community trust funds *Reform* subsidy programs (Cisneros-Montemayor and Sumaila 2019)	Governments, corporations	Disproportionate concentration of value and power	Strong leadership, disincentives for not contributing to redistribution programs, support for effective policy mechanisms

3.3.2 Democratise Ocean Knowledge

Knowledge is power, and ocean knowledge is primarily generated in high-income countries. The current scientific understanding of the ocean and its associated industries, technologies and impacts is not well-suited to addressing issues of global ocean equity. Greater attention is needed to democratise knowledge, train international researchers (in social and transdisciplinary science) and document how benefits of the ocean and ocean-related knowledge flow to different groups (see also Fenichel et al. Blue Paper: 'National Accounting for the Ocean and Ocean Economy'). Knowledge exchange, co-production and transfer (Pohl et al. 2010) can be stimulated by cross-regional exchanges to compare lessons learned and the benefits of diverse approaches, cultures, values and understanding. Programs of this nature should aim to modify academic incentives that militate against equitable knowledge production and sharing (e.g., the emphasis on publishing and barriers to open-access work). It should value and promote effective and equitable partnerships with scientific researchers in low- and middle-income countries. Governments, scientists and communities should make concerted efforts to co-develop mechanisms for identifying, considering and expressing benefits gained from the ocean so that these can be integrated into development policies across scales.

	Opportunities for action	Main target actors	Barriers	Overcoming barriers
a	*Increase* knowledge co-production, exchange, capacity-building, technology transfer and availability, and knowledge infrastructure *Develop* multilateral networks capable of harnessing technological capacities to facilitate marine technology transfer *Foster* an integrated approach to the advancement, sharing and application of scientific knowledge (Harden-Davies 2017)	Governments, research institutions	Access to information, lack of capacity	Mandating high-income countries to commit to long-term funding of ocean science centres in low-income countries, providing access to knowledge networks and mentoring, developing partners in scientific endeavours and closing data gaps
b	*Recognise* that people are part of the ocean. A broader vision for ocean science, one that includes the human dimensions and marine social sciences (Bennett 2019), is needed to identify how to produce more equitable outcomes from ocean development	Governments, funding agencies, NGOs, civil society	Lack of knowledge and capacity	Developing collaborations, building capacity, fostering mentorships, obtaining support from the UN Decade of Ocean Science
c	*Train* international networks of young students and cross-regional exchanges to compare lessons learned and understand the benefits of human diversity	Research institutions, governments, funding agencies	Lack of capacity, time and cost investment	Developing collaborations, providing mentorship, leading by example
d	*Understand* and *develop* transparent accounting of how the benefits of ocean activities, resources and ecosystem services flow to different nations and groups of people within nations so that this understanding can be integrated into development policies across scales *Co-develop* mechanisms for identifying, considering and expressing the benefits gained from the ocean in ways that respect cultural norms and do not appropriate traditional knowledge	Governments, research institutions, NGOs, international organisations, civil society	Self-interest, established norms	Ensuring that information on ocean resources is publicly available, promoting trans-parent practices, rewarding exemplary behaviour

3.3.3 Create Inclusive Governance Processes at All Scales

Governance refers to who makes decisions and how decisions are made, which can significantly impact both what management actions are taken and to what effect. In terms of the blue economy, governance can impact 'how the ocean will be developed and by whom, how and to whom benefits will be distributed, how harms will be minimised and who will bear responsibility for environmental and social outcomes' (Bennett et al. 2019b, p. 2). In short, equity can depend on governance, and creative processes can be developed to incorporate local voices and visions into plans for the ocean economy. Many successful marine governance initiatives in the developing world are based on grassroots efforts. The FAO Small-Scale Fisheries guidelines is an example of a bottom-up initiative that resulted in a set of broad-scale instruments aimed at all actors striving to secure sustainable small-scale fisheries, end hunger and poverty, as well as strengthen human rights.

	Opportunities for action	Main target actors	Barriers	Overcoming barriers
a	*Design* governance processes at all scales—from global deliberations, to negotiations related to local ocean development initiatives—to be inclusive of governments, business and civil society, focusing on marginalised groups such as women, small-scale fishers and Indigenous Peoples	Governments, international institutions, NGOs	Lack of time and funds	Highlighting as priority to funding and development partners, developing mechanisms to ensure participation
b	*Allow* solutions to emerge from the bottom up.	Governments, international institutions	Lack of time, capacity and knowledge	Developing and implementing codes of practice that enable active engagement with grassroots initiatives

3.3.4 Place Limits on Growth and Consider Degrowth Within the Capacity of the Biosphere

There are numerous examples around the world where economic development activities have produced or are producing ecological and/or social impacts that could be deemed to have gone beyond acceptable thresholds. Some examples include oil development in Nigeria or Venezuela and overfishing in Mauritania or Senegal (Belhabib et al. 2016; Doumbouya et al. 2017). When thresholds are being exceeded, limiting growth or even degrowing the ocean economy to bring it in line with the capacity of the biosphere may be an obvious alternative. In this context, 'degrowth' means scaling back overexploitation that gives the illusion of what is in fact merely temporary growth and ultimately disastrously exhausts natural capital. Given the increasing debate about inequities, governments, corporations and scientists should consider alternative approaches to the ocean economy based on collaborative and equitable approaches that make well-being, livelihoods and natural resource maintenance their primary goals (Kostakis and Bauwens 2014).

Opportunities for action	Main target actors	Barriers	Overcoming barriers
Investigate and *pilot* approaches to limits on growth and degrowth	Governments, international institutions, research institutions	Existing narratives of perpetual growth and growth first, environment later	Constructive and science-based conversations, scenarios, piloting of approaches

4 Conclusions

This Blue Paper has illustrated that access to ocean resources and benefits is distributed inequitably, as is exposure to harms, resulting in negative effects on the environment and human well-being. Challenging this inequality directly threatens powerful interests that benefit from existing arrangements. However, inequality is increasingly endangering ecological sustainability, economic development and longer-term political and social stability. Increased scientific attention to inequality is starting to shape debates associated with the ocean. We argue that addressing issues of equity is critical to a sustainable ocean economy. We provide a set of complementary reinforcing opportunities for action, from the simple to the transformative. These opportunities range from activities that aim to recognise, identify, document and report, as well as to promote, respect, clarify, showcase, build, create or facilitate. The opportunities include assigning and demanding responsibilities, piloting, implementing and enforcing existing and novel policies, and even rethinking existing growth paradigms. Combined, they aim to overcome the existing general policy blindness to equity and have an ambition to effectively support a sustainable and just ocean economy.

Acknowledgements The authors thank the paper's technical reviewers, Meryl Williams, Mads Barbesgaard and Elisa Morgera, as well as its arbiter, Nicola Frost, who all provided helpful technical comments. The authors also thank the World Resources Institute for providing support as the Ocean Panel Secretariat.

While our colleagues were very generous with their time and input, this report reflects the views of the authors alone. The authors thank Alex Martin for copyediting and Jen Lockard for design.

Appendix 1: Inequities Associated with Small-Scale Fisheries

Inequity of Benefits

Inequalities in wealth shape the distribution of benefits from ocean resources for small-scale fishers at multiple scales. Many small-scale fishing households in Kenya and the Philippines, for instance, are enmeshed in structural inequality along value chains (Knudsen 2016; Wamukota 2009; Rosales et al. 2017). Coastal households specialised in fishing cannot compete with richer, more powerful fishers with better gear and the capacity to bribe local officials (Fabinyi 2012). Consequently, coastal households may depend on unequal trading relationships (Crona et al. 2016) and tend to sell the best-quality fish, consuming the lower-quality ones (Wamukota 2009; Hicks et al. 2019). Small-scale fishers often receive a relatively small proportion of the value of their catch (Rosales et al. 2017), especially when compared to prices associated with luxury consumption (Trinidad et al. 2014; Purcell et al. 2017). Meanwhile, small-scale fishers may be the most vulnerable to the loss or degradation of marine resources (Crona et al. 2015; Sadovy de Mitcheson et al. 2018).

Invisible Gendered Inequities

Women's contributions in fisheries are often overlooked, underestimated and/or undervalued, often resulting in women's marginalisation in the management of marine resources. Coastal activities are usually highly gendered, both in where and how women participate in value chains and how their contributions are valued and prioritised (Yodanis 2000; Williams 2008; De Silva 2011; Harper et al. 2013, 2017; Lentisco and Lee 2015; Fortnam et al. 2019). Women play an important role in both harvest and post-harvest activities with important implications for families, communities and economies. In the Pacific region, more than half of small-scale catches are taken by women. Coastal fisheries management policies that better represent their needs could lead to more secure livelihoods and more sustainable catches. Despite this, policies, data collection and stakeholder consultations remain gender-blind in many places. This further marginalises women's voices and interests, further devalues the benefits women's work provides and makes it hard to know how women are affected as the fisheries sector develops.

Gender blindness results from a focus on formal and paid fishing activities (traditionally male-dominated) in research, management and policies, disregarding informal and unpaid activities, usually dominated by women (Harper et al. 2013). Fisheries agencies are also commonly focused on the production segment of fish value chains, even though twice as many people may be employed in related activities, such as processing and marketing, which are often dominated by women (World Bank 2012). In Senegal, a study found that women represent 90% of the country's seafood processor workforce, valued at $30.5 million (Belhabib et al. 2014). Such marginalisation has often happened despite increasing recognition that women play a critical role at every link in small-scale fisheries value chains (De Silva 2011; Lentisco and Lee 2015). Failing to account for the gender and other social differentiation in fisheries management can lead to policy interventions that undermine sustainable livelihoods (Bennett 2005; Daw et al. 2015).

Inequity of Access

Gendered access barriers (ones that affect women and men differently) occur at several points along the fisheries value chain. Overall, women in fishing communities across the world face barriers to more profitable segments of supply chains, due to a variety of socioeconomic and cultural obstacles, as well as conflicting household roles (O'Neill and Crona 2017). These can include indirect barriers, such as gender norms in the Philippines that limit women's ability to fish far from home (Yater 1982). More direct barriers include lack of access to fishing gear, fishing grounds, fishing markets or financial capital, including credit, as well as lack of education or alternative livelihoods (Matsue et al. 2014). Gendered power relations are often context-specific. For instance, in Zambia, fishing gear is largely owned and controlled by men (Cole et al. 2018), whereas in Ghana and Brazil women can inherit fishing boats and gear and either use them themselves (Kleiber et al. 2017) or lease them to men for fishing (Walker 2001). In Norway, women are often not able to buy bigger boats or more profitable quotas because they are denied bank loans (Gerrard and Kleiber 2019), while in western Zambia, women have overcome lack of credit by participating in village savings and lending groups, which they use to buy and resell fish (Cole et al. 2015). Women may be excluded from markets, such as in Bangladesh, where only the poorest women sell fish at the market, or in Kenya, where women only have access to the less profitable parts of the catch and have limited trade connections (Matsue et al. 2014; Wamukota 2009). In Guadalajara, Mexico, in contrast, women dominate, often holding influential positions, having attained these through family networks, skills and cultural heritage (Pedroza 2019). Policies on matters such as spatial management can also have a disproportionate impact on women and other marginalised groups that may not have access to boats or motors that would allow them to reach other fishing zones (Eder 2005). For example, in Madagascar, when a no-take area was placed in the community gleaning areas, women were no longer able to fish or resorted to fishing illegally at night (Baker-Médard 2017).

Decision-Making and Governance

Women also often face access barriers to governing institutions, resulting in fewer women's voices included in small-scale fisheries decision-making institutions. In Tanzania, female fish traders were excluded from formal fisheries management groups (Fröcklin et al. 2013). In Bangladesh, women were not included in decision-making because they were perceived as lacking the necessary knowledge and experience (Kleiber et al. 2017). In Senegal, women make up less than 5% of fisheries governing bodies (Harper et al. 2017). Customary rules may also exclude women, such as in some communities in the Solomon Islands, where women are not allowed to be under the same roof as men with whom they have previously had relationships (Faye Siota, pers. comm.), effectively barring many women from public meeting spaces. Again, gendered norms and power relations in relation to the ocean mirror or enhance general gender inequities, such as those surrounding access to education, health care, food and nutritional security.

Appendix 2: Voluntary Environmental Programs

Name	Mission	Website
Aquaculture Stewardship Council (ASC)	To transform aquaculture towards environmental sustainability and social responsibility using efficient market mechanisms that create value across the chain	www.asc-aqua.org
Coalition of Legal Toothfish Operators (COLTO)	To promote sustainable toothfish fishing and fisheries; facilitate its members' working together and with outside groups, including through continued provision of high-quality scientific data to CCAMLR (Commission for the Conservation of Antarctic Marine Living Resources) and other bodies; and provide effective representation for its members.	https://www.colto.org
Global Aquaculture Alliance (GAP)	To promote responsible aquaculture practices through education, advocacy and demonstration	https://www.globalgap.org
Global Compact Ocean Action Platform	To determine how ocean industries can advance progress towards the Sustainable Development Goals (SDGs). The work of the platform builds upon the 10 principles of the UN Global Compact, which outline business responsibilities in the areas of human rights, labour, environment and anti-corruption	https://www.unglobalcompact.org/take-action/action-platforms/ocean
Green Coastal Shipping Program	To find scalable solutions for efficient and environmentally friendly shipping. Its multiple pilots are crucial for the phasing in of zero- and low-emission solutions in shipping towards 2030.	https://www.dnvgl.com/maritime/green-shipping-programme/index.html
International Association of Oil and Gas Producers (IOGP)	To create alignment and facilitate continuous health, safety and environment (HSE) improvements across oil and gas exploration and production	https://www.iogp.org
International Council on Mining and Metals (ICMM)	To promote a safe, fair and sustainable mining and metals industry	https://www.icmm.com
IPIECA (International Petroleum Industry Environmental Conservation Association)	To provide a forum for encouraging continuous improvement in offshore oil and gas industry performance, for example improvements associated with the SDGs	http://www.ipieca.org
Marine Stewardship Council (MSC)	To use its ecolabel and fishery certification program to contribute to the health of the world's oceans by recognizing and rewarding sustainable fishing practices, influencing the choices people make when buying seafood and working with its partners to transform the seafood market to a sustainable basis	https://www.msc.org/se
Ocean Energy Europe	To promote the development of ocean energy, improved access to funding and enhanced business opportunities for its members	https://www.oceanenergy-europe.eu
Sustainable Shipping Initiative (SSI)	To facilitate oriented efforts such as the 'Ship Recycling Transparency Initiative', which brings together ship owners, banks and other key stake-holders to improve transparency in the global ship recycling value chain	https://www.ssi2040.org
WindEurope	To promote wind power and coordinate international policy, communication, research and analysis	https://windeurope.org

About the Authors

Co-authors

Henrik Österblom is Professor and Science Director at the Stockholm Resilience Centre, Stockholm University.

Colette C.C. Wabnitz is a Senior Research Scientist at the Institute for the Oceans and Fisheries, University of British Columbia and Stockholm Resilience Centre, Stockholm University.

Dire Tladi is a Professor of International Law at the Department of Public Law and the Institute for International and Comparative Law in Africa, University of Pretoria, as well as an extraordinary professor in the Public Law Department, University of Stellenbosch (South Africa).

Contributing Authors

Edward H. Allison is an Honorary Fellow at WorldFish (Malaysia) and an Affiliate (Honorary) Professor in the School of Marine and Environmental Affairs, University of Washington.

Sophie Arnaud-Haond is a Research Scientist at Ifremer, in the UMR MARBEC (Marine Biodiversity, Exploitation and Conservation) at Montpellier University, CNRS, IRD (France).

Jan Bebbington is a Professor in the Department of Accounting, Birmingham Business School, University of Birmingham (UK).

Nathan Bennett is a Research Associate at the Institute for the Oceans and Fisheries, University of British Columbia, and is the Chair for the People and the Oceans Specialist Group for the International Union for the Conservation of Nature.

Robert Blasiak is a Researcher at the Stockholm Resilience Centre, Stockholm University and a visiting researcher at the Graduate School of Agricultural and Life Sciences, University of Tokyo.

Wiebren J. Boonstra is an Associate Professor at the Stockholm Resilience Centre, Stockholm University.

Afrina Choudhury is a Research Fellow (Senior Gender Specialist) at WorldFish Bangladesh.

Andrés M. Cisneros-Montemayor is a Research Associate and Deputy Director of the Ocean Nexus Program at the Institute for the Oceans and Fisheries, University of British Columbia.

Tim Daw is a Researcher at the Stockholm Resilience Centre, Stockholm University.

Michael Fabinyi is an Associate Professor at the School of Communication, University of Technology Sydney.

Nicole Franz is a Fishery Planning Analyst with the Food and Agriculture Organization of the United Nations.

Harriet Harden-Davies is a Research Fellow at the Australian National Centre for Ocean Resources and Security (ANCORS), University of Wollongong.

Danika Kleiber is a Research Fellow at the ARC Centre of Excellence for Coral Reef Studies (Australia) and WorldFish (Malaysia).

Priscila Lopes is an Associate Professor in the Department of Ecology at the Universidade Federal do Rio Grande do Norte.

Cynthia McDougall is the gender research leader for WorldFish (Malaysia) and the CGIAR Research Program on Fish Agri-Food Systems (FISH).

Budy P. Resosudarmo is an Associate Professor at the Crawford School of Economics and Government, Australian National University.

Samiya A. Selim is an Associate Professor and the Director of the Center for Sustainable Development at the University of Liberal Arts Bangladesh.

Highlights

- The foundation of a sustainable ocean economy is healthy, productive and resilient marine ecosystems. Currently, our ocean is under pressure from the diversity and multitude of human activities, driven by our need for food, energy, transportation and recreation. These pressures are amplified by climate change, loss of biodiversity and pollution. Despite progress on some fronts, the current trajectory is in the wrong direction and rapidly growing more serious.
- Efforts to implement effective sectoral management of ocean-based human activities and address issues such as climate change are necessary but insufficient for achieving a sustainable ocean economy. Integrated ocean management (IOM) is essential.
- Extensive and diverse experiences with IOM provide a wealth of models, best practices and guidance for success. Common features of success include harnessing science and knowledge, establishing partnerships between public and private sectors, engaging relevant stakeholders through legitimate processes, improving capacity building, implementing regulatory frameworks and developing adaptive management systems.
- It is vital to strengthen our knowledge about the ocean by developing and disseminating new data as well as better using existing knowledge, including traditional knowledge. We urge policymakers to further develop interna-

tional cooperation in marine science and related sciences by building on established structures such as the Intergovernmental Oceanographic Commission and using the United Nations (UN) Decade of Ocean Science for Sustainable Development as a vehicle for this.
- Private businesses are central for achieving a sustainable ocean economy. Ocean-related businesses at all scales should be encouraged to cooperate in developing principles and guidelines for sustainable conduct. For example, the UN Global Compact's Sustainable Ocean Business Action Platform, which has developed principles and guidelines for sustainable ocean business that several of the world's largest ocean- related businesses have signed on to, can serve as an inspiration. This can help ensure IOM takes place across all sectors of ocean business, and through partnerships between the private and public sectors.
- Another avenue for success is stakeholder engagement and stewardship. In all stages of developing and implementing IOM, governments should ensure transparency and the active involvement of local communities and other relevant stakeholders. In designing well-managed engagement processes, it is vital to consider the scientific, cultural, societal, economic and political contexts.
- One obvious opportunity for action is for each nation, or regions with multiple nations, to develop IOM that is appropriate for their circumstances. Capacity building is key for achieving IOM in all parts of the world. It is well-documented that scientific capacity is inadequate in many countries, and that lack of institutional capacity is also a challenge. Nations and other entities that have pursued IOM must share their experiences, and regional cooperation can therefore accelerate capacity building. Successful regional efforts at IOM should inspire similar efforts in other regions.
- Failure to implement existing international instruments is one of the most important weaknesses of our ocean governance systems. It is vital to have mechanisms in place not just to develop IOM plans, but also to implement them. States need to ensure effective implementation of international agreements. Regulations for managing human activities in the high seas should be compatible with and at least as strict as those that are applied in areas under national jurisdiction.
- One of the most serious challenges facing our ocean today is climate change. This also highlights the dynamic nature of the ocean, which calls for adaptive and holistic ocean management. A static approach in, for example, establishing marine protected areas, may—due to climate change—lose its efficiency over time. Ocean governance must therefore consider expected changes in the marine environment and in human interactions with the ocean, by using the best available scientific knowledge on climate change and including adaptive mechanisms as a vital part of IOM.

1 Introduction

With the unprecedented growth in economic activities relating to the ocean economy, the need for a sustainable concept where socioeconomic development can occur without environmental degradation is widely recognised. This is manifested at the global level by the 1982 United Nations Convention on the Law of the Sea (UNCLOS), which provides the basic global framework for ocean governance (United Nations 1982). Since then, the ocean economy has continued to grow alongside our need for food, energy, transportation and recreation from the ocean. Existing ocean industries expand while new ones appear. At the same time, new challenges are emerging as a result of climate change, loss of biodiversity, pollution and extractive activities. Our ocean is now facing these pressures at unprecedented rates and magnitudes. The mismatch between the drive for short-term economic gain versus long-term prosperity and a healthy, resilient ocean is increasingly apparent. As a result, we see a pressing need for holistic, knowledge- based and ecosystem-based approaches to ocean management. Integrated ocean management (IOM) is such an approach.

IOM considers multiple uses and pressures simultaneously and helps reconcile competing uses with the objective of ensuring the sustainability of societies and marine ecosystems. The need for a comprehensive perspective on the management of marine ecosystems and their resources was observed many years ago (e.g. Underdal 1980) and is now widely recognised at the global as well as regional and national levels of governance. There are, however, still many challenges relating to the implementation of existing governance frameworks, including knowledge and capacity shortages, incomplete legislation, lack of enforcement, poor coordination among ministries and other government bodies, and no overarching mandate across ministries or mechanisms to harmonise conflicting mandates among ministries.

The goal of IOM is to support a 'sustainable ocean economy': long-term, sustainable use of ocean resources in ways that preserve the health and resilience of marine ecosystems and improve livelihoods and jobs, balancing protection and production. IOM brings together relevant actors from government, business, academia and civil society from the entire spectrum of ocean-related human activities (e.g. petroleum, fishing, aquaculture, shipping, tourism, mining, renewable energy, conservation) to collaborate toward a sustainable future for our ocean environment. Here, 'ocean' refers to both marine and coastal areas. The functions of IOM include promoting environmentally sound economic development, protecting coastal and marine habitats and biodiversity, providing ecosystem services and balancing and deconflicting interests through spatial planning. IOM also addresses issues such as the conservation of coastal and marine habitats and biodiversity, protection of coastal and marine environments from land-based pollution, fisheries and tourism, as well as impacts from climate change such as sea level rise, ocean warming and deoxygenation, ocean acidification, changing storm intensities and more. IOM is a dynamic process, building on existing initiatives and bringing industries and sectors together, whether under the umbrella of marine spatial planning, ecosystem-based management or others. Biodiversity, intact habitats and ecosystem functioning are essential to a healthy, productive and resilient ecosystem. A comprehensive toolbox of measures to accomplish this exists, including area-based management measures.

The purpose of this paper is to provide an overview of how the framework of IOM is established at different levels of governance and what is lacking in terms of both frameworks and implementation. Implementation failure is a key issue for IOM, and we discuss cases of IOM from different parts of the world to exemplify this. While these lessons learned are useful for further developing IOM, we also recognise that successful implementation is highly context dependent, making capacity building and location flexibility critical to achieving effective IOM globally.

This paper is written as an input to the work of the High Level Panel for a Sustainable Ocean Economy. It begins by outlining the concept of IOM, explaining its key components and providing an overview of the global ocean governance framework. The paper continues by discussing IOM both in the exclusive economic zones and in areas beyond national jurisdiction. This is followed by a discussion of IOM implementation—both its challenges and the key components for success. Next, we present selected case studies of IOM in practice. To conclude, the paper offers opportunities for action on how IOM can contribute to a sustainable ocean economy.

Box 14.1 Integrated Ocean Management and Related Planning and Management Approaches

To discuss integrated ocean management (IOM) further, it is vital to define a few central terms that are often associated with IOM. The below list is not exhaustive but demonstrates the variety of means that have evolved to achieve smart planning and management in coastal and marine areas. IOM uses a variety of these tools to ensure the sustainability of marine ecosystems. These ideas, terms and concepts have evolved through time and have had different histories in different places. They are not necessarily interchangeable, and they often overlap.

Ecosystem-based management

Ecosystem-based management (EBM), also referred to as an 'ecosystem-based approach', is central to IOM and defined as management of natural resources focusing on the health, productivity and resilience of a specific ecosystem, group of ecosystems or selected natural assets as the nucleus of management (Domínguez-Tejo et al. 2016). EBM is a management approach that recognises the full array of interactions within an ecosystem, including with humans, and drives the integration of management planning and implementation across sectoral agencies. Focusing on recognising connections and ensuring coherence, EBM differs from historical approaches that focus on a single species, sector, activity or concern, considering the cumulative impacts of different factors. Specifically, ecosystem-based management has the following features:

- Emphasis on the protection of ecosystem structure, functioning and key processes
- Accounts explicitly for the interconnectedness within systems, recognising the importance of interactions between many target species or key services and other non-target species
- Acknowledgement of the interconnectedness among systems, such as that among air, land and sea
- Integration of ecological, social, economic and institutional perspectives, recognising their strong interdependencies
- Focused on a specific ecosystem and the range of human activities affecting it

Integrated coastal zone management

Integrated coastal zone management (ICZM) is 'the process of managing the coast and nearshore waters in an integrated and comprehensive manner with the goal of achieving conservation and sustainable use' (Katona et al. 2017). It is also called 'integrated coastal management'.

ICZM covers the full cycle, including information collection, planning, decision-making, management and implementation. The approach seeks informed participation and cooperation from all relevant stakeholders. It seeks integration of the goals and instruments needed to meet these objectives; of different policy areas, sectors and levels of administration; and of the land and sea components of the target area.

Marine spatial planning

Marine spatial planning (MSP) is used to create geospatial plans that identify what spaces of the ocean are appropriate for different uses and activities. These plans have similarities with sustainable ocean economy plans, which describe how to sustainably use the ocean and its resources to advance economic and social development.

Marine spatial planning (also known as 'maritime spatial planning' and 'coastal and marine spatial planning') extended the ICZM approach further out to sea in the 2000s. Marine spatial planning aims to create a framework for the ocean that minimises conflicts between economic sectors and maintains 'good environmental status' of the ocean through the identification of ocean spaces that are appropriate for different uses and activities. MSP is increasingly seen as a practical way to create and establish a more rational organisation of the use of marine space and the interactions between its uses, to balance demands for development with the need to protect marine ecosystems and to achieve social and economic objectives in an open and planned way. MSP is widely used for setting targets for and implementing ecosystem-based management (Katona et al. 2017). The characteristics of effective marine spatial planning include the following:

- Ecosystem-based, balancing ecological, economic and social goals and objectives toward sustainable development
- Integrated across sectors, agencies and levels of government
- Area-based
- Adaptive and capable of learning from experience
- Strategic and anticipatory, focused on the long term
- Focused on participation, with stakeholders actively involved in the process

Adaptive ocean management

Adaptive ocean management is 'a systematic process for continually improving management policies and practices toward defined goals by learning from the outcomes of previous policies and practices' (Katona et al. 2017). It recognises the inherent variability and dynamic nature of the ocean in terms of its bio-chemo-physical properties and social and economic factors in addition to scientific uncertainties. By scheduling periodic reviews of and updates to management plans, in addition to adding ad hoc opportunities for responding to unexpected events, adaptive ocean management acknowledges that changes in conditions and knowledge are likely.

Area-based measures including marine protected areas

Area-based measures are important tools in the management of the ocean and seas and can be used in all approaches outlined here. A marine protected area (MPA) is 'a clearly defined geographical space, recognized, dedicated and managed, through legal or other effective means, to achieve the long-term conservation of nature with associated ecosystem services and cultural values' (Oregon State University et al. 2019). Likely developed independently in many cultures, area-based measures are a regulatory tool for conserving the natural or cultural resources of the ocean and for managing human uses.

If managed in isolation, coastal and marine protected areas are vulnerable to the impacts of resource development and exploitation occurring outside these areas, in particular overfishing, alteration and destruction of habitats, climate change and marine pollution. Thus, protecting coastal and marine areas—including species, habitats, landscapes and seascapes—should be integrated into spatial development strategies for larger areas, under the umbrella of integrated coastal and ocean management, including land-ocean interactions.

2 The Concept of Integrated Ocean Management

This chapter outlines the global governance framework. International ocean governance is based on coastal states' [1] jurisdiction over their 200 nautical mile exclusive economic zones (EEZs). The authority to manage the EEZs and activities rests with (often multiple) agencies and the laws governing those agencies. While useful for efficient management, divisions of authority over different activities and zones can create challenges for oversight and coordination and thus limit holistic approaches to management. It is therefore important to identify and harmonise the possibly conflicting mandates of different agencies, as well as cover the gaps where no agency or entity is responsible. As pressures on the ocean increase, assessing the cumulative impacts of increasing uses and pressures also becomes increasingly important.

The purpose of IOM is to enhance our ability to use and manage ocean resources sustainably, and ensure that the health, productivity and resilience of ocean ecosystems, which provide multiple benefits to humans, are not impaired

[1] A coastal state is a nation state that exercises jurisdiction and sovereign rights in its exclusive economic zone and continental shelf. 2022 Note that when using this term regarding the United States, it is applicable to the country as a federal state. U.S. states have jurisdiction over 3 nautical miles from the coastline, while the area from 3 to 200 nautical miles is under federal jurisdiction.

by human activities. Examples of some supporting, regulating and cultural ecosystem services provided by ocean ecosystems include partial climate regulation, control of pests and pathogens, nutrient cycling, primary production, cultural identity, inspiration and recreation. Management institutions need to effectively measure, monitor and manage ocean space adaptively as complex adaptive systems (Lubchenco et al. 2016). To achieve this, incorporating participation from governance institutions, academic knowledge (multidisciplinary), other knowledge (transdisciplinary) and multiple stakeholder interests is crucial. Therefore, we argue that stakeholder involvement, the effective use of science and capacity building are keys to achieving real integration.

2.1 The Global Ocean Governance Framework

Responding to technological developments, increasing demands for natural resources and a growing use of ocean space for human activities, the global framework for ocean governance has evolved significantly over the last decades. The centrepiece of this framework is the UN Convention on the Law of the Sea—'the constitution of the ocean'—which was negotiated between 1973 and 1982 and entered into force in 1994 (United Nations 1982). UNCLOS states in its preamble that 'the problems of ocean space are closely interrelated and need to be considered as a whole'. The convention aims to establish 'a legal order for the seas and oceans which will facilitate international communication, and will promote the peaceful uses of the seas and oceans, the equitable and efficient utilization of their resources, the conservation of their living resources, and the study, protection and preservation of the marine environment'. As of 2019, 168 countries are parties to the convention. The implementation of UNCLOS is overseen by the UN General Assembly, which adopts annual resolutions on the ocean and the law of the sea addressing a comprehensive range of issues relating to the implementation of the convention.

UNCLOS establishes a legal order for the ocean where coastal states can exert sovereign rights over the natural resources in a 200 nautical mile exclusive economic zone and on the continental shelf also beyond 200 nautical miles (Fig. 14.1). Where continental shelves extend beyond 200 nautical miles, their outer limits are established based on recommendations of the Commission on the Limits of the Continental Shelf. The mineral resources at the deep seabed beyond national jurisdiction ('the Area') are considered the common heritage of mankind, and the International Seabed Authority (ISA) is tasked with their management. The ISA is currently responsible for developing regional environmental management plans for deep-sea mining regions. The International Tribunal for the Law of the Sea is one of several options for resolving disputes.

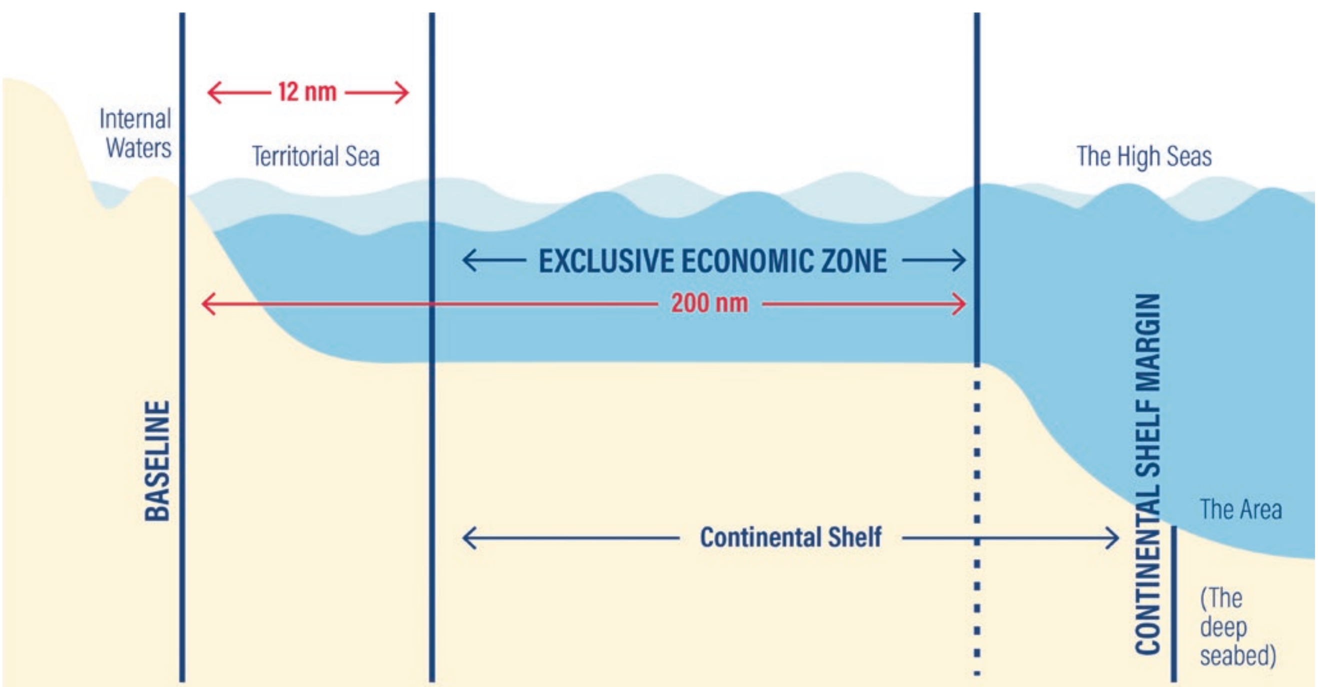

Fig. 14.1 Maritime zones as defined by the UN Convention on the Law of the Sea. (*Source: Anders Skoglund, Norwegian Polar Institute 2020*)

To provide guidance on the implementation of the convention, implementation agreements have been negotiated for deep seabed minerals (United Nations 1994) and fisheries (United Nations 1995). The latter require application of a precautionary approach to fisheries management and regional cooperation in the management of fisheries on the high seas. In response to growing concerns related to conservation and use of marine biodiversity, a third implementation agreement is under negotiation, addressing area-based management, marine genetic resources, environmental impact assessments and technology transfers, and capacity building for the areas beyond national jurisdiction. Governance bodies are also in place for specific themes. For example, the International Maritime Organization (IMO) regulates the shipping industry. IMO has adopted a number of international agreements setting out the standards for the industry related to the environment, operations and labour, among others.

In fisheries, additional layers of governance to the convention and the 1995 implementing agreement are provided by agreements adopted by the UN Food and Agriculture Organization (FAO) that address the ecosystem effects of fishing as well as the need to confront illegal activities. One example of this is the 2009 *Agreement on Port State Measures to Prevent, Deter and Eliminate Illegal, Unreported and Unregulated Fishing* (FAO 2009). Regional cooperation is important in the management of transboundary fish stocks on the high seas, with about 20 regional fisheries management organisations providing international cooperation for the management of such stocks.

Separately, many environmental concerns are addressed in instruments relating to various types of pollution, climate change (e.g. the United Nations Framework Convention on Climate Change) and the 1992 Convention on Biological Diversity at global as well as regional levels of governance. This includes the UN Environment Programme (UNEP) and its regional seas programmes.

International cooperation in marine science is centred around the Intergovernmental Oceanographic Commission (IOC) and the Regular Process under the UN General Assembly at the global level, as well as in several regional bodies such as the International Council for the Exploration of the Sea (ICES) in the North Atlantic, and the North Pacific Marine Science Organization (PICES).

With increasing uses and pressures on the ocean and its ecosystems, concern for the cumulative impact on marine ecosystems has grown. UNCLOS explicitly recognises this concern. Various efforts have been made to address these issues; however, solutions are often insufficient to address the accelerating challenges facing the ocean, such as biodiversity depletion and plastic pollution. Several global summits, such as the 2012 Rio Conference and its 'The Future We Want' declaration, have highlighted the need to consider the total impacts of ocean use.

The World Ocean Assessment of the Regular Process to assess the status of the marine environment under the UN General Assembly concluded with the following in its first report (United Nations 2015):

> *The sustainable use of the ocean cannot be achieved unless the management of all sectors of human activities affecting the ocean is coherent. Human impacts on the sea are no longer minor in relation to the overall scale of the ocean. A coherent overall approach is needed. This requires considerations of the effects on ecosystems of each of the many pressures, what is being done in other sectors and the way that they interact.*

The annual UN General Assembly resolutions on the ocean and law of the sea address these issues and have done so since 1999 in what constitutes a de facto global ocean coordination. The preamble of the 2018 resolution states the following:

> . . . the problems of ocean space are closely interrelated and need to be considered as a whole through an integrated, interdisciplinary and intersectoral approach, and reaffirming the need to improve cooperation and coordination at the national, regional and global levels, in accordance with the Convention, to support and supplement the efforts of each State in promoting the implementation and observance of the Convention and the integrated management and sustainable development of the oceans and seas . . .

Also, as a follow-up to the Millennium Development Goals, the UN General Assembly in 2015 adopted 17 Sustainable Development Goals (SDGs) as part of the 2030 Agenda. Several of the SDGs are relevant to the ocean and contain specific targets and timetables for achieving them. Goal 14, 'Life below water', addresses marine issues specifically. This goal provides opportunities to facilitate concrete actions for ocean sustainability and to foster greater integration among the sectors of ocean governance.

It is, however, evident that the implementation of the global governance framework leaves a lot to be desired. In some regions, pollution levels (from toxins, nutrients and plastic) are high, about one-third of the world's fish stocks are overfished, illegal fishing is a serious problem and the ocean is increasingly impacted by the effects of increased emissions of anthropogenic carbon dioxide such as warming, acidification and deoxygenation. As coastal states' abilities and capacities to implement existing rights and obligations are hampered by inadequate science and weak and poorly enforced regulatory frameworks, it is widely recognised that institutional capacity building is a critical factor to strengthen ocean governance. Capacity building is therefore now at the forefront of the global ocean debate and on the agendas of the UN General Assembly and subsidiary bodies such as the FAO and the IOC. The 2005 Millennium Ecosystem

Assessment and the 2019 Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services' global assessment of biodiversity provide further understanding of why we should care about biodiversity and what the major drivers of change are.

Integrated ocean management can be implemented across several ocean economy sectors, jurisdictions and spatial scales. These applications may take the form of localised ocean management within national waters, sector-defined ocean management across adjacent jurisdictions, at regional seas or at ocean basin scales, or international ocean management occurring across large ocean areas in areas beyond national jurisdiction, including in the Area (i.e. the deep seabed beyond national jurisdiction).

3 The Implementation of Integrated Ocean Management

This chapter analyses the challenges of implementing IOM and identifies key components of success. It continues by discussing how IOM can contribute to a healthy, productive and resilient ocean for long-term, sustainable economic growth. It highlights the need to calibrate the sophistication of management plans to the situation at hand, authority and political will, available data and societal values. It concludes by arguing that supplementing sector-based management with collaborative and coordinating mechanisms across sectors would be highly beneficial.

The rising demand for various uses of ocean space increases the complexity in modern ocean governance and management, and thus calls for better coordination among sectors and other stakeholders (Klinger et al. 2018). In some countries, the legal and institutional arrangements that divide ocean management are long-standing and the legal mechanisms to coordinate these arrangements at the domestic level as well as with adjacent nations are lacking. This makes it difficult to account for the cumulative effects—including those over time—of economic development, management and environmental change on marine ecosystems. Overcoming such institutional barriers requires political will from government leaders as well as from businesses and civil societies across all sectors of human activity. For the benefit of both human and natural resource values, a defined mechanism to coordinate sector management and enhance collaboration within and among countries is essential for defining and advancing IOM. A complex adaptive systems lens has thus emerged as a new approach to help identify key indicators to refine IOM. The rapidly growing data and knowledge about our ocean will clearly add feasibility in this regard.

3.1 Components of Successful IOM

Every IOM plan depends on the country or region, as specific problems, challenges and institutional conditions vary and are highly context dependent. However, regardless of the legal underpinning of IOM, experience demonstrates that the following components are important:

- A survey of the existing institutional structures within a given context, including an assessment of agency authorities, how they overlap and their regulatory responsibilities.
- An evaluation of the current situation, variations and future trends in the environment and ecosystem by examining the available data and scientific knowledge, and initiation of science and monitoring programmes for establishing and maintaining marine data.
- An assessment of human activity information and trends, including conflicts of interest and cumulative impacts.
- Engagement of relevant ocean user groups.

These components must be structured thoughtfully for IOM to be effective. More importantly, every integrated ocean management plan should be specific to the country or region. The variation in institutional conditions and challenges also underlines the importance of local capacity building, particularly to enable the collection and adequate use of marine data and transformation of these data into useful information and knowledge.

3.1.1 Institutional structures

A legal structure can provide direction for IOM within or among nations, thus creating the context for defining and advancing cross-sectoral, long-term, ocean-related goals and objectives. In many cases this is absent, and alternatives such as interpreting existing law to take an integrated management approach, adding provisions to existing laws, issuing an administrative order or finding other mechanisms can also be effective. At the regional level, the European Union (EU) created the 2008 Marine Strategy Framework Directive (European Union 2008). This is an EU legal instrument that provides a framework and requirements for member countries to implement marine plans aiming for 'good environmental status' by 2021. A different example is from U.S. state Massachusetts, which created legislation with the Oceans Act of 2008 that provided authority and direction to create an ocean plan (Commonwealth of Massachusetts 2008). This act also provided guidance and identified representation categories for who should serve on the science and policy advisory bodies that made recommendations as the management plan was developed.

Reinterpreting or adding to existing legislation, or finding other mechanisms such as administrative orders and directives to establish authority for IOM, can facilitate improved coordination and supplement the sector-by-sector approach. The Netherlands took the reinterpretation-of-existing-law approach as it developed an integrated ocean management plan for its nearshore areas through an Inter-Ministerial Consultation Body for the North Sea involving all relevant ministries, such as defence, transport, public works and water management, economic affairs and the environment (Douvere and Ehler 2009). U.S. state Rhode Island voluntarily developed an ocean plan in partnership with the federal government that implements ecosystem-based management principles by reinterpreting the state Coastal Resources Management Council's authorising legislation within the national Coastal Zone Management Act (CZMA). The plan was approved by the National Oceanic and Atmospheric Administration's Office for Coastal Management, which enhances the state's influence in federal waters through the Federal Consistency provisions in the CZMA.

Legislative provisions can also be added to existing law to establish authority and provide clarity for developing a more holistic management process. This can potentially be achieved by adding provisions to legislation that regulates new ocean uses to make IOM a requirement for new development to be permitted. These provisions can include making strategic environmental assessments a requirement. Developing directive language that ensures positive outcomes for the regulated sector for which the original legislation was written is necessary to demonstrate the added value of requiring a more integrated approach with other sectors.

Administrative orders or directives can also be used to define a framework for coordinated management. These directives may articulate high-level targets and leave the definition of specific management goals and objectives to relevant regulatory agencies or planning entities. This approach was taken by the United States for its entire EEZ through an executive order from the president that instructed federal agencies to coordinate with state and tribal authorities to develop regional ocean plans for each Large Marine Ecosystem in U.S. waters (Executive Office of the President 2010; Lubchenco and Sutley 2010). The executive order provided a clear overarching mandate: to protect and restore ocean ecosystems to a healthy, productive and resilient state. Two regions, the Northeast and Mid-Atlantic, successfully completed and are implementing their regional ocean plans. Norway is another example demonstrating that IOM does not have to be grounded in law if political authority is provided. Norway's integrated management plan is based on mapping and assessing the status of marine ecosystems, identifying ecologically valuable and vulnerable areas and setting conditions for the use of ocean space including for the petroleum industry (Norwegian Ministry of the Environment 2006). These examples are further explored later in this paper.

It is recognised, however, that a comprehensive legal regime alone is not enough to achieve the desired outcome when, for example, illicit activities or lacking enforcement or capacity create a gap between the legal framework and reality.

3.1.2 Ocean and Coastal Data and Use Of Science

Many countries do not have enough monitoring and scientific capacity to provide the knowledge foundation required to implement the international governance frameworks they are bound by. The 2017 Global Ocean Science Report demonstrated clearly that many countries lack fundamental scientific capacity to underpin their efforts at ocean governance (IOC-UNESCO 2017). Scientific capacity to assemble the information required to manage the ocean's ecosystems and economic activities and establish regulatory measures needs to be developed. New technologies have revolutionised how governments can monitor and police inappropriate behaviour at sea. Global Fishing Watch, offering near real-time tracking of fishing activity via a public map, is an example of how new technologies and transparency can lead to improved means for sustainable governance. If such tools are combined with coordinated policing efforts and effective prosecution, they can become very powerful.

In developing IOM, it is critical to take a systematic approach to building scientific capacity that addresses the needs in the regions concerned. Capacity building needs to remain at the top of the international agenda. Regional solutions do have the potential to be effective, as demonstrated by ICES in the North Atlantic. Regional cooperation can help pool resources for IOM and facilitate the sharing of experiences. The UN Decade of Ocean Science for Sustainable Development (2021–2030) could be a suitable process and platform to accelerate the development and use of ocean science. The purpose of the UN Decade is to provide a common framework to ensure that ocean science can fully support countries' actions to sustainably manage the ocean and achieve the 2030 Agenda for Sustainable Development.

Furthermore, we recognise the extensive knowledge on the ocean that already exists. Thus, there is a need to not only foster new science but also use existing and historical information—and lack of data should not limit action. There must be explicit mechanisms in place in the IOM decision-making process to make use of existing science. A body of knowledge, for reference, exists on how to cope with data-poor situations in managing, for example, fisheries (Pilling et al. 2008). Incorporating traditional knowledge into the management process must also be a priority. The challenge is to integrate new information while simultaneously managing a dynamic ocean environment within IOM.

3.1.3 Engagement of Relevant User Groups

Planning at the local level, especially in developing countries and small island developing states (SIDS), requires taking approaches tailored to the diverse environmental, socioeconomic and governance systems in those regions. Incorporating local knowledge can ensure active community participation to develop appropriate strategies for IOM. Participatory approaches have proven to be effective at the local level for all phases of establishing and operating ocean governance. However, even with thorough planning, implementation remains constrained. Scaling up and reorienting local actions to larger-scale activities, governance regimes at national and regional levels and appropriate ecological scales are important and difficult and require specific time and resources in themselves (Fig. 14.2).

In the context of IOM, it is particularly important to engage ocean businesses at the global, national and local levels. There are different ways of organising this, and recent years have seen several cases of ocean businesses joining forces for sustainability. One example is the UN Global Compact Action Platform for Sustainable Ocean Business, which has developed principles and guidelines for sustainable ocean businesses—several of the largest ocean-related businesses globally have signed on to it.

Fig. 14.2 The Ecosystem is at the Core of Integrated Ocean Management. *Note: An ecosystem- and knowledge-based integrated ocean management ensures a sustainable ocean economy. Stakeholder engagement is key. (Source: Centre for the Ocean and the Arctic, Norway 2019)*

As will be demonstrated by the case studies later in this paper, while successful engagement processes will vary as they take into account the local context, engaging relevant user groups is always a central component of successful IOM.

3.2 The Case of the 'Collective Arrangement': Toward IOM in Area-Based Management in Areas beyond National Jurisdiction

The development of integrated ocean management approaches in areas beyond national jurisdiction (ABNJ) is hindered by legal gaps in the global ocean governance framework. One of the key functions of the new global agreement for the conservation and sustainable use of marine biological diversity beyond national jurisdiction (BBNJ) is to provide a legal framework for the development of a comprehensive approach to area- based management, including marine protected areas (Gjerde et al. 2019).

One of the few examples of how integrated approaches in area-based management in ABNJ can be developed is the 'Collective Arrangement' between the OSPAR Commission and the North East Atlantic Fisheries Commission, or NEAFC (NEAFC and OSPAR 2014). The objective of the Collective Arrangement is to facilitate cooperation on area-based management between legally competent organisations for the conservation and sustainable use of marine resources in the Northeast Atlantic. In 2010, the OSPAR Commission established the world's first network of marine protected areas in ABNJ. But OSPAR does not have the mandate to establish legally binding measures to regulate human activities such as fisheries, shipping or, in the future, deep seabed mining. However, in a parallel process, NEAFC as the competent organisation for fisheries management has closed fisheries to protect vulnerable marine ecosystems in broadly the same areas (Kvalvik 2011). Both organisations received scientific advice from ICES leading to a coherent approach in establishing those area-based measures. To facilitate future coordination and cooperation in the region, OSPAR and NEAFC set up the Collective Arrangement—which includes regular meetings between the parties and exchanges of relevant information and planned activities—and invited others, including the IMO and ISA, to join (Ásmundsson and Corcoran 2015).

The agreement has already demonstrated its value by providing a framework for consultations with other sectors in the process of establishing new high seas MPAs in the Northeast Atlantic, though it remains somewhat incomplete without the other management bodies. The Collective Arrangement does not include any legal changes to the current governance framework in the Northeast Atlantic. Instead, it can be seen as a first step in the departure from a purely sectoral approach in ocean management to a more integrated one that could inform the development of comparable approaches in other regions and the negotiation of the new global legally binding agreement for marine biodiversity in areas beyond national jurisdiction.

3.3 A Healthy, Productive and Resilient Ocean for Long-Term Economic Growth

The overall goal of IOM is to enable economic development while maintaining a healthy ocean ecosystem. The ocean has always attracted multiple uses, including fisheries, oil and gas extraction, shipping and transportation, military, mining, and recreation, among others. Many areas attract a variety of competing uses, which cause conflicts between users (user-user conflicts) and users and the environment (user- environment conflicts) (Tuda et al. 2014). The need to minimise user-user and user-environment conflicts while taking advantage of new economic opportunities offered by the ocean—and maintaining a sustainable marine ecosystem—has seen increased interest and action at varying political levels in the spatial management of marine resources (Gustavsson and Morrissey 2018; Domínguez-Tejo et al. 2016).

Marine spatial planning is an emerging paradigm for sustainable ocean management (Douvere 2008; Domínguez-Tejo et al. 2016) and the operationalisation of a sustainable ocean economy. MSP aims to move away from a traditional, sectoral focus to a more holistic approach which takes into account the full use of the ocean space (White et al. 2012). Within the sustainable ocean economy framework, MSP should ideally be a means of creating an optimal investment climate for maritime sectors and give operators more certainty as to what opportunities for economic development are possible, though inequity, greater conflict and faster rates of degradation may occur if not calibrated appropriately with ecosystem goals and monitored over time. As a management tool, MSP allocates areas of the ocean for different uses and activities to reduce conflicts and achieve ecological, economic and social objectives. A key theme of MSP is the adoption of an ecosystem-based approach to ocean management. This involves focusing on the functional relationships and processes within the marine ecosystem, paying attention to the distribution of benefits that flow from ocean ecosystem services, using adaptive management practices, carrying out management actions at multiple scales and cooperating at an intersectoral level (Douvere and Ehler 2009). This approach is in direct contrast to current ad hoc, sector-by-sector responsibilities and practices for the management and regulation of ocean activities.

Although MSP is currently underway in 66 countries worldwide, only 22 countries have government-approved marine spatial plans (Santos et al. 2019).

4 Integrated Ocean Management in Practice

Below are a set of case studies selected to illustrate differences in implementation goals, jurisdictional types and management scales of IOM in different parts of the world: the Coral Triangle, the Seychelles, Norway, the United States and China (Fig. 14.3). There are common traits among them, such as the need for robust information about the relevant ecosystems and human activities, the need to tailor IOM to local contexts and the use of mechanisms to estimate the cumulative impact of uses and pressures on marine ecosystems.

4.1 The Coral Triangle and the Seychelles

Tropical nearshore coastal ecosystems (i.e. mangrove forests, seagrass beds and coral reefs) are among the most diverse and productive ecosystems in the ocean. A wide range of stakeholders, particularly low-income coastal communities, are highly dependent on the goods and services provided by these ecosystems, which are also the most vulnerable to climate change. Strengthening the resilience of these ecosystems to sustain the direct and indirect goods and services they provide is at the core of ocean management initiatives at the national and transnational levels.

This section discusses how IOM has been used with a focus on climate change adaptation, marine protected areas and fisheries management to address social, economic and conservation objectives simultaneously in some SIDS—here exemplified by the Coral Triangle (Indonesia, Malaysia, Papua New Guinea, Philippines, Solomon Islands and Timor-Leste) and the Seychelles.

4.1.1 Conservation and the Case of Fisheries Management in the Coral Triangle

MPAs range from small, local and community-based networks to national networks to regional, multistate initiatives. In SIDS, most MPAs are managed by local community members, particularly small-scale fishers. Since these MPAs are small, there is often a spatial mismatch relative to important ecological processes (Horigue et al. 2012; Mills et al. 2010). To date, a major challenge with implementing MPAs has been that they are seen as serving conservation or protectionist interests, not human interests, thus driving a top-down, nature-centric agenda that alienates local communities and ends up marginalising conservation. If MPAs are seen as promoting only a nature-centric agenda and not supported by local users, or their relevance to recovering depleted fisheries is not obvious, then a more comprehensive approach involving ecosystem- based management, marine spatial planning or ocean zoning might be a better option. Nonetheless, area-based management measures are important and the most

Fig. 14.3 Map of Case Studies of IOM in Practice. (*Source: Authors*)

prevalent management intervention used to meet conservation and fisheries management goals in developing tropical states, including SIDS. To maximise their impact, MPA planning should be integrated into broader marine spatial planning and ocean zoning efforts (Agardy et al. 2011).

Regarding effectiveness, improvements in fish biomass—including the recovery of functionally important groups reported for many small MPAs—indicate that conservation objectives can also be achieved at the local scale. For example, in community-based MPAs in Papua New Guinea that protect grouper aggregations, there was a 10-fold increase in the reproductive population compared with an unprotected site after five years (Hamilton et al. 2011). In the Philippines, a study on fish biomass showed that 32 percent of MPAs had estimated fish biomass within and above the estimated maximum sustainable yield (MSY) (McClanahan et al. 2015). However, further research (Muallil et al. 2019) found that areas adjacent to the MPAs were below the MSY. This indicates that small, locally managed MPAs alone are not enough for coral reef fisheries management. However, despite limited perceived impact on improving the state of the local fisheries resources, community- based MPAs have been effective in empowering the local fishing communities (Maliao et al. 2009). Thus, the MPAs provide social benefits and enable active community participation in resource management. Further, demonstrating the local impacts of MPAs has been important in sustaining and scaling up efforts.

On a regional scale, MPAs are part of a holistic approach of the Coral Triangle Initiative on Coral Reefs, Fisheries, and Food Security (CTI-CFF). The CTI-CFF is a formal intergovernmental partnership among the six countries: Indonesia, Malaysia, Papua New Guinea, Philippines, Solomon Islands and Timor-Leste to sustain marine and coastal resources and address food security, climate change and marine biodiversity. The adoption of a regional plan of action (RPOA) by member countries and implementation of national plans of actions illustrate implementation at regional and national levels. Establishment of marine protected areas and networks is a centrepiece of national plans on integrated coastal resources management to address conservation and local fisheries enhancement.

Box 14.2 Goals and Targets of the Coral Triangle Initiative's Regional Plan of Action

The regional plan of action of the Coral Triangle Initiative (CTI) has the following goals and targets:

- Goal 1: 'Priority Seascapes' Designated and Effectively Managed
  – Target 1: 'Priority seascapes' are designated, with investment plans completed and sequenced.
  – Target 2: Marine and coastal resources within all priority seascapes are sustainably managed.
- Goal 2: Ecosystem Approach to Management of Fisheries and Other Marine Resources Fully Applied
  – Target 1: Strong legislative, policy and regulatory frameworks are in place for achieving an Ecosystem Approach to Fisheries Management (EAFM).
  – Target 2: Improved incomes, livelihoods and food security exist in an increasingly significant number of coastal communities across the region through a new sustainable coastal fisheries and poverty reduction initiative ('COASTFISH').
  – Target 3: Effective measures are in place to help ensure that the exploitation of shared tuna stocks is sustainable, with tuna spawning areas and juvenile growth stages adequately protected.
  – Target 4: More effective management of and a more sustainable trade in live reef fish and reef-based ornamentals is achieved.
- Goal 3: Marine Protected Areas Established and Effectively Managed
  – Target 1: The region-wide Coral Triangle MPA System is in place and fully functional.
- Goal 4: Climate Change Adaptation Measures Achieved
  – Target 1: The region-wide Early Action Plan for Climate Change Adaptation for the nearshore marine and coastal environment and small island ecosystems is developed and implemented.
  – Target 2: Networked national Centers of Excellence (COEs) on climate change adaptation for marine and coastal environments are established and in full operation.
- Goal 5: Threatened Species Status Improving
  – Target 1: Improved statuses are achieved for sharks, sea turtles, seabirds, marine mammals, corals, seagrass, mangroves and other identified threatened species.

Source: Coral Triangle Initiative 2019.

The RPOA is guided by principles of integration, inclusive stakeholder participation, multilevel governance mechanisms to implement action plans, and recognition of the uniqueness, fragility and vulnerability of island ecosystems. There are technical working groups for each of the five programmes to address each goal; government working groups for financial resources, monitoring and evaluation; and other committees for various cross-cutting themes for capacity building, such as a regional leaders' forum, a female leaders' forum and local government networks. The CTI-CFF also has international development partners and collaborators that provide financial and technical assistance.

To support systematic conservation planning, guidelines for designing marine reserve networks within broader spatial planning and management frameworks to address biodiversity conservation, fisheries management, climate change adaptation and coastal management have been formulated (Green et al. 2014). A geospatial database and analyses of those data have been useful to inform planning efforts at different scales and provide a knowledge base for improved decision-making (Asaad et al. 2018, 2019). National plans of action support the regional goals through national interagency and multisectoral partnerships and programmes. Each member country has its own implementation activities aligned with improving governance of the ocean.

4.1.2 Climate Change Adaptation in the Seychelles

Coping with climate change impacts, such as sea level rise, is complicated in the SIDS because of the countries' small sizes, isolation and exposure, and high dependence on natural resources for their populations' livelihoods. Ecosystem-based adaptation (EBA) has been highlighted as one approach to address declines in ecosystem health and enable sustainable adaptation to climate change at national or community scales.

As in other countries, MSP has been used to support ecosystem-based management.

The Seychelles was the first nation to participate in an ocean-based debt-for-nature swap. Part of the agreement required incorporating climate change adaptation into a marine spatial planning process in support of the country's ocean economy goals. The goals of the Seychelles Marine Spatial Plan (SMSP). Initiative are to address climate change adaptation, protect 30 percent of the Seychelles' waters, including 15 percent with high protection status, and support the Blue Economy Roadmap and other national strategies. The geographic scope of the SMSP Initiative is the entire 1.4 million square kilometres (km^2) of the EEZ and territorial sea. The process is led by the Ministry of Environment, Energy and Climate Change of the government of the Seychelles (GOS), with planning and facilitation managed by The Nature Conservancy (TNC) and TNC Canada, in partnership with the government management system for the United Nations Development Programme (UNDP) and the Global Environmental Facility (GEF) environmental programme in the Seychelles (the GOS-UNDP-GEF Programme Coordination Unit). Funding for the initiative is being provided through several grants to the government of the Seychelles from The Nature Conservancy and a number of philanthropic foundations, and through the creation of blue bonds.

The MSP Executive Committee has representation from all the ministries and parastatal agencies related to the marine sectors. The process includes public workshops and public information sessions to generate input from all major sectors including commercial fishing, tourism and marine charters, biodiversity conservation, renewable energy, port authority, maritime safety, and non-renewable resources (SMSP Initiative 2019). The process began in February 2014 and will be completed by December 2020. The SMSP Zoning Framework has three zones: high biodiversity protection; medium biodiversity protection and sustainable use; and multiple use.

Existing uses were mapped in 2014–2015 and are used to inform proposals for new marine protection areas. Notably, the SMSP Initiative is a component of the government-led Debt-for-Climate-Change-Adaptation swap. The Seychelles Conservation and Climate Adaptation Trust, which was operationalised in November 2016 to fund climate change adaptation and conservation projects in the Seychelles, will also provide partial funding to implement the SMSP Initiative.

Other SIDS have not gone through a national, government-led, comprehensive MSP process as that in the Seychelles but have experiences in ecosystem- based management and spatial planning linked to climate change adaptation (CCA) strategies. However, these experiences have often not been successful without a national, government-led framework. This demonstrates that both political will and funding are needed in addition to robust stakeholder engagement processes. For example, in the central Pacific, top-down coastal adaptation approaches usually fail because coastal communities in the tropical Pacific have customary land, island and coastal tenure, supported by traditional governance (Grantham et al. 2011). To facilitate active participation, global climate change is addressed in the Pacific context in discussions with communities. Traditional adaptations—for example, to maintain food security given unpredictable climate events—are incorporated in CCA planning to engage communities and boost awareness. Planning is primarily small scale, with bottom-up processes directly engaging local communities through participatory approaches supporting spatial planning. In the Caribbean, an analysis by Mercer et al. (2012) has shown inconsistencies in EBA theory and practice. The CCA plan in the Caribbean centred upon coastal ecosystems at a regional level as opposed to the full range of ecosystems, which is especially important given the tight linkages between terrestrial and marine ecosystems in small island states. Likewise, integrating local knowledge with external knowledge was identified as a gap in developing appropriate context-specific adaptation strategies (Mercer et al. 2012).

4.1.3 Challenges and Lessons Learned

There are various ongoing initiatives in SIDS and tropical island developing states that are working toward a more integrated ocean management regime. We have presented two examples where key priorities have focused on improving the resilience of coastal communities and marine ecosystems linked to the overarching need for climate change adaptation. Despite various challenges, experiences in planning and ecosystem-based management provide valuable lessons that may help make future efforts more efficient and effective.

First, planning at the local and national levels requires taking into consideration the local environmental, socioeconomic and governance systems. In all cases, stakeholder participation and incorporation of local knowledge are essential in developing appropriate strategies. Experiences in these countries indicate that ecosystem-based management and MSP should build on and strengthen community-based management. Participatory approaches have been demonstrated to be effective at the local level for climate change adaptation planning and all phases of the MPA process (i.e. MPA planning, implementation, monitoring and evaluation, feedback and adaptation of the management plan).

Second, scaling up and reorienting local actions to larger-scale activities and appropriate ecological scales are essential and require improved governance regimes at national and regional levels. In many cases, even with improved planning, implementation remains constrained. There are many challenges to integrated ocean management in the CTI (Weeks et al. 2015) that constrain effective implementation at the regional and national levels. They include a failure to institutionalise conservation planning within governments at different levels nationally and systematic planning across nations with different governance systems, poor integration of planning efforts across these governance systems and levels, and failure to overcome short-term funding and political cycles relative to long-term planning and implementation timeframes (Weeks et al. 2015). Funding and technical support for IOM planning including MSP in the CTI and SIDS have been facilitated through various development programmes, partnerships with nongovernmental organisations (NGOs) and public- private partnerships, but national funding mechanisms for the long-term implementation of plans, such as the Seychelles Conservation and Climate Adaptation Trust, are needed (SMSP Initiative 2019).

Third, formal and informal social networks for data sharing and capacity building are essential at different levels of government to accelerate integration and scale. Regional alliances such as the CTI have been forged to facilitate regional and broader-scale policy support and frameworks to harmonise national plans of actions. The SIDS Accelerated Modalities of Action (SAMOA) pathway is anchored on the conviction that sustainable development can be achieved through strong partnerships. These high-level alliances are supported by social networks for capability building and implementation, and multisectoral consortia of private and public organisations, researchers, practitioners, and policy-makers. Examples include Many Strong Voices, a collaboration between the Arctic and SIDS (Mercer et al. 2012), and the MPA Support Network in the Philippines (Horigue et al. 2012).

Knowledge gaps on socioecological interactions at various scales are a persistent limitation in integrated ocean management planning and implementation in the SIDS and CTI (e.g. Khan and Amelie 2015; Mills et al. 2010). To help support capacity building and address the lack of sufficient information, technical assistance programmes on MSP have been provided, studies to address data gaps (e.g. socioeconomic data) undertaken and information compiled to make it more accessible (e.g. in databases). For example, the CTI atlas, initiated through partnerships among international NGOs supporting the CTI, is a repository of geospatial information and used to track progress. However, keeping the information up-to-date and enhancing functionality remains a challenge due to a lack of local capabilities and financial resources (Cros et al. 2014; Asaad et al. 2019).

4.2 The Norwegian Ocean Management Plans

Norway's ocean areas span 3,000 km from boreal to polar climates and measure 2.1 million km^2, five times the country's land area. The dominate physical influence is the Atlantic current transporting heat from the southwest Atlantic to the north, making the country (and northwestern Europe) several degrees Celsius warmer than corresponding latitudes in North America. Its three major marine regions are the Barents Sea in the north, the Norwegian Sea, and the North Sea in the south. While the Barents and North Seas are shallow shelf seas, the Norwegian Sea is a deep ocean with a narrow continental shelf along the coast. Ocean currents and other oceanographic conditions are favourable for biological productivity, and these seas are therefore very rich in fish resources. Also, the fjords provide favourable conditions for aquaculture, and the continental shelves contain abundant petroleum resources as well as other minerals.

The Barents Sea (1.4 million km^2) is divided between Norway and Russia following a boundary agreement in 2010 and is limited to the north by the high seas in the central Arctic Ocean. The Norwegian Sea is bound to the west with the waters of Greenland, Iceland and the Faroes, as well as the high seas there. In the North Sea, Norway's waters (and continental shelf) meet those of the United Kingdom, Denmark and Sweden (Fig. 14.4). That Norway shares ocean boundaries with seven other countries is an important determinant of its marine policies, as transboundary resources and ecosystems require international cooperation for their management, at bilateral as well as regional levels of coopera-

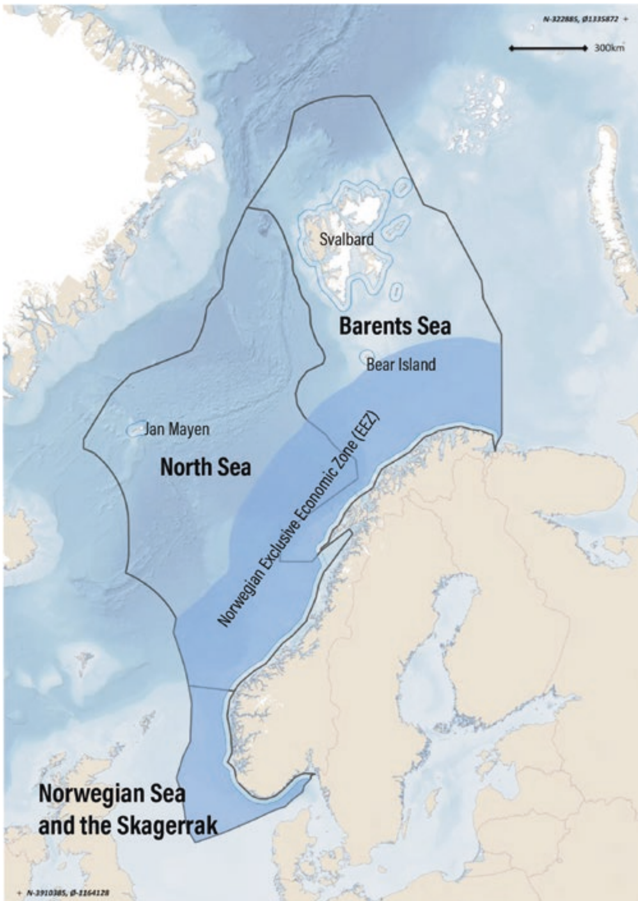

Fig. 14.4 Map of Norway's Marine Management Plan Areas. (*Source: Data from Barentswatch 2020 (*https://kart.barentswatch.no/ *arealverktoy). Map by Centre for the Ocean and the Arctic, Norway 2020*)

tion. Another important determinant is the global framework for ocean governance described at the outset of this paper.

4.2.1 Economic activity and ocean governance

Petroleum is by far the most important industry in Norway, contributing US $60 billion in 2018—approximately one-quarter of Norway's export earnings. Fisheries and aquaculture contribute about $11 billion in export value. In addition, shipping, shipbuilding, tourism, petroleum services and other ocean-related activities are significant contributors to Norway's ocean economy, together constituting 70% of the national gross domestic product. Recent developments include increasing interest in renewables, exploitation of new species of living marine resources, minerals other than petroleum and marine bioprospecting. The ocean economy is critical to the welfare of both the general population and, in particular, coastal communities.

The management of the ocean has evolved over centuries, with active government regulation in the fisheries sector dating back to at least the mid-1800s. The petroleum and aquaculture industries started in earnest in the 1970s and were accompanied by the development of management institutions and legal regimes for their regulation. At the same time, regulations to protect the marine environment were established. Since then, the regulatory regime has evolved significantly. Today, all major sectors—including petroleum, the environment, transportation, fisheries, aquaculture and minerals—have modern and effective regulatory regimes based on sector-specific acts.

Following the growth in the ocean economy, the need for more and better regulation of the various economic activities was accompanied by a need for more oversight over an increasingly complex regulatory environment—to reconcile competing interests and address management challenges in an integrated and comprehensive manner (Hoel and Olsen 2012). The issue was first recognised in the 1970s, with efforts to this end in relation to petroleum activities and fisheries. The northward expansion of the petroleum industry brought a recognition that more comprehensive approaches to ocean management were needed. A report to the Norwegian Parliament in 2002 represented a turning point in this regard, laying the foundation for what became the management plans for the ocean and explicitly recognising the need to manage entire ecosystems as opposed to individual sectors and activities (Norwegian Ministry of the Environment 2002).

4.2.2 Comprehensive management plans

The first comprehensive management plan for the Barents Sea and the coast of northern Norway was adopted by the parliament in 2006 (Norwegian Ministry of the Environment 2006). The plan's overall objective was to facilitate value creation through the sustainable use of natural resources and goods while maintaining the structure, functioning and productivity of ecosystems. [2] Its geographic scope was limited to the waters outside one nautical mile off the baseline with nearshore ocean and coastal zone management outside the remit of the plan. It was also limited in time, foreseeing regular updates as new knowledge became available. Key features of the plan were the identification of valuable and vulnerable areas, and limitations on where petroleum activities could take place. Updates to the plan were adopted in 2011 and 2015. The first plan for the Norwegian Sea was adopted in 2009 and updated in 2017. The first North Sea plan was adopted in 2013. Apart from the effects of climate

[2] The original text in Norwegian reads as follows: 2022 'Formålet med denne forvaltningsplanen er å legge til rette for verdiskaping gjennom bærekraftig bruk av. ressurser og goder i Barentshavet og havområdene utenfor Lofoten og samtidig opprettholde økosystemenes struktur, virkemåte og produktivitet.'

change, the challenges are rather different in the three areas covered by the plans.

The foundation of the work on the plans is an ambitious scheme for collecting and assembling information about the marine ecosystems, undertaken in the course of fisheries surveys and mapping programmes (Olsen et al. 2014). This work is institutionalised in the Advisory Forum on Monitoring, with participation from central research institutions and agencies. Stakeholder consultations are also an important element in the decision-making process. The development of the scientific and practical basis for the plans is carried out by a coordination group consisting of government agencies, now called the Management Forum on Norwegian Sea Areas. The work is overseen and coordinated at the ministerial level by a group of ministries coordinated by the Ministry of Climate and Environment. The interministerial group is responsible for developing the actual management plans and reconciling the various concerns that are brought to bear on the work. In 2020, the work on the three plans will be merged into one report to the parliament, and subsequent updates and revisions will occur on a decadal basis (Fig. 14.5).

4.2.3 Challenges and Lessons Learned

After nearly two decades of work, Norway offers several important lessons on holistic ocean management. The first is that the work relies on comprehensive and demanding scientific monitoring (Olsen et al. 2016). These monitoring efforts are largely part of regular monitoring programmes as opposed to efforts designed specifically to monitor work related to the management plans.

Second, at the level of the two forums, the work on the plans has brought research institutes and agencies from vari-

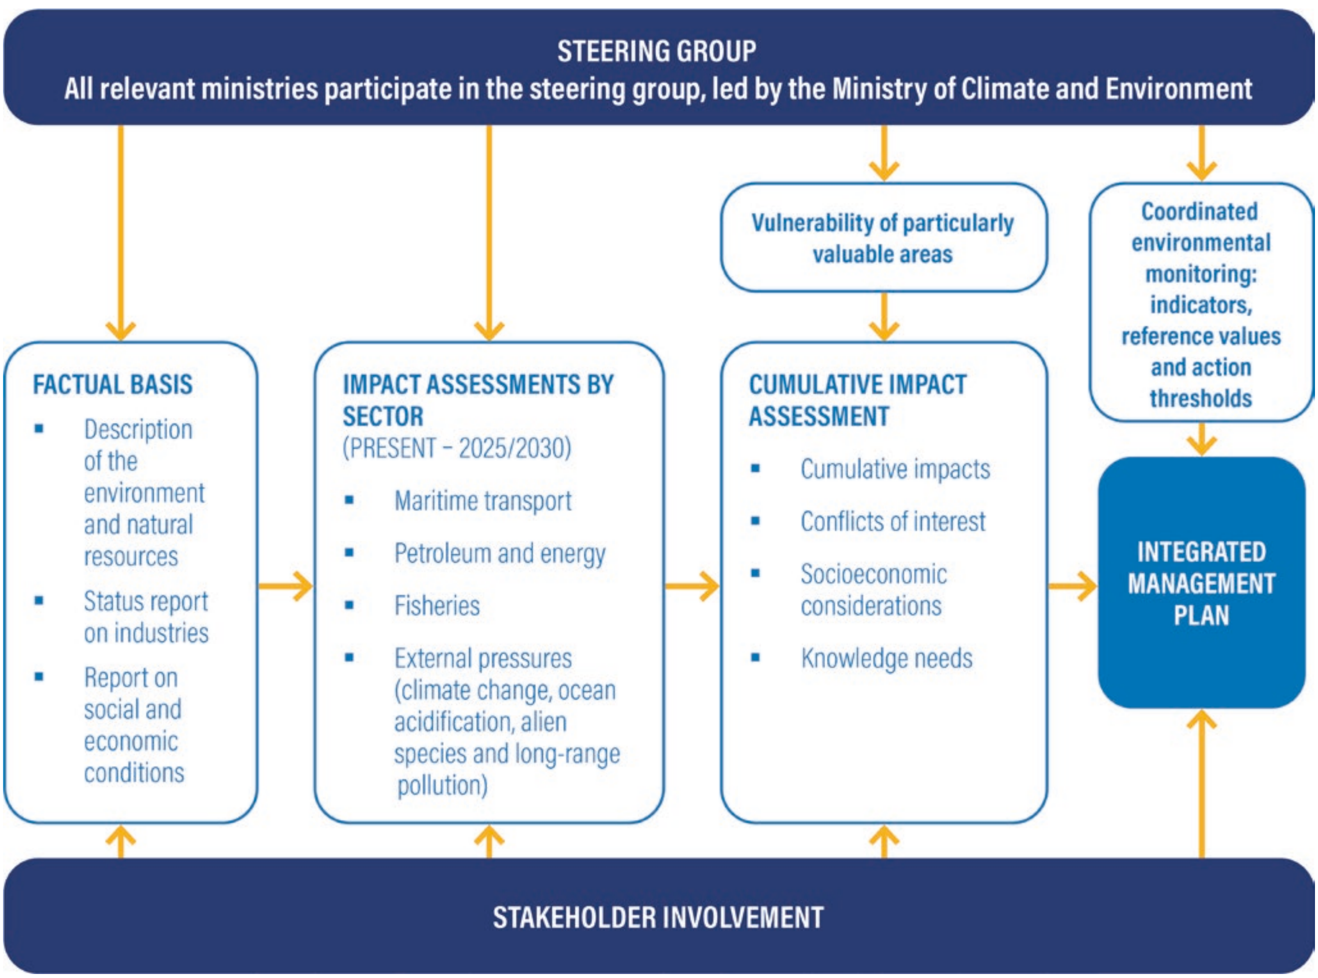

Fig. 14.5 Process for Developing an Integrated Ocean Management Plan in Norway. (*Source: Norwegian Ministry of the Environment* 2009)

ous sectors together, contributing to a better understanding of each other's missions and methods.

Third, the plans are adopted by parliament based on government white papers, lending the plans political authority.

Fourth, the plans are implemented through sector-based legislation and regulatory measures. The management plans are just that—plans. However, since they are adopted by parliament, and reflect compromises in government, they represent national policy. Modern and efficient sector-based legislation is an effective vehicle for bringing the plans from paper to practice.

Fifth, the plans evolve over time as new scientific knowledge is generated and new management challenges arise. It is important that the plans be dynamic and provide for adaptive management through regular updates and revisions.

4.3 Approaches to Integrated Ocean Management in the United States

The United States has approached integrated ocean management at three scales: state, regional (multiple state) and national. Several U.S. states—Massachusetts, Rhode Island, Washington, Oregon, New York and Connecticut—have developed ocean plans for state waters (0–3 nautical miles offshore). Regions, comprised of multiple states and defined mostly by ecosystems, have worked toward IOM within federal waters (3–200 nautical miles), in response to and consistent with a national directive in the form of a presidential executive order. State plans often have a clear legal structure through legislation that provides direction for integrated ocean management as was the case for Massachusetts, Washington, Oregon and Connecticut. States that do not have a clear legal structure for IOM can also develop and implement ocean plans by reinterpreting existing legal authorities, as Rhode Island did. Regional IOM plans were developed in response to an executive order that provided guidance for regions to take an ecosystem-based management approach. As part of the executive order, federal agencies with a stake in ocean management were directed to engage with regional planning bodies to develop plans for areas where there was interest in improving coordination among management agencies (Executive Office of the President 2010). The executive order directed federal agencies but engagement by states and tribes was voluntary.

4.3.1 Northeast and Mid-Atlantic Regional Ocean Plans

Administrative orders or directives can define a framework for coordinated management. These directives may articulate high-level targets but look to regulatory agencies to define specific management goals and objectives. The ocean plans in the Northeast and Mid-Atlantic regions of the United States, which largely align with major ecosystems, are examples of management plans developed without an overarching legislative structure to provide a directive or framework. Both plans were created through a presidential executive order that provided an overarching mandate, outlined federal authority, and built on the existing legal authorities of management agencies. The order provided guidance for regions to take an ecosystem-based management approach through the development of ocean plans, but no new laws were created (Executive Office of the President 2010). Planning was voluntary, and two of the nine defined regions of the United States completed plans by late 2016. In 2018, a new presidential administration rescinded the earlier executive order directing management agencies to develop plans. A new executive order was issued that allows planning to continue in those regions where IOM is supported and directs federal agencies to coordinate with states and regions to solve management challenges (Executive Office of the President 2018). Such political transitions can challenge the stability of IOM, especially in cases with no overarching legislative structure.

The Northeast and Mid-Atlantic regions, where Massachusetts and Rhode Island had already developed state ocean plans, were the first two regions to advance more integrated approaches to ocean management. The impetus for regional planning was a combination of the collaboration among state, tribal and federal management authorities and ocean users already ongoing in the region, leadership provided by state and federal agency representatives, political will and an interest in avoiding potential conflicts with existing users and emerging industries such as offshore renewable energy. The Northeast and Mid-Atlantic regions both completed regional ocean plans in 2016 (Northeast Regional Planning Body 2016; Mid-Atlantic Regional Planning Body 2016) (Fig. 14.6). Goals for both regional plans focused on the following:

- Improving decision-making by coordinating managing authorities and stakeholders, coordinating early in the process and enhancing awareness of human activity needs, interests and resources.
- Promoting healthy ocean and coastal ecosystems by characterising the region's ecosystems, economy and cultural resources, and by identifying opportunities to conserve, restore and maintain healthy ecosystems.
- Ensuring compatibility among past, current and future ocean uses.

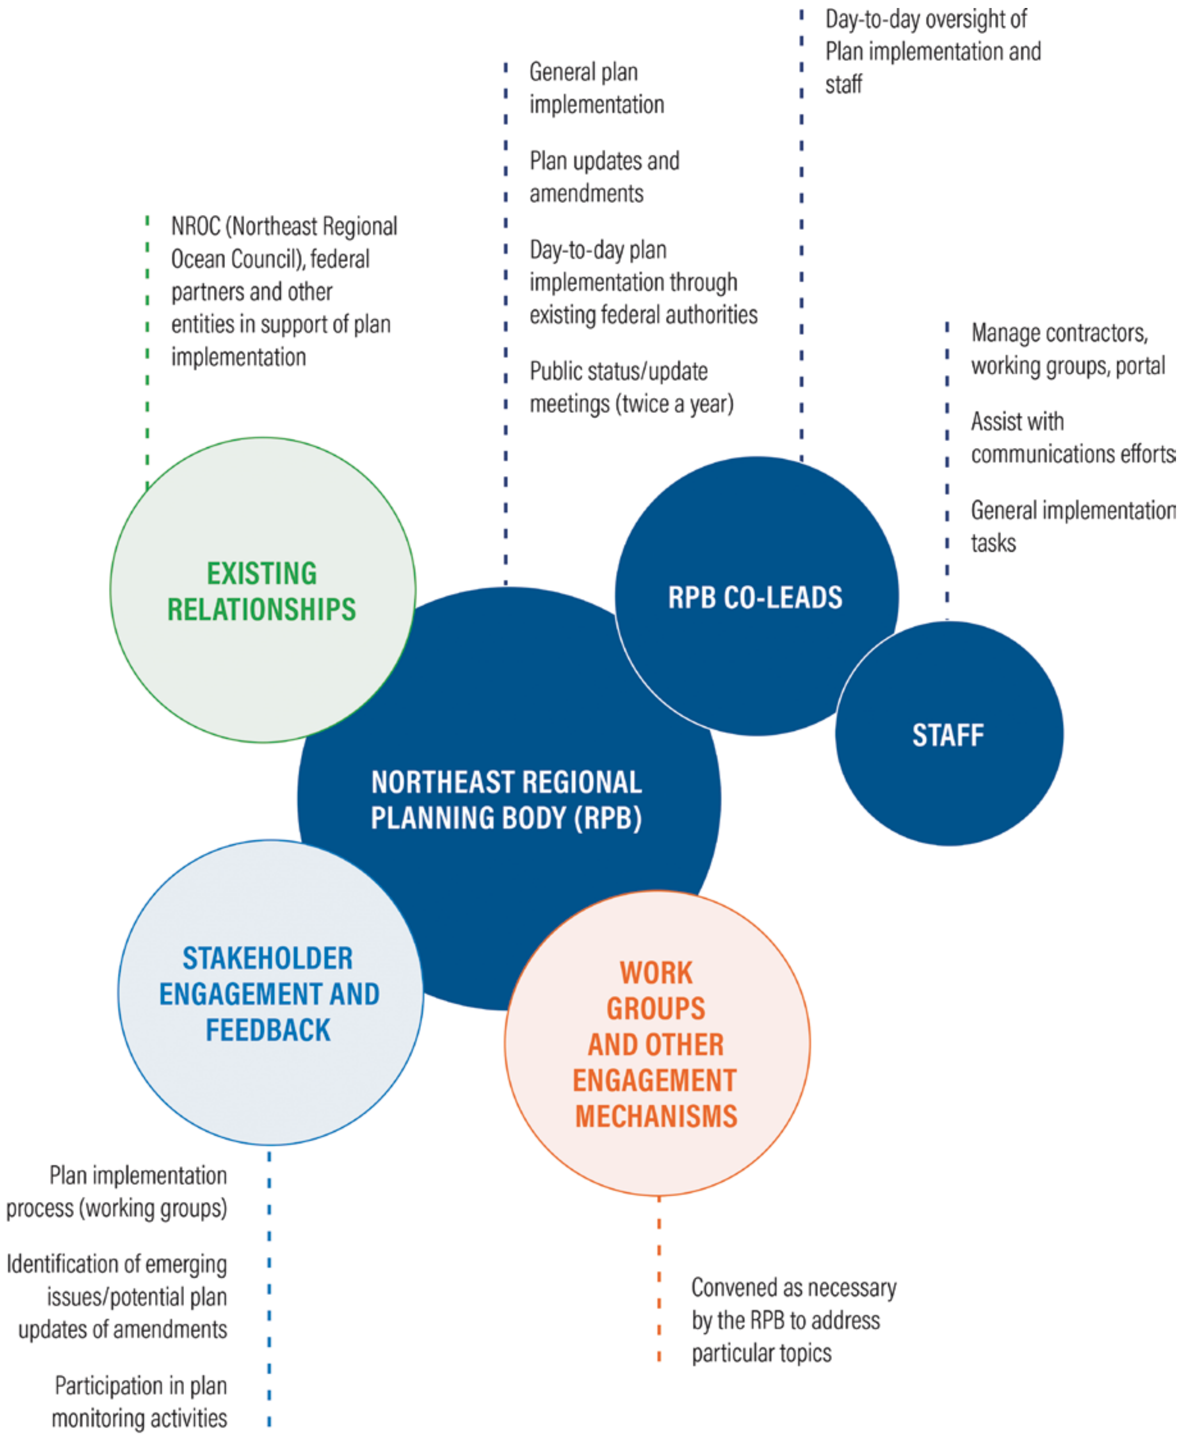

Fig. 14.6 Framework for Implementing the Northeast Ocean Plan. (*Source: Northeast Regional Planning Body* 2016)

With regional plans now in the implementation phase, it is apparent how public and private sector organisations are benefitting from the data information systems—referred to as 'regional ocean data portals'—that were developed as part of the ocean plans. Examples of how the Northeast Ocean Data Portal has been used include the following (Northeast Ocean Data 2009):

- To create a new economic opportunity by establishing the first shellfish aquaculture farm in federal waters off the Atlantic coast.
- To increase maritime safety and improve weather forecasts through a wave-monitoring buoy.
- To select a test site for an unmanned underwater vehicle for the United States Navy.
- To assist the New England Fishery Management Council in balancing deep-sea coral protection and commercial fisheries.

4.3.2 Balancing Ecosystems and Economy with the Rhode Island Ocean Special Area Management Plan

As the United States enters a new era with offshore renewable energy innovation, a project in Rhode Island demonstrates the value of using an IOM approach. Faced with increased demands on ocean space, an ambitious renewable energy goal for the state and political leaders interested in advancing offshore wind, the state management agency, the Coastal Resources Management Council, took the lead in developing an Ocean Special Area Management Plan (McCann 2010). With an overall goal of balancing ocean resources with development, the state created an open and transparent planning process that was backed with science, critical stakeholder input and productive public fora (Fig. 14.7).

Data collected through this plan not only identified a renewable energy area that would minimise conflicts with other ocean users and ecological resources but also provided information on aspects like key fishing grounds, marine mammal migration routes and recreational boating activities.

4.3.3 Challenges and Lessons Learned

IOM can be harder to achieve without a mandate and structure defined by law. For states with new legislation directing management agencies to coordinate and develop plans, it was, in general, easier to define goals and objectives because legal authority and overall direction were clear. Reinterpreting existing legal structures is also an option, as demonstrated by the Rhode Island experience. External drivers such as a new ocean use or emerging technology can stimulate integrated management approaches by creating the political and societal will for IOM.

In the case of regional plans developed through an executive order, administrative leadership provided the overarching mandate of maintaining healthy ocean ecosystems. The executive order also created clear direction for federal agencies to act within their legal authorities to coordinate among agencies and with states to advance IOM. The challenge is that these orders are voluntary for states so the key players in the regions—including representatives from states, tribes, fishery management councils, industry, academia, nongovernmental organisations and local communities—must perceive added value from taking a holistic, integrated approach. In the United States, two of the nine regions have completed integrated ocean management plans and an additional one is in development. If a state, region, territory or nation wants to commit itself to IOM, the clearest and most efficient path is with a new law directing specific actions. However, other approaches can be taken depending on political context and institutional arrangements.

Under the United States system outlined above, experience demonstrates that data and information are the foundation of IOM. Ocean businesses want managers to understand their interests when developing a comprehensive management plan. Data and specific information help managers demonstrate their understanding of different ocean uses. Ocean users should have an opportunity to provide and verify data, and therefore see their activities reflected explicitly within the IOM process. This data can be used to describe not only existing human activities or ecological resources but also future goals and trends. Developing a regional ocean data portal (information management system) that is open and transparent and has all relevant data, including the metadata, in a central location will go a long way toward building support from decision- makers, local communities, scientists, nongovernmental organisations and various sectors of human activity.

If resources and available data permit, government entities should consider prioritising the development of information management systems, referred to in the United States as ocean data portals. A centralised ocean data portal not only improves coordination among various management agencies with responsibility for human use activities but also has the potential to improve coordination among ocean users who can now view all activities in one central location. A data portal is not needed to define societal objectives and express those in a holistic plan, but the United States' experience demonstrates their value for facilitating an integrated management approach.

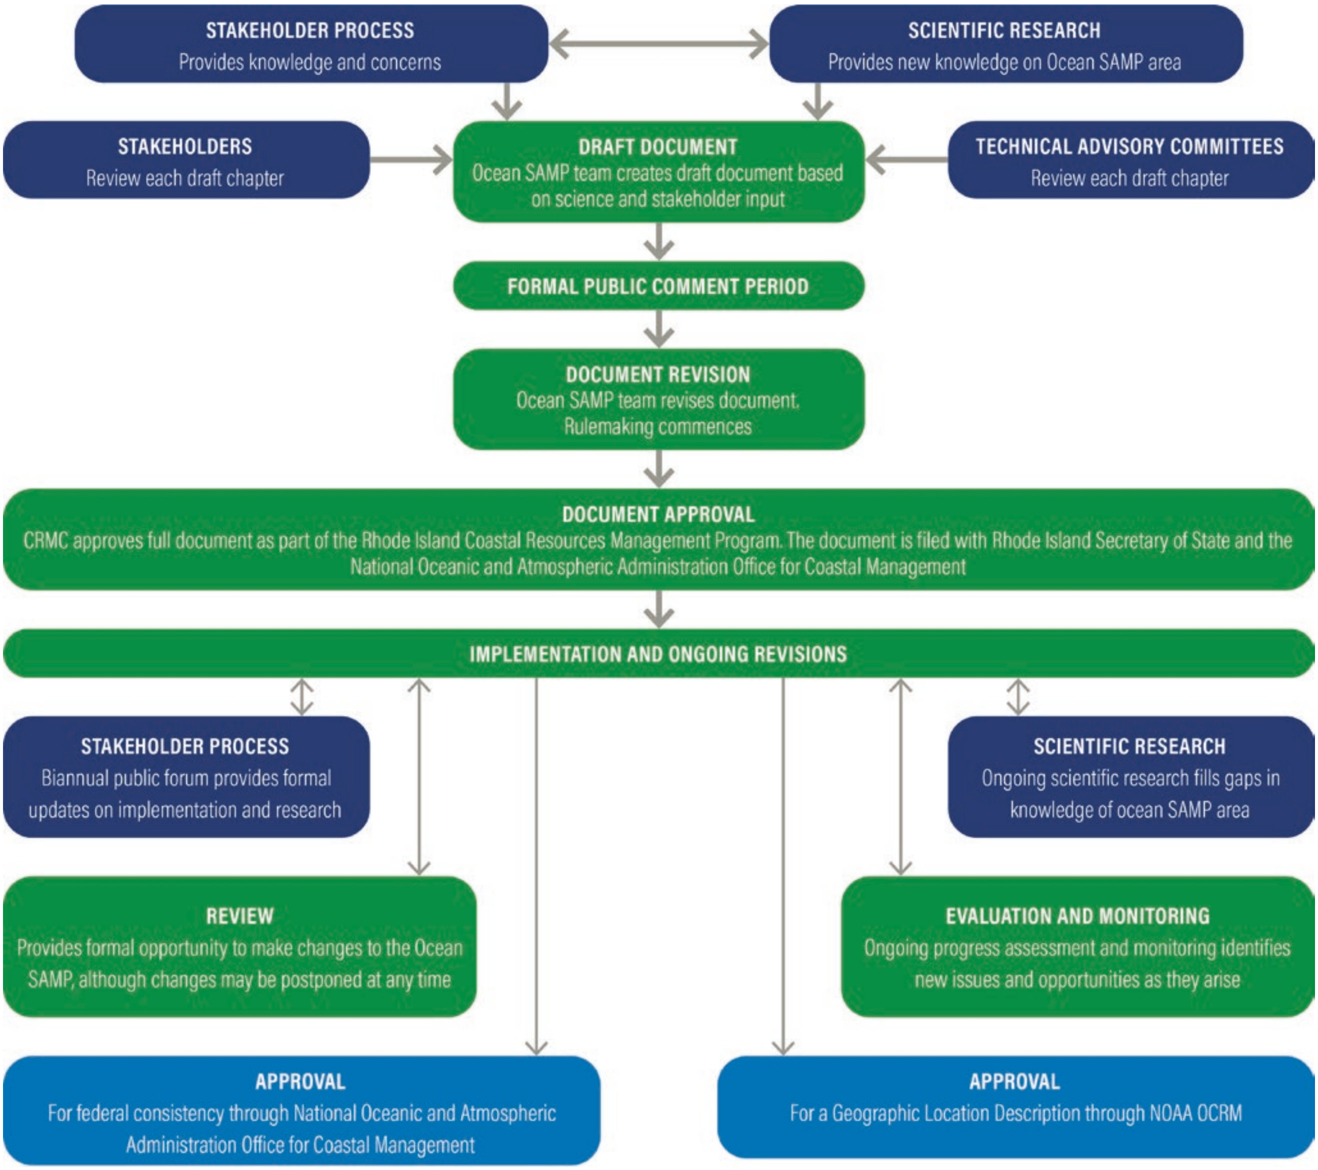

Fig. 14.7 Methods Flowchart for the Rhode Island Ocean Special Area Management Plan. (Note: CRMC stands for Coastal Resources Management Council and NOAA OCRM for National Oceanic and Atmospheric Administration Office for Coastal Management. NOAA approved as a state plan amendment May 11, 2011 (Federal Consistency authority granted for state waters). NOAA approved Geographic Location Description for federal consistency September 2011 (Federal Consistency authority granted for Federal Waters in the GLD for 15 Federal Authorizations which now needed Consistency sign offs by CRMC). (*Source: Adapted from Mulvaney* 2013)

Stakeholders, or ocean users, need to be consulted and involved in data collection, to corroborate the accuracy of data and provide data about anticipated future activities and trends. This consultation process helps establish collaboration and trust within IOM.

Several mechanisms to gather information have proven beneficial in the United States. These include the following:

- Arranging sector-specific meetings to gain a better understanding of a sector's needs, concerns and future trends.
- Developing industry-specific white papers that review the current status, future trends and planning needs of a specific sector—through the white paper approach, industry can easily share information with interested members to gather comments and feedback.
- Identifying data gaps and, where possible, outlining stakeholder-driven projects that could fill those gaps.

Developing a research and science agenda to better understand the ecosystem within the IOM framework can help advance and fill priority gaps in the data. In the United States, federal agencies with various management authorities have collaborated to identify data gaps and, even more importantly, to determine how to prioritise them to best meet planning objectives. Defining a research and science agenda provides management entities with a common goal of advancing data objectives to ensure that future iterations of the plan will have the necessary additional information to better inform decisions. This process also allows for collaboration on budget discussions and prioritises time and resources within a structure that all engaged entities have agreed to.

Robust stakeholder engagement is critical to successful IOM. A key component and lesson learned from the United States is to reach out to sector-specific thought leaders or trusted organisers who are proven leaders in the community and can help disseminate information to and enlist participation of those within their given sectors. For example, variations in the fishing community must be taken into consideration as an IOM process moves forward since data and information will differ depending on gear type, port community and fish species. This approach of seeking adequate representation across industry, the nonprofit sector and the scientific community should be taken with all groups.

Ocean users may have a natural distrust of the new and potentially complex process that is IOM. It is vital that IOM remains an inclusive and transparent process so trust can be built. Meeting stakeholders where they are and ensuring that their input is adequately incorporated throughout the process has been shown to be more effective at ensuring stakeholders find value in a holistic approach rather than selling them on a concept.

4.4 Integrated Coastal Management in Xiamen, China

Xiamen, with a population of 4.11 million in 2018, is a port city located on the west coast of the Taiwan Strait. As of 2018, it was the 7th largest container port in China and the 14th largest in the world. Xiamen Island is surrounded by 394 km^2 of sea and has a coastline of about 234 km. Xiamen Bay, including the Jiulong River Estuary, West Sea, Tongan Bay and East Sea (Fig. 14.8), is home to nearly 2,000 marine species including protected species like Chinese white dolphins, lancelets and egrets. The bay has been a vital part of Xiamen's economy for centuries.

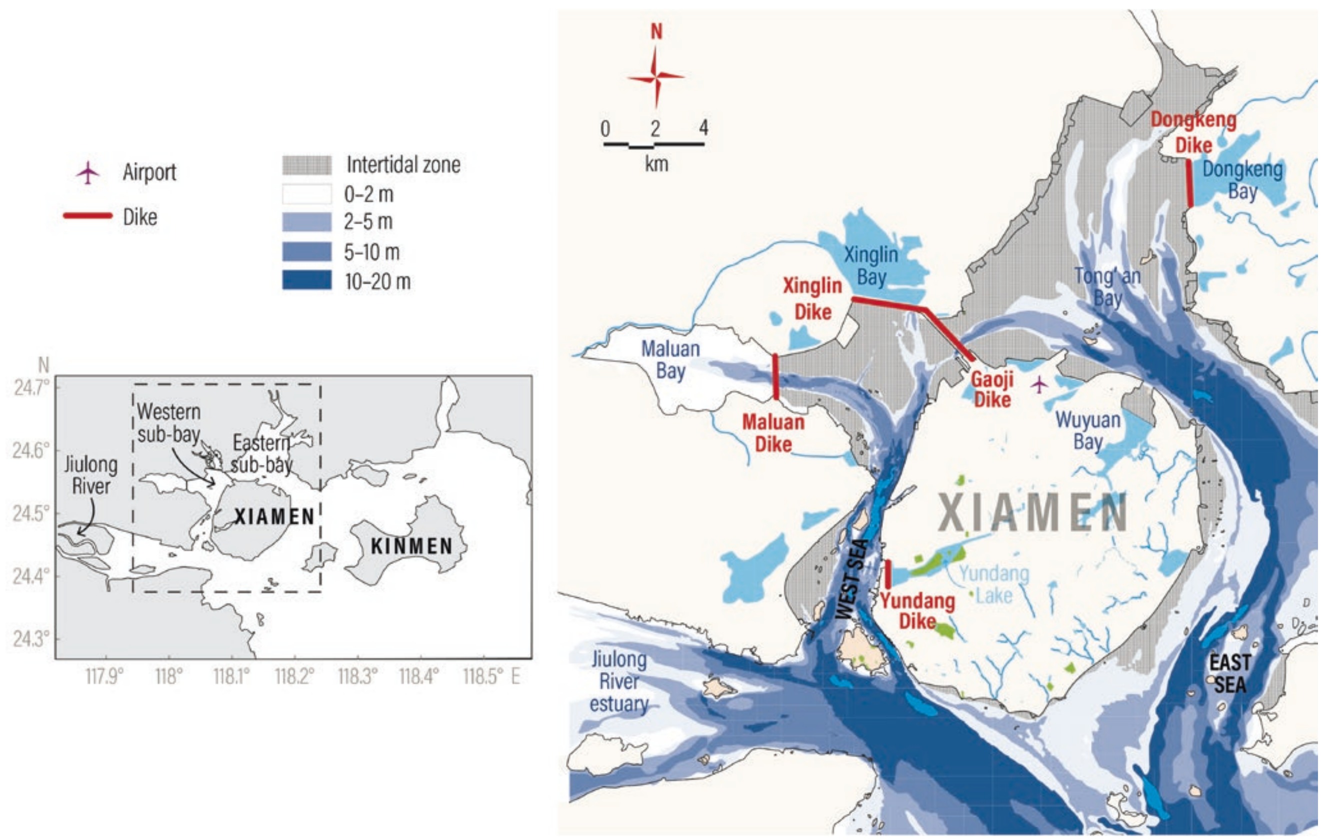

Fig. 14.8 Map of the Xiamen Area. (Note: In the legend, m stands for water depth in metres. (*Source: Redrawn from Wang et al.* 2013))

Following China's major reform initiative in the late 1970s, Xiamen became one of the first four special economic zones. Since then, Xiamen has experienced an economic boom that has brought with it a series of resource use conflicts and pollution problems. This was particularly visible in the early stages as little attention was paid to ecosystems and the environment (Chua et al. 1997; Xue et al. 2004). Seawall constructions and reclamations drastically modified the coastal morphology and hydrodynamics and reduced the area of surface water and tidal influence.

Starting in the 1980s, marine aquaculture grew rapidly and was further intensified in the mid-1990s. By 2001, it covered nearly half of the West Sea area. Waste from coastal aquaculture ponds and excess feeds from fish cages polluted the marine environment. Nearly all domestic and industrial wastewater was discharged into the sea untreated. Many natural habitats were damaged by pollution. Mangrove forests declined from 1.8 km^2 in 1987 to 0.2 km^2 in 1995. Major events of fish deaths occurred around twice per year in the period from 1984 to 1996 (PEMSEA 2006a) and populations of dolphins, egrets and lancelets declined (ITTXDP 1996; XDPO 1998; Xue et al. 2004; Lin et al. 2005; PEMSEA 2006a, b).

Faced with environmental degradation, sea-use conflicts and ineffective management as well as deficiencies in legislation, funds, public awareness, information and pollution-prevention capabilities (PEMSEA 1998), Xiamen implemented a new ocean and coastal management system in 1994. Integrated coastal management (ICM) in Xiamen has undergone four stages of development: structural design from 1994 to 2000, marine ecosystem rehabilitation from 2000 to 2009, co-governance of land and sea from 2009 to 2015 and sustainable ocean economy since 2015 (Hou et al. 2019).

4.4.1 Early Stages of ICM in Xiamen

With this backdrop, the Chinese government decided in 1994 to make Xiamen a demonstration site for ICM in collaboration with GEF, UNDP and IMO's regional programme (Xue et al. 2004; Cao and Wong 2007; Fang et al. 2011; Mao and Kong 2018; Hou et al. 2019).

Between 1994 and 2000, in the early stage of ICM in Xiamen, a coordinating, law-enforced and science- supported mechanism was established. From 1994 to 1996, to advance ICM, individual projects were selected under the guidance of international organisations such as GEF, UNDP and IMO. These projects included, for example, establishing pollution management plans and sea use zoning (GEF et al. 2009). In 1996, the municipality of Xiamen initiated an ICM leadership group consisting of the mayor and officials from different governmental departments, under which an ocean office was established and tasked with organising regular meetings with ocean-related sectors within aquaculture, transportation, construction and science and technology (Xue et al. 2004) (Fig. 14.9). During this phase, a series of marine laws and regulations, including the Administrative Regulations on Xiamen Sea Area Use for development and use and the Regulation on the Management of Natural Protected Areas for Chinese White Dolphin for environmental protection and ecological conservation, were adopted. A series of spatial planning programmes, including the Functional Zoning of Xiamen Sea Area, were also initiated. To provide support in developing these new tools, a municipal ocean specialist team consisting of leading researchers was formed.

4.4.2 Ecosystem Rehabilitation

Xiamen's ICM entered a new phase in the early 2000s with the initiation of several marine ecosystem rehabilitation projects. The first was established in the Yundang Lagoon, located in the downtown area of Xiamen Island. This lagoon used to be a fishing harbour connected to the Western Sea of Xiamen, enriched by mangroves, and had once sheltered huge flocks of egrets. During the 1970s, a dam was built at the mouth of the lagoon to cut off the water flow, converting the lagoon into an enclosed body of water. In addition, the surface water area was reduced from 10 km^2 to 2.2 km^2 due to reclamation for agriculture purposes. Untreated industrial and domestic wastewater was also being discharged into the lagoon. Residents began leaving the area (PEMSEA 2006b). Due to the poor environmental conditions, the site was blacklisted by the national Environmental Protection Agency. This situation was not resolved until a series of cleaning actions were implemented, including improving the waste management systems, constructing sewage treatment plants, building a retaining wall and performing dredging. The water exchange between the Yundang Lagoon and the sea was improved and mangroves were replanted.

According to the Functional Zoning of Xiamen Sea Area, the dominant functions of the area are ports, shipping and tourism. However, aquaculture was its primary function until the 1990s. In 2002, Xiamen stopped its aquaculture activity to solve ocean-use conflicts and initiate ecosystem rehabilitation in the area.

The aquaculture facilities were completely removed, and waterways were dredged to ensure their prime functionality.

Several other rehabilitation initiatives were also implemented, including building a wetland park, restoring the shoreline, planting mangroves, building uninhabited islands for birds to forage and improving the sewage treatment system (Wang et al. 2018). In Wuyuan Bay, 89 hectares of wetland were established. Various measures improved the water exchange in the East Sea by 30 percent. Combined with bet-

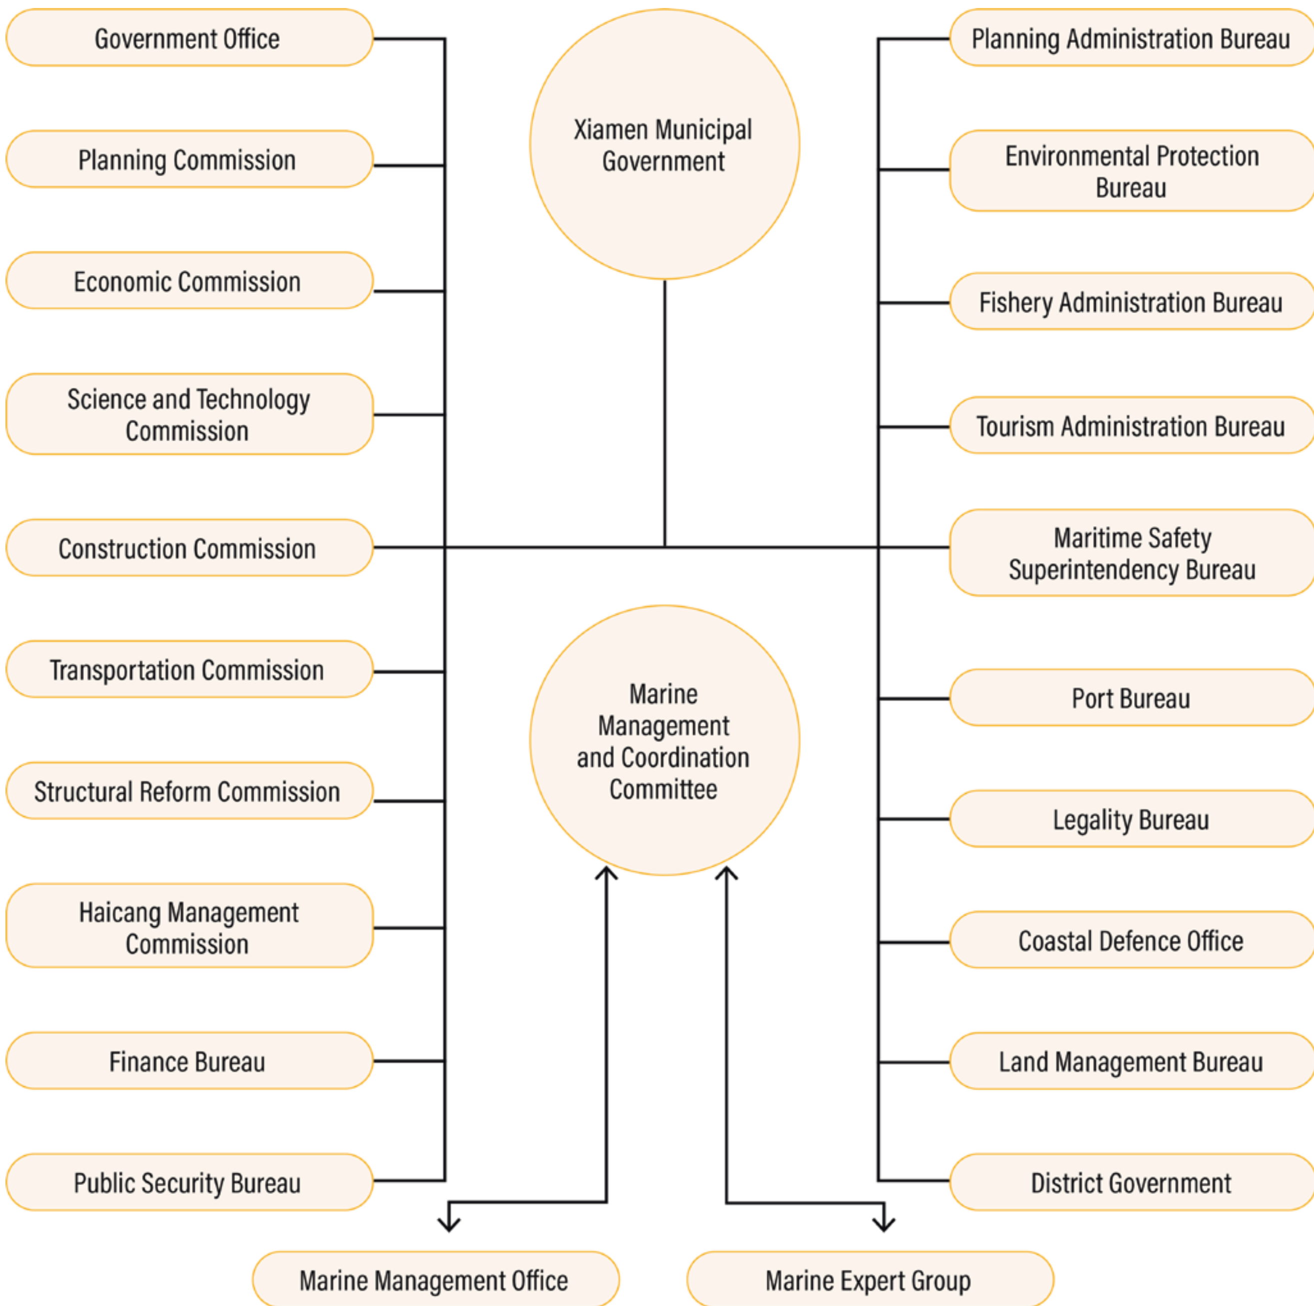

Fig. 14.9 Organisational Structure for Integrated Coastal Management in Xiamen. (*Source: Xue et al.* 2004)

ter water quality, the conditions for the Chinese white dolphins improved significantly.

Following the successful rehabilitation projects, Xiamen's efforts in ICM during 2009–2015 were mainly focused on governing the rivers and sea by establishing a system for controlling the terrestrial pollution. Since 2015, after over 20 years of ICM practices and in response to major national guidelines ('Managing Land and Sea as a Whole' and 'Constructing Ecological Civilization'), Xiamen has begun stage four of development—integrating land-sea management and the concept of developing 'blue growth' (Mao and Kong 2018).

4.4.3 Challenges and Lessons Learned

ICM in Xiamen can be characterised by the establishment of a legal framework and enforcement mechanisms, science-policy integration, marine monitoring system and information sharing, and public awareness mechanisms. As a management instrument to rationalise the use of marine and coastal resources and environment, marine spatial planning (called 'marine function zoning' in China) is a significant component of the ICM programme in Xiamen (Su and Peng 2018). There are a number of lessons to be learned from Xiamen's experience.

First, coordinating numerous stakeholders—from sectors including urban planning, fisheries, shipping, transportation, science, port authority and conservation—has been a challenge. To meet this challenge, the existing and successful concept of 'River Chief System', where one stakeholder is given extended responsibility, is also being implemented for the ocean space, as the 'Bay Chief System'.

Second, a comprehensive ICM system for laws and regulations was developed without fully aligning with existing regulations for terrestrial management in the same area (Su and Peng 2018; Peng et al. 2006). Thus, land and ocean management has been insufficiently integrated, something that needs to be refined when ICM in Xiamen is further developed. This may include, for example, creating zoning plans that account for both land and ocean.

Third, more management efforts and enforcement measures are needed to control non-point source pollution from land-based activities in watersheds with runoff to estuaries and bays.

Finally, integrating science and technological guidance throughout the process—including during design, implementation, evaluation and refinements—has been very valuable.

4.5 What Does Experience Teach Us about IOM Implementation?

The five case studies of IOM reviewed here represent vastly different situations with respect to climatic and oceanic conditions, geographical scales, the nature of economic activities and regulatory environments. Nevertheless, there are some significant commonalities—described below—that provide useful lessons for other contexts. The common denominator is that increasing uses and pressures on marine ecosystems drive the need to consider the totality of pressures on the entire ocean space.

First, climate change is manifesting itself in tropical, temperate and Arctic marine environments and represents a major challenge to ocean management. In this respect, IOM is a critically important way of addressing multiple ocean uses while considering the impacts of climate change.

Second, due regard needs to be given to the local context. It is critically important to tailor IOM to the characteristics and needs of the region in question. The concrete economic activities, community needs, societal goals and environmental pressures should be the point of departure for the development of IOM.

Third, information is critical. It is essential to have robust data series on the evolution of critical environmental variables as well as on economic activities. Without information, management decisions cannot be effectively made. Information should be accessible, easy to find and subject to data quality standards in appropriate formats for public accessibility.

Fourth, implementation—moving from paper to practice— is essential. Several cases demonstrate that this can be done effectively without a separate legal basis for IOM.

Fifth, stakeholder involvement is critical to ensuring that the practical information needed to develop IOM measures is available and building the understanding and legitimacy required for effective implementation.

Finally, institutional mechanisms for IOM are needed, whether formal or informal. There has to be a designated process for how to consider the various pressures and uses of ocean space in a comprehensive manner and make decisions on that basis.

5 Conclusions and Opportunities for Action

This paper argues for the need for integrated ocean management and has identified several central components of successful IOM. Achieving a healthy, productive and resilient ocean requires taking a holistic perspective on ocean use and management, and effectively implementing relevant national and international measures. Given current levels of pressures on our ocean, few human activities can be viewed in isolation. Most activities have impacts that need to be accounted for and viewed in relation to other activities and concerns to fully capitalise on the economic potential of the ocean in a sustainable way. Achieving effective sectoral management is necessary, but not enough. We also need to realise that a sustainable ocean economy depends directly upon healthy, productive and resilient ocean ecosystems and act accordingly. Thus, the need for an integrated, ecosystem-based and knowledge-based approach to ocean governance is pressing.

We need to ensure that ocean industries do not degrade the environment that they and others depend on. It is critical that short-sighted solutions with negative environmental impacts are replaced with long-term, sustainable solutions that strike a better balance between protection and production. Quantitative assessments and strategies for factoring in long-term benefits by implementing sustainable solutions should be developed. Despite progress on some fronts, the current trajectory is in the wrong direction and rapidly growing more serious, e.g. biodiversity loss and plastic pollution.

Moreover, important information often exists but is not used in decision-making. Effective ocean governance must consider developments in technology, the impacts of climate change, the dynamic nature of the ocean and seas and the interactions and synergies between land, ocean and people. Connecting management plans for coastal land areas with the adjacent ocean management plans would significantly improve today's situation in many regions.

The statuses of marine ecosystems and their properties and characteristics vary considerably. IOM provides not only an understanding of the totality of ocean uses and pressures but also guidance for how to prioritise among these various uses. Government solutions need to be tailored to the characteristics and problems of the specific marine region—one size does not fit all, and context is essential. The relevant economic activities, community needs, societal goals, traditional and local knowledge and environmental pressures should be included in a tailor-made IOM process.

That said, IOM supplements but does not replace sector-based management. It is important to maintain and further develop effective sector-based legislation and other measures and keep them up to date with the most recent international standards in, for example, shipping and fisheries. However, coordinating across sectors is needed, including regarding how to collectively prepare for future scenarios.

Furthermore, the need for regional collaboration is evident. Ecosystems and economic activities often occur in several jurisdictions and across national boundaries. Also, activities in the marine realm can have widespread impacts. In the case of such transboundary situations, regional cooperation in, for example, fisheries management or the prevention of marine pollution is necessary to address the problems at an appropriate geographical scale. Also, regional collaboration would greatly benefit from those nations or entities with experience with IOM providing mechanisms for sharing information, data and knowledge. At the local level, connectivity—particularly increased dialogue among locals and institutions—plays a vital role in ensuring sustainable ocean governance.

Finally, as pointed out when summarising experiences from our case studies, climate change represents a challenge vastly larger than anything we have faced before, and the future of the ocean depends on our ability to address this issue properly. Questions of adaptation and risk management loom large in this respect and are critical dimensions of all opportunities for action discussed below. Adaptive ocean management must make use of the best available science to account for how future climate change will affect ocean businesses (individually and combined), ecosystems and societies. For example, when localising MPAs or ocean industries, authorities must account for changing conditions in the relatively near future due to climate change.

Through five case studies, we have emphasised that conditions vary across countries and regions. We have identified key features for successful IOM such as the need for both a mandate (top-down) and engagement (bottom-up) approach, adequate funding and explicit mechanisms to implement plans, not just create them. Practical and implementable solutions of ocean governance can serve as inspiration and guidance. We can also learn from mistakes. Developed countries with established institutions for marine planning and management do of course not represent the whole picture. In this context, some countries have a clean slate to work with, and therefore the opportunity to get it right the first time. This may be an advantageous starting point for building capacity and establishing IOM.

This paper identifies six main aspects of successful IOM:

- harness science and knowledge.
- establish partnerships between public and private sectors.
- strengthen stakeholder engagement.
- improve capacity building.
- implement regulatory frameworks.
- develop adaptive management systems.

The following opportunities for action respond to each of these in turn.

5.1 Opportunity for Action 1: Harness Science and Knowledge

Tools to develop, strengthen and coordinate governance of the ocean include increased science and monitoring efforts, sharing of knowledge, and transfer of technology and digital infrastructure, especially in the least developed countries and SIDS. For example, the goal of ecosystem-based management is impossible to achieve if data on the ecosystems and the societies depending upon them are lacking. Relevant data and clearly defined goals for management coupled with research and science plans are important to advance and achieve IOM.

In some regions, there are large knowledge gaps for a range of ocean-related issues such as the abundance and interactions among living marine resources, impacts of human activities (existing and future), opportunities embedded in the expected digital and technological revolution, consequences of marine litter and the impacts of climate change. To address this, we recommend strengthening the global ocean science enterprise—including social science—building on the efforts by the UN Regular Process and the IOC, as well as the ongoing efforts at the regional level. Strengthening the role of IOC in IOM would build on already existing structures, enhance the attention given to marine science and help generate the resources needed to develop scientific knowledge and scientific capacity building worldwide. A platform for its development could be the coming UN Decade of Ocean Science for Sustainable Development (2021–2030) as a framework to be hosted within the IOC. Another important output would be the World Ocean Assessments following up on the 2015 and 2020 editions, which can support regional and national ocean governance.

We suggest strengthening the global ocean science enterprise and better using existing knowledge, building on established structures such as the IOC and using the UN Decade of Ocean Science for Sustainable Development as a vehicle for further developing international cooperation in marine and related sciences.

5.2 Opportunity for Action 2: Establish Partnerships Between Public and Private Sectors

With a growing blue economy and increasing use of ocean space for human activities, maintaining a productive and healthy ocean becomes more difficult. Currently, investments and infrastructure in the ocean space are developed across various industries and sectors with differing standards of performance and governance. In practice, enduring sustainability can be achieved only if best practices are applied in both the public and private sectors and where productive partnerships between the two are encouraged and advanced. Good governance can bring long-term solutions that advance the economy while supporting societies and protecting the environment.

Advancing and clarifying the responsibilities of the private sector by developing 'Ocean Principles' for a sustainable ocean economy, modelled after the Carbon Principles, is a way forward. The UN Global Compact Action Platform for Sustainable Ocean Business has developed principles and guidelines for sustainable ocean businesses that several of the largest ocean- related businesses and financial institutions globally have signed on to (UN Global Compact 2019). A further development would be to give credits to nations and retailers that are able to develop transparent and traceable supply chains that demonstrate sustainability and contribute to the implementation of the 2030 Agenda for Sustainable Development. We suggest strengthening the commitments in business to further develop technological solutions with transparency at their core, thus empowering consumers to change the markets.

We suggest that ocean-related businesses at local, regional, national and international levels cooperate to develop principles and guidelines for the sustainable conduct of ocean businesses.

5.3 Opportunity for Action 3: Strengthen Stakeholder Engagement

To achieve sustainability in the uses of the ocean, including the achievement of the UN Sustainable Development Goals, it is critical to incorporate the insights, ownership and engagement of local stakeholders. National strategies for strengthening ocean management will not work without implementing sustainable projects at local levels of governance. Thus, actively involving communities and including local knowledge are important. Planning at the local level in developing countries, especially SIDS, requires tailoring approaches to the diverse environmental and socioeconomic contexts and governance systems in these regions.

For successful IOM, both mandate (top-down) and engagement (bottom-up) elements are needed. As demonstrated in the case studies, there are a number of approaches to local stakeholder engagement, which are highly context dependent. In all cases, however, designing well-managed engagement processes that consider the scientific, cultural, societal, economic and political contexts and encourage active stakeholder participation is crucial.

We suggest that governments support the active involvement of local communities in all stages of planning and development for integrated ocean management.

5.4 Opportunity for Action 4: Improve Capacity Building

Capacity building—efforts to enhance scientific and regulatory proficiency as well as institutional and collaborative capability—is vital for developing integrated ocean management. In this regard, IOM must address how to handle current and future challenges such as climate change, biodiversity loss and pollution. The scientific capacity needed to implement international governance frameworks is severely lacking in many countries (IOC-UNESCO 2017). Capacity building, primarily building on but also amplifying existing regional and intergovernmental organisations and institutions, needs to remain at the top of the international agenda. At the national level, it is essential that government agencies involved in ocean management are properly institutionalised, and have the skills, knowledge, authority and capacity—including funding—to address challenges relating to the ocean and coastal communities in a long-term, integrated manner. Here, collaboration and coordination among stakeholders is essential. New technologies combined with transparency give rise to new opportunities for monitoring and policing inappropriate behaviour at sea, bringing practical and inexpensive solutions for the transfer of know-how.

Additionally, the ocean science enterprise is advancing technologies that allow us to collect scientific data with less cost and greater efficiency than ever before. To effectively advance capacity, this must be done with transparency, tailored to context, and with data standards in place. In this respect, regional cooperation can be an effective vehicle for strengthening the role of science and providing advice for management, as demonstrated by ICES in the North Atlantic and Western Indian Ocean Marine Science Association (WIOMSA) in the western Indian Ocean.

We suggest identifying and using the best and most relevant principles, practices and procedures from regional efforts at IOM to develop integrated management in other regions.

5.5 Opportunity for Action 5: Implement Regulatory Frameworks

Failure to implement existing international instruments is perhaps the most important weakness of our ocean governance systems. It is vital to have mechanisms in place not just to develop IOM plans, but also to implement them. A comprehensive global ocean governance framework, supplemented with many regional instruments and often adequate national laws, does exist. However, implementation of the legal framework is too often inadequate and ineffective. In some cases, only immediate needs are prioritised in the allocation of resources to implement laws and regulations. There is also a need for local and subnational action plans and direct leadership to achieve successful implementation of IOM. Furthermore, inadequate implementation of existing regulatory frameworks in coastal states is a bottleneck for efficient and sustainable governance.

Important work is underway to address these shortcomings, including efforts to implement regional fisheries management organisation regulations, negotiations on biodiversity beyond national jurisdiction and the development of the seabed mining code by the International Seabed Authority.

A leading principle should be effective implementation of international agreements in domestic legislation and practices, including activities in the high seas. In practice, this means that rules for managing human activities in the high seas should be compatible with and at least as strict as those that apply in areas under national jurisdiction. Ratification of the basic international instruments for ocean governance and adherence to their provisions provided by UNCLOS is a precondition for this.

We suggest that regulatory frameworks for areas beyond national jurisdiction as well as those in areas under national jurisdiction be effectively implemented, building on the best available science. Rules for managing human activities in the high seas should be compatible with and at least as strict as those that apply in areas under national jurisdiction.

5.6 Opportunity for Action 6: Develop Adaptive Solutions

The ocean is highly dynamic, and its governance needs to reflect this. The dynamic nature of the ocean contrasts with the relatively static land areas, and it is important to address land-ocean interactions when developing integrated management of coastal regions.

This dynamism is further amplified by climate change. Many regions are already suffering from the effects of climate change, especially developing countries and small island states where coastal communities and even entire populations are threatened. Climate projections suggest that forward-looking, adaptive solutions where risk is explicitly considered will become an even more important element of IOM.

We suggest that IOM capture the connectivity and differences between land and ocean in an integrated and adaptive manner. Further, we suggest that ocean governance consider the expected future changes in the ocean environment by using the best available scientific knowledge on climate and other environmental changes.

Acknowledgements The authors thank the paper's technical reviewers, Tundi Agardy, David Balton, Joachim Claudet, Stuart Green and Louise Lieberknecht, as well as its arbiter, Jane Lubchenco, who all provided helpful technical comments. The authors also thank World Resources Institute for providing support as the Ocean Panel Secretariat. While our colleagues were very generous with their time and input, this report reflects the views of the authors alone. The authors also thank Sarah DeLucia for copyediting and Billie Kanfer for design.

About the Authors

Lead Authors

Jan-Gunnar Winther is the director of the Centre for the Ocean and the Arctic in Norway. He is also a specialist director at the Norwegian Polar Institute, and serves on a number of national and international committees and delegations including World Economic Forum, UN Global Compact Sustainable Ocean Business Action Platform, China Council for International Cooperation on Environment and Development and the Expert Group for the High Level Panel for a Sustainable Ocean Economy.

Minhan Dai is a chair professor at Xiamen University in China, where he serves as director of the faculty of Earth Science and Technology, and director of State Key Laboratory of Marine Environmental Science. His research interests include ocean biogeochemistry and sustainability. He has served on many national and international committees including the Expert Group for the High Level Panel for a Sustainable Ocean Economy.

Contributing Authors

Fanny Douvere has been the coordinator of the Marine Program at UNESCO's World Heritage Centre in Paris, France, since October 2009. The mission of the programme is to ensure that the 49 marine sites on UNESCO's World Heritage List are conserved and sustainably managed.

Leanne Fernandes is a senior manager and the marine coordinator at the International Union for Conservation of Nature. Over the last decade she has applied her knowledge to address marine resource management problems on the islands of Hawaii, the Maldives and the Caribbean and in the North Sea and coastal Australia.

Patrick Halpin is a professor of marine geospatial ecology at Duke University in the United States. He leads the Marine Geospatial Ecology Lab with laboratory facilities located at the main campus of Duke University as well as the Duke University Marine Lab.

Alf Håkon Hoel is a professor at UiT The Arctic University of Norway. He is a political scientist who has written extensively on issues relating to the management of living marine resources and the marine environment. His core interest is international relations in the field of ocean management, in particular in the Arctic and the Antarctic. Recent publications include analyses of the use of ecosystem-based management approaches in the Arctic.

Marie Antonette Juinio-Meñez is a professor at the University of the Philippines. Her research interests are invertebrate ecology and culture, coastal resources management, and marine science and marine biology.

Yangfan Li is a professor at Xiamen University in China. His main research interest is integrated coastal management. His work focuses on understanding the coupling mechanisms of coastal land-sea and social-ecological systems.

Karyn Morrissey is a senior lecturer at Exeter University in the United Kingdom. She is an economist specialised in the science-policy-industry interface and focused on understanding the impact of socioeconomic and environmental inequalities on health outcomes, using data both big and small.

Therese Rist is an advisor at the Centre for the Ocean and the Arctic in Norway, whose mandate is to contribute to a sustainable blue economy. She holds a postgraduate degree in public and international law from Melbourne Law School.

Fabio Rubio Scarano is a professor at the Federal University of Rio de Janeiro in Brazil. His main research interests are climate change adaptation, sustainability science, the science-policy interface and biodiversity conservation.

Amy Trice is the director of ocean planning at the Ocean Conservancy. She is a policy expert and scientist advancing solutions that integrate marine industry, conservation and science in ocean management decisions. Her research informs congressional staff as well as state and federal agencies on the value of comprehensive and coordinated ocean policies for economic and ecosystem resilience.

Sebastian Unger is the research group lead for ocean governance at the Institute for Advanced Sustainability Studies in Germany. His research focuses on global governance processes for ocean sustainability, including the development of a new international agreement for marine biodiversity in areas beyond national jurisdiction, the UN Sustainable Development Goals and the governance of deep seabed mining.

Sandra Whitehouse is a scientist and consultant at the Ocean Conservancy who has served for over 20 years as an ocean policy advisor to multiple organisations and institutions.

Illegal, Unreported and Unregulated Fishing and Associated Drivers

15

Sjarief Widjaja, Tony Long, Hassan Wirajuda, Hennie Van As, Per Erik Bergh, Annie Brett, Duncan Copeland, Miriam Fernandez, Ahmad Gusman, Stephanie Juwana, Toni Ruchimat, Steve Trent, and Chris Wilcox

Highlights

- By agreeing to Sustainable Development Goal (SDG) 14.4 to end illegal, unreported and unregulated (IUU) fishing and overfishing by 2020, countries have acknowledged the importance of combatting IUU fishing. However, they will fall well short of this goal without an immediate, forceful and unified effort.
- Ocean food production is threated by overfishing and habitat destruction often caused by IUU fishing and exacerbated by climate change, which in turn leaves coastal communities more vulnerable to the impacts of this loss.
- Continued IUU fishing will deplete fish stocks and destroy habitats, decrease the value of many fisheries, threaten species extinction, disrupt marine food webs, increase food security risks and disrupt coastal communities' social cohesion. Many of these effects are already being felt.
- The worst examples of IUU fishing are often connected to transnational crimes, including human rights abuses, bonded labour, tax evasion, piracy, and drug, arms and human trafficking. Fraudulent papers, hidden ownership and a lack of transparency facilitate extraction of fish in a way that is difficult to track.
- The global fishing fleet is two to three times larger than needed to catch the amount of fish that the ocean can sustainably support. Technological improvements in fish detection and fishing gear have made each vessel more efficient, allowing it to further deplete resources.
- Fish harvested legally and sustainably can be properly managed to provide animal protein for generations to come. Improved management and ending IUU fishing are imperative to achieving this.
- The three main drivers of IUU fishing are **economic incentives** that make IUU fishing a low-risk, highprofit activity; **weak governance** that fails to enact or live up to fisheries management regulations; and **barriers to enforcement** of fishing regulations caused by lack of political will, lack of enforcement capacity, and sometimes corruption.
- The illegal fishery is highly profitable because it is not effectively regulated. Economic incentives can be changed if countries and the fishing industry insist on transparent tracking of vessels and of their catches throughout the value chain to document legality. This type of documentation is now possible with new technology. Governments must follow through with tough responses to violations.
- Weak governance at the national, regional and international level creates a regulatory patchwork that has allowed IUU fishing to flourish. Ocean governance mechanisms can be strengthened by addressing the non-uniformity of regional fishery management organisation regulations and improving coordination and data transparency between these organisations, flag states, regional bodies, scientific establishments and coastal and market states.
- Barriers to enforcement must be removed by building the capacity of developing coastal states to enforce regulations at ports and on the water, including adopting new tracking technologies.
- This paper offers a checklist of actions that could be taken by various stakeholders to regulate IUU fishing and could be submitted in support of the SDG 14.4 in 2020.
- The most urgent action opportunities are:
  - **Adopt global transparency in fisheries.** Technological advances in tracking methods—both for tracking fishing vessel movements and for tracking a fish catch through the value chain—offer new hope for fisheries management. This, applied to existing regulations and combined with better public understanding of which vessels are authorised to tranship or fish and where, will drive better compliance.

- **Enact tighter controls at ports.** All port states should ratify and implement the Food and Agriculture Organization of the United Nations' (FAO) Port State Measures Agreement (FAO 2009) to stop IUU-caught fish entering the market. The agreement requires parties to place tighter controls on foreign-flagged vessels seeking to use their ports to detect and prevent the trade of IUU products.
- **Enhance collaboration.** Because IUU fishing does not honour political boundaries, regional collaboration among nations is essential. Collaboration between government departments and governments, and also among businesses and financial institutions, scientific establishments and the civil sector, will generate new solutions, maximise impact and lower costs.

1 Introduction

1.1 Overview

Illegal, unreported and unregulated (IUU) fishing accounts for 20% of the world catch and up to 50% in some areas. This industry often uses bonded labour, destructive fishing practices and deceptive practices to reap profits at the expense of local fisheries, coastal states and the marine environment. Although international resolutions and reports have been issued for decades, countries have failed to enact and enforce regulations to stop these practices due to a lack of political will, resources and capacity.

At the beginning of a new decade, with deadlines approaching for the Sustainable Development Goals, nations have a major opportunity to form the partnerships and enforcement mechanisms to stop illegal, unreported and unregulated fishing practices.

Advancing, and more affordable, technologies also present new opportunities to implement and enforce new and old agreements and regulations. These technologies can track not only the location and documentation of fishing vessels but also the progress of a particular fish catch through the value chain to ensure legality.

By exploring the underlying drivers of IUU fishing—economic incentives, weak governance, and poor enforcement—we propose effective actions that can be taken in the current international framework to address the issue. The best use of appropriate technologies, combined with good policy and international cooperation, partnerships and collaboration can be costeffective and scaled globally to transform fisheries. Fish harvested legally and sustainably can provide animal protein for generations to come.

UN Sustainable Development Goal 14.4 commits countries, by 2020, to effectively regulate fishing; end overfishing, IUU fishing, and destructive fishing practices; and implement science-based management plans to restore fish stocks in the shortest time feasible, at least to levels that can produce maximum sustainable yield as determined by their biological characteristics. The world is clearly not yet on track to achieve those goals.

In this paper, we outline the state of knowledge and trends in IUU fishing, ways in which it contributes to overfishing, how it exacerbates the impacts of climate change, and specific aspects of how it operates in coastal areas, on the high seas and in areas beyond national jurisdiction. Successful country strategies are highlighted, that, if more widely adopted, will help transition the IUU fishing fleet to one of compliance.

As one of a series of Blue Papers prepared as an input to the High Level Panel for a Sustainable Ocean Economy, this paper provides scientific and policy background as well as opportunities for action to reinvigorate international cooperation and efforts to effectively regulate IUU fishing.

1.2 Context

The promotion, regulation and monitoring of responsible fishing practices, through robust fisheries management and governance frameworks, are essential for the sustainability of fisheries resources in both coastal areas and high seas. The principles of responsible fisheries management have been prescribed in a number of international ocean and fisheries instruments. However, states do not always satisfactorily fulfil their duties in line with such instruments and IUU fishing often occurs, undermining national, regional and global efforts to manage fisheries sustainably. It is not enough for states to detect IUU fishing; they must strengthen fisheries laws and regulations and be able to take effective action against perpetrators to deter non-compliance (FAO 2018).

Illegal, unreported and unregulated (IUU) fishing threatens the sustainability of global fisheries in national coastal waters and on the high seas (SEAFDEC 2015). Developing countries are most at risk from illegal fishing, with estimated actual catches in West Africa, for example, being 40% higher than reported catches. IUU fishing is widespread (Sumaila et al. 2006), and such levels of exploitation severely hamper the sustainable management of marine ecosystems (Agnew et al. 2009). This exploitation causes enormous economic losses to coastal developing countries, disrupts social and environmental situations in coastal communities, enables crimes and human rights abuses, and even threatens military conflict over scarce resources. It also exacerbates the effects of climate change on ocean resources.

1.3 Economic Losses to States and Communities

One in every five wild-caught fish is likely to be illegal or unreported (Agnew et al. 2009); thus, the economic value of these fish never reaches the communities that are the rightful beneficiaries.

Annual global losses due to this illegal activity are valued at US $10 billion to $23.5 billion, representing 11–26 million tonnes of fish (Agnew et al. 2009). The volume of illegal trade in Pacific Ocean marine resources is 4–7 million tonnes per year, costing Pacific nations $4.3 billion to $8.3 billion per year in loss of gross revenues. The losses substantially increase when impacts across the fish value chain are considered (Konar et al. 2019). Another recent study reveals that IUU fishing in one Pacific Islands region represents $616 million annually, with 276,000–338,000 tonnes of Pacific tuna illegally caught each year (MRAG Asia Pacific 2016).

1.4 Social and Environmental Costs

Although monetary values often take the headlines, illegal fishing has significant social and environmental costs, such as the loss in value of fisheries from depleted stocks, the threat of species extinction, the impact on marine food webs, increased food security risks and potential disruption to coastal communities' social cohesion (Tinch et al. 2008; Sumaila 2018). Moreover, destruction of habitats and overfishing of mature adult fish compromise the health of the ecosystem and therefore the opportunity for fisheries and other uses in the future.

1.5 Crime and Human Rights Abuses

The worst examples of IUU fishing are often connected to transnational crime, including human rights abuses, tax evasion, piracy and drugs, arms, and human trafficking (Sumaila and Bawumia 2014; Telesetsky 2014). Much of today's IUU fishing activity takes place on an organised, systematic scale across multiple jurisdictions (Haenlein 2017). These crimes are net losses to a country's economy and will result in lost economic, environmental and social opportunities, both short term and long term, and may diminish food security (FAO 2002; Sumaila 2018).

1.6 Possibility of Military Conflicts

The military departments of many nations study the environment and resources as an aspect of national security. The UK Ministry of Defence's 2018 *Global Strategic Trends* makes clear that habitat destruction and overexploitation will lead to loss of biodiversity and the need to secure diminishing resources may lead to conflict (DCDC 2018). Long-term strategies to ensure continued production and resource abundance are key for national and regional security.

1.7 Worsening the Effects of Climate Change

Climate change is significantly changing ocean ecology in ways that will affect fisheries, including reducing fisheries catches, especially in the tropics. Unsustainable fishing practices worsen the effects of these negative changes; therefore, sustainable and adaptive fishing management practices should be employed to help mitigate them.

1.8 The International Situation

The need to combat IUU fishing is increasingly enshrined in high-level institutions. See Appendix A for current institutions and agreements. Recent international actions are outlined below.

- A 2018 UN resolution on sustainable fisheries refers to the need to address IUU fishing and the importance of policies available to combat it.
- The 2015 UN Sustainable Development Goals (SDGs) include SDG 14.4 [1] on overfishing. This SDG is unlikely to be implemented by the 2020 deadline.
- The Convention on Biological Diversity, having fallen short on previous commitments, has set clear targets for 2020 on sustainable harvests for many of its goals, and the threat from IUU fishing and overfishing is made clear.
- Declarations on combatting IUU fishing were issued at the G7 (Charlevoix Blueprint 2018) and the G20 (Osaka Leaders' Declaration 2019).
- In 2019, Asia-Pacific Economic Cooperation officials and ministers officially endorsed a roadmap to combat IUU fishing.
- The 2019 UN Framework Convention on Climate Change Conference of Parties, referred to as the Blue COP to underline the emphasis on ocean conservation, sought to offer leadership and financial resources to gather momentum and address ocean issues.

[1] SDG 14.4: By 2020, effectively regulate harvesting and end overfishing, illegal, unreported and unregulated fishing and destructive fishing practices and implement science-based management plans, in order to restore fish stocks in the shortest time feasible, at least to levels that can produce maximum sustainable yield as determined by their biological characteristics.

- An ongoing UN intergovernmental conference is considering a new legally binding instrument under the UN Convention on the Law of the Sea (UNCLOS) that could result in robust protection for marine biological diversity in areas beyond national jurisdiction.
- In December 2017, the UN General Assembly proclaimed 5 June—the date the Port State Measures Agreement (PSMA) came into force—as the international day for the fight against IUU fishing—a significant milestone that raised the importance of the issue to global awareness.

1.9 Significant Reports on IUU Fishing

IUU fishing is recognised as a serious problem that must be addressed through national action and cooperation. Two significant reports have recommended reform: the High Seas Task Force's (2006) Closing the Net and the Global Ocean Commission's (2014) From Decline to Recovery: A Rescue Package for the Global Ocean.

This paper aligns with these reports and with key voluntary guidance such as the Food and Agriculture Organization of the United Nations' (FAO) 2001 International Plan of Action to Prevent, Deter and Eliminate Illegal, Unreported and Unregulated Fishing (IPOA-IUU), which highlighted the need for countries to share information and implement its recommendations either through their fisheries management agencies, regional organisations or the FAO. It also recommended encouraging full participation of stakeholders—including industry, fishing communities and non-governmental organisations (NGOs)—in combatting IUU fishing.

1.10 Need for National Good Governance

Because of the complexity and the scale of IUU fishing, a comprehensive global system of enforcement and compliance is needed to tackle this issue. Although many efforts to stem IUU fishing are international, national governments must initiate much of the action, including regulating their own coastal fisheries, enacting regulations at ports of entry, ratifying international agreements, and employing new tracking and transparency technologies.

1.11 Three Drivers of IUU Fishing

Despite many official statements and reports, and some traction, the problem remains a huge threat to future fisheries, food and social security and healthy ocean ecosystems. This paper assesses the nature of the problem and suggests approaches needed to tackle it.

We assess three major drivers of IUU fishing and offer some actions that would be decisive if adopted by the majority of stakeholders. The three main drivers are the large economic incentives for illegal fishing, weak governance at all levels that creates an easily evadable regulatory patchwork, and barriers to enforcement, mainly the lack of surveillance, monitoring and consistent prosecution of illegal activities.

- **Economic incentives** drive IUU fishing and other illicit activities such as bonded labour. IUU fishing is a low-risk, high-gain activity. Market and government mechanisms that promote traceability and transparency throughout the supply chain can help shift these incentives.
- **Weak governance** at the national, regional and international levels creates a regulatory patchwork that has allowed IUU fishing to flourish. Coordinated ratification and implementation of strong international fisheries governance regimes, such as the FAO's PSMA, can begin to fill these gaps.
- **Barriers to enforcement** stemming from a lack of resources and the logistical difficulties of effective monitoring, control and surveillance (MCS) over vast areas of the ocean undermine attempts to stop IUU fishing. Emerging low-cost, yet powerful technologies for surveillance and catch documentation coupled with regional partnerships offer new opportunities to overcome these barriers. Decisive penalties for violators of fishing regulations must follow.

This paper summarises detailed opportunities for action to combat each driver. Chapter 7 describes some immediate opportunities for action. Appendix A summarises existing fisheries agreements and bodies, and Appendix B offers a list of specific actions for various stakeholders as possible voluntary actions to submit under SDG 14.4.

2 The Need to Combat IUU Fishing

Global fishing is important for food security. This chapter discusses the importance of the global fishery for food security, the scale of the IUU problem and how the illegal fishery operates. See Box 15.1 for the official definition of IUU fishing.

2.1 Trends in the Global Fish Catch and Its Importance to Global Food Security

Reported global fish catch plateaued in the late 1980s and has declined slightly. Adding an estimate for illegal and

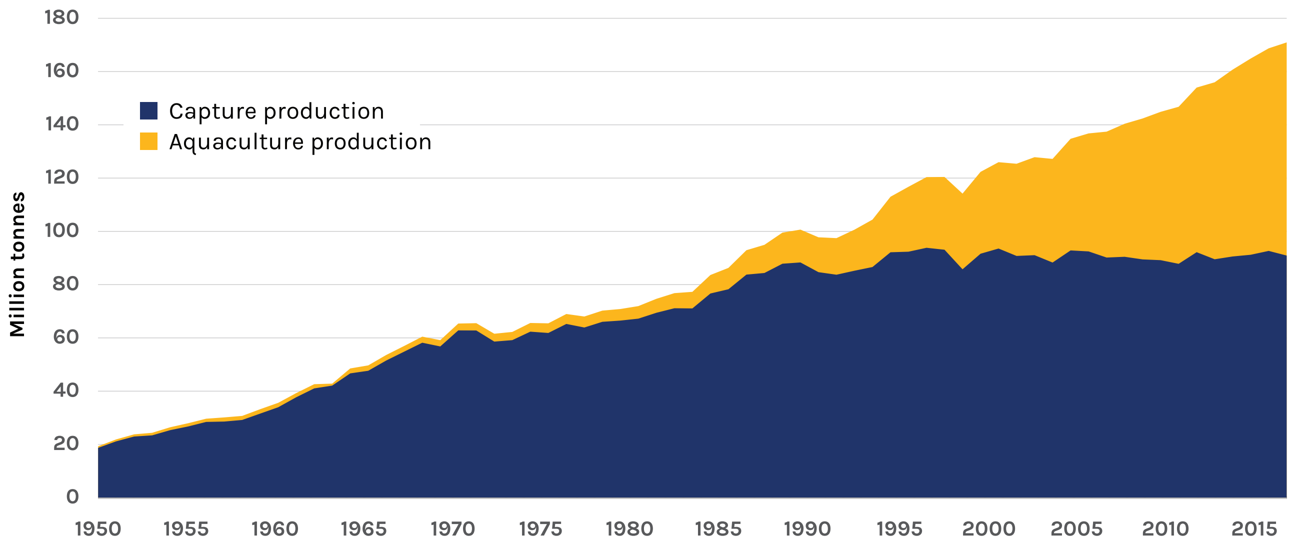

Fig. 15.1 World capture fisheries and aquaculture production, 1950–2016. *Note: Excludes aquatic mammals, crocodiles, alligators and caimans, seaweeds and other aquatic plants.* (*Source:* FAO 2018*)*

unreported catches significantly boosts the catch estimate but indicates that the global fishery may be in decline. Aquaculture is expanding but it relies heavily on capture fisheries for feed. Meanwhile fish consumption is rising at a rate faster than population growth. Fish is an excellent source of nutrition, and preferable to many other protein sources for climate change mitigation.

2.1.1 Estimated Global Fish Catch

The FAO reported in its 2018 *State of World Fisheries and Aquaculture* report that global fish [2] production peaked in 2016 at 171 million tonnes (with aquaculture representing 53% of this amount), which was valued at $362 billion (FAO 2018). Wild-caught fisheries increased steadily since 1950 but broadly plateaued in the late 1980s (Fig. 15.1). Since 1974, the percentage of underfished stocks has continued to reduce, and today only 7% of the world's fisheries are underfished while 33% are overfished.

To add estimated illegal catches to the FAO reported data, Pauly and Zeller (2016) reconstructed unreported fish catches from 1950 to 2010. Their results showed not only the enormity of the illegal catch but the possibility that due to sustained overfishing and under-reporting of catches, global marine fisheries catches are declining much more than FAO data indicates (Fig. 15.2). This decline in reconstructed catches reflects declines in industrial catches and to a smaller extent a decline in discarded catches, despite the expansion of industrial fishing from industrialised countries to the waters of developing countries. The differing trajectories suggest a need for improved monitoring of all fisheries, including often-neglected small-scale fisheries, and illegal and other problematic fisheries, as well as of the discarded bycatch.

2.1.2 Aquaculture Depends on Capture Fisheries

With capture fishery production relatively static or declining since the 1980s, aquaculture has continued impressive growth to supply fish for human consumption. Yet this sector remains heavily dependent on wild-caught fish as feed and therefore remains inextricably linked to the issues of IUU fishing and threats to the ocean ecosystem through heavy extraction of 'trash fish'; fish too young or too small for human consumption. An estimated 63% of all wild-caught forage fish are used for fish meal and account for upwards of 1 trillion fish taken from the ocean annually, valued at $17 billion (Pikitch et al. 2012). Significant expansion of fed mariculture systems, seen as necessary to producing more food, is predicated on major innovations in feed to make production less dependent on capture fisheries. Until that innovation is achieved, management of capture fishery resources will be critical to ensuring environmental and economic sustainability as well as food security (Costello et al. 2019).

2.1.3 Fish Consumption Expands Beyond Population Growth

Fish consumption is increasing at 3.2% annually, outpacing the global population growth of 1.6% (Fig. 15.3).

[2]The term fish in reference to the FAO's State of World Fisheries and Aquaculture indicates fish, crustaceans, molluscs and other aquatic animals but excludes aquatic mammals, crocodiles, caimans, seaweeds and other aquatic plants. Global fish production peaked in 2016 at about 171 million tonnes, with aquaculture representing 47% of the total and 53%, if non-food uses (including reduction to fishmeal and fish oil) are excluded.

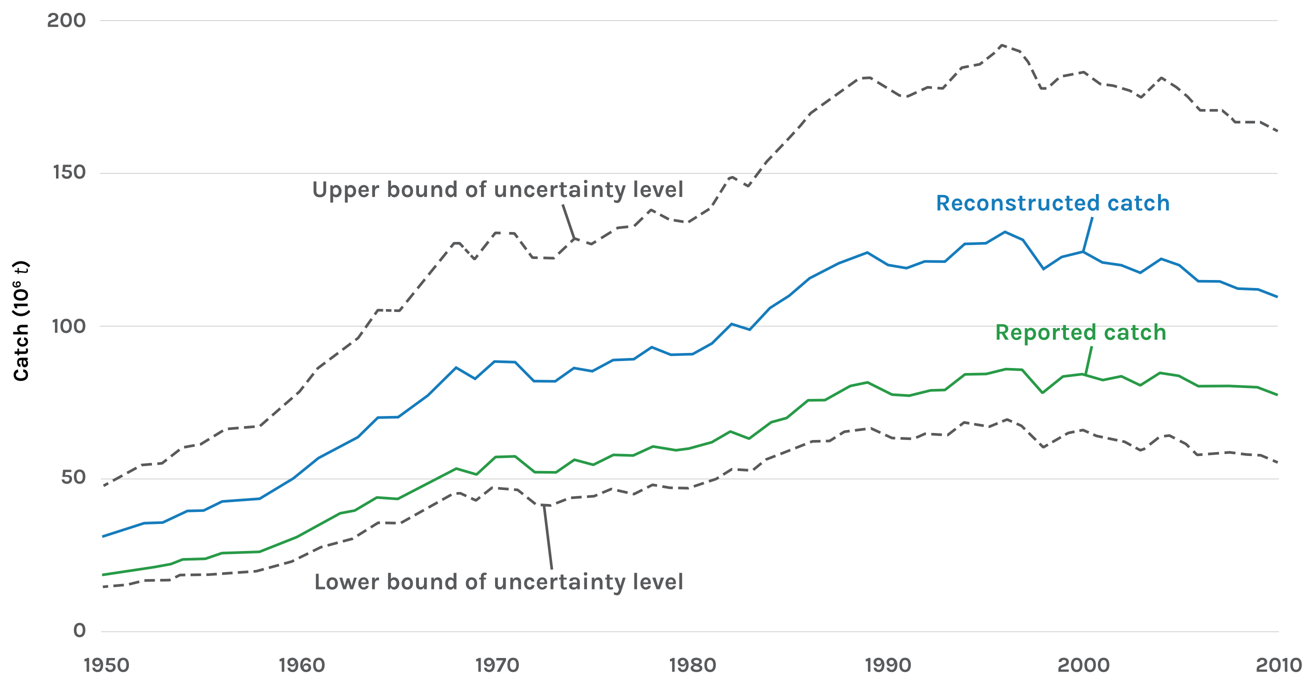

Fig. 15.2 Trajectories of reported and reconstructed marine fisheries catches, 1950–2010. (*Source:* Pauly and Zeller 2016)

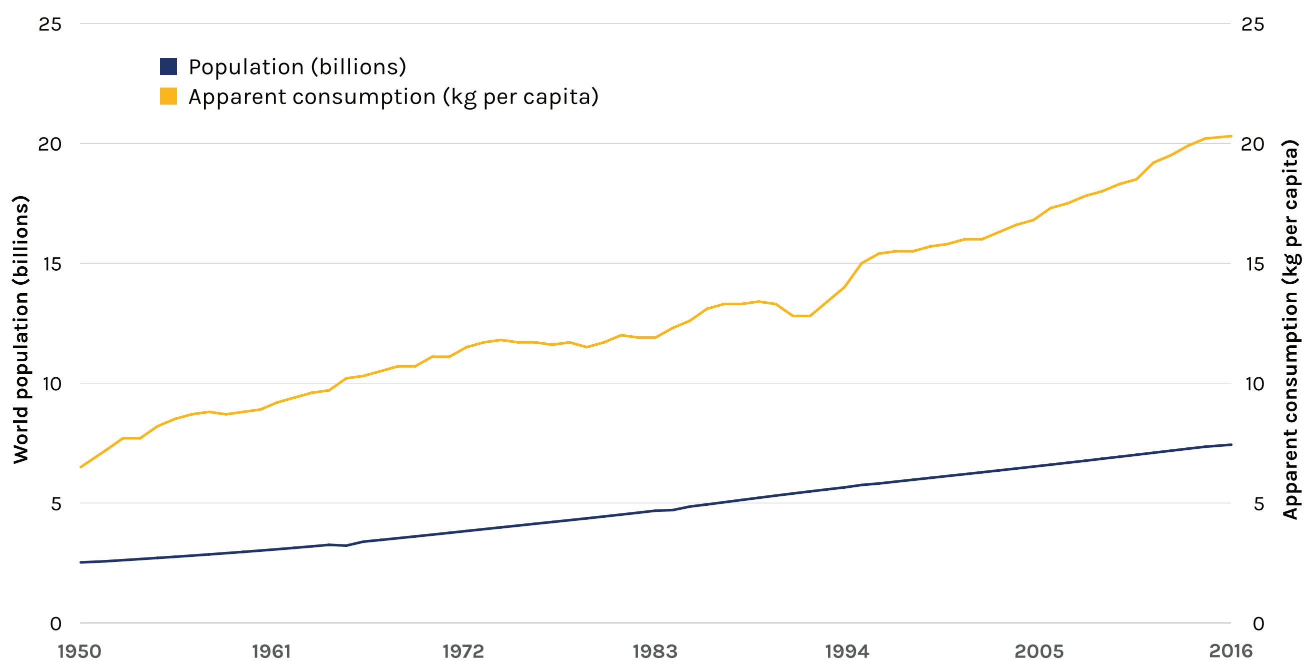

Fig. 15.3 Increase in world population and apparent consumption of fish, 1950–2016. (*Source:* FAO 2018)

Urbanisation is leading to increased fish consumption (Béné 2015), especially in the emerging Asian economies. Asia's share of world fish consumption increased from 67% in 2008 to 70% in 2013 (FAO 2017). Many Southeast Asian markets, including Indonesia and the Philippines, prefer fish to other types of animal protein. Total global consumption of seafood is projected to increase by 20% (30 million tonnes) by 2030, with most of the increased demand coming from developing nations in Latin America, Africa, Oceania and Asia (FAO 2018).

Fish provide almost 20% of the average per capita intake of animal protein globally. The percentage is higher in some areas, such as in Bangladesh, Cambodia, the Gambia, Ghana, Indonesia, Sierra Leone, Sri Lanka and some small island developing states, where over 50% of people's animal protein intake can come from fish (Fig. 15.4).

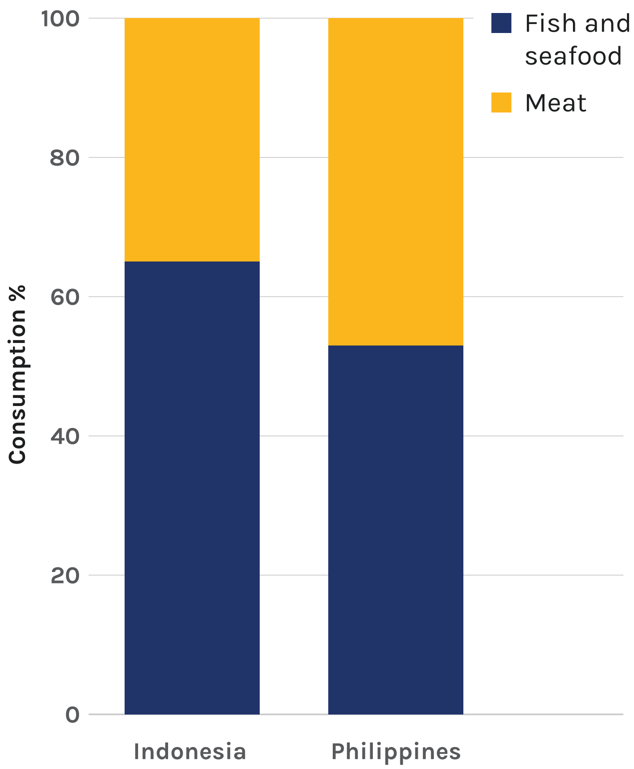

Fig. 15.4 Comparisons of meat and seafood per capita consumption in Indonesia and the Philippines, 2014. (*Source:* Friend 2015)

2.1.4 The Importance of Seafood for Nutrition and Food Security

Food from the sea is uniquely poised to contribute to food security because fish is a highly efficient form of protein—150 g of fish provide 50–60% of an adult's daily protein requirement (FAO 2018). Fish is also a unique source of essential nutrients, including omega-3 fatty acids, iodine, vitamin D, and calcium. Fish consumption by expectant mothers aids their children's neurodevelopment and these proteins and nutrients remain particularly crucial in the first 2 years of a child's life (FAO 2018).

Shifting diets towards fish consumption could also help mitigate climate change because ocean-based proteins are substantially less carbon intensive than land-based proteins (especially beef and lamb). It is estimated that shifting diets to ocean-based proteins can result in mitigation potential of 0.24–0.84 Gt of carbon dioxide equivalent (GTCO2e) per year in 2030 (Hoegh-Guldberg 2019).

IUU fishing impacts fisheries management because it skews scientific data, making assessments of fish stocks unreliable and therefore risking the collapse of the populations of overfished species. Fish harvested legally and sustainably can be properly managed to provide animal protein for generations to come. With judicious conservation and improved management, capture fisheries could produce as much as 20% more catch than today and up to 40% more than projected future catch under current fishing pressures (Costello et al. 2019).

2.2 The Scale of IUU Fishing

IUU fishing, as the name implies, is fishing that is illegal, unreported and/or unregulated (Box 15.1). Estimating the scale of IUU fishing is challenging. The most recent global estimate suggests that the global illegal and unreported annual catch is between 11 million and 26 million tonnes of fish, with a value of $10 billion to $23 billion. IUU fishing accounts for up to 20% of the world's catch and as much as 50% in some fisheries. This often-quoted report is based on data from 2005 and focuses on industrial-scale fisheries (Agnew et al. 2009).

A more recent regional study of the western and central Pacific Ocean found lower estimates of IUU fishing volume and value: the value was estimated at $707 million to $1.56 billion (MRAG Asia Pacific 2016). Whereas Agnew et al. (2009) made regional and global estimates across a suite of species (e.g., demersal fish, shrimp), which included parts of Indonesia and the Philippines (across FAO Area 71), MRAG Asia Pacific (2016) focused on tuna and included Indonesia and the Philippines; thus, direct comparisons should be made with caution.

The FAO is considering developing a new report on the state of IUU fishing. The first step was to review studies estimating IUU fishing and methods they used (Macfadyen et al. 2016). The decision to go ahead with a new report was pending as of late 2019.

Box 15.1 Definition of Illegal, Unreported and Unregulated Fishing

The IPOA-IUU provides the following definition of IUU fishing.

Activities are classified as illegal fishing if they are:

- conducted by national or foreign vessels in waters under the jurisdiction of a State, without the permission of that State, or in contravention of its laws and regulations;
- conducted by vessels flying the flag of States that are parties to a relevant regional fisheries management organization but operate in contravention of the conservation and management measures adopted by that organization and by which the States are bound, or relevant provisions of the applicable international law; or

- in violation of national laws or international obligations, including those undertaken by cooperating States to a relevant regional fisheries management organization.

Unreported fishing refers to activities which:

- have not been reported, or have been misreported, to the relevant national authority, in contravention of national laws and regulations; or
- are undertaken in the area of competence of a relevant regional fisheries management organization which have not been reported or have been misreported, in contravention of the reporting procedures of that organization.

Finally, a catch is considered **unregulated** if fishing is conducted:

- in the area of application of a relevant regional fisheries management organization that is conducted by vessels without nationality, or by those flying the flag of a State not party to that organization, or by a fishing entity, in a manner that is not consistent with or contravenes the conservation and management measures of that organization; or
- in areas or for fish stocks in relation to which there are no applicable conservation or management measures and where such fishing activities are conducted in a manner inconsistent with State responsibilities for the conservation of living marine resources under international law (FAO 2001).

2.3 The Modus Operandi of IUU Fishing

The perpetrators of IUU fishing tend to follow particular methods to achieve their goals. Identifying these practices and patterns can help monitoring authorities or law enforcement officers detect IUU fishing or other crimes. These include moving the catch from one vessel to another at sea (transshipment), using flags of convenience or non-compliance, using ports of convenience which offer little inspection, deactivating vessel monitoring or automatic identification and tracking systems, using a complex network of ownership, carrying fraudulent ship's documents and maintaining poor conditions for the ship's crew. IUU fisheries operate mainly offshore but have also infiltrated small artisanal fisheries.

2.3.1 Transshipment: Moving the Catch from Vessel to Vessel

Transshipment—moving the fish catch from one vessel to another, at sea or in port—is a common practice in the global fishing industry. At sea, transshipment facilitates the efficient delivery of fish to ports while allowing fishing vessels to continue to fish without having to put in to a port.

However, poorly governed transshipment has significant costs. The benefit of transshipment is generally with the industry in terms of improved profits, while the costs are felt most by the legal fishers and the society that owns the resource. Think of a transshipment vessel as a floating port. The fish transferred to this vessel do not always land at the adjacent coastal states port; indeed, the catch is often taken far away, and the economic benefits are not fully felt at the point of catch. In the western and central Pacific Ocean alone, a recent study estimated that more than $142 million worth of tuna and tuna-like products are lost in illegal transshipments each year (MRAG Asia Pacific 2016).

Transshipment is pervasive in high seas fisheries. Both refrigerated cargo vessels and larger fishing vessels transfer fresh catch from thousands of fishing vessels and take it to the first point of landing for onshore processing. Although transshipment touches a wide range of seafood products, tuna makes up a particularly large portion of it, in part because this highly prized fish can be frozen and brought from distant waters and still command high values at the market. Although moving catch from vessel to vessel may seem harmless, a lack of effective monitoring allows bad actors to obscure or manipulate data on their fishing practices, the species or amounts caught and the catch locations, thus badly distorting supply chains and efforts to make them more transparent.

Transshipment allows fishing vessels to remain at sea longer, which means more continuous fishing effort and, ultimately, additional overfishing of vulnerable fish stocks, especially tuna. While at sea, fish are kept in holds for longer periods, leading to co-mingling of IUU and non-IUU caught fish prior to landing and further muddying the traceability of supply chains.

Global Fishing Watch used 5 years (January 2012 to December 2017) of Automatic Identification System data to produce a report which showed that 694 vessels were capable of transshipping fish at sea. It produced a map showing 46,570 instances in which these transshipment capable vessels were going slow enough long enough to make a transshipment and 10,233 instances in which a fishing vessel was in the proximity of a transshipment vessel long enough to engage in transshipments. Figure 15.5 shows a global map of possible ship contacts for transshipment.

2.3.2 Using Flags of Convenience and Flags of Non-compliance

Flags of convenience Under international law, the country whose flag a vessel flies is responsible for regulating and controlling the vessel's activities. Flags of convenience (FOCs) refer to the registration of a vessel to a flag state with no genuine link to the vessel's owners or operators. This

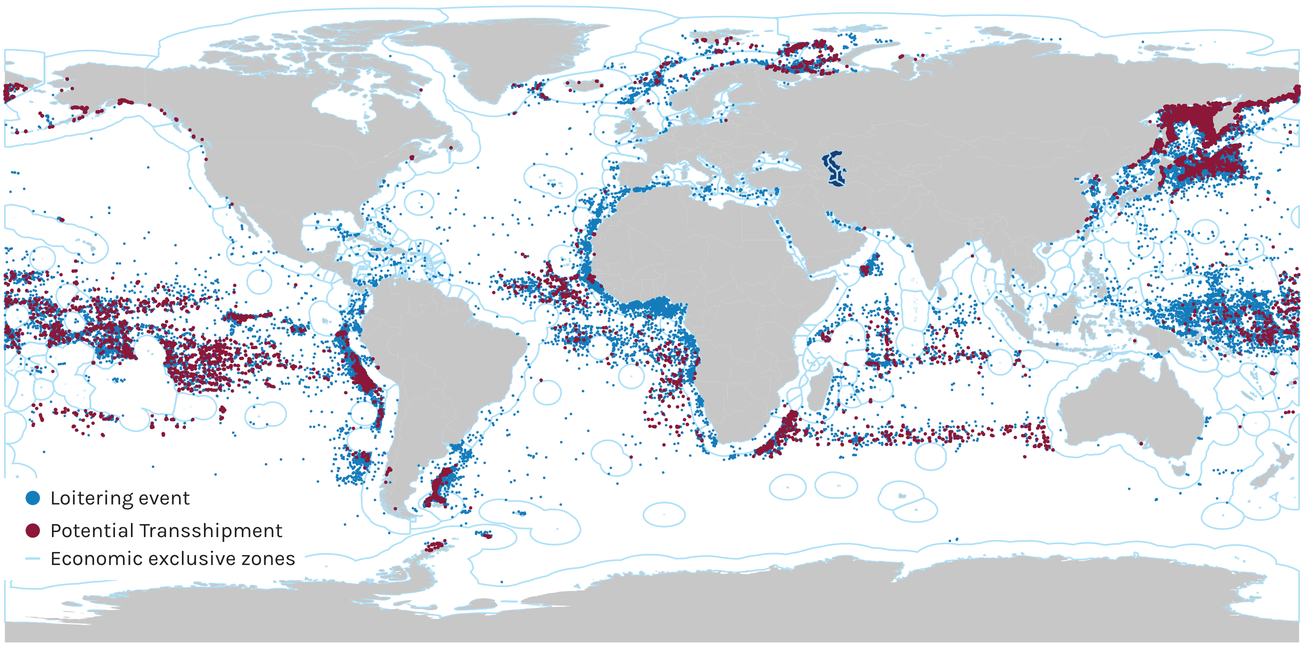

Fig. 15.5 Loitering events and potential transshipment at Sea, January 2012 to December 2017. (*Source: Global Fishing Watch* 2017)

offers competitive advantages to vessel owners, including limited regulatory oversight, ease of registration, reduced taxation, and ability to obscure beneficial ownership. Generally, an FOC country has an open registry, making a business from granting its flags to vessels (including fishing vessels) that are owned by nationals from other states.

FOCs are one of the simplest and most common ways in which unscrupulous fishing operations can circumvent management and conservation measures and avoid penalties for illegal fishing. Fishing vessels can use FOCs to re-flag and change ship names rapidly to confuse management and surveillance authorities, a practice known as flag hopping (EJF 2009). Extensive labour abuses and lack of safety protocols are well documented on FOC vessels (International Transport Worker Federation 2020). The use of FOCs has existed for decades, and the majority of today's merchant marine fleet is flagged to FOC countries (International Chamber of Shipping 2015).

In international waters, measures to regulate fishing apply only to countries that are members of regional fisheries management organisations (RFMOs), but if a vessel re-flags to a state that is not a party to these agreements, it can fish with total disregard for agreed management measures. A 2009 report by the Environmental Justice Foundation shows that RFMO blacklists are dominated by vessels with FOCs or flags unknown (EJF 2009). In recent years, many FOC countries have become members of RFMOs and do abide by the regulations.

Just because a vessel has an FOC does not mean it is fishing illegally, but the proven culpability of many FOC vessels in illegal fishing cases presents a compelling argument for an end to their use by fishing vessels. States that offer FOCs are listed by the International Chamber of Shipping, but many of these flags are not used significantly by fishing vessels. The International Transport Workers' Federation maintains a list focused on labour conditions.

Flags of non-compliance Many flag states without open registries have poor reputations for combatting illegal fishing and associated crimes. These countries often offer 'flags of non-compliance,' which means they grant authorisation to a vessel to fly its flag as well as authorisation to fish, but they lack the resources or the intent to monitor and control these vessels.

The obligations of flag states have been tested. The International Tribunal for the Law of the Sea issued an advisory opinion (April 2015) on Case 21 posed by the West African Sub-Regional Fisheries Commission (SRFC), which stated that a flag state remains obligated for the conduct of a vessel, even when it is in a third country's exclusive economic zone (EEZ), because a flag state 'is under the "due diligence obligation" to take all necessary measures to ensure compliance and to prevent IUU fishing by fishing vessels flying its flag' and that 'the SRFC member states may hold liable the Flag State' (Owen 2016).

Similarly, the International Court of Justice was involved in fisheries cases (1974 and 1998) and remains a jurisdiction to be considered in pursuing IUU fishing violations.

2.3.3 Using Ports of Convenience

In an attempt to avoid adequate inspections, companies engaging in IUU fishing send their vessels to ports with poor or no inspection controls. Ports of convenience are ports where catches can be landed with minimum inspection due to a lack of capacity, poor recording systems for catch landings, or corruption among inspectors. These ports of convenience allow the illegal fishing industry to gain access to the marketplace and to ensure logistical support for their vessels.

Some ports of convenience are also free trade ports (or free economic zones). These zones have favourable customs regulations and little or no controls for landings or transshipment. Illegally caught fish can easily enter the market and be shipped onwards undetected by the flag state or even the port state. The increasing transport of fish by refrigerated container is a growing challenge because these containers often transit through different areas of a port (or separate ports) and are frequently under the jurisdiction of government agencies other than those responsible for fisheries.

2.3.4 Deactivating Vessel Identification and Monitoring Systems

Monitoring is always challenging work in fisheries. The main tools used for monitoring fishing vessel activities are the Vessel Monitoring System (VMS) and the Automatic Identification System (AIS). Yet, IUU fishing vessels often deactivate or manipulate these systems to hide their identity and location.

Many authorities use VMS to combat IUU fishing and manage their fisheries. However, not all countries operate a VMS system, and those that do often do not operate the same system or have information-sharing agreements; thus, information transfer is hampered, does not happen or is costly. Additionally, some flag states fail to uphold their responsibilities to monitor their fleet (see earlier discussion of FOCs). That being said, a properly used VMS system can be very effective.

AIS is a tracking system for ships, designed for collision avoidance. It allows vessels to be 'seen' by each other regardless of their size or the weather conditions. AIS was originally a coastal ground station system limited to coastal zones or between ships at sea, but since the satellite transmission of AIS data became possible, the resulting global coverage made it quickly useful for understanding vessel behaviour with applications beyond collision avoidance.

The AIS data set, however, has limitations. There is no global mandate for fishing vessels to use AIS, although several states, including the European Union, do mandate its use. Vessels that use AIS can turn off or tamper with it. Some fishers turn off their AIS to hide their fishing locations from competitors or because of security or piracy risks in the area. Others turn off their AIS because they are engaging in IUU fishing and wish to hide their activities. Some vessels may simply have malfunctioning AIS devices. The FAO recently published a *Global Atlas of AIS Fishing* which provides further insight in the value of AIS in monitoring fishing activity (Taconet et al. 2019).

2.3.5 Ships Operated and Financed by a Complex Network of Ownership

Investigating and prosecuting illegal fisheries cases throughout the value chain is a complex and resource intensive process (Box 15.2). Because fisheries operations occur in a number of jurisdictions, investigators need close cooperation and information sharing among countries, agencies and relevant international institutions. Unfortunately, most illegal fishing cases at the national level focus on prosecuting only the vessel and its crew for the alleged violation. There is often little effort to identify illegal activities that may have taken place by the same vessel in other jurisdictions or to prosecute the networks, and ultimately the owners, behind these IUU operations. The use of shell companies and joint-venture agreements to 'own' and operate fishing vessels makes it even more complex to identify and target the individuals benefitting from the illegal activities.

A shell company holds funds and manages financial transactions for another company. Although shell companies are legal in many countries, their use can benefit those involved in illegal fishing, both in terms of avoiding taxes and hiding true ownership of fishing operations.

A joint venture agreement is an arrangement in which two entities develop a new entity for their mutual benefit. Joint ventures are used widely, and often perfectly legally, in fisheries around the world. In countries where access to fisheries resources is prioritised for nationals, joint ventures allow foreign players to access the fishery. While many joint-venture agreements are legal, these types of agreements can be exploited to perpetuate illegal fishing. Local partners, who in theory are majority shareholders, can in fact have little say in or control of the fishing operation, and it is frequently unclear how profits are shared. Joint ventures are also linked to corruption to protect vessels and their owners from prosecution and fines.

Box 15.2 The Complex Case of the Fishing Vessel *F/V Viking*

An example of a complex ownership network is found in the operation of the *F/V Viking*. This vessel changed its name 12 times and used 10 different flags. The identity of the owner was well hidden. Interpol and the governments of Indonesia, Norway, Spain and South Africa worked together to uncover the beneficial owners and bring an end to their operation. The *F/V Viking* was caught and sunk in Indonesia in 2016. While the *F/V Viking* was operating, its catches were exported to Hong Kong, Malaysia, Vietnam and Taiwan through an investment company in South Africa. The *F/V Viking* was owned by Spanish and Panamanian companies and operated by an agent in Seychelles and Southeast Asia, which domiciled in several countries. The *F/V Viking* was also operated from Singapore for crewing, logistics and financing (Fig. 15.6).

2.3.6 Use of Fraudulent Documents and Vessel Identification

Documents carried on a fishing vessel should provide information about the vessel's identity, registration, physical characteristics, authorised fishing activities and authorised locations, and whether it has been certified as compliant with required safety regulations. However, documents can be altered, replicated or obtained by illegal means, so it is essential that vessel documents are systematically verified as part of the fisheries MCS process.

False documents are used to hide illegal activities or to avoid obligations and costs. False vessel registration certificates, fishing licenses or catch certificates are key elements in many cases of illegal fishing; illegal operators either alter existing documents or create forged documents. There are several reasons an illegal fishing operator may use false documents, including for the following purposes:

- **Concealing the true identity of a vessel.** For example, to cover up a history of illegal activity or unpaid fees, a vessel owner may falsify the vessel's identity when seeking port access, registration or licensing by using false documents.
- **Avoiding complying with safety regulations.** For example, false certificates may be used to conceal that a vessel has not passed safety inspections or that safety equipment may be out of date or not suitable for the vessel size or type.
- **Avoiding or underpaying fees.** For example, the cost of vessel registration, licensing, port access and other services is often linked to vessel capacity or size, with vessels in a larger tonnage or length category paying more.
- **Gaining illegal access to resources or services.** For example, inshore fisheries waters may be reserved for smaller vessels, or authorisation to transship may be granted only to vessels of a certain type or carrying a certain fishing license.
- **Gaining additional benefits.** For example a vessel registered with one flag state with genuine documents could remain registered with a second flag state to secure access to benefits available from each flag state, such as access to subsidies under one flag and fisheries access under the other.

False documents can take a number of forms: they can be obtained by deception and/or by corruption; they can be used incorrectly, such as for the wrong vessel; original documents can be doctored; and false documents can replicate authentic ones.

Verification of documents relating to fishing vessels is therefore a key component of fisheries MCS. Documents should be checked and verified when a fishing vessel is inspected during at-sea or port inspections, and when a fishing vessel operator provides documents to an authority; for example, when applying for a fishing license. Flag, coastal, port and market states are all vulnerable to false documents, and all have a responsibility to have robust document verification capacity and routines in place. This should include through visual analysis, cross-referencing of information, and verification by issuing authorities.

Vessel identity fraud is used to hide fishing and operational history and activity; reduce costs; misinform and confuse licensing, flagging and inspection authorities; cover up a history of IUU fishing; and evade sanctions when caught violating regulations or breaking laws. Three main forms of vessel identify fraud are common:

- A vessel may use the genuine identity of another vessel, which results in two or more vessels using the same identity simultaneously—cases have been detected involving up to five vessels using one identity.
- A single vessel may use more than one identity, appearing under different names, flags and so on in different jurisdictions and records.
- A vessel may use a new identity that has not been registered with any national authority.

An individual vessel may be involved in more than one of these forms of identity fraud at any one time. Identity fraud can enable a vessel to operate illegally under the cover of a legal and authorised vessel's identity—for example, a vessel operator might purchase one legal fishing license which is used by the vessel named on the license as well as by several other vessels that assume its identity.

Vessel identity fraud can also involve changes to the physical vessel appearance. Inspectors should look for signs that a vessel's name, call sign and other identifiers have recently been repainted or altered. It is also important to check that any historic name or other identifiers visible under paint on the hull match the name history of the current vessel identity—this can be done through verification with the flag state and using sources such as RFMO authorised vessel lists. The systematic collection and comparative analysis of vessel photographs is also important to detect vessel identity fraud.

2.3.7 Poor Working Conditions and Safety Standards

Sub-standard working conditions and poor safety standards are a hallmark of vessels engaged in IUU fishing. Operators who under-report catch or fish illegally are less likely to provide their crews with adequate labour conditions, training or safety equipment and more likely to fish in hazardous weather. To minimise up-front costs, their vessels might have inadequate equipment or inappropriate modifications and might operate for extended periods without undergoing inspections or safety certifications. International investigations have shown that some migrant workers seeking employment overseas have been tricked with false promises of jobs on land and end up toiling in abhorrent working conditions on board unsafe fishing vessels roaming the high seas (Pew Charitable Trusts 2018).

To ensure the safety of crews on board fishing vessels and improve working conditions, governments can implement the International Labour Organization (ILO) Work in Fishing Convention (C188) and accede to the Cape Town Agreement (CTA). Enforcing labour standards will impact on the profit margins of IUU fishers and drive better behaviour.

The CTA is not yet in force but will set minimum requirements on the design, construction, equipment and inspection of fishing vessels 24 m or longer that operate on the high seas. Its entry into force would empower port states to carry out safety inspections that could be aligned with fisheries and labour agencies to ensure transparency of fishing and crew activities.

2.4 IUU Fishing Invades Small-Scale and Artisanal Fisheries

IUU fishing also has significant impacts in small-scale and artisanal fisheries. The challenges faced by these fisheries are different from those of industrial and high seas fisheries. In the first place, most small-scale fisheries are open access in nature, and entry into the fishery remains unrestricted in many fisheries throughout the world. Fishing restrictions, however, have been implemented in a substantial number of artisanal fisheries, recognising that nowadays these fisheries are capable of generating significant economic exchanges and exert substantial fishing effort.

IUU fishing practices in small-scale fisheries are common and diverse, including the use of dynamite and other explosives and poisons to kill fish; the use of fine mesh fishing nets and other destructive gears, methods and techniques; the use of traps and weirs; the destruction of mangroves and coral reefs; and the catch of juvenile and immature fish and invertebrates, among others.

One clear indication of the lack of regulations or enforcement is growing evidence that worldwide, small unassessed stocks are in substantially worse condition than large assessed stocks. Local decline of small-scale stocks has been related to IUU fishing practices. Recent studies in West Africa showed a tenfold increase in fishing effort in the past 50 years, correlated with a onethird decline in the catch per unit of effort (Belhabib et al. 2017).

In high-value species targeted by artisanal fisheries, such as abalone, lobster, swim bladder and bêche-de-mer, the illegal catch may be higher than the legal catch, and this has been identified as the main cause of fisheries collapse (Hilborn et al. 2005).

Box 15.3 Regulations Fail to Stop Illegal Fishing for High-Value Chilean Loco

Artisanal fisheries are socially and economically important in Chile, engaging nearly 90,000 fishers. The existence of 2 management strategies regulating the exploitation of most benthic resources for the past 15 years allows comparisons of fishing mortality under co-management in the novel territorial use rights for fisheries (TURF) system and under traditional top-down management (e.g., bans, minimum legal size) in open access areas (OAAs). Enforcement is more efficient in TURFs than in OAAs since the fishers themselves have a vested interest in protecting their TURF. Access to fishing grounds and enforcement level seem to be critical factors determining the abundance of exploited resources.

Comparative studies conducted in two management areas of central Chile showed that densities of all benthic resources and coastal fishes were higher in TURFs than in nearby OAAs. The densities of locos (Concholepas concholepas), the most valuable resource, are also significantly higher in co-managed TURFs and Marine Protected Areas than in OAAs, despite loco exploitation being completely banned in OAAs since 1993. This pattern of abundance suggests that illegal fishing of locos seems to occur in OAAs and offers a platform to analyse the extent of illegal fishing in traditional, open access management regimes. To date, illegal fishing of locos has been reported inside TURFs, and it seems to be relevant. Illegal fishing in OAAs may have tremendous impacts on the abundances of locos and other resources, especially considering the large fraction of the coast under an open access regime observing poor enforcement. This is of global interest since the problems are common in artisanal fisheries worldwide (datapoor fisheries, illegal fishing, poor enforcement), highlighting, with precautions, the value of TURFs for management and conservation in such scenarios.

Source: Andreu-Cazenave et al. (2017).

Unreported fish catches are substantial. The consequences are large, considering that artisanal fisheries account for 30% of the world catch and employ 90% of all fishers. Indeed, the recent *Hidden Harvest Report* (Fluet-Chouinard et al. 2018) suggests it is more like 50% of world catch. Moreover, 90% of the landings from artisanal fisheries are currently directed to human consumption, in contrast with 50% of the landings of industrial fisheries.

Artisanal fisheries are an important source of employment and income in the developing world, yet most strategies to overcome the IUU catches concentrate on large stocks and larger ships. While this focus will have a positive impact where large and small vessels are targeting the same stock, there is a need to more closely monitor small-scale fleets and improve small-scale fishing behaviour. The cost of technology needed to track smaller vessels currently inhibits widespread use, but costs will drop, and consequently, the number of small vessels being tracked will increase. There is increasing evidence, thanks to the growing number of fisheries projects focused on artisanal fisheries, that smaller-scale fishers want to be tracked to speed up their access to ports and to protect them from unscrupulous larger vessels.

IUU fishing causes a significant threat to global fisheries and to the health of the ocean. It damages legitimate fishing activity and associated livelihoods. Illegal gear impacts biodiversity and abundance, which in turn impacts food and economic security. Plus, unreported IUU fishing skews the scientific data, making sustainable fisheries management difficult to implement.

3 The Impacts of IUU Fishing

3.1 Impacts on Biodiversity

Fishing has had by far the greatest impact on loss of biodiversity in the ocean (IPBES 2019). IUU fishing, which undermines fisheries management and conservation measures, obscures accurate assessment of fish stocks and fishing pressure, which allows stocks to be fished beyond sustainable limits to the risk of collapse.

Before 2015, limited monitoring and control and poor enforcement, exacerbated by open access regimes and subsidies, made Indonesian waters a haven for IUU fishing. The Arafura Sea, one of Indonesia's most productive areas since the 1970s, became a hot spot for illegal shrimp trawling by domestic and foreign fleets. From reporting, it became evident that the populations of shrimps, hair tails, snappers and groupers in the Arafura Sea were steadily declining, as well as the average size of the catches. Similar problems were being seen in the South China Sea and Java Sea.

In central Chile, coastal artisanal fisheries have experienced the illegal and unreported removal of highly valued gastropod (Box 15.3) and a carnivorous fish, which produces a cascading effect on trophic interactions driving a deterioration of natural habitats (kelp forest), affecting species richness and generating unpredictable consequences on the sustainability of several benthic fisheries (Andreu-Cazenave et al. 2017).

A significant court decision further illustrates the damage that can be done to coastal fisheries. From 1987 to 2001, Arnold Bengis, Jeffrey Noll and David Bengis engaged in an elaborate scheme to illegally harvest large quantities of rock lobsters off the south and west coasts of South Africa for export to the United States in violation of both South African and U.S. law. Their actions led to the collapse of the rock lobster fishery, and a New York court ordered a restitution award for what it would cost South Africa to restore the fishery to the level it would have been had the defendants not engaged in overharvesting—almost $30 million (United States v. Bengis 2013).

Impacts on non-target species have been significant. For instance, catch of albatross by IUU toothfish fisheries in Antarctic waters under the Convention on the Conservation of Antarctic Marine Living Resources has been estimated to be one of the primary drivers of decline in some albatross populations (Michael et al. 2017). Some trawling and dredging gear disturbs or destroys seafloor habitat. For example, Clark et al. (2019) found that benthic communities associated with biogenic habitats formed by deep-sea corals and sponges on seamounts are among the most susceptible to fishing impacts because their resilience is apparently very low. The researchers found little recovery 15 years after trawling. Recovery times of benthic communities on seamounts may be on the order of decades—making restoration unachievable in the short term, as well as prohibitively expensive in the deep sea.

The growing literature on the extent of bottom trawling, together with a greater recognition of the potential severity of human impacts in the deep sea and the long recovery periods from such impacts, support the contention that spatial management is likely to be the most effective strategy to conserve benthic communities of seamount ecosystems (Clark et al. 2019).

3.2 Social and Economic Impacts

IUU fishing has economic impacts for fishers and consumers. In the short term, these impacts may be positive because any fish catch brings returns to fishers and cheaper fish to consumers. However, in the medium and long terms, the impacts become negative since a reduction in fish stocks leads to increased fishing costs, higher prices to consumers and economic losses to the tourism sector (Tinch et al. 2008; Zimmerhackel et al. 2018).

Indirect impacts continue across the value chain, which rarely ends when the catch is landed (except for subsistence fisheries where the catch is directly consumed). Instead, value is created each time the fish changes hands; for example, it is sold to markets and resold to consumers or to an intermediary who purchases large quantities for processing and resale to a retail outlet (Dyck and Sumaila 2010). Therefore, a reduction in catch results in a potential loss of added value across the fish value chain in the legitimate formal sector as well as a loss in household income to fisheries workers. For example, illicit trade in the marine resources of West Africa, including illegal fishing practices, is estimated to cost the region nearly $1.95 billion in lost economic impact across the fish value chain and $593 million per year in lost household income (Sumaila 2018). Another study estimated the economic and household income impact losses to be up to $21.1 billion and $5.4 billion respectively per year for the Pacific Ocean (Konar et al. 2019). The same study estimated the loss in tax revenues at $200 million to $1.6 billion per year, which means this money is not available for public spending on, for example, infrastructure, education or health care (Konar et al. 2019).

Decreased fish stocks due to overfishing may lead to social impacts, loss of cohesion and migration away from the coast towards urban areas, ultimately even stretching to conflict over resources (DCDC 2018). More likely is local disorder among fishers as a consequence of a decrease in household income due to reduced catch opportunities and reduced employment. For example, in Sierra Leone, skirmishes between artisanal and larger IUU fishing vessels is common in the inshore area, where trawlers often fish to within 100 m of the shoreline, placing them in direct competition with smaller vessels. Gear conflicts also occur, and there is often damage the artisanal fisher's nets or boats (Drammeh 2000). Another study using data from the Arafura Sea in Indonesia demonstrated that IUU fishing is one of the main drivers of gear conflict and gear loss (Richardson et al. 2018). For another example, see Box 15.4.

IUU fishing has created a culture of non-compliance because it takes advantage of corrupt administrations and exploits weak management regimes, especially those of developing countries that lack the capacity for effective MCS. IUU fishing can take fish from the waters of bona fide fishers, which can lead to the collapse of local fisheries, with small-scale fisheries in developing countries particularly vulnerable. Legal fishers and aquaculture producers, who are forced to compete with the unfair practices of IUU operators, face loss of market share and trade distortions due to the different cost structures of legal and illegal operators (Tinch et al. 2008). Products derived from IUU fishing can find their way into overseas trade markets, thus throttling local food supply (FAO 2018).

Fisheries-related crimes are closely linked with IUU fishing operations. These include forged fishing licenses, tax evasion, money laundering and inappropriate working conditions. More serious crimes, such as drug trafficking, human trafficking, arms trafficking and piracy, are also linked to IUU fishing. For more information, see the forthcoming Blue Paper 'Organised Crimes in Fisheries'.

3.3 Climate Change and Fisheries Management

Climate change is significantly changing ocean ecology in many ways that will affect fisheries, including reducing the fisheries catches, especially in the tropics. Unsustainable fishing practices worsen the effects of these negative changes; therefore, sustainable and adaptive fishing management practices should be employed to help mitigate them.

Box 15.4 IUU Fishers Impinge on Artisanal Fishery in Ghana
Saiko is the local name for illegal fish transshipments in Ghana, where industrial trawlers transfer frozen fish to specially adapted canoes out at sea. It used to be a practice whereby canoes would buy the unwanted bycatch of industrial vessels. However, the practice has developed into a lucrative industry in its own right, for which industrial fishers actively fish. Today, industrial trawlers target not only the demersal (bottom-dwelling) species for which they are licensed but also the same species as the artisanal fishing community, including the severely depleted small pelagics such as sardinella and mackerel. These catches, which often contain juvenile fish, are landed by the saiko canoes for onward sale to local markets. This has severe implications for Ghana's artisanal fishing sector, which is critical to food security and provides significantly more jobs than the saiko industry. Saiko is prohibited under Ghana's fisheries laws, attracting a fine of $100,000 to $2 million. The minimum fine increases to $1 million when catches involve juvenile fish or the use of prohibited fishing gear. Although saiko activities are widespread, there is a very low risk of arrest and sanction. Cases are generally settled through opaque out-of-court settlement processes, and there are no known examples of the minimum fines in the legislation being paid. In addition, most of the industrial vessels engaged in saiko are linked to foreign beneficial owners, which also contravenes Ghanaian law.

From March to September 2018, after a 2-month closed season for industrial trawlers, the government of Ghana intensified enforcement action against saiko, resulting in at least one high-profile arrest. This action led to a notable decline in saiko activities at the major saiko landing site of Elmina in Ghana's Central Region. During this period, trawlers were required to land their bycatch at either the Sekondi or Tema port: this 'official' bycatch was packed in cardboard and labelled with information on the trawler company that caught the fish, for onward transport to local markets.

This allowed government fisheries inspectors to monitor this catch and to check that it did not contain juveniles.

Some confusion now exists on the legality of saiko, and since 2018, landings have re-commenced at Elmina, with up to 15 saiko canoes landing fish each day. The 2010 Fisheries Regulations specifically prohibits the transshipment of fish at sea from Ghanaian industrial vessels to canoes. A recent legal opinion found that since the entry into force of the 2010 Fisheries Regulations, only those forms of transshipment that are not expressly prohibited under the regulations may be considered legal if supervised by an authorised officer. Since saiko is prohibited in the regulations, the legal opinion concluded it cannot be authorised (Fig. 15.7).

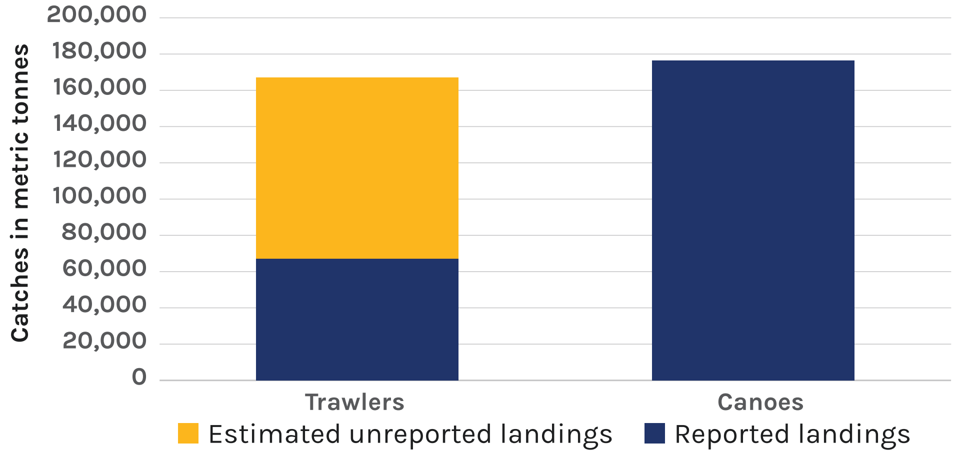

Fig. 15.7 Impacts of Saiko Fishing. (*Source: EJF and Hen Mpoano* 2019)

A recent Intergovernmental Panel on Climate Change (IPCC) special report, Ocean and Cryosphere in a Changing Climate (IPPC 2019), predicted that changes in global temperatures will impact the footprint of fisheries, consequently changing the behaviour of fishers, the incidence of IUU fishing and the connected ocean economy.

The report offered likely changes with low, medium or high confidence at various emissions scenarios. It predicted (with medium confidence) a decrease in the global biomass of marine animal communities, their production, and fisheries catch potential, and a shift in species composition over the twenty-first century from the surface to the deep seafloor under all emission scenarios. The rate and magnitude of decline are projected to be highest in the tropics (high confidence), whereas impacts would be diverse in polar regions (medium confidence). Projected impacts increase in high-emission scenarios. The report states that ocean warming has contributed to an overall decrease in maximum catch potential (medium confidence), compounding the impacts of overfishing for some fish stocks (high confidence; IPCC 2019). As fish stocks decline, fisher competition will likely increase, probably resulting in more IUU fishing (FAO 2018).

As the ocean has warmed, marine fish and invertebrates have shifted to track their preferred temperatures (Perry et al. 2005; Dulvy et al. 2008; Poloczanska et al. 2013; Pinsky et al. 2013). In general, this has resulted in shifts of fish populations poleward and into deeper waters. At a mean rate of 72 km per decade, marine species have been moving an order of magnitude faster than terrestrial species (Poloczanska et al. 2013). This redistribution of marine resources in effect redistributes wealth among coastal states, since some will lose their fisheries while others will gain. New fishing opportunities will emerge, while some established fisheries will be reduced (Bell et al. 2011; Fenichel et al. 2016). Areas under fisheries management could be destabilised, and some fish stocks could shift into unregulated fishing areas (Cheung 2016). This type of change often triggers conflict over access to resources (DCDC 2018).

The IPCC report underlined risks of severe impacts on biodiversity, which are projected to be higher for elevated temperatures under high-emissions scenarios. Projected changes include losses of species habitat and diversity and degradation of ecosystem functions. The capacity of organisms and ecosystems to adapt is higher at lower-emissions scenarios (high confidence). For sensitive ecosystems such as sea grass meadows and kelp forests, high risks are projected if global warming exceeds 2 °C above pre-industrial temperature, combined with other climate-related hazards (high confidence). Warm water corals are at high risk already and are projected to transition to very high risk even if global warming is limited to 1.5 °C (very high confidence).

Reducing the pressure of IUU fishing could lessen ocean degradation. Although nations must take rapid ambitious action to curb climate change, they must also fast-track adaptive fisheries management, along with new agreements that take a system-wide approach to marine resources management and ensure that benefits are shared fairly. Such a response would not only improve resilience and future-proof these vital industries but could also improve profits in some regions (Gaines et al. 2019).

The actions of fishers, management institutions and markets all influence the benefits derived from fisheries (Costello et al. 2016) and could mitigate many of the negative impacts of climate change (Gaines et al. 2018). Gaines et al. (2018) document the benefits of implementing climate-adaptive fisheries management reforms that address both changes in species distribution and productivity caused by climate change (Free et al. 2019). Incentivising cooperation to establish data sharing and collaborative management will require overcoming prevailing management mentalities that one party 'wins' while the other 'loses' when stocks shift across boundaries (Gaines et al. 2019).

This is a point to keep in mind as the UN Intergovernmental Conference negotiates a new legally binding instrument under the UNCLOS that, if successful, will result in robust protection for marine biological diversity in areas beyond national jurisdiction. While negotiating countries have agreed that the new instrument should avoid undermining existing bodies, they remain divided over whether the instrument should address fisheries management directly. Clearly, they should address the impacts of fisheries on biodiversity and are in a position to reduce gaps in governance and change the mentality of 'win-lose'.

Economic incentives are the first of the three drivers of illegal fishing described in Chap. 1. Economics directly drives IUU fishing activities (Sumaila et al. 2006). Increasingly thin margins in legal fishing operations and high potential revenues from IUU fishing are strong motivators for illegal activity (Becker 1968; Gallic and Cox 2006). However, voluntary market instruments supported by governments and new technological capability can begin to reshape these incentives. See also Appendix B for action suggestions.

4 Reframing the Economic Incentives for IUU fishing

4.1 Understanding Economic Incentives for IUU Fishing

In the most straightforward economic terms, IUU fishing is a high-reward, low-risk activity. There are too many highly lucrative opportunities where fishers' expected benefits from breaching regulations—large catches with low operating costs—outweigh the downside, in particular the risk of being detected and suffering any punishment.

4.1.1 Too Much Fishing Capacity

The global fishing fleet has increased, and fish stocks are facing record levels of overexploitation (Watson et al. 2013). The result is a global fishing fleet that is two to three times larger than needed to catch the amount of fish that the ocean can sustainably support (Joseph et al. 2010). At the same time, technological improvements in fish detection and fishing gear have made vessels more efficient, allowing them to further deplete resources (Knauss 2005). Access to deep-sea fisheries resources requires technology only available to industrialised countries with the capacity to build or acquire the large vessels. Developing countries, which are unable to partake in this industry and often have little capacity for enforcement, often see vessels from industrial countries fishing off their own coasts, which has been described predatory behaviour (Hornidge and Hadjimichael 2019).

In 2002, the FAO estimated that $3 million in revenue was gained from 1335 fishing vessels flying FOCs from 21 countries. This value was considered an underestimate because it did not include money gained from franchise/royalty fees or tonnage taxes.

Fishing farther away or differently is not always an alternative for small-scale artisanal fishers, who continue fishing the same overfished stocks, in many cases violating management regulations (e.g., spatial or reproductive bans, minimum legal size).

Without large government subsidies, as much as 54% of the present high-seas fishing grounds would be unprofitable at current fishing rates (Sala et al. 2018). Worldwide, governments spend about $35 billion annually—about 20% of the total value of all marine fish caught at sea and brought to port—to support the fishing sector (Martini 2019; Sumaila et al. 2016). Unfortunately, many of these subsidies are harmful and drive unsustainable practices. For example, the largest reported subsidy is for fuel, and this subsidy is the one most directly linked to overfishing.

Government subsidies and other fishing incentives pad the thin margins in many fisheries. The patterns of fishing profitability vary widely among countries, types of fishing and distance to port. Deep-sea bottom trawling often produces net economic benefits only thanks to subsidies, and much fishing by the world's largest fishing fleets would largely be unprofitable without subsidies and low labour costs (often associated with IUU fishing operations). These results support recent calls for subsidy and fisheries management reforms on the high seas. As of 2019, no real progress to eliminate capacity enhancing subsidies had been made (Sumaila 2019).

4.2 Changing Economic Incentives

If IUU fishing is a low-risk high-gain activity, the response must be to increase the risk of detection and reduce the gain. Regional entities with strategic roles in the seafood market can use market tools to eliminate IUU fishing products entering the region. Governments can build on these tools with sanctions and strict standards for the industry.

4.2.1 Transparent Supply Chains

Voluntary efforts in the seafood industry can achieve clearer supply chains by encouraging transparency and more due diligence in the buying chain. Several organisations—including Sustainable Fisheries Partnership, International Seafood Sustainability Foundation, Seafood Business for Ocean Stewardship, and the Marine Stewardship Council—are examples of such initiatives. These traceability efforts can provide assurance to consumers of the provenance of seafood while creating pressure for other market actors to adopt full supply chain transparency. Financing institutions such as banks and insurance companies can create additional pressure by requiring traceability and transparency as conditions of contracts. There are downsides; for example, they can act as trade barriers to developing countries where the fisheries sector is still evolving and the price tag and complexity of certification is a significant barrier.

4.2.2 Smart New Tracking Technologies

New technologies are making full supply chain traceability more technically and economically viable. For instance, the recent development of blockchain technology promises to allow for full traceability of fish products from their origin to their ultimate fate. Blockchain is an incorruptible, distributed digital ledger of transactions, which allows users to effectively and transparently measure, record and transact value. A 'transaction' can involve contracts, records, currency or almost any other information of value. Through a series of cryptographically secure algorithms, multiple blockchain nodes validate the transaction in a process known as consensus protocol. That transaction is combined in a block of data, which forms a chain of records maintained simultaneously across thousands of distributed nodes, hence forming a 'blockchain' that is permanent and unalterable. In effect, blockchain enables a single source of truth for chain of custody of any commodity along entire supply chains, from producer to consumer. Because of blockchain's immutable and verifiable nature, it offers greater levels of transparency and trust in supply chain transactions. It is a powerful lever to impose on market forces.

4.2.3 Consequences for Bad Behaviour

Governments can support industry action through regulation. For example, the European Union adopted an IUU fishing regulation to limit access of IUU fish to the market. Under this regulation, non-EU countries identified as having inadequate prevention mechanisms for illegal fishing may be issued a formal warning (known as a 'yellow card') to improve the situation within 1 year. If they fail to do so, they face having their fish banned from the EU market (known as a 'red card'), among other measures. The mechanism is seen as a success. As an example, South Korea and the Philippines received yellow cards, and both countries responded by diverting resources to deal with the problem. The cards were lifted following good responses from both countries. South Korea now has sufficient means to proactively prevent, deter and eliminate IUU fishing by closing loopholes in its systems. The Philippines has strengthened its commitment to fighting IUU fishing at the international level by ratifying the UN Fish Stocks Agreement (UNFSA) and initiating procedures to ratify the PSMA (EJF et al. 2015). Another example of an effort to control IUU fishing is given in Box 15.5.

Box 15.5 Increasing the Risk to IUU Fisheries

There is increasing interest in how private companies can reduce IUU fishing by increasing the risk to IUU fishers and their beneficial owners. At the first Ocean Risk Summit, held in Bermuda in 2018, leaders from across the political, economic, environmental and risk sectors identified potential exposures to ocean risk and prepared to generate new and dynamic solutions. As a result, the Ocean Risk and Resilience Action Alliance (ORRAA) was launched. This progressive concept brings together organisations from the public and private sectors and civil society focused on developing risk management strategies to deal with climate change and threats to communities which could include IUU fishing, the presence of bonded labour or other illicit activities. The Canadian government, AXA XL, Willis Towers Watson, the Nature Conservancy and Ocean Unite led the conception and development of ORRAA. Additional partners include the Inter-American Development Bank, Bank of America, KfW, the United Nations Development Programme and Rare. The Stockholm Resilience Center at Stockholm University will be a key scientific and knowledge partner. Companies like Planet Tracker are also driving change by engaging financial markets for sustainable practices across several commodities, including fish.

4.2.4 Corruption Can Undermine the Process

Corruption undermines good governance in fisheries. Vulnerabilities to corruption occur throughout the whole value chain, from rich countries' negotiations of access to territorial waters, to malpractices in fisheries management at the local level. Processors and distributors, and of course fishers themselves, can engage in corrupt practices (Sumaila et al. 2017).

5 Overcoming Weak Governance

5.1 Governance Gaps

IUU fishing is propelled by governance gaps internationally, regionally and domestically. These gaps are exploited by the IUU fishers and create obstacles to enforcement by authorities and fisheries managers. Weak governance is the second of the three drivers of IUU fishing. See also Appendix B for action suggestions.

5.1.1 Governance Problems Persist

The High Seas Task Force's (2006) *Closing the Net Report* found that, despite the appearance of a strong legal framework based on the UNCLOS, there were serious concerns about whether the UNCLOS can deliver an effective management regime and flag states can fulfil their responsibilities. An analysis of the discussions for the report indicated broad agreement on the following main governance-related problems:

- Failure of some states to participate in existing multilateral instruments as a critical constraint to effective implementation and enforcement.
- Inadequate implementation of existing instruments at the regional level, including lack of effective institutional arrangements, conservation and management measures that do not meet the standards set by the existing legal framework, and lack of coordination between regional bodies and inadequate harmonisation of measures.
- Inadequate flag state control over fishing vessels.
- Geographical and structural gaps in the system of high seas governance.
- Subsidies and other perverse signals that displace rather than eliminate unsustainable fishing.

Contributions to this Blue Paper indicate that little has changed in the 13 years since the High Seas Task Force report, but many of the tools predicted to be available are now mature and ready to be applied. The 2014 Global Ocean Commission report also named poor governance as a driver of decline in the ocean, stating, 'The existing high seas governance framework is weak, fragmented and poorly implemented. Different bodies regulate different industries and sectors, and in many cases, modern principles of ecosystem-based management, precaution…have yet to be brought to bear' (Global Ocean Commission 2014, 18).

5.1.2 Regional Fisheries Management Organisations and High-Seas Governance

The UNCLOS governs fishing in areas beyond national jurisdictions. Many of the world's most valuable fisheries, including tuna, are in international waters. However, human activities such as maritime transportation, marine pollution and fishing have caused serious depletion in high seas fish stocks (Freestone 2010). The UNCLOS, under Article 116, expresses a state's 'right to fish' the high seas, but this freedom is subject to the condition that marine living resources be used sustainably and with the rights and duties of coastal states in terms of straddling stocks.

The 1995 UNFSA [3] complements and strengthens the UNCLOS by requiring fisheries management to be based on precautionary and ecosystem approaches. It also enhances monitoring, control and enforcement (and even extends to boarding of non-compliant vessels) both by flag states and through international cooperation. Regional action, particularly through RFMOs, is necessary to implement the agreement effectively. However, there are regulatory gaps in the management regime created by RFMOs (Rayfuse and Warner 2008). In the case of high seas fishing, which is managed primarily by RFMOs, severe challenges result from a lack of cooperation between states; conflicting interests in resource use and conservation; fragmented responsibilities; lack of political will; lack of enforcement; and perverse economic incentives for 'free riders' to cheat the system (Global Ocean Commission 2014).

RFMOs are principally membership organisations. While under the UNCLOS all states have the general obligation to cooperate with each other in the conservation and management of living resources of the high seas, and parties to the UNFSA can only fish on the high seas if they apply the conservation and management measures set by the RFMO competent over that area or species, there are loopholes in the regional fisheries management scheme. RFMOs cannot exert control over non-member state fleets, and their members have limited capacity to apply some sanctions—for example, trade restrictions and import bans on certain types of fish products—to uncooperative non-member countries. Because RFMOs do not have uniform provisions across convention areas, this creates a patchwork of governance (Table 15.1).

RFMOs vary on their policies on how to set catch limits, monitor catches and impose penalties. The nonuniformity of RFMO policies makes some areas more vulnerable to IUU fishing. The five tuna RFMOs worked to remedy this patchwork by coordinating through the Kobe Process named after its launch in Kobe, Japan, in January 2007. The Kobe Process seeks to improve coordination across the whole range of RFMO policy, including scientific research, market issues, monitoring and surveillance, the impact of bycatches, and support for developing countries. One of the main concerns of the Kobe meeting and subsequent action plan was to secure support for developing nations to implement the recommended management measures, particularly those intended to prevent IUU fishing. However, only tuna RFMOs are involved.

NGO advocacy and UN General Assembly Resolutions 59/25 (2004) and 61/105 (2006) show a positive response to unregulated deepwater bottom fishing. Three new RFMOs—

[3]Officially, the United Nations Agreement for the Implementation of the Provisions of UNCLOS relating to the Conservation and Management of Straddling Fish Stocks and Highly Migratory Fish Stocks.

Table 15.1 Comparisons of several provisions among Tuna RFMOs

	International Commission for the Conservation of Atlantic Tunas (ICCAT)	Inter-American Tropical Tuna Commission (IATTC)	Indian Ocean Tuna Commission (IOTC)	Western and Central Pacific Fisheries Commission (WCPFC)	Commission for the Conservation of Southern Bluefin Tuna (CCSBT)
Requirement of International Maritime Organization (IMO) number	For vessels 20 m and greater	For vessels greater than 12 m	For vessels greater than 24 m	For vessels greater than 12 m	For vessels 100 gross tonnage and greater
100% observer coverage	For vessels 20 m and greater during specific times or closures, as well as for bluefin fishery	For large-scale purse seine vessels		For large-scale purse seine vessels	
Resolution on Labour Standards for Crew on Fishing Vessels				*Resolution on Labour Standards for Crew on Fishing Vessels* (Resolution 2018-01). Non-binding	
Cross-listing of IUU fishing vessels list	Allows cross-listing with other RFMOs		Allows cross-listing with other RFMOs		Allows cross-listing with other RFMOs
Prohibition of drift nets	Drift nets prohibited for fisheries of large pelagic in Mediterranean		Large-scale drift nets prohibited	Large-scale drift nets prohibited	
Allowing at-sea transshipment	Allowed for large-scale pelagic longline vessels, defined as those greater than 24 m length overall. Purse seine vessels (with some exceptions) prohibited from transshiping at sea and must transship in port	Allowed for large-scale tuna fishing vessels. Purse seine vessels (with some exceptions) prohibited from transshiping at sea and must transship in port	Allowed for largescale tuna fishing vessels. Purse seine vessels (with some exceptions) prohibited from transshiping at sea and must transship in port	Not allowed for other than purse seine vessels except in cases where the CCM has identified and reported vessels as being impractical not to transship at sea. Allowed for purse seine vessels 600 metric tonnes or less from Papua New Guinea and Philippines, New Zealand, domestic purse seine vessels, and for other vessels where Conservation and Management Measures has determined that it is impracticable to prohibit at-sea transshipment	Allowed for tuna longline fishing vessel with freezing capacity of storing 500 kg of southern bluefin tuna at −30 °C or below

Source: Drawn from Commission Webpages 2020

South Indian Ocean Fisheries Agreement, South Pacific Regional Fisheries Management Organisation and North Pacific Fisheries Commission—have formed to manage deep-sea bottom fisheries on the high seas. However, the deepwater bottom fisheries—particularly bottom trawl fisheries in all three Pacific and Indian Ocean RFMOs, and to a lesser extent in portions of the Atlantic—are not yet managed consistently with actions called for by the UN General Assembly. These actions are based on key conservation provisions of the UNFSA as well as the FAO Code of Conduct for Responsible Fisheries. Therefore, these fisheries could fit the definition of IUU fisheries, even though technically they are regulated (Gianni et al. 2016).

Further, RFMOs are not equipped with their own MCS systems. To track movements at sea, states use monitoring systems such as VMS, but only authorised people, typically the government officials in relevant flag or coastal states, can access this information. Most RFMOs require the use of VMS by large vessels authorised to fish within their convention areas. However, the member flag states are the ones with the authority, jurisdiction, and enforcement responsibility for mandating installation and operation of VMS and enforcing reporting obligations. Some RFMOs have initiated policies to allow direct transmission of VMS data to the RFMOs' secretariats. The effectiveness depends on the member states, and RFMOs have not yet established consequences for failure to comply. Some have considered or are considering the use of AIS as a more cost-effective means of tracking.

The performance of RFMOs has been under scrutiny for some time. The High Seas Task Force (2006) and the Global Ocean Commission (2014) have raised concerns with their effectiveness, and NGOs continue to press for better performance in the annual commission meetings.

5.1.3 Lack of Universal Mechanism to Assess State Compliance

Although some NGOs have produced reports to assess states' performance in combatting IUU fishing, there are insufficient tools and mechanisms to assess and evaluate states' adoption and implementation of the most important international instruments relating to IUU fishing. Therefore, states with poor performance do not have sufficient information on what areas need improvement and do not receive enough pressure to make improvements.

The FAO's IPOA-IUU is by far the most relevant international guidance, providing a set of measures that states should adopt to combat IUU fishing. Many countries have developed their own national plans of action (NPOAs) to reflect this guidance in their national context. However, the FAO does not assess the content or implementation of these national plans. Moreover, now close to 20 years old, the IPOA may benefit from a revision to reflect the latest developments in technological tools and transparency measures, as well as the inclusion of measures to support adoption and implementation of NPOAs. If the FAO could benchmark states against the measures detailed in the IPOA-IUU, states with poor performance would get a clearer understanding of areas needing improvement. In addition, the FAO, ILO and IMO can do more to help states ratify and implement the important suite of international treaties relevant to the fight against IUU fishing: the FAO'S Port State Measures Agreement, ILO Work in Fishing Convention and IMO Cape Town Agreement.

5.1.4 Gap Between Fisheries Management and Preventing Human Rights Abuses

The causal relationship of human rights abuses within IUU fishing has been described above. However, there is a gap between international organisations that manage fisheries and those that work to prevent human rights abuses. For example, currently only one tuna RFMO, the WCPFC, has a resolution addressing workers' human rights protection. However, there are opportunities within the existing international legal framework—for example, the ILO C188 and the CTA on fishing vessel safety—to protect fishers from human trafficking and forced labours.

The financial drivers behind illegal fishing can lead to poor safety and labour conditions for vessel crews. When stocks are overfished, fishers' catches and income are further reduced. The CTA sets minimum safety standards and allows flag, coastal and port states to inspect commercial fishing vessels. It is therefore a powerful tool that states can use to ensure that fishers are safe, conditions are decent and fishing operations are legal. But as long as enough countries do not ratify the agreements, they remain weak. It should be noted that at the meeting of the IMO in Torremolinos, Spain, in 2019, 48 countries committed to ratify the CTA by 2022. The WCPFC's recent Resolution on Labour Standards for Crew on Fishing Vessels (Resolution 2018-01) is groundbreaking yet falls short of providing adequate protections due to its status as a non-binding resolution with no non-compliance penalties.

The issue could be more adequately handled through licensing provisions specific to crew welfare agreed on in 2019 and due to be imposed at a sub-regional level by the Pacific Islands Forum Fisheries Agency (FFA) in 2020.

5.2 Solutions to Weak Governance

Strong, uniform governance is needed at the national, regional and global levels to combat IUU. Several international agreements provide a path forward towards consistent and effective fisheries management. States can adopt and implement these agreements to reduce IUU fishing. The IPOA-IUU provides clear and comprehensive guidance.

5.2.1 Adopt the Port State Measures Agreement

Since international efforts to combat IUU fishing cannot depend solely on the regime of flag state responsibility, more opportunities could be given to authorities of port and coastal states to address all impacts of IUU fishing. Illegal fishing operations cannot operate without a market for their catch. Fishing vessels (or supporting vessels such as reefers) must at some point visit a port to land fish, refuel, re-supply and take on crew, and vessels involved in illegal fishing operations are no exception. State regulation of access to port facilities is therefore a highly effective way of controlling illegal fishing.

The FAO adopted a key instrument targeting IUU fishing—the PSMA—at its 36th session on 22 November 2009. This agreement in principle strengthens the comprehensive and integrated approach to combatting IUU fishing, since it supports previously adopted instruments in the FAO framework, such as better performance by flag states, MCS, market access and trade measures. Generally, the PSMA authorises port states to apply it to vessels not entitled to fly a state's flag that are seeking entry to its ports or are in one of its ports. In particular, the agreement encourages each party to integrate its port state measures with the broader system of port state controls and measures in accordance with the IPOA-IUU at the national level.

The PSMA aims to prevent IUU catches from being landed and entering international markets. Since vessels must come to port prior to their fish entering the market, port state measures are potentially the most effective means to combat IUU fishing. The agreement sets a global standard of port inspection, improves information exchange and puts developing states in a better place to combat IUU fishing with the funding mechanisms provided by the agreement. Importantly, the PSMA is applicable to any vessel supporting IUU fishing, so it can be used to address fuelling/bunkering vessels or the carrier vessels that bring the fish to port. There is a further advantage; ports with low inspection resources can simply deny a vessel port entry under the PSMA. The more ports that implement the PSMA, the more effective it becomes.

5.2.2 Close the FOC Registry to Fishing Vessels

FOC states are those that register foreign-owned fishing vessels with minimum requirements and assessments. Closing such registries to the registration of fishing and fisheries-support vessels is an important and low-cost measure to combat IUU fishing. The FOC registries often have little connection to national fisheries ministries and are likely to represent a small source of income that is outweighed by the reputational damage done to the countries associated with IUU fishing; for example, the risk that legitimate national operators lose the right to export seafood to important markets such as the European Union (Fig. 15.8).

Although they appear to incur short-term loss, transitioning policies and efforts to combat IUU fishing efforts are economically beneficial in the long run. After imposing a closed registry policy in 2015, Indonesia has gained tax and non-tax revenue from the fisheries sector (California Environmental Associates 2018). Once the foreign-owned vessels, which all had committed various fisheries violations, were eliminated from the Indonesian registry and waters, they were replaced by new vessels owned by Indonesian industry. Since 2015, government agencies have been equipped with more advanced monitoring tools and supported by better fisheries governance, resulting in increasing tax and non-tax revenue from fisheries (Fig. 15.6).

5.2.3 Create Strong Deterrents

Deterrence is a key element in the battle to combat IUU fishing. Deterrence can be achieved via strong port controls, at-sea patrols, heavy fines or sanctions and other measures.

Port controls In terms of port controls, this paper emphasises the importance of the PSMA and encourages more states to ratify and implement this agreement. Because IUU fishing is a complex activity, those working to deter or eliminate it need a selection of mechanisms to make sure IUU fishers cannot slip though.

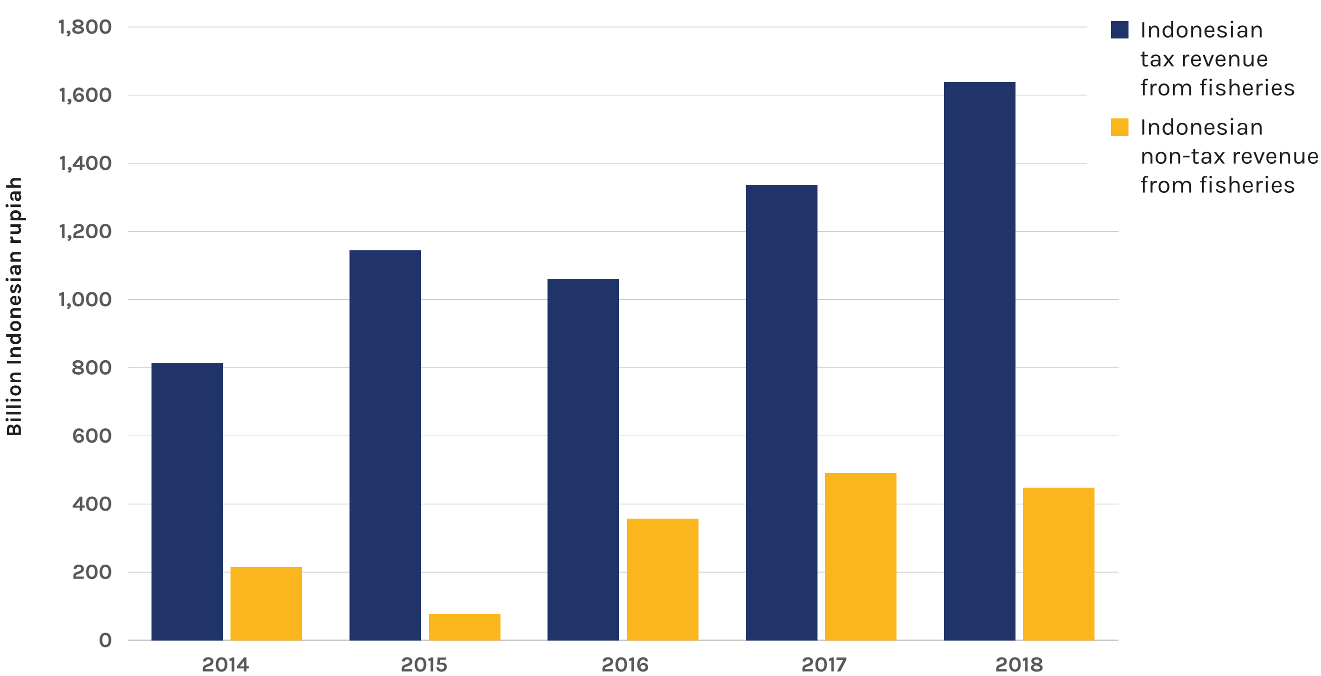

Fig. 15.8 Indonesian revenue from fisheries. (*Source: Ministry of Marine Affairs and Fisheries of the Republic of Indonesia* 2019)

Sanctions It is often said that sanctions for IUU fishing are not sufficient to hurt the fisher and are seen as a cost of doing business. The IPOA-IUU calls on states to ensure that sanctions are heavy for IUU fishing offenders. Realising the immense loss caused by IUU fishing, countries are executing stronger penalties. In May 2019, Thailand's criminal court handed out a fine of over $16 million to 6 defendants in the prosecution of the overseas fishing vessel *Chotchainavee 35* (Undercurrent News 2019). In 2018, the owner of the pirate fishing vessel F/V Thunder was fined $10.1 million in a civil case brought by the Spanish government (Holland 2018). In another example, Indonesia has elected to sink offending vessels as an optimum penalty to create a strong deterrent. Minister of Maritime Affairs and Fisheries Susi Pudjiastuti reported in her farewell speech in October 2019 that 556 vessels engaged in IUU fishing had been sunk during her tenure. This policy has resulted in a reduction of at least 25% in fishing effort within the Indonesian EEZ, based on VMS data together with AIS and night light satellite imaging data (Cabral et al. 2018).

IUU vessel lists published individually by each RFMO and as a combined historical list by Trygg Mat Tracking act as a deterrent to a degree, but there is now a movement to see all fines and sanctions be published and transparent. This would show who is being fined or sanctioned and for what, and also which states and organisations are taking seriously the need to act against IUU fishers (EJF 2018).

Transparency A vessel whose behaviour is public is likely to become compliant. Again, several NGOs have promoted ten principles of transparency. These measures are in line with reports from organisations such the High Seas Task Force (2006), the Global Ocean Commission (2014), the Royal United Services Institute (Haenlein 2017) and the Organisation for Economic Co-operation and Development (Hutnikzac and Delpeuch 2018). Countries are also steadily embracing transparency, with notable action by Chile, Panama, Peru and Indonesia in sharing VMS vessel tracking data and the European Union, Taiwan, Thailand and Mozambique in publishing authorised vessel lists.

At-sea patrols Patrols will always be necessary but are a relatively high-cost option.

Multilateral agreements Where possible, resource sharing and multilateral agreements should ensure that at-sea assets can be effectively tasked and made as costeffective as possible. Agreements such as the Niue Treaty Subsidiary Agreement (NTSA) should be replicated. The NTSA is an agreement in which FFA members agree on monitoring, control and surveillance of fishing—including provisions on exchange of fisheries data and information, as well as procedures for cooperation in monitoring, prosecuting and penalising operators of IUU fishing vessels.

5.2.4 Improve Transboundary Case Handling

Enhanced cooperation on investigation and prosecution processes can be achieved through the framework of temporary multilateral investigative support teams, mutual legal assistance between states and an established international team such as the Global Fisheries Enforcement Team supported by Interpol. Even in the absence of a mutual legal assistance framework, states across regions have come to work together in handling transboundary cases (Box 15.6).

Box 15.6 Case Study: *HUA LI 8*—Transboundary Cooperation to Catch an Illegal Fishing Vessel

A success story in tracking and capturing an IUU vessel is the case of the vessel HUA LI 8. The vessel was detected fishing illegally within Argentina's 200-nautical-mile EEZ. Two ships and a helicopter from the Argentine naval command confronted the vessel, which proceeded to take evasive action. Ignoring several requests to stop broadcast in Spanish and English on applicable international VHF channels, as well as visual and audio signals (on Maritime Mobile Service VHF Channel 16) and warning shots, the boat endangered its crew, Argentinian authorities and other ships in the vicinity by continuing to sail. The pursuit was subsequently called off, and visual contact was lost after the boat's entry into Uruguayan waters.

Given the obstructive way in which the vessel evaded security forces, Argentina requested the assistance of Interpol through the Environmental Crime Programme's Project Scale in alerting other member countries to the illegal fishing activities of HUA LI 8 through issuance of a Purple Notice (an international communication mechanism alerting authorities to the modus operandi in IUU fishing), as well as engagement with other countries to track the vessel as it travelled across the Atlantic and Indian Oceans. On 21 April 2016, the Indonesian navy (Lantamal 1 Naval Base at Belawan, North Sumatera) detected the HUA LI 8 in waters near Aceh, Indonesia, and successfully boarded and began its inspection of the vessel.

Source: Interpol (2016).

5.2.5 Enhance Transparency in Fisheries

Global transparency in the fishing industry is a solution to governance issues that has relatively low cost and is a manageable action. The Environmental Justice Foundation publication *Out of the Shadows* contains ten principles for global transparency in the fishing industry that all countries could adopt:

- Give all vessels a unique number.
- Make vessel tracking data public.
- Publish lists of fishing licences and authorisations.
- Publish punishments handed out for fisheries crimes.
- Ban transferring fish between boats at sea—unless pre-authorised and carefully monitored.
- Set up a digital database of vessel information.
- Stop the use of FOCs for fishing vessels.
- Publish details of the true owners of each vessel—who takes home the profit?
- Punish anyone involved in IUU fishing.
- Adopt international measures that set clear standards for fishing vessels and the trade in fisheries products (EJF 2018)

Transparency is highlighted by the Fisheries Transparency Initiative (FiTI), a unique effort that complements and supports other national, regional and global efforts to achieve responsible fisheries governance. The purpose of the FiTI is to increase transparency and participation in fisheries governance for the benefit of a more sustainable management of marine fisheries. The FiTI is not owned or operated by one organisation, nor does it represent the work of a single interest group. Instead, the diversity of stakeholders is a central feature of how the FiTI works, for national implementations as well as international governance.

The FiTI is a global initiative, and its implementation is country centred. The intention to join the FiTI and the initiation of the official process must come from a country's government. It is a voluntary initiative with mandatory requirements, built on a multi-stakeholder governance structure, ensuring that stakeholders from government, companies and civil society are equally represented. The FiTI embraces the following principles:

- Public registry of national fisheries laws, regulations and official policy documents
- Summary of laws and decrees on fisheries tenure arrangements
- Publication of all foreign fishing access agreements
- Publication of existing national reports on the state of fish stocks
- Public online registry of authorised large-scale vessels, as well as information on their payments and recorded catches
- Information on the small-scale sector, including the numbers of fishers, their catches and financial transfers to the state
- Information on the post-harvest sector and fish trade
- Information on law enforcement efforts, including a description of efforts to ensure compliance by fishers and a record of offences in the sector
- Information on labour standards in the fisheries sector
- Information on government transfers and fisheries subsidies
- Information on official development assistance regarding public sector projects related to fisheries and marine conservation
- Information on the country's status regarding beneficial ownership transparency

6 Ensuring Effective Enforcement

Even strict regulations are not always implemented or enforced. Lack of enforcement is the third of the three drivers of IUU. This section identifies barriers to enforcement and makes suggestions on how to improve enforcement. See also Appendix B for action suggestions.

6.1 Barriers to Enforcement

Lack of political will, coupled with the logistical difficulties in monitoring and reaching vast areas of the ocean, often results in weak enforcement. In some instances, the penalties imposed by courts of law have been described as a 'slap on the wrist' or 'part of the costs of doing business'. The penalties imposed by courts should reflect the importance with which marine living resources are viewed. The public and potential transgressors should be made aware of instances in which severe penalties are imposed. The judiciary should therefore be sensitised in this regard. National bodies, such as organisations representing prosecutors and/or judges, should disseminate information among their members in attempts to encourage uniformity at an appropriate scale.

These barriers to effective enforcement allow IUU fishers to exploit weaknesses in the system to fish undetected. New technological capabilities, alongside tighter port controls and clearer understanding of vessel activity and authorisations, show new possibilities for how these can be overcome.

These actions often fall to governments, but industry and the private sector can play a vital role in driving their supply chains towards better-governed and more diligent fisheries, vessels and ports. Action by the private sector could help port states focus on better enforcement against illegal and unreported fishing activities. Some enforcement is hampered by the unwillingness of states to enforce the law against their own fishing fleets. Some states do not have adequate facilities to conduct MCS. Monitoring is also a responsibility of flag states. As stipulated in the UNCLOS, flag states' responsibility includes ensuring the level of compliance of their fleets operating inside and outside of their waters. But some resource-challenged states find this difficult, while others have other priorities. A forthcoming global review by Australia's Commonwealth Scientific and Industrial Research Organisation (CSIRO) of the scientific literature on the causes of fisheries depletion is expected to document that the lack of MCS is the most common driver of fisheries depletions. This lack is cited as one of the key drivers in 90 out of 164 studies. Given the tight link between fisheries depletion and illegal fishing, the resulting weak control of fisheries operations further exacerbates depletion as a driver for both domestic and foreign illegal fishing.

In reality, no mechanism obligates all states to share monitoring data publicly. One initiative has been created—Global Fishing Watch—but it remains voluntary, so its effectiveness depends on states' awareness and willingness to cooperate. States currently use different types of fisheries monitoring platforms that do not integrate data routinely, which leads to inefficiencies in fisheries monitoring systems globally. Systems like OceanMind and Skylight are designed to improve the sharing of non-public data and drive direct enforcement action. Beyond fisheries, there is a trend to create fusion centres, designed to bring monitoring of different maritime issues, including fishing, together in one centre. This is a positive concept. Such systems are a positive step forward in the fusion of military and civilian data.

The enforcement of RFMOs' respective instruments is still frequently hampered by the willingness of their member states to enforce the regulations against their own vessels and the activities of non-parties. Principally, enforcement is undertaken by flag states, as laid down in Article 92(1) of the UNCLOS. However, Article 21 of the UNFSA includes provisions allowing various types of enforcement by states other than flag states on the high seas, although this exception can only be invoked under certain conditions. First, it only applies in high seas areas that fall within the geographical competence of RFMOs. Second, only members of these RFMOs are allowed to take enforcement measures, and only for the purpose of ensuring compliance with conservation and management measures of these RFMOs. Third, only fishing vessels flying the flag of a state party to the UNFSA can be subjected to these enforcement measures, whether or not that state is also a member of these RFMOs. Fourth, the procedures for high seas enforcement as set out in paragraphs 4–18 of Article 21 and Article 22 of the agreement shall be applicable if RFMOs do not establish their own procedures (Molenaar 2011).

Looking at those strict conditions that invoke this exception, it is argued that it hardly affects the flag state primacy. Once an infringement is detected, the flag state should be notified to pursue enforcement process. Therefore, the effectiveness of enforcement remains subjected to flag state willingness and capacity, unless RFMOs have their own procedures. Conversely, viable penalties for flag states are not in place in case of non-compliance.

6.2 Improving Enforcement

Improving enforcement will require capacity building and support for port states and coastal states, regional and global information sharing, and heightened monitoring of fishing fleets, transshipment incidents and catch data.

6.2.1 Build Capacity and Support

In some areas, illegal fishing perpetrators are largely unpunished or poorly punished for many reasons. Among others are poor awareness among law enforcement officers, difficulties in communication between related agencies and inadequate capability to conduct a thorough investigation. Effective law enforcement requires law enforcement officers and other role players in the criminal justice system to have adequate skills to handle the complexities of IUU fishing operations, which are often associated with other crimes. A joint capacity-building program accommodates sharing of ideas and experiences besides capacity building trainings.

FishFORCE Academy, a platform for training officials who are involved in the fight against fisheries crime, has been established at the Nelson Mandela University. The project will aim to establish fisheries crime law enforcement as a new and emerging fisheries compliance model and will endeavour to achieve knowledge and intelligence-led investigations and increase successful prosecutions of criminals engaged in fisheries crime. While building capacity, the project will also enable fisheries law enforcement officers to obtain formal qualifications in their chosen field of expertise. These qualifications will include higher certificates, diplomas and a post-graduate diploma, which will also provide access to further academic qualifications.

Similarly, the Australian government recently ran a capacity-building program implemented by the CSIRO, Australia's national science institution, to build capacity among fisheries monitoring and surveillance officers across the Southeast Asian region. The two-phase program included country visits to understand capacity and needs for fisheries MCS analysis and to identify key emerging enforcement issues, followed by a customised training course targeting MCS analysts. The training course included three fisheries staff members from each of the 12 regional countries. The weeklong training course included instruction and tools for identifying abnormal patterns in monitoring and surveillance data; analysing spatial and temporal data such as VMS, landings and observer records; and developing risk assessment models and prioritising inspections and other MCS activities.

In recent years, NGOs are increasingly involved in enforcement, through provision of capacity such as vessels, technology or training, and work closely with coastal states in global geographies such as Italy, Gabon, Ghana, Namibia, Benin and Cape Verde to help combat IUU fishing.

6.2.2 Establish Regional Information Sharing and Cooperation Mechanisms

The experiences of the FISH-i Africa and Fisheries Committee for the West Central Gulf of Guinea West Africa Task Forces, as well as the FFA's Niue Treaty Subsidiary Agreement and associated Niue Treaty Information System, have demonstrated the value of groups of countries establishing mechanisms and communication platforms for the increased sharing of fisheries intelligence, cooperation of MCS operations and cases, and coordination and harmonisation of fisheries management and regulations. This approach has clearly demonstrated that regional cooperation and information sharing, coupled with dedicated analysis and technical expertise, can exclude high-risk vessels and operations from a region, prevent IUU catch from entering ports and getting to market, and significantly hinder the ability for illegal operators to operate and make a profit. The basic structures of successful cooperation are in line with and benefit from increased availability and, where possible, transparency of information—including sharing of information on licensed vessels, port inspections and vessel movements—and cooperation on investigations. If this can be achieved, the results have proved to be significant, with a range of illegalities quickly uncovered and acted on, including arrests, settlements, payments of fines, exposing and shutting down fraudulent licenses and other documents, and an increase in license revenue.

6.2.3 Monitor Transshipments

The monitoring and control of transshipment poses a significant problem because so much of the activity takes place out of sight and reach of authorities. This is especially true for at-sea transshipment, which occurs far from land. Even in port, proper oversight often cannot be guaranteed because of limited inspection capacity or insufficient port state processes, protocols or procedures. Collectively, these practices contribute to IUU fishing. To make matters worse, the lack of transparency regarding the monitoring and control over transshipment fosters conditions conducive to other criminal activities, such as trafficking in weapons, drugs and people, and contributes to concerns about labour conditions on board vessels that are at sea for extended periods (Box 15.7).

Box 15.7 Case Study: *Silver Sea 2*—Transshipment and Human Trafficking

The fishing vessel Silver Sea 2 was seized by the Indonesian navy in August 2015 amid a crackdown on illegal fishing and after an Associated Press investigation showed its links to human trafficking in the fishing industry. When identified by the SkyTruth analysts through AIS and Digital Globe satellite images, the Silver Sea 2 was in Papua New Guinea waters, receiving illegal Indonesian catch from two fishing trawlers via transshipment. It was captured by an Indonesian navy vessel off the island of Sumatra after returning to Indonesian waters. The Thai captain was detained, and a probe was launched into suspected human trafficking, transporting illegal fish and offloading the catch at sea. The Associated Press investigation resulted in the freeing of more than 2000 men from Myanmar, Cambodia, Thailand and Laos, more than a dozen arrests, the changing of U.S. legislation, and lawsuits.

Source: McDowell et al. (2015).

Emerging transparency tools, like Global Fishing Watch, or more proprietary systems, like OceanMind and Skylight, that fit the more traditional enforcement-focused models, provide new capabilities to identify and monitor these transshipment activities. The private sector is key here, since it brings into the commercial space new capabilities that can then be used to monitor effectively. A good example of this is HawkEye 360, which has used military technology to develop a commercial system that can detect radio and radar emissions from vessels. This could be very useful for detecting vessels attempting to avoid transmitting on their AIS or VMS.

Flag, coastal and landing states can also play a major role in this area. For instance, Thailand now equips all of its fish carrier vessels with electronic monitoring, including on-demand real-time video cameras. This allows fisheries officials in the national monitoring centre to oversee vessel operations, including location, use of onboard machinery, access to refrigerated storage, and other activities in real time. If suspicious activity is detected, the staff can bring the onboard video cameras online via satellite connection, allowing them to see any suspicious activity, including transshipment.

Surveillance technologies for monitoring non-compliant vessels combined with onboard monitoring of carrier vessels has the potential to remove transshipment completely as a source of IUU fishing risk.

6.2.4 Improve Monitoring of the Fishing Fleet

Leading experts are calling for a conscious reframing of the perception of what is possible in terms of monitoring the fishing fleet and support vessels and for people to act now and at scale. Seeing transparency and compliance as a vital tool in the good stewardship of our global ocean is part of that reframing—to fight illegal fishing, to protect fish stocks and livelihoods and to increase the safety and well-being of fishers. If countries publicly share their fishing vessel monitoring data, then a more complete and connected picture of global fishing activity can be created. Law-abiding fishers are tracked easily and openly, demonstrating their compliance. Rogue operators stand out due to their patchy track record or suspicious behaviour. Compliant fishers can be rewarded through faster, more efficient port entry and landings. Unauthorised vessels and those that have a history of non-compliance can be prioritised for inspection or even denied port entry. By embracing transparency, nations have a more cost-effective way of monitoring vessels that puts the burden on fishers to demonstrate compliance rather than on the country to prove illegality. Transparency can incentivise, recognise and reward honest fishers, while exposing, penalising and ultimately putting out of business those who act outside the law.

The simplest way to combat the absence of tracking data is to make it a condition of landing fish. If a vessel cannot explain or display its track history since its last landing, then it should not be able to land its catch. At the very least, it should be subject to robust inspection and verification.

7 Three High-Level Decisive Opportunities for Action

Three specific opportunities for action provide a robust yet achievable response to the global threat of IUU fishing and help ensure ocean health, biodiversity and a sustainable ocean economy in the future. These actions are clear and tangible routes to implementing global policy or supporting existing vital policies. They are directly associated with solving the key drivers of IUU fishing identified in this paper—economic incentives, weak governance, and poor enforcement—and they can be sustained and are not dependent on consensus in the face of a belligerent state or actor. They can be addressed by flag, port, coastal and market states. Business, industry, private sector organisations, scientists and civil society can also contribute through advocacy, leadership and firm actions of their own. These three actions are:

- adopt global transparency in fisheries,
- ratify and implement the FAO's PSMA, and
- enhance regional cooperation.

7.1 Adopt Global Transparency in Fisheries

The first opportunity for action is to adopt global transparency in fisheries. There are several elements to this shift in narrative away from an enforcement-focused system to one that rewards compliance and good behaviour. In promoting transparency, the international community will be addressing all three drivers of IUU fishing. Transparency makes it far more difficult to bring IUU fish to port by shifting economic incentives. Vessels with missing information can be treated as suspicious and prioritised for inspection or action. Transparency is an effective way to support key policies such as the PSMA. It makes monitoring and inspections easier to prioritise and more cost-effective. It addresses weak governance and barriers to enforcement by improving information and data sharing. It shifts the burden to the fisher to prove compliance, rather than the state to prove malpractice. Actions in this category can be achieved quickly and will have a positive impact on the fight to end IUU fishing and will not disadvantage the more resource-challenged countries. Significant commitment could be demonstrated before the end of 2020 in support of SDG 14.4:

- Flag or coastal states could make unedited VMS data, or other proprietary tracking systems, public or mandate AIS for fishing vessels. Industry and other private sector organisations should seek this action as a part of their conditions of contract or in doing business.
- Coastal states could publish up-to-date lists of all fishing licenses, authorisations and vessel registries, transshipment authorisations and refrigerated vessels registries. Private sector organisations should seek these documents as a part of their conditions of contract or in doing business.
- Port, flag or coastal states could mandate IMO numbers for all eligible vessels and implement a national Unique Vessel Identifier (UVI) scheme for non-eligible vessels, maintaining a vessel registry and providing all information to the FAO Global Record of Fishing Vessels. Industry and private sector organisations should seek this action as a part of their conditions of contract or in doing business.
- Business, industry and finance institutions are encouraged to make fisheries transparency and traceability conditions of their contracts.
- All sectors should make sure of the accuracy of ownership information to avoid the use of shell companies.

More progressive actions would include the following efforts:

- Publish information on beneficial ownership in all public lists and require companies to provide information on true beneficial ownership when applying for a fishing license, fishing authorisation or registration to their flag.

- Mandate and implement the near-term adoption of cost-effective digital tools that safeguard in a digital form key information on vessel registration, licenses, unloading records, catch location and information and crew documentation that should be designed in such a way as to support a rapid move towards a universal, interoperable digital catch certification scheme.
- Improve transshipment activities information through mandatory and public pre-authorisation and robust and verifiable electronic monitoring scheme by the end of 2020 in support of SDG 14.4.
- All states should publish information on arrests and sanctions imposed on individuals and companies for IUU fishing activities, human trafficking and other related crimes to an accessible international platform.

7.2 Ratify and Implement the FAO's Port State Measures Agreement

The second opportunity for action is the ratification and proper implementation of the FAO's PSMA by all port states. Again, it addresses all three drivers of IUU fishing. Fully implemented, it represents a cost-effective method of stopping IUU-caught fish from entering the market. The PSMA is the first binding international agreement that deals specifically with IUU fishing by requiring parties to place tighter controls on foreign flagged vessels seeking to use their ports, with a view to detect and prevent the trade of IUU products. States implementing the PSMA can refuse entry to ports or access to port services to vessels known to have engaged in IUU fishing, allow vessels entry into port for inspection for vessels suspected of having engaged in IUU fishing, and encourage information-sharing mechanisms with other relevant states and organisations to facilitate cooperation in enforcement actions. The PSMA changes behaviour and stops the formation of ports of convenience that undermine good governance. The CTA and the ILO C188 are complementary regulations and can be considered during ports inspections under the PSMA. Industry and the private sector should seek this action as a part of their conditions of contract or in doing business.

7.3 Enhance Regional Cooperation

The third opportunity for action is to enhance regional cooperation. To make marked progress in addressing the drivers of IUU fishing activities, we need a more 'joined-up' approach among governments, civil society, science, industry and the private sector for a system that is coherent and consistent in its actions to combat IUU fishing. Actions under this banner would include the following efforts:

- An international forum or other mechanism should address the non-uniformity of RFMO regulations.
- Coordination and data transparency must be improved among RFMOs, flag states, regional mechanisms and the coastal and market states. Coastal states should communicate information on IUU fishing–related infringements to neighbouring coastal states. Port states should provide information to flag states on transshipments, landings and denials of use of port involving vessels flying their flag, as well as the result of inspections. Flag states should cooperate with the RFMO or nation state to investigate and take action in cases of presumed IUU fishing by their vessels.
- All RFMOs should adopt strong policies on monitoring and enforcement and also create sanctions for flag states not performing enforcement measures.
- In terms of institutional arrangement, an authorised international body should oversee the performance of each RFMO, identify the gaps where fisheries management is non-existent and push forward marine protected areas in the high seas.
- Digital schemes for documenting catch data should be implemented in order to promote global exchange of information. All states should mandate and implement the near-term adoption of cost-effective digital tools that safeguard in a digital form key information on vessel registration, licenses, unloading records, catch location and information and crew documentation. These digital systems must be secure and have built-in procedures to prevent the unauthorised deletion or overwriting of data.
- Regional information-sharing and coordination bodies, such as Regional Plans of Action to address IUU fishing, should be developed. The Regional Plan of Action in the Southeast Asian region is a key forum for countries in the region to discuss IUU fishing–related issues and coordinate actions.

These actions are tangible and transformational if achieved. It should be noted that as well as addressing the three drivers of IUU fishing, they can be pressed home by industry, the private sector and civil society, as well as by governments.

Appendix A outlines existing fisheries agreements and organisations, and Appendix B summarises the voluntary actions that can be taken by various stakeholders to meet the goals of SDG 14.4.

Acknowledgements The paper's technical reviewers, Alf Hakon Hoel, Adriana Fabra, Paulus Kaigne, Jim Leape and Juan Mayorga, as well as its arbiter, Nicola Frost, all provided helpful technical comments on this Blue Paper.

The authors also thank the World Resources Institute for providing support as the Ocean Panel Secretariat.

While our colleagues were very generous with their time and input, this report reflects the views of the authors alone.

The authors thank LSF Editorial for copyediting and Jen Lockard for design.

About the Authors

Co-authors

Sjarief Widjaja is a Professor of Production Management and Shipping Operations and is the Director General of Agency for Marine and Fisheries Research and Human Resources, Ministry of Marine Affairs and Fisheries (Indonesia).

Tony Long is the CEO of Global Fishing Watch (USA) and retired Royal Navy officer (UK).

Hassan Wirajuda is a scholar of International Ocean Law and Policy, a former Minister for Foreign Affairs (Indonesia), and a co-founder of the Indonesia Ocean Justice Initiative.

Contributing Authors

Hennie Van As is a Professor of Public Law and a Director at the Nelson Mandela Metropolitan University, Port Elizabeth (South Africa).

Per Erik Bergh is CEO of Nordenfjeldske Development Services (NFDS), Managing Director of NFDS Africa.

Annie Brett is an André Hoffman Fellow at Stanford Center for Ocean Solutions and a Fellow at the World Economic Forum Center for the 4th Industrial Revolution (USA).

Duncan Copeland is the Executive Director of Trygg Mat Tracking (TMT) (Norway).

Miriam Fernandez is a Senior Research Fellow at the Knowledge Media Institute (KMi), Open University, and a member of KMi's Social Data Science Group.

Achmad Gusman is the Vice Dean and an assistant professor at the Law Faculty, Universitas Padjadjaran (Indonesia).

Stephanie Juwana is a founder of the Indonesia Ocean Justice Initiative and former legal counsel at the Special Task Force to Combat IUU fishing (SATGAS 115).

Toni Ruchimat is a lecturer at Jakarta University of Fisheries and former Director of Fisheries Research Center, Ministry of Marine Affairs and Fisheries (Indonesia).

Steve Trent is co-founder and Director of Environmental Justice Foundation (UK).

Chris Wilcox is a research scientist with Commonwealth Scientific and Industrial Research Organisation (CSIRO) (Australia).

Appendix A: Instruments and Tools to Combat IUU Fishing

Binding International Instruments on IUU Fishing

Legally binding instruments are available to states, which accommodate state measures and set standards on combatting IUU fishing within their jurisdictions, such as the UN Convention on the Law of the Sea, the Port State Measures Agreement, the UN Fish Stocks Agreement and the Food and Agriculture Organization of the United Nations (FAO) Compliance Agreement. Several instruments related to IUU fishing operations address other issues such as safety of life at sea and human rights abuses of fisheries workers; namely, the International Labour Organization (ILO) Work in Fishing Convention and the Cape Town Agreement. These instruments do not prevent illegal fishing in artisanal fisheries, which rely on local, usually informal, markets.

- **UN Convention on the Law of the Sea (UNCLOS).** The UNCLOS is a landmark instrument sometimes described as a 'constitution for the ocean'. It provides the international legal basis for the protection and use of living and non-living resources of the world's ocean. However, the UNCLOS did not devote much attention to high seas fishing (FAO 2000). The UNCLOS includes the following key features concerning IUU fishing:
  - All states enjoy the traditional freedoms of navigation, over-flight, scientific research and fishing on the high seas; they are obliged to adopt, or cooperate with other states in adopting, measures to manage and conserve living resources.
  - Every state shall effectively exercise its jurisdiction and control in administrative, technical and social matters over ships flying its flag.
  - Disputes can be submitted to the International Tribunal for the Law of the Sea established under the UNCLOS, to the International Court of Justice, or to arbitration.
- **Agreement to Promote Compliance with International Conservation and Management Measures by Fishing Vessels on the High Seas (Compliance Agreement).** In 1993, the FAO Conference adopted the Compliance Agreement. The principal aim of this agreement is to enhance the role of flag states and to strengthen their control over their vessels in ensuring compliance with relevant international instruments.

The FAO Compliance Agreement in principle applies to all fishing vessels that are used or intended for fishing on the high seas. It acknowledges the issue regarding the failure of flag states to fulfil their responsibilities in ensuring the compliance of vessels entitled to fly their flag with international conservation and management measures for living marine resources. Therefore, it heavily focuses on measures to be taken by flag states to address such a failure. The FAO Compliance Agreement also underscores the importance of international cooperation, particularly cooperation with developing countries and cooperation as an effort to encourage non-state parties to adopt laws and regulations consistent with the provisions of the agreement.

Despite the importance of this instrument, some observers have indicated that most states often involved with IUU fishing and the practice of flags of convenience (FOCs) are not willing to ratify the FAO Compliance Agreement (Tanaka 2012). As of July 2018, the agreement only had 42 parties.

- **UN Fish Stocks Agreement (UNFSA).** The 1995 UNFSA further elaborates possible mechanisms for international cooperation, as stipulated in the UNCLOS, concerning the conservation and management of straddling and highly migratory fish stocks, especially through the establishment of sub-regional and regional fisheries management organisations (RFMOs) and arrangements. These organisations and arrangements need to address the following essential matters:
  - Stocks to which conservation and management measures apply
  - Area of application
  - Relationship between the work of the new organisation or arrangement and the role, objectives and operations of any relevant existing organisations or arrangements
  - Mechanisms by which the organisation or arrangement will obtain scientific advice and review on the status of the stocks

Non-binding International Instruments on IUU Fishing

Non-binding instruments provide voluntary guidelines for states to follow.

- **FAO Code of Conduct for Responsible Fisheries (CCRF).** The FAO has also initiated the CCRF, which was adopted in Resolution 4/95 by the FAO Conference on 31 October 1995. This voluntary, non-binding instrument aims to set 'international standards of behavior' for responsible practices with regard to the conservation, management and development of marine living resources. Although the CCRF does not create legally binding obligations, it may be given or have already been given binding effect as a result of the implementation of relevant rules of international law by state parties, such as the UNCLOS and the UNFSA. In addition, despite the fact that it is a voluntary instrument, the CCRF has been regarded as an influential instrument in guiding national governments in developing their fisheries sector policies (Allison 2001).
- **International Plan of Action to Prevent, Deter and Eliminate Illegal, Unreported and Unregulated Fishing (IPOA-IUU).** The IPOA-IUU underscores the importance of a comprehensive and integrated approach in combatting IUU fishing. In this regard, this instrument encourages states to adopt measures necessary to address the failure of flag states in fulfilling their responsibilities, including port state measures, coastal state measures, and market-related measures. As with the CCRF, commitments under the IPOA-IUU are built on relevant international legal instruments, particularly the UNCLOS, the UNFSA, and the Compliance Agreement. Such commitments are also supported through the adoption of a plan of action at the national level (National Plan of Action to Prevent, Deter and Eliminate Illegal, Unreported and Unregulated Fishing, or NPOA-IUU) as well as the regional level (Regional Plan of Action to Prevent, Deter and Eliminate Illegal, Unreported and Unregulated Fishing, or RPOA-IUU).
- **Voluntary Guidelines for Flag State Performance and Voluntary Guidelines for Catch Documentation Schemes.** The FAO has also adopted Voluntary Guidelines for Flag State Performance and Voluntary Guidelines for Catch Documentation Schemes. These non-binding instruments complement international efforts taken under the aegis of the FAO in combatting IUU fishing. It could therefore be concluded that the FAO has attempted to galvanise all key and crucial factors in combatting IUU fishing. These include the adoption of multiple state jurisdictions (flag state, coastal state and port state) in enforcing laws and measures against IUU fishing, as well as the acknowledgement of the role of non-state entities in addressing all impacts of IUU fishing.

Data Sharing and Data Enabled Technology to Detect and Combat IUU Fishing

Date-Sharing Organisations

- **Regional Plans of Action (RPOAs) to address IUU fishing.** Upon request and reports, the RPOA Secretariat may circulate the information through the RPOA website and/or official letter, as well as requesting RPOA-relevant participating countries to deny the vessel port entry or access to port facilities. Programs and activities are held, such as workshops and trainings, and information is exchanged on IUU fishing vessel lists and capacity-building programs on port state measures. While the RPOA is a voluntary instrument, it provides a framework for countries to take individual or collective action to enhance conservation and sustainable use of fisheries resources and combat IUU fishing in the region. These measures involve a range of coastal, flag and port state requirements which in most cases require political will, significant resources and time to address fully (APEC 2008).

- **Interpol's Project Scale.** Interpol's Global Fisheries Enforcement initiative, launched in 2013 under the name Project Scale, supports enforcement agencies in the organisation's 192 member countries in identifying, deterring and disrupting transnational fisheries crime. As a part of this initiative, several Purple Notices have been requested by member countries and issued by Interpol for fishing vessels. The Purple Notice is used to seek information on modus operandi, objects, devices and concealment methods used by criminals and have led to the apprehension of several notorious vessels that conducted IUU fishing.
- **West Africa Task Force.** The Fisheries Committee for the West Central Gulf of Guinea (FCWC) West Africa Task Force (WATF) was formally established in 2015 by the 6 member states of the FCWC—Benin, Côte d'Ivoire, Ghana, Liberia, Nigeria and Togo. Facilitated by the FCWC Secretariat and supported by a technical team which includes Trygg Mat Tracking (TMT) and Stop Illegal Fishing, the WATF was initially supported by a Norwegian Agency for Development Cooperation–funded project entitled Fisheries Intelligence and Monitoring, Control and Surveillance Support in West Africa, and based on the regional cooperation model pioneered by the FISH-i Africa Task Force in the Western Indian Ocean.
- The WATF's core objectives are to improve cooperation, coordination and communication among member states, and to operationalise important fisheries monitoring, control and surveillance (MCS) enforcement commitments of the FCWC, including the 2014 Convention on the Pooling and Sharing of Information and Data on Fisheries in the Zone of the FCWC and the recently updated FCWC RPOA on IUU fishing.
- **FISH-i Africa.** FISH-i Africa was formed in 2012 as a regional task force of coastal states which share a common problem with IUU fishing and hoped to find a common solution by working together. FISH-i is a partnership between the eight East African coastal countries of Comoros, Kenya, Madagascar, Mauritius, Mozambique, Seychelles, Somalia and the United Republic of Tanzania, supported by a technical team of experts. This alliance is showing that regional cooperation and information sharing, coupled with dedicated analysis and technical expertise, can stop illegal catch from getting to market and prevent illegal operators from pursuing their lucrative business unhindered. Task force members share information on licensed vessels, port inspections and vessel movements and cooperate on investigations—and the results have been significant, with a range of illegalities quickly uncovered and acted on. Results have included arrests, settlements, payments of fines, a fraudulent licensing operation being closed and an increase in license revenue.

Data-Enabled Technology and Tools

- **Fisheries Analytical Capacity Tool (FACT).** The use of FOCs, opaque company structures, limited public data on many important global fishing fleets and associated companies, and compliance history presents a significant challenge to the global community's ability to tackle illegal fishing operators effectively. TMT has developed FACT, a fisheries intelligence management and analytical system built with the express purpose of capturing and analysing the identities, characteristics and operations of the global industrial fishing fleet and the companies that operate it. FACT supports 'deep' analysis by providing information on vessel movements, identity, authorisations, operators, ownership and operational structures and whether vessels and companies are involved in violations of fisheries law or broader crimes.

  FACT directly populates the Combined IUU Vessel List website (www.iuu-vessels.org), TMT's public service website that provides the best available, up-to-date information on all vessels that appear on the lists of IUU fishing vessels published by RFMOs. Unlike the IUU lists published on RFMO websites, which may update vessel details only annually, the Combined IUU Fishing Vessel List is kept up-to-date through FACT's processes with the best available information regarding changes to vessel identity, flag state, ownership and location. The aim of the site is to improve the effectiveness of the original IUU lists as a tool to combat illegal fishing and broader fisheries crime.
- **International Monitoring, Control and Surveillance (MCS) Network.** The International MCS Network aims to improve the efficiency and effectiveness of fisheries-related MCS activities through enhanced cooperation, coordination, information collection and exchange among national organisations and institutions responsible for fisheries-related MCS.
- **Information Fusion Centre (IFC) Singapore.** The IFC aims to provide actionable information to cue responses by regional and international navies, coast guards and

other maritime agencies to deal with the full range of maritime security threats and incidents. This includes piracy, sea robbery, maritime terrorism, contraband smuggling, illegal fishing and irregular human migration.

- **Public sector data, technology and capacity development providers.** Australia's national research institution, the Commonwealth Scientific and Industrial Research Organisation (CSIRO), runs a program which develops open source analytical tools for the Automatic Identification System (AIS), the Vessel Monitoring System (VMS), satellite radar and other data sources. These analytical tools are supported by the development of new low-cost surveillance technologies, such as hydrophones to record underwater sound from vessels. The CSIRO embeds these technologies in a capacity-building framework, working with fisheries agencies in the Southeast Asian, Pacific, European, and North and South American regions. The CSIRO makes all of its products available free of charge.
- **Not-for-profit technology platforms.** Global Fishing Watch is leading the way in implementing technology and computational power to analyse a massive amount of data on ocean activity under a not-for-profit banner. Yet other non-profits, such Conservational International, the Nature Conservancy and WWF are working to provide a wide variety of data sources, including satellite observations, vessel tracking data, electronic monitoring, vessel identity databases, fishing license information, and detailed fisheries rules and regulations, accessing both public and proprietary data sources. Data sources are added continually as new technologies become available. Machine learning techniques and big data analytics applied to these data sets can immediately identify non-compliance with global fishing regulations and generate real-time marine intelligence for immediate investigation of illegal activity.
- **Global Fishing Watch.** Global Fishing Watch has focused on transparency and has revolutionised fisheries monitoring by bringing this data into one platform, publicly available and free of charge, to provide the first global view of industrial fishing (monitoring 70,000 vessels). The result has been a global push for transparency in fisheries that includes initiatives by top fishing nations such as Peru, Panama and Indonesia to share their VMS data and has led to Chile, Costa Rica and Namibia publicly committing to share vessel tracking data. Researchers increasingly use data and analysis tools on this free access platform.
- **OceanMind.** Ocean Mind's mission is to advance ocean sustainability through providing actionable intelligence on fishing activities to maritime authorities, government agencies, ocean conservationists and seafood buyers. OceanMind tends to work on proprietary data and works closely with a country's MCS staff. The best example of this is the productive relationship between OceanMind, the Seafood Task Force and the Thai government in the successful response to an EU yellow carding.
- **Vulcan's Skylight.** Skylight operates on a vision which is similar to that of OceanMind but under a forprofit model. Skylight provides maritime intelligence software and service solutions for identifying suspicious vessel behaviors and "dark vessel" activity and delivers this through an online alerting platform and watch floor service.

Institutions, Organisations and Tribunals Governing the World's Fisheries

- **Food and Agriculture Organization of the United Nations (FAO).** The FAO was established in 1945 as a specialised agency under the United Nations that leads international efforts to defeat hunger and to achieve food security. In this context, fisheries have been long regarded as a vital sector in achieving the mission of the FAO. A subsidiary body known as the Committee on Fisheries (COFI) was established in 1965 to serve as the global intergovernmental forum tasked with examining major international fisheries and aquaculture problems and issues. COFI has two main functions: to review FAO programs in fisheries and aquaculture and their implementation and to conduct periodic general reviews of international fisheries and aquaculture problems and recommend possible solutions. The FAO has adopted several binding legal instruments and voluntary guidelines addressing IUU fishing. In 1993, the FAO Conference adopted the Compliance Agreement. The FAO has also initiated the Code of Conduct for Responsible Fisheries (CCRF), which was adopted in Resolution 4/95 by the FAO Conference on 31 October 1995. On 2 March 2001, it adopted the International Plan of Action to Prevent, Deter and Eliminate Illegal, Unreported and Unregulated Fishing (IPOA-IUU).

  The FAO also adopted the Agreement on Port State Measures to Prevent, Deter and Eliminate Illegal, Unreported and Unregulated Fishing (Port State Measures Agreement) at its 36th session on 22 November 2009. In addition to these instruments, the FAO has adopted Voluntary Guidelines for Flag State Performance and Voluntary Guidelines for Catch Documentation Schemes.
- **Regional fisheries management organisations.** Regional measures in the conservation and management of fish resources through RFMOs may have been regarded as the most reasonable approach in dealing with issues arising from the use of transboundary marine living resources. These organisations reflect the essential duty of states under international law to cooperate in ensuring the

conservation and sustainable use of transboundary resources or resources beyond areas of national jurisdiction. Nevertheless, unresolved issues have become obstacles for states in effectively implementing the commitments made through their RFMOs. These issues arise from the activities of nonparticipating states, since according to international law, treaties are only binding on their parties and do not create rights or obligations to third parties without their consent. Thus, vessels registered under the flag of states that are not parties to a particular RFMO are not obliged to comply with the rules that have been agreed by the state parties of the RFMO. Such states are known as 'free riders', and they might undermine conservation and management measures and any incentive for member state nationals to comply.

Some scholars have proposed a new approach to resolve the problem of free riders by recognising that each element of IUU fishing needs to be tackled individually and that there is a need to examine the situation of non-RFMO members in a more detailed manner (Serdy 2017). Currently, there are 18 Regional Fishery Bodies in the world:

- International Commission for the Conservation of Atlantic Tunas (ICCAT)
- Indian Ocean Tuna Commission (IOTC)
- Western and Central Pacific Fisheries Commission (WCPFC)
- Inter-American Tropical Tuna Commission (IATTC)
- Agreement on the International Dolphin Conservation Program (AIDCP; sister organisation to IATTC)
- Commission for the Conservation of Southern Bluefin Tuna (CCSBT)
- North-East Atlantic Fisheries Commission (NEAFC)
- Northwest Atlantic Fisheries Organization (NAFO)
- North Atlantic Salmon Conservation Organization (NASCO)
- South East Atlantic Fisheries Organisation (SEAFO)
- South Indian Ocean Fisheries Agreement (SIOFA)
- South Pacific Regional Fisheries Management Organisation (SPRFMO)
- Convention on the Conservation of Antarctic Marine Living Resources (CCAMLR)
- General Fisheries Commission for the Mediterranean (GFCM)
- Convention on the Conservation and Management of Pollock Resources in the Central Bering Sea (CCBSP)
- Western Central Atlantic Fishery Commission (WECAFC)
- Fisheries Committee for the Eastern Central Atlantic (CECAF)

• **International Tribunal for the Law of the Sea (ITLOS).** As of May 2019, 27 cases had been brought before ITLOS, including cases related to the question of prompt release of vessels, the use of marine living resources, the protection and preservation of the marine environment, and maritime boundary delimitation. Of these cases, the judgments of ITLOS with regard to prompt release of vessels are perhaps mostly relevant to fisheries issues. These include, for instance, the *Camouco* case *(Panama v. France*), the *Volga* case (*Russian Federation v. Australia*) (ITLOS 1999a), and the *Tomimaru* case (*Japan v. Russian Federation*). Although these cases did not directly touch on the issue of IUU fishing, the judgments of ITLOS provided useful guidance with regard to administrative procedures and law enforcement undertaken by coastal states as parts of combatting IUU fishing. In addition, the judgment of ITLOS on the *M/V Saiga* (No. 2) case (*Saint Vincent and the Grenadines v. Guinea*) (ITLOS 1999b) presented the response of ITLOS on the application of a 'genuine link' between the vessel and the flag state as stipulated under the UNCLOS, and its relation to the implementation of the UNFSA and the FAO Compliance Agreement. In this case, Guinea argued that there was no genuine link between the Saiga and Saint Vincent and the Grenadines as the flag state. Therefore, Guinea contended that it was not obliged to recognise the claims of Saint Vincent and the Grenadines in relation to the ship.

Appendix B: Voluntary Actions for Ocean Fishery Stakeholders Under SDG 14.4

IUU fishing is a global problem that threatens food security, livelihoods and ecosystem health. Effectively combatting IUU fishing begins by recognising its major drivers: economic incentives for illegal behaviour; weak governance regimes at the national, regional and international level; and barriers to effective enforcement.

As this paper makes clear, many actions are available to address each problem area. Readers are encouraged to consider the potential of the full range of actions—local, national, regional or international—to have an impact on IUU fishing. Collaboration maximises effects and rationalises costs. Collaboration must be considered across government, businesses and private sectors; the civil sector; and science establishments.

Sustainable Development Goal (SDG) 14 is to conserve and sustainably use the ocean, seas and marine resources for sustainable development. Subgoal 14.4 states: By 2020, effectively regulate harvesting and end overfishing, illegal, unreported and unregulated fishing and destructive fishing practices and implement science based management plans, in order to restore fish stocks in the shortest time feasible, at least to levels that can produce maximum sustainable yield as determined by their biological characteristics.

Obviously, this subgoal will not be met, but we encourage new voluntary action commitments by the end of 2020.

We offer the following actions for consideration that can be taken by any stakeholder, including countries; regional associations; industry, labour, or financial organisations; or non-governmental organisations.

Strengthen Existing Ocean Governance Mechanisms

- The non-uniformity of regional fisheries management organisation (RFMO) regulations should be addressed through an international forum/mechanism. The UN General Assembly may be the most efficient. The Kobe Process is a foundation for any call to action; however, this should involve all of the world's RFMOs, not just the tuna RFMO.
- Coordination and data transparency among RFMOs, flag states, regional mechanisms and the coastal and market states should be improved.
- All RFMOs should adopt strong transboundary policies on monitoring and enforcement, including on the high seas.
- Sanctions should be created for flag states which are not performing enforcement measures.
- A mechanism or authorised international body should be considered to oversee the performance of each RFMO.
  - The gaps and inconsistencies in fisheries management should be identified.
  - Transshipment practices should be properly regulated.
- Specific efforts should be focused on the management of small-scale and artisanal fisheries.
- The significant gaps in high seas governance should be addressed.
- The Food and Agriculture Organization of the United Nations (FAO) and RFMOs should ban unsustainable fishing gears and practices.

Flag State Actions and Responsibilities

- Flag states should exert adequate control over the vessel registry, including ensuring that the management of the registry is within the flag state (and not held by an external private company). Flag states must demonstrate and maintain a genuine link between the vessel and the flag state. Open registries should be closed to fishing vessels.
- The significant gaps in high seas governance should be addressed.
- All states registering a fishing vessel should require companies to provide information on the vessel's true beneficial owner and apply sanctions if it is found that the information provided is false.
- In addition to the beneficial owner, the vessel registry should include details of vessel characteristics and history, including prior flag and name changes; information on the operator; and information on markings and Unique Vessel Identifiers (UVIs), in line with international standards.
- A list of fishing license holders should be made publicly available (for example, online) and regularly updated. It should contain the same information as in the vessel registry, as well as details of any quota or other limits allocated to vessels (if applicable), period of license, gears and target species and areas where the vessels are authorised to fish.
- Eligible vessels should be required to apply for and install an International Maritime Organization (IMO) number as a condition of registration.
- Any vessel that is in non-compliance should be 'blacklisted' from the registry.
- Catch certificates should be digitally validated. Flag states should implement controls and verification/data cross-checks for the reliable certification of catches for export to countries that require the validation of a catch certificate. This should be done through (non-exhaustive list) checks of logbook data and landing/transshipment declaration, verification of fishing location using Vessel Monitoring System (VMS) positions, inspections at sea and in port, and presence of observers on board.
- Due diligence should be shown for new license holders. All states granting fishing authorisations to vessels should maintain a register of license holders that is up-to-date and in line with the vessel registry. States should verify the infraction history of vessels and vessel owners when a license is requested.

Coastal State Actions and Responsibilities

- Effective monitoring, control and surveillance (MCS) measures should be adopted to ensure compliance with Conservation and Management Measures (CMMs).
- VMS should be required on board all industrial fishing vessels (with regular reporting), and a fisheries monitoring centre for monitoring VMS data should be established. VMS should be made public, or Automatic Identification System (AIS) should be mandated for public tracking.
- Vessel captains should be required to maintain a logbook (and consider mandating e-logbooks), and vessels should be required to report fisheries related data, including catches and fishing effort. In case of non-compliance, states should take prompt action with respect to the iden-

tified infringements and apply deterrent sanctions in a consistent and transparent manner.
- Transshipments at sea should be banned unless they are pre-authorised and are subject to robust and verifiable electronic monitoring and/or are covered by a human observer scheme appropriate to the fishery.
- Labour regulations should be sufficient to facilitate the identification and investigation of forced labor, labor abuse and human trafficking cases detected on board fishing vessels. Regulations should also be sufficient to allow for the lawful prosecution and penalisation of perpetrators of these crimes. The Cape Town Agreement (CTA) and International Labour Organization (ILO) Work in Fishing Convention (C188) should be ratified and adopted.
- Appropriate port-side and at-sea inspection regimes should be initiated to facilitate the identification and investigation of labour abuses. These should involve a trained labour inspector who can detect the common indicators of forced labor and human trafficking. These indicators should follow the 11 ILO indicators of forced labor and/or the ILO indicators for human trafficking. These inspections should follow a precautionary and victim-centred approach to labor investigations, ensuring that fisher workers' safety, security and privacy are always a top priority. Wherever applicable, trained and qualified translators should be included to facilitate communications with foreign workers.
- Specific efforts should be focused on the management of small-scale and artisanal fisheries.

Port State Actions and Responsibilities

- The Port State Measures Agreement (PSMA), a key tool in the fight against IUU fishing that directly supports SDG 14.4, should be ratified. While it can take more than a year to adjust legislation to permit the ratification of the PSMA, states should make clear commitments to do so without delay. Implementation of any ratified states must be a priority for those states.
  - The PSMA should be implemented.
- To ensure the safety of crews on board fishing vessels and improve working conditions, the ILO C188 should be implemented and countries should accede to the CTA.
  - The Cape Town Agreement and ILO C188 are complementary regulations and can be considered during port inspections under the PSMA.

Market State Actions and Opportunities

- Regulations similar to the European Union's IUU fishing Regulation should be adopted.
- The PSMA should be implemented.
- Transparency measures should be implemented.
- Incentives (e.g., waive import tariff) should be given to countries with good performance in combatting IUU fishing.
- The significant gaps in high seas governance should be addressed and a commitment made to doing so where the timescale is more than 2 years.

Legal Frameworks for Actions

- Strong legal frameworks are needed for improved MCS, enforcement and sanctions.
- Market, flag, port and coastal states should ensure that they ratify, accept or accede to, as appropriate, relevant legal instruments (Appendix A), including the following key instruments:
  - UN Convention on the Law of the Sea (UNCLOS)
  - UN Fish Stocks Agreement (UNFSA)
  - Port State Measures Agreement (PSMA)
  - FAO Compliance Agreement
- National legislation should be adopted/updated to ensure that the legal framework is consistent with these requirements, as well as CMM measures established by the RFMO of which the country is a member.
- Legal frameworks should establish a clear, comprehensive and transparent system of proportionate and deterrent sanctions for IUU fishing offences, including for nationals supporting or engaging in IUU fishing.
- There should be a legal basis for all MCS and enforcement measures that may include issuing licenses to vessels, requiring vessels to carry and operate VMS or AIS, conducting inspections of vessels, investigating infringements, refusing access of IUU vessels to port, and regulating beneficial ownership.
- States should publish or provide information on their legislation and actions in combatting IUU fishing to an authorised international body, such as the FAO.

Adopt Global Transparency Rules and Technology

- All state registries should be made available to the FAO Global Record of Fishing Vessels.
- Unedited VMS, or other proprietary tracking system, data should be made public with regular transmission intervals sufficient to ensure vessels can be permanently tracked, or AIS should be required for fishing vessels.
- Up-to-date lists should be published of all fishing licenses, authorisations and vessel registries, transshipment authorisations and refrigerated vessels registries.

- IMO numbers (free to obtain) should be mandated for all eligible vessels, and a national UVI scheme should be implemented for non-eligible vessels, maintaining a vessel registry and providing all information to the FAO Global Record of Fishing Vessels (which ultimately includes all eligible vessels over 12 m in length overall).
- States should be encouraged to publish information, on an accessible international platform, on arrests and sanctions imposed on individuals and companies for IUU fishing activities, human trafficking and other related crimes.
- Transshipment activities information should be improved through mandatory and public preauthorisation and robust and verifiable electronic monitoring schemes.
- There should be mandatory near-term adoption of cost-effective digital tools, such as blockchain, that safeguard in a digital form key information on vessel registration, licenses, unloading records, catch location and information and crew documentation; these should be designed in such a way as to support a rapid move towards a universal, interoperable digital catch certification scheme.
- Information on beneficial ownership should be published, and companies should be required to provide information on true beneficial ownership when applying for a fishing license, fishing authorisation or registration to their flag.

Enhance International Cooperation

- All countries should cooperate to prevent, deter and eliminate IUU fishing at the bilateral and sub-regional levels. Where mechanisms exist, they must be prioritised within government agendas.
  - States should develop and implement a national plan of action on IUU fishing in line with the recommendations of the International Plan of Action to Prevent, Deter and Eliminate Illegal, Unreported and Unregulated Fishing. Such cooperation should include the following measures:
  - Coastal states should communicate information on IUU fishing-related infringements to neighbouring coastal states.
  - Port states should provide information to flag states on transshipments, landings and denials of use of port involving vessels flying their flag, and the result of inspections.
  - Flag states should cooperate with investigations and act in cases of presumed IUU fishing by their vessels.
  - All states should build capacity to support analysis, implementation and application of policy and technology.

Domestic Fisheries Actions by Coastal States

- There should be well-established and adequately resourced domestic fisheries management arrangements, supported by sound and properly enforced legislation.
- Clear and transparent CMMs should be established in national legal frameworks, based on the best available scientific advice and consistent with obligations under UNCLOS, UNFSA and RFMO rules.
- A national fisheries management plan should be developed and implemented, and total allowable catch based on the best available scientific evidence should be determined.
- Vessels operating in the exclusive economic zone (EEZ) should be required to hold a license, and there should be a balance between the number of licenses granted/size of fishing activity in the EEZ and the status of stocks. This should be based on scientific and precautionary stock assessments in accordance with maximum sustainable yield and total allowable catch.
- A record of vessels licensed to fish in the EEZ should be established, made publicly available (online) and kept up-to-date. The record should contain vessel details (name, tonnage, flag, registration number); vessel and/or gear type and target species; details of any quota allocated (if applicable); and details of the vessel's legal owner and operator, including beneficial owner, period of the license, license fee and crew manifest.
- IMO numbers should be required for foreign-flagged eligible fishing vessels as a condition of their license to operate.

Digital Documentation for All States

- All states should implement digital schemes for documenting catch data to promote global exchange of information, vessel registration and licenses, unloading records, catch location and information and crew documentation.
  - These digital systems must be secure and have built-in procedures to prevent the unauthorised deletion or overwriting of data.

Actions for Business, Industry, Financial Institutions, Scientists and Civil Society

- Enhanced action by private sector organisations can create strong pressure on fisheries businesses to maintain a high level of compliance.

- Financial institutions (e.g., banks and insurance companies) are encouraged to make fisheries transparency and traceability conditions of contracts.
- Buyers and lenders should establish the accuracy of ownership information to avoid the use of shell companies.
- Private sector organisations should not deal with flag states that fall short of their duties under the UNCLOS.
- The use of PSMA-ratified ports should be made a condition of contract or insurance.
- Assurance should be provided to consumers on the traceability and quality of the fish products (e.g., provide such information on the packaging).
- Zero-waste products should be promoted by creating other products from waste.
- Appropriate machineries and methods for a cost effective production should be used.
- Science has a crucial role in policymaking. Scientists are expected to provide the following information to create better fisheries governance:
  – The best assessment of fish stocks globally
  – Change of fish behavior/migration pattern caused by climate change
  – Advancing technology of sustainable fishing gears

Civil Society Can Bring Communities Together for Collective Action

- Civil society can promote awareness on fisheries sustainability to educate consumers to choose fish products with guaranteed traceability.
- Civil society can advocate for artisanal fisheries to be aware of fisheries sustainability.

Organised Crime in the Fisheries Sector

16

Emma Witbooi, Kamal-Deen Ali, Mas Achmad Santosa, Gail Hurley, Yunus Husein, Sarika Maharaj, Ifesinachi Okafor-Yarwood, Inés Arroyo Quiroz, and Omar Salas

Highlights

- The fisheries sector, like most economic sectors, is impacted by organised crime. Organised crime deprives states of national revenue and threatens the legitimate fishing industry and the livelihoods of those that rely on it.
- Organised crime in fisheries undermines the rule of law, threatens peace and security, jeopardises food security for coastal states and communities, and adversely impacts fishing communities and fish stocks at the national, regional and global levels.
- Manifestations of organised crime in fisheries take many forms: fraud, corruption, tax crime, money laundering, crime in the labour market, security offences, drug trafficking, smuggling of fuel and migrants and fisheries offences. These offences occur throughout the fisheries value chain, often in combination, and frequently transnationally.
- The continuation of organised crime in fisheries undermines the global commitment to sustainable development and the realisation of a sustainable ocean economy.
- Yet despite significant evidence of the dynamic and destructive impact of organised crime in the fisheries sector, the need remains for an effective, coordinated enforcement response at the national level and globally.
- This paper summarises the current state of knowledge on the phenomenon of organised crime in the fisheries sector and its impact on sustainable development, using case studies and examples, and drawing on available scholarly literature, technical documents, media reports and expert input. The paper identifies opportunities for action for moving forward at a global level to address this challenge to the realisation of a sustainable ocean economy.
- To comprehensively address organised crime in fisheries, states should, first, build a shared understanding of the problem globally and, second, undertake intelligence-led, skills-based cooperative law enforcement at the domestic level facilitated by enabling legislative frameworks and increased transparency.

Methodology and Sources

This Blue Paper is based on invited input from the contributing authors, who are located around the globe and represent practitioners, academics and law enforcement. They were recommended to the lead authors based on their experience and knowledge of particular aspects of the topic, as well as the need for gender balance and to elevate voices from the Global South. The lead authors incorporated the contributors' written submissions into the body of the text. The paper is further shaped by feedback from expert consultations.

The paper was compiled over a three-month period. It draws on existing reports and outcome documents on the topic from international governmental organisations, non-governmental organisations, governments and knowledge institutes, as well as published academic research, operational knowledge and expert input. The concept of 'knowledge' is interpreted widely; faced at times with sparse formal documentation of the manifestations of organised crime in fisheries, some of the illustrative examples referred to draw on anecdotal accounts, personal expert observations or journalist reports (or a mixture thereof), rather than citing scientific research or decided cases. Additionally, as the breadth of the issues covered is vast, it is recognised that various topics could benefit from further dedicated research, such as the scope of organised crime in the fisheries sector at a global level, analyses of the causal nexus between organised crime in fisheries and the highlighted potential impacts, and critical assessment of the suggested promising practices. Addressing such issues would require empirical research employing a

different methodology than the one used here. In sum, this paper contributes to the knowledge pool on the topic under examination while remaining mindful that there is scope for increased understanding of many facets thereof.

Aim

This Blue Paper aims to present an accessible summary of the current state of knowledge on the phenomenon of organised crime in fisheries and its impact on sustainable development, using case studies and examples sampled from contributors and experts, and to provide a suite of practical opportunities for action for moving forward at 2 | High Level Panel for a Sustainable Ocean Economy a global level to address the challenge organised crime poses to the realisation of a sustainable ocean economy.

1 Introduction

The modern fisheries sector is globalised, industrialised and integrated into the worldwide financial market. Like most other economic sectors, it is exposed to organised crime (UNODC 2011), the underbelly of globalisation (e.g. Madsen 2009; Abadinsky 2007; Obokata 2010).

While sometimes referred to as an 'emerging' crime (Stringer and Harré 2019), there is little reason to believe that organised crime in the fisheries sector is a novel problem. The infamous gangster Al Capone, for instance, exploited the fishing industry for rum-running during the 1920s, when the United States prohibited the production, importation, transportation and sale of alcoholic beverages (Ensign 2001; Demont 2003). The more likely scenario is that organised crime in fisheries is a recent label for a phenomenon that has existed for many years, fuelled by overfishing of declining fish stocks and greed, among other causes. In this narrative, an emerging focus on sustainable fisheries management and the role of the blue economy has heightened global attention to organised crime in fisheries, which is giving rise to a shadow blue economy and undermining the competitiveness of both the legitimate industry and the livelihoods of coastal communities. This heightened attention is allowing policymakers, researchers, and civil society to re-examine the dynamics and destructiveness of the shadow blue economy and the role of organised crime in it.

Organised crime is, by its clandestine nature, a difficult object of scientific inquiry. Verifiable data tend to be scarce, and, since these crimes often either go unidentified or are unsuccessfully prosecuted, statistics from domestic law enforcement agencies may lead to significant underestimations of the problem. For our present purposes, we offer two case studies to explain organised crime in fisheries. While these case studies are not, on their own, dispositive of the global scale of organised crime in the fisheries sector, they shed light on the activities that are manifestations of such crime and the challenges they pose to criminal law enforcement.

In the past two decades the global community has increasingly raised concern about the threat of organised criminal networks in the fisheries sector, where they accrue high profits at very low risk of sanction. In 2008 the UN General Assembly warned of the 'possible connection between international organised crime and illegal fishing in certain regions of the world' (UNGA Resolution 63/112, para. 59). Highlighting the need for additional research into, and evidence of, the link between organised crime and illegal fishing internationally, the General Assembly 'encourages States, including through the appropriate international forums and organisations, to study the causes and methods of and contributing factors to illegal fishing to increase knowledge and understanding of those possible connections, and to make the findings publicly available, bearing in mind the distinct legal regimes and remedies under international law applicable to illegal fishing and international organised crime'. (UNGA Resolution 63/112, para. 59).

A comprehensive report by the UN Office on Drugs and Crime (UNODC 2011) highlighted the vulnerability of the global fishing industry to organised criminal networks. The report's main finding was that the opaque nature of the fishing industry renders it susceptible to multiple crimes that are largely transnational in nature and frequently organised. The report also found that the traditional fisheries management approach applied to date in the fisheries sector seems insufficient to deal with the nature and magnitude of the problem. It recommended that this approach be complemented by a cooperative criminal law enforcement response. This finding was echoed by the UN Commission for Crime Prevention and Criminal Justice (CCPCJ), which, in a 2011 resolution on transnational organised crime at sea (UN CCPCJ Resolution 20/5 (2011)), highlighted the imperative of 'international cooperation to prevent and control' transnational organised crime taking place at sea.

Significant efforts have since been made to understand the phenomenon of organised crime in the fisheries sector. In 2013, member countries of the International Criminal Police Organization (INTERPOL) established the Fisheries Crime Working Group. Using this cross-border cooperation platform, law enforcement officers have formed joint operations to target well-known fisheries crime networks and close down some of the most notorious. The lessons learned from these operations were shared with the global community through the International Symposium on Fisheries Crime, an annual event held between 2015 and 2018, which brought together high-level law enforcement officers, civil society representatives and academics to discuss trends, challenges and solutions in relation to transnational organised crime in the fisheries sector (CCPCJ 2017).

In September 2018, this process culminated in the adoption of the International Declaration on Transnational Organised Crime in the Global Fishing Industry (Copenhagen Declaration) (Appendix A) by the ministers present during the Fourth International Symposium on Fisheries Crime in UN City, Copenhagen. As of 5 March 2020, the Copenhagen Declaration has received the support of 28 nations, most of which are 'large ocean nations', that is, territories highly dependent on the marine resources in their large ocean areas (LON Forum Report 2019). The supporting nations are Benin, Chile, Costa Rica, the Faroe Islands, Fiji, Ghana, Greenland, Iceland, Indonesia, Kiribati, Liberia, the Maldives, the Marshall Islands, Mexico, Mozambique, Myanmar, Namibia, Nauru, Norway, Palau, the Philippines, São Tomé and Principe, Scotland, Seychelles, the Solomon Islands, South Africa, Sri Lanka and Timor Leste. The declaration places the issue of transnational organised crime in the fisheries sector within the context of Sustainable Development Goals (SDGs) 14 and 16, and as part of an integrated and globalised world economy. The supporting countries also identify a course for a global commitment to combat this problem, stating that 'inter-agency cooperation between relevant governmental agencies is essential at a national, regional and international level in order to prevent, combat and eradicate transnational organised crime in the global fishing industry'.

In February 2019, submissions to the UN Security Council spoke to the threat that transnational organised crime at sea, including fisheries crime, poses to international peace and security (UN Security Council 2019).

This Blue Paper is the 16th in a series of Blue Papers commissioned by the High Level Panel for a Sustainable Ocean Economy. The authors of this Blue Paper were asked to address the question of how organised crime in the fisheries sector impedes the realisation of a sustainable ocean economy, and what practical measures can be taken to counter this. The authors were moreover directed to examine the various types of 'fisheries crime' in which organised criminals engage. This Blue Paper therefore explains the phenomenon of organised crime in fisheries, including the serious crimes indicative of its existence, using illustrative case examples to highlight the forms it might take, the ways organised crime in fisheries adversely impacts a sustainable ocean economy, and the associated law enforcement challenges. The paper also draws together a set of suggested practical means or 'opportunities for action' to address organised crime in fisheries.

2 State of Knowledge

2.1 What Is Organised Crime?

The premise of any discussion about organised crime in fisheries is a common understanding of what organised crime is. Although most people give the term 'organised crime' a similar meaning, there is little agreement on its exact characteristics, and numerous definitions of organised crime have therefore been put forward (for an analysis of these, see Varese 2017). In common parlance, there is a tendency to connect organised crime to hierarchical, exclusive and monopolistic groups—often with a strong ethnic or societal commonality—leaning towards violence, a criminal subculture or otherwise deviant behaviour (Abadinsky 2007). A broader understanding of organised crime—one that this Blue Paper adopts—is that it consists of networks of individuals who converge and collaborate over time to commit crime (Shaw and Kemp 2012). The networks' profile may vary significantly from loosely knit flat structures to strict hierarchical chains of command. Their criminal enterprise, geographical spread or crime script (modus operandi) may be equally diverse (Madsen 2009). Organised criminal groups may share with 'conventional' businesses many characteristics in their structure and capability (Australian Crime Commission 2009). These networks can form in any layer of society, or transgress these, with many examples found among white-collar criminals, people of professional authority and power who commit financial crime (Gottschalk 2012). Some authors also emphasise the ability to protect operations ('protection economy') through violence, bribery or extortion as a common, but not necessarily defining, feature of organised crime (Shaw and Kemp 2012).

Organised crime is also defined in law. One of the most widely accepted legal definitions internationally (through state ratifications) is that of the UN Convention on Transnational Organised Crime (the Palermo Convention) (UN 2004a). The Palermo Convention paints a broad picture, according to which organised crime can be defined as a serious crime committed by a structured group of three or more people for financial or other material benefit (UN 2004a, Article 2(a)). The convention defines a serious crime as an offence 'punishable by a maximum deprivation of liberty of at least four years' or a more serious penalty (UN 2004a, Article 2(b)). The Annual European Union Organised Crime Report (EUROPOL 2004) offers a slightly different definition, referring to organised crime as a collaboration of more than two people suspected of committing serious criminal offences in the pursuit of profit and/or power and for a prolonged or indefinite period (Fröhlich 2003).

It is recognised that while international instruments provide a clear legal benchmark of what constitutes organised crime, outside the letter of the law, both conceptually and in practice, there is often ambiguity around what is regarded as ‘criminal behaviour’. In particular, views differ regarding the extent to which criminal economies associated with organised crime are ‘normalised’ in any given society (Shaw 2017; Gilman et al. 2011).

A distinction could be made between organised crime taking place within the fishing industry and ancillary to its business operations (e.g. illegal fishing or human trafficking) and organised crime taking place outside the industry using the sector as a cover for other criminal activities (UNODC 2011), such as the smuggling of contraband (like Capone’s rum running in the 1920s). With regards to the latter, an organised crime operation may enter the fishing industry in order to launder proceeds from its illicit activities and/or to provide a legitimate reason for being at sea so as to illicitly traffic goods (Parks 2014). In practice many of the same issues pertaining to law enforcement will arise regardless of whether the organised crime is embedded in the industry or not.

From a law enforcement perspective, organised crime networks in fisheries can be involved in a broad range of criminal offences. The most common are economic crimes, such as money laundering, fraud, forgery, tax and customs evasion, corruption and human trafficking, in addition to criminal offences found in sector regulations, such as in the fisheries, health and safety, and maritime sectors. In practice, crime in the fisheries sector, often referred to as ‘fisheries crime’ and ‘fisheries-related crime’ (UNODC 2019a; FAO 2019), covers criminal offences taking place throughout the fisheries value chain, from the preparatory stage (including vessel insurance and registration) to at-sea activities (including harvesting and catch documentation) to landing, processing, transportation, trade and sale (UNODC 2017). Criminal offences may thus be committed at sea, on land, in cyberspace, or at the coastal interface. A commonality is that the offences are profit-driven, that is, they are economic crime and are frequently committed by white-collar criminals (UNODC 2019a). Many of these offences are conducted or continued (in whole or in part) extraterritorially, on the high seas and in other areas beyond national jurisdiction, such as regional seas, making most fisheries crime cases transnational, with the added complication of jurisdictional obscurity (NA-Fig 2017).

2.1.1 Case Study 1: The Viking Case

In February 2016 the Indonesian navy intercepted and detained the fishing vessel *Viking* in Indonesian waters. The vessel was the subject of an INTERPOL purple notice, that is, an alert about the crime script of a criminal network. The purple notice issued on the *Viking* notified law enforcement agencies around the world of the network’s use of numerous vessel identities and nationalities (flag states) and the vessel’s unclear ownership structures. This crime script made it difficult for law enforcement agencies to identify which country had jurisdiction over the vessel and which country was responsible for its activities. As a result, for more than a decade, the owners and operators of the *Viking* were able to land and enter into the market illegally caught Patagonian toothfish from the Southern Ocean, an extremely valuable species dubbed ‘white gold’, in contravention of the multilateral fisheries management regime in these waters. The network’s turnover from the activities of this vessel alone was estimated by crime analysts to be about half a billion dollars during the time of its operation, and there is good reason to believe that the network operated several such vessels (expert consultations 2019).

During their preliminary inquiries Indonesian authorities established that the documents presented on behalf of the vessel were forgeries, meaning that the vessel sailed under a false identity and flag. It also proved impossible to trace the company stated to be the vessel’s owner, suggesting that this was a fictional company. Indonesian authorities regarded the vessel to be stateless and subjected it to Indonesian jurisdiction. In Indonesia, document forgery can be penalised by imprisonment of up to six years (Indonesian Criminal Code, Article 263). The vessel’s hold was also found to contain gillnets exceeding 2.5 km in length, which is an infringement of Indonesian law and subject to five years’ imprisonment and a fine of up to 2 billion Indonesian rupiah (US $150,000) (Indonesian Fisheries Law, Article 85).

Further investigations led by the Indonesian authorities revealed the level of organisation of the network behind the *Viking*’s operations. The master of the vessel was in frequent communication with an Australian national based in Singapore who acted as the operator of the vessel and provided logistics, supplies and financing. The master was also in contact with a Spanish national, domiciled in South Africa, who was later identified as the likely beneficial owner of the vessel. These were allegedly the three core members of the network at the time. Other members included at least one other master of the vessel (the masters rotated on shifts throughout the year) and a Singaporean financier. Together the network’s members conducted a highly complex transnational business operation. The vessel operated out of ports across Southeast Asia and Africa, using forged documents with numerous identities and nationalities. It landed, shipped and traded Patagonian toothfish and sourced crew, supplies, spare parts, gear and fuel around the world.

This case is an example of transnational organised crime in the fisheries sector: It involved a network of at least three members who orchestrated the commission of serious criminal offences, including illegal fishing and fraud, across multiple jurisdictions for significant material gain and over a prolonged period.

2.1.2 Case Study 2: The Rock Lobster Case

In May 2001, following a tip, officials from the South African Marine and Coastal Management branch seized and opened a container destined for the United States belonging to the South African company Hout Bay Fishing Industries (Pty) Ltd. This company was one of the largest seafood producers in the country at the time and a major employer. The container's contents comprised unlawfully harvested lobster tails and Patagonian toothfish. The South African officials alerted the relevant U.S. authorities, who intercepted the next container the company exported to the United States. In August 2003, following a protracted investigation by South African and U.S. law enforcement, the director of Hout Bay Fishing Industries and two others were arrested and criminal proceedings launched in both South Africa and the United States.

The investigation revealed that between 1987 and 2001 a network consisting of three directors of Hout Bay Fishing Industries illegally harvested large quantities of west and south coast rock lobster in South African waters for export to the United States. The network systematically exceeded the authorised quota for lobster during this period; in 1990, around 90 percent of the west coast rock lobster they exported to the United States was caught illegally. To facilitate the operation, the network established companies in both South Africa and the United States, bribed many government fisheries officers and other officials, and laundered profits in a complex web of properties and offshore banks and trusts.

South African authorities charged the main director of Hout Bay Fishing Industries with a range of offences including fraud, corruption and bribery under the Prevention and Combatting of Corrupt Activities Act, racketeering under the Prevention of Organised Crime Act, violations of the Marine Living Resources Act and activities contrary to the Customs and Excise Act. In the United States, the Lacey Act makes it illegal to introduce into the United States any fish or wildlife taken in contravention of the laws of another country. The directors of Hout Bay Fishing Industries were arrested and found guilty in the United States of violating the Lacey Act, as well as smuggling and conspiracy, and in 2004 they were sentenced to imprisonment and forfeiture. A U.S. court also awarded the South African government $22.5 million in restitution for damages, but investigators had a hard time locating and freezing the main director's assets to secure the restitution amount. In September 2018, more than 15 years after the activity was first detected, investigated and tried by the U.S. court, a final settlement agreement of $7.5 million was ordered.

The rock lobster network is a good illustration of a criminal network that started out as legitimate business and transitioned into transnational organised crime in the fisheries sector. The network consisted of at least three members (or business associates) who conspired to commit serious crime in at least two jurisdictions and with bank accounts in numerous other offshore jurisdictions for significant material gain over a prolonged period. The case also illustrates the lengthy and complex cross-border investigations required to address transnational organised fisheries crime, in this case more than a decade and a half.

2.2 Manifestations of Organised Crime in Fisheries

This section describes several serious offences that are committed as part of organised crime in the fisheries value chain.

2.2.1 Fraud

Fraud refers to deliberate misrepresentation or concealing of facts for undue benefit (UNODC 2017). *Forgery*, or misrepresentation by falsifying a document, is often regarded as a subset of fraud. Some jurisdictions also have distinct offences of false declarations to public authorities.

A large amount of documentation is produced throughout the fisheries value chain, creating significant potential for fraud and forgery. This is particularly true of documents with a high cash value, such as vessel registration certificates, landing documents and fishing licences. In the case of the *Viking*, false vessel registration documents were submitted at port, comprising text clearly cut and pasted from Google Translate and using ordinary word processing software (NA-Fig 2017). Fishing vessel identity fraud is used by criminals to change their vessel's identity with relative ease by, for example, giving more than one vessel in a fishing fleet the same name and operating all vessels under the same fishing licence, not flying the correct flag at port, or physically hiding or painting over a vessel's name in order to render it anonymous (NA-Fig 2017). Vessel identity fraud is closely associated with 'flag-hopping', a pattern of re-registering a vessel with new flag states to confound investigations into its illegal operations, as was the case with the *Viking* (NA-Fig 2017).

Fraud can, moreover, be committed at the harvesting stage when inaccurate catch records are maintained pertaining to, for example, in which waters the fish were caught, the amount of fish caught and the species harvested (UNODC 2011). At the subsequent processing stage (at sea or on land), fish and fish products may be fraudulently labelled to avoid paying higher customs duty on high-value species (EUROPOL 2018). One example is that of the fishing vessel *STS-50*, also known as the *Andrey Dolgov* and later the *Sea Breeze*, which was found with falsified information regarding the species of fish (mislabelling) on numerous occasions, leading to its apprehension by Chinese authorities in 2017 (Gray 2019). Deliberate mislabelling may also occur at the retail stage in order to obtain a higher asking price or to disguise the species of fish (if it was caught illegally) or the fish's country of origin (OECD 2013; Oceana 2018). On landing, false or forged customs and health documentation may be used to disguise the catch's country of origin or the true identity and flag of the vessel that caught the fish, to avoid paying import tariffs or having to comply with food hygiene regulations (UNODC 2017). For instance, on the basis of fraudulent landing certificates, Trinidad and Tobago is cited as the world's sixth-largest shark fin exporter to Hong Kong (Pew Charitable Trusts Environmental Group 2012), despite the fact that its domestic fleet lacks the capacity to catch and land such quantities; the fins are, in fact, landed from foreign fishing vessels and sent in transit through Trinidad and Tobago ports.

2.2.2 Corruption

An act of corruption is the giving, solicitation or receipt of an undue advantage with the purpose of making a person (working as an official for a private or public entity) act or refrain from acting (UN Convention on Corruption: UN 2004b, Chap. 3). Most people will associate corruption with bribery (UN 2004b, Articles 15 and 17), but variations such as embezzlement (Article 17) and abuse of function (Article 19) are also within the purview of the definition.

Corruption manifests in the fishing sector in various forms (UNODC 2019a): On shore, abuse of function may occur when political figures or senior government officials use their positions to influence the allocation of fishing licences to companies or businesses in which they have a personal business interest (UNODC 2017; Standing 2015, 2008). One case currently under investigation involves an Icelandic fishing company that allegedly used a bank of a neighbouring country and shell companies in the Pacific to channel bribes to obtain fishing licences in Namibia (Wilhjálmsson 2019).

In the context of ship registration, some corporate entities operating ship registries on behalf of flag states may have obtained the rights to do so corruptly (UNODC 2011). Corruption in the context of monitoring and inspection may occur in the form of fines paid to fisheries authorities without independent review, funds from fines not properly accounted for by the competent authority or bribes paid to reduce penalties (INTERPOL 2014). Bribes may also be paid to enforcement officers or fisheries inspectors (at sea or on land) to ignore illegal harvesting of fish, particularly high-value species such as abalone (UNODC 2019a; UNODC 2017). Bribery is also prevalent in fishing ports where inspectors endorse, for instance, landing data that are clearly false (see, e.g., the rock lobster case above). Bribery may extend throughout the fisheries value chain (UNODC 2017). For example, in a San Diego court, where a U.S. company was alleged to have illegally brought into the United States approximately $17 million worth of sea cucumber from Mexico, papers suggested that the U.S. company sent money to Mexico to bribe officials, including law enforcement officers, along the entire supply chain (U.S. Department of Justice 2017; Kaplan-Hallama et al. 2017). Bribes may also be paid to officials to ignore irregular crew work permits, which may be used to facilitate human trafficking for forced labour on fishing vessels (UNODC 2019a).

2.2.3 Tax Crime

Tax crime, also known as tax evasion or tax fraud, is the violation of tax and revenue regulations, including income tax, value added tax, property tax, company tax and other forms of state levies and duties, including customs duties. If the offences are criminalised in law, they amount to tax crime.

Tax crime can be difficult to identify and prove, as not all jurisdictions require transparency regarding the beneficial ownership of bank accounts and companies. These jurisdictions, often labelled 'tax havens' or 'secrecy jurisdictions', perpetuate the grey area between legitimate tax planning and criminal tax evasion (Shaxon 2011; Galaz et al. 2018).

The fisheries sector lends itself to tax crime, including unreported tax, misreported or underreported tax, and tax evasion. In light of the relative ease with which criminals in fisheries can change a vessel's country of origin and identity, and use fictitious companies as registered owners, it would seem that the likelihood of profit-shifting, that is, channelling profit to shell companies in tax havens to avoid paying tax in the country where the profit was generated, is commonplace among these actors (NA-Fig 2017). Mis-invoicing also appears to be widespread in fisheries. Mis-invoicing happens by deliberate falsification of the value, volume and/or type of commodity in an international commercial transaction of goods or services by at least one party to the transaction (Global Financial Integrity 2019). Facilitated by financial secrecy jurisdictions, mis- invoicing commonly involves disguising the origin of fish, under-declaring the size of a catch and incorrectly describing the species or products caught or sold (OECD 2013).

The Organisation for Economic Co-operation and Development (OECD 2013) estimates that tax revenue lost to tax crime in fisheries is significant, undermining the development benefits of the sector, and notes that it has a particularly adverse impact on developing countries. It was recently estimated that, combined, the potential tax revenue losses due to the likely illicit seafood trade in African and Asian marine resources account for 72 to 74 percent of global tax revenue losses in this trade, amounting to between $1.6 and $3.1 billion annually (Sumaila et al. 2020). In Indonesia in 2016, tax crime by 187 fishing companies triggered a comprehensive audit of those companies by the Tax Directorate

General, which found that the fishing companies in question had failed to report or misreported tax amounting to potential unpaid tax revenue of 235 billion Indonesian rupiah (more than $16 million). The Tax Directorate General used the audit data to pursue enforcement measures and collect the unpaid taxes from the companies.

2.2.4 Money Laundering

Money laundering is defined in the Palermo Convention as the intentional concealing or disguising of the illicit origins of the proceeds of crime (UN 2004a, Article 6). The recommendations of the Financial Action Task Force (FATF 2012–19), an intergovernmental body promoting legislative and regulatory reforms to combat money laundering, terrorist financing and other related threats to the integrity of the international financial system, detail standards of universal application towards its aims, including that all countries designate serious crimes as 'predicate offences' (i.e. offences that are a component of a 'primary' crime) to money laundering. The Egmont Group, a united body of 164 financial intelligence units, provides a platform for the secure exchange of expertise and financial intelligence in support of national efforts to respect international global standards regarding anti–money laundering and counter-financing of terrorism, including those of the FATF. The Egmont Group (2014) has published a set of successfully prosecuted case examples to assist analysts and investigators pursuing money-laundering cases.

Many offences committed by organised crime groups in fisheries will be regarded as serious crimes and thus as predicate offences. A common denominator of organised crime networks operating in the fisheries sector is that they engage in money laundering to integrate into the legitimate economy the proceeds of crimes committed along the fisheries value chain, or the proceeds of their other crimes. They may do so by acquiring large capital assets, such as fishing vessels, or making cash salary payouts to crews of fishing vessels (OECD 2013, 33).

In Indonesia, illegal fishing is expressly cited as a predicate offence under the Prevention and Eradication of Money Laundering (Anti–Money Laundering) Law (Article 2). The law facilitates prosecution of money laundering and asset recovery through a number of criminal procedural tools, including reversal of the burden of proof during prosecution, giving defendants the burden of proving that their assets were not derived from crimes, and express permission of the inclusion of information in electronic form as legal evidence (Husein 2014).

2.2.5 Crime in the Labour Market

The labour market is a large economic sector that attracts organised crime in the form of 'labour market crime'. Such offences may range from breaches of work and safety regulations to fraud, tax evasion, document forgery and deception. In extreme cases, crimes in the labour market include abduction, unlawful confinement, physical injury, culpable homicide, murder and sexual abuse, as well as forced labour and human trafficking. *Forced labour* refers to 'all work or service which is exacted from any person under the menace of any penalty and for which the said person has not offered himself voluntarily' (ILO 1930, Article 2(1)). In the fishing sector it is often a consequence of human trafficking (ILO 2016) or 'trafficking in persons', which broadly refers to the procuring of and trading in human beings for the purposes of exploitation (UN 2004a, Annex II).

Criminal networks in fisheries use forced labour to significantly cut costs and boost profits (see, e.g., Tickler et al. 2018). The International Labour Organization (ILO 2016) highlights a number of indicators of forced labour in the fishing industry, including abuse of vulnerability, deception, restriction of movement, isolation, physical and sexual violence, intimidation and threats, retention of identity documents, withholding of wages, debt bondage, abusive working and living conditions, and excessive overtime. Facilitating forced labour is the practice of offshore transhipment of crew, which means that crew can stay at sea on different fishing vessels for years at a time without having to dock at port, frustrating detection of victims of trafficking for forced labour and making them de facto prisoners onboard (UNODC 2011).

Forced labour in the fisheries sector appears to be pervasive around the globe. For instance, in 2017 three employees of a Scottish family-owned company operating a fleet of scallop dredgers were arrested following a police raid on one of their vessels in southern England. The company has a track record of non-compliance with maritime safety rules. Nine crew, eight West Africans and one Sri Lankan, were removed from the vessel as victims of trafficking. A police investigation is ongoing (Lawrence and McSweeney 2017).

In the port of Puntarenas, Costa Rica, police rescued 36 Asians who had been subjected to labour exploitation on two fishing boats in 2014. The 15 Vietnamese, 13 Indonesians, 5 Filipinos, 2 Taiwanese and 1 Chinese national said they were forced to work up to 20 hours a day and were regularly flogged. They were underfed and had never been paid. Four individuals from Taiwan and Costa Rica were arrested in connection with the case and were charged with human trafficking (Zueras 2010).

In 2011, the Fiji Labour Department accompanied a Fijian fisher in filing a lawsuit against a fishing company on the basis of abuse endured in 1999 when he was employed on two South Korean fishing vessels. The fisherman had been subjected to a harsh working environment, received insufficient food and endured unhygienic living conditions. He had been forced to work in a refrigerated room at -40oC without gloves or any safety equipment, resulting in frostbite that required the amputation of his fingers. He told the media that he did not complain about the poor working conditions because he had been afraid of losing his salary (Human Rights at Sea 2019).

Forced labour and human trafficking can also take place in the land-based fishing industry. In 2015, Indonesian authorities discovered 322 migrant fishers from Burma, Cambodia and Laos stranded within the area of a fish factory in the island village of Benjina, part of the Maluku chain. The fishers were all in very bad condition, having been exploited for approximately 10 years without any payment, over which time they had been harassed, overworked (up to 20–22 h per day) and physically abused. They had been smuggled into Indonesia using forged Indonesian identity documents. In March 2016, an Indonesian court sentenced eight people—five Thai citizens and three Indonesians—for involvement in the crime of human trafficking. Each was sentenced to three years' imprisonment and a fine of 160 million rupiah ($11,300). The court also ordered the fishing company to pay 884 million rupiah ($62,500) in restitution to the victims of human trafficking.

Recruitment agencies play a central role in smuggling migrant workers to work aboard fishing vessels as victims of human trafficking for forced labour. In 2016, Norwegian authorities identified a foreign network, operating out of the north of Norway, that recruited at least 49 Indonesian fishers, a Spanish national and a number of Ukrainians to crab fisheries in the Barents Sea. Several deaths, serious injuries and threats of violence were reported by the fishers to the Norwegian coast guard and local police, and the coast guard identified very poor living and working conditions onboard the vessels (Dagbladet 2018a; Dagbladet 2018b). The network allegedly used a South Korean operator, a Seychelles recruitment agency and Norwegian port agents to facilitate the movement of the migrant fishers from Indonesia to Norway. Similarly, in 2016, Indonesian authorities learned that about 14 Indonesian victims of forced labour were working as fishers on a Chinese fishing vessel in Dargahan, Iran. The victims were recruited by an Indonesian recruitment agency affiliated with another recruitment agency in Taiwan.

2.2.6 Security Offences at Sea

Various offences occurring at sea present a threat to peace and security; this can include offences falling within the ambit of organised crime in the fisheries sector. 'Fisheries conflicts', which may arise from a combination of factors, including illegal fishing (along with climate change and food security concerns), also pose a potential threat to maritime security (see e.g. Spijkers et al. 2019; Sumaila and Bawumia 2014; Pomeroy et al. 2007). At an international level, the UN Security Council is influential in determining whether threats exist to international peace and security. In 2019, the Security Council explored transnational organised crime at sea and the threat it poses. Focusing on the Gulf of Guinea, various submissions noted that transnational maritime crime—broadly defined to include organised fisheries crime at sea—not only undermines national social and economic development but also destabilises the region and poses broader security risks (UNSC 2019).

The fisheries sector is also vulnerable to exploitation by terrorists due to vessels' seeming legitimate presence at sea; the lack of transparency as to their movement, identity and ownership; vessels' ability to tranship and access small harbours; and their sometimes erratic movements. For instance, in the 2008 terrorist attack in Mumbai, an Indian fishing trawler was hijacked to transport the terrorists and arms closer to the city (UNODC 2011). A recent Security Council resolution expressed concerns about the links between international terrorism and organised crime, including transnational organised crime at sea (UN Security Council Resolution 2842/2019 (2019).

Piracy, defined in the UN International Law of the Sea (UN 1982, Article 101) as illegal acts of violence or detention for private gain by occupants of one private vessel against another on the high seas or in waters beyond national jurisdiction, has been high on the agenda of the UN Security Council for a number of years. In 2016, the Security Council noted the interface between various types of criminal activities within the maritime domain in the Indian Ocean, highlighting the 'complex relationship' between large-scale illegal fishing in the region and the increasing piracy in Somali waters (UN Security Council Resolution 2316 of 2016 (2016); this relationship is also discussed by, e.g., Devlin et al. 2020; Samatar et al. 2010). A similar link has been argued for in the case of Southeast Asia (Liss 2007). And in 2012, in Senegal, fishers threatened to resort to piracy if the large-scale illegal fishing taking place in the Gulf of Guinea was not halted (Vidal 2012).

Also in the Gulf of Guinea, there is evidence that fishing vessels are being used for illicit trafficking of weapons (Okafor-Yarwood 2020; Beseng 2019; UNODC 2011). In 2018, the Cameroonian navy arrested forty-three people onboard three Nigerian fishing vessels; they were found to be illegally in the country's territorial waters, and automatic weapons, including AK47s, were recovered (Okafor-Yarwood 2020). There are also reports of the involvement of fishing vessels in gun-running elsewhere, including off the African east coast (UN 2003) and in the Caribbean (UNODC and World Bank 2007).

2.2.7 Drug Trafficking

Drug trafficking refers to the illicit trade, involving the cultivation, manufacture, distribution and sale, of substances subject to drug prohibition law (UNODC 2019b).

Fishing vessels are ideal modes of transport for drugs for the same reasons that the sector is vulnerable to security offences at sea. The UNODC 2011 study found that fishing vessels are used in various ways to facilitate illicit trafficking in drugs: as mother ships, that is, as a base station from which smaller vessels traffic drugs to and fro, as support vessels (providing fuel and supplies) for go-fast boats transiting trafficking routes (as is common in the Caribbean) or, for smaller fishing vessels, to traffic drugs directly to and from coastal landing sites in smaller quantities, frequently transhipping drugs to mother ships outside the territorial jurisdiction of the coastal state (UNODC 2011), for example in the Gulf of Guinea (INTERPOL 2014, 29).

In Indonesia, some 90 percent of illicit drugs smuggled in and out of the country are allegedly transported by sea (Indonesian National Narcotics Board 2012; Antara News 2018). In 2018, Indonesian authorities uncovered drug trafficking using four foreign-flagged fishing vessels, one of which was transporting one tonne of methamphetamines to Indonesia. The captain of the vessel produced forged Indonesian fishing permits and failed to present proper certification of competence to captain a fishing vessel, adding to the suspicion that the fishing vessel was merely a vehicle to transport illicit drugs (Antara News 2018). Private ports are frequently used in such trafficking operations. (Indonesian National Narcotics Board 2012).

Drug trafficking using fishing vessels is at times carried out in conjunction with the transport of other illicit goods. In Trinidad and Tobago, for example, Venezuelan gangs, in cooperation with local counterparts, engage artisanal fishing vessels to transport drugs and guns from Venezuela to Trinidad and Tobago. Cocaine transiting Trinidad and Tobago via Venezuela, originating in Colombia and destined for the U.S. market, is also known to travel on artisanal fishing vessels. In Jamaica, fishing canoes engage in a 'drugs-for-guns' trade with neighbouring Haiti, in which local marijuana is exchanged for illegal weapons (U.S. Department of State 2018) and increasingly, also, for cocaine (Neil 2018). In the Gulf of Guinea, in 2006, the fishing merchant vessel *Benjamin*, flying a Ghanaian flag, trafficked about 78 parcels (2340 kg) of cocaine into Ghana labelled as shrimp (Ali 2015).

Case examples also suggest that fishing companies, fish processing plants and fish distribution networks may act as storage facilities and legitimate covers for the transport of drugs and that some fishing operators launder proceeds from drug trafficking through investments in fishing infrastructure (U.S. Department of Justice 2019; UNODC 2011). Illicit drugs are hidden among or inside deep-frozen fish as the smell impedes the effectiveness of drug detector dogs, and enforcement officers are hesitant to inspect frozen fish, which would necessitate thawing the product (potentially damaging it and providing grounds for compensation claims should their suspicions prove unfounded) (UNODC 2011). In Mexico, in 2009, authorities intercepted over a tonne of cocaine concealed inside shark carcasses. The smugglers claimed that the drugs were 'preserving agents' (Emmort 2009).

In some cases there is evidence of a close connection between high-value species and drug trafficking networks. Off the west coast of South Africa, evidence suggests that abalone poached by divers is bartered with middlemen from local gangs involved in the drug trade for the ingredients to manufacture the synthetic drug 'Mandrax' (an addictive barbiturate-like sedative used in the poorer communities). These activities appear to be part of organised criminal networks involved in the black market export trade of abalone to East Asia (de Greef and Raemaekers 2014; Steinberg 2005). In Mexico, the high returns from the illegally harvested Totoaba bladders ('maws'), which are exported to China and whose price can reach US $15,000 per kilogram straight off of the boat and up to $150,000 per kilogram on the international market, have attracted the involvement of organised crime groups (mostly Mexican and Chinese) who operate criminal enterprises and networks with links to drug cartels, corrupt officials and institutions (e.g. law enforcement and border control), as well as human trafficking networks, which control the supply chain and allow the products to reach markets (Alvarado Martínez and Martínez 2018; Crosta et al. 2018).

In Colombia, enforcement has traditionally focused on addressing drug trafficking in the ocean domain through inter-agency cooperation. Authorities have found that crime in the fisheries sector manifests in a range of interrelated offences, including trafficking of illegal drugs and arms, human trafficking, smuggling of fuel and other contraband, large-scale illegal fishing, and wildlife trafficking. A task force against drug trafficking in the Caribbean (no. 73 'Neptune'), under the command of the Colombian navy (command post in the Gulf of Urabá), has been mandated to help restore security in the maritime and coastal area (Colombian National Navy 2015). Coordinated operations by the national police, navy and air force (such as the Agamenón II campaign in 2015) resulted in 2782 arrests and the seizure of 887 firearms and 360.4 tonnes of cocaine during the years 2015–2018.

2.2.8 Smuggling, in Particular of Fuel

Smuggling, that is, the movement of otherwise legal goods from one jurisdiction to another in violation of the law, is often engaged in to avoid customs or other duties. The fishing industry provides ideal cover for smuggling given the vast ocean domain within which it operates and the associated law enforcement challenges.

Fishing vessels and fishers, for example, are known to be involved in fuel smuggling worldwide. In Ecuador, artisanal fishers routinely use their fishing vessels to smuggle small quantities of subsidised Ecuadorian fuel to the neighbouring coast of Colombia, where it can be sold at considerable profit (Ralby 2018). Trinidad and Tobago fishing vessels have also been implicated in the illegal trade of fuel. Prior to the 2017–18 government reforms, subsidised diesel and regular fuel were sold to foreign vessels (reportedly flagged to Guyana, Suriname and Venezuela) by local coastal communities and from fishing vessels at sea. When the Trinidad and Tobago government discontinued the subsidy and the provision of regular gasoline to the domestic market, local fishers began to purchase fuel illegally for one-sixth of the domestic price from Venezuelan vessels in Trinidad and Tobago waters. Ghana has also seen an exponential rise in fishing vessels and canoes involved in fuel smuggling. The country is reported to be at risk of losing about 1.5 billion Ghanaian cedi ($300 million) in revenue to the smuggling of fuel, much of it trafficked by fishing vessels and canoes (Banaseh 2017). Fuel is also known to be smuggled alongside illicit goods, such as drugs, illegal weapons and illegally harvested fish, as well as migrants (Ralby 2018).

2.2.9 Migrant Smuggling

Broadly understood, *migrant smuggling* refers to helping a migrant enter a country illegally in exchange for a (direct or indirect) financial or material benefit (UN 2004a, Annex III, Article 3(a)).

The use of fishing vessels to smuggle migrants is alleged to be prevalent. Although it is not well documented formally, public media reports on the use of fishing vessels in migrant smuggling are widespread (e.g. EURONEWS 2019; Grey and Ismail 2016). In the Caribbean, fishing vessels, mainly from the artisanal sector, have for the past 10 years been increasingly used to traffic migrant women, in particular from mainland South America, to Trinidad and Tobago. Some are forced into prostitution in Trinidad and Tobago, while others are transited to the United States (The Guardian 2019). There are also indications that fishing vessels are involved in migrant smuggling in the Mediterranean (Dambach 2019; UN 2019, para. 8; UNODC 2011), Australia (Lindley et al. 2018) and Thailand (Lefevre 2014).

2.2.10 Fisheries Offences

Marine fisheries are regulated by national fisheries management laws and subject to multilateral treaties, the international law of the sea and management measures established by regional fisheries management bodies. *Illegal fishing* refers to fishing in violation of domestic fisheries laws and measures and can take various forms, including fishing without the requisite licence or permit in a coastal state's exclusive economic zone, engaging in transhipment contrary to coastal or flag state law, harvesting beyond an assigned legal quota and fishing for legally protected species. Many illegal fishing activities occur at sea, where they are subject to a complex jurisdictional regime dependent primarily on the maritime zone in which the vessel is located as well as the nationality (flag) of the vessel and, to a lesser extent, of its owner and crew.

An illegal fishing activity may also be a criminal offence if the activity in question is criminalised under the law in the relevant domestic jurisdiction. A recent study of fisheries legislation in 91 countries conducted by the Food and Agriculture Organization of the United Nations (FAO) suggests that more than half of these countries have both criminal and administrative penalties for the violation of fisheries rules, and nearly a quarter have criminal penalties only (FAO 2019). A little more than a quarter of the countries have administrative penalties alone, of which the largest proportion are in Europe. Some jurisdictions impose severe criminal penalties for fisheries offences. In Norway, for instance, the Marine Resources Act provides for prison sentences of up to six years, in addition to asset forfeiture, for particularly grave offences. When considering whether an offence is grave, the act requests that the court consider the monetary value of the offence and whether the offence was committed systematically and over time, was transnational or was part of organised activities (Norwegian Marine Resources Act, Article 64).

In practice, illegal fishing, along with unregulated and unreported fishing (referred to cumulatively as IUU fishing), is frequently associated with other types of criminal offences along the fisheries value chain (particularly fraud) (de Coning 2016). INTERPOL therefore takes the view that, regardless of whether or not illegal fishing has been criminalised in a jurisdiction, IUU fishing is a strong risk indicator of fisheries crime (INTERPOL 2018).

2.3 The Impact of Organised Crime in Fisheries on the Sustainable Ocean Economy

The pursuit of a sustainable ocean economy requires balancing use of the ocean space and its resources, on the one hand, with the long-term carrying capacity of the ocean's ecosystems, on the other (Kraemer 2017).

In line with the three-pillared concept of sustainable development under the Rio process, a sustainable ocean economy is premised on the economically, socially and environmentally sustainable use of the ocean (UN 2012). Agenda 2030 extends the three dimensions of sustainability to five areas of critical importance— people, prosperity, peace, partnership and planet— which should inform synergised inter-agency policy interventions towards achievement of the Sustainable Development Goals (SDGs) (UN General Assembly Resolution 2015).

Organised crime in the fisheries sector could severely undermine states' ambitions to achieve the SDGs. Given the multifaceted and far-reaching implications of organised crime in fisheries, addressing this problem is relevant to the achievement of a range of SDGs, including SDG 2 ('zero hunger'), 8 ('decent work and economic growth'), 12 ('responsible consumption and production') and 14 ('life below water'). SDG 16 ('peace, justice and strong institutions') is regarded as a core enabler of the other SDGs (Kercher 2018), and the targets in SDG 16, including on promoting the rule of law (16.3), reducing illicit financial and arms flows and organised crime (16.4), reducing corruption and bribery (16.5) and developing effective, accountable and transparent institutions (16.6), are particularly resonant in the context of addressing various manifestations of organised crime in fisheries (Kercher 2018).

There are ample illustrative examples highlighting how organised crime in the fisheries sector may undermine the global commitment to sustainable development and to a sustainable ocean economy in particular. Examples of the adverse economic, social and environmental impacts of organised crime in fisheries on the pursuit of a sustainable ocean economy are provided below. These examples underscore the cross-cutting nature of fisheries crime offences and the range of their complex adverse impacts on communities.

2.3.1 Social Impacts

Organised crime in the fisheries sector can have a negative impact on the affected coastal state and its population by, amongst others, undermining the rule of law, threatening peace and security, jeopardising food security and adversely impacting fishing communities.

Peace and Security

Regional and international peace and security is threatened by a range of organised criminal activities in the Gulf of Guinea (UNSC 2019). This encompasses piracy and armed robbery at sea, other violent crimes including ship hijackings, incidents involving 'firing on boats', hostage-taking and kidnapping for ransom, fuel and gas robbery and smuggling, drug and arms trafficking, illegal fishing and maritime terrorism (UNSC 2019). These criminal activities also seriously undermine the ability of the states in the region to pursue socio-economic development. Criminal activities have prompted increased insurance premiums for cargo vessels using the maritime space, which, in turn, impedes trade, hindering the movement of goods and services, and resulting in lost income for businesses and governments and higher prices for fuel, food and other goods for consumers (Chatham House 2013; Gilpin 2007; One Earth Future 2018).

In the Caribbean countries of Jamaica and Trinidad and Tobago, transnational networks using fishing vessels to facilitate drug and arms trafficking, as well as migrant smuggling, are known to cooperate with local criminal groups (UNODC and World Bank 2007; regarding Jamaica specifically, see Witbooi 2020; for Trinidad and Tobago, see Bassant 2019). This contributes to a rise in national violent crime, brings illicit drugs into coastal communities and fuels local criminal gang activities, such as fraud and extortion (Leslie 2010; Government of Jamaica 2007). In South Africa, organised criminal networks involved in the illegal harvesting and export of high-value coastal species, such as west and south coast rock lobster and abalone, and the associated illicit money flows and interface with drug trafficking, weaken governance and the rule of law. In Russia, authorities have warned about the association of the 'crab mafia' (Akhmirova 2012) with assassinations of high-ranking public officials and competitors, as well as money laundering and illegal fishing (Otto 2014). Russia has taken a number of strong measures in an attempt to bring organised crime in the crab fisheries under control (Akhmirova 2012).

Food Security

Fisheries resources are a major source of protein globally, providing an estimated 17 percent of animal protein consumed worldwide, with the highest per capita consumption in small island developing states (FAO 2018). According to the UN Special Rapporteur on the Right to Food, it is imperative to curtail illegal fishing to prevent its further adverse impact on food security and coastal livelihoods (UNGA 2012).

In the West African region of the Gulf of Guinea, for example, fish is the predominant (and sometimes only) source of animal protein consumed by the roughly 40 percent of the population that resides in coastal communities (Okafor-Yarwood 2019). In Sierra Leone, one of the poorest countries in the world (UNDP 2018), fish provides an estimated 75 percent of the animal protein consumed by the population (Agnew et al. 2010), highlighting the inseparability of fish from the country's food security. This is well illustrated by the role fish played during the Ebola crisis, when it became a substitute for infected bush meat (USAID 2016). For coastal communities, such as those in Nigeria's Niger Delta area, fishing also provides basic income to pay for social services, including medical care and education, that are not provided by the Nigerian state (Okafor-Yarwood 2020; 2019).

Large-scale overfishing in Jamaica has left most reef fish stocks overexploited (World Bank 2017). As a result, Jamaica is almost entirely dependent on imported fish for domestic consumption. According to 2014 data, 79 percent of all fishery products consumed in Jamaica were imported (World Bank 2017). The value of fish imports for food in Jamaica in 2015 was $103.8 million (CRFM 2018).

Criminality In Fishing Communities

Organised crime in fisheries can shape criminality in fishing communities in a number of ways. With few livelihood options beyond fishing, coastal communities are particularly vulnerable to recruitment by criminal networks operating in the fisheries sector.

In the Gulf of California in Mexico, research indicates that the government's incomplete implementation of 2002 environmental management regulations (Alvarado Martínez and Martínez 2018; Santos-Fita 2018) has contributed to the tendency of fishers—adversely affected by these conservation efforts—to turn to totoaba poaching due to lack of legitimate alternative livelihoods (Alvarado Martínez and Martínez 2018; Crosta et al. 2018).

On the South African coast, overexploitation of west coast rock lobster (*WWF South Africa v Minister of Agriculture, Forestry and Fisheries and Others* 2018) has impacted thousands of subsistence fishers who traditionally harvested the species. No longer able to catch enough to sustain themselves, fishers have been forced to seek alternative, sometimes illegal, ways of generating income (Cochrane 2017). In Nigeria, evidence suggests that coastal fishers, who fear putting out to sea due to frequent violent attacks from illegal fishing vessels, are susceptible to recruitment by organised criminal networks engaging in armed robbery at sea and oil smuggling (Okafor-Yarwood 2020).

Moreover, many coastal communities are transformed by organised crime and the illicit goods and associated economies of violence it brings. Trinidad and Tobago has seen a rise in violent crime nationwide, but particularly in coastal areas not traditionally known for gang activities (such as Moruga, Claxton Bay, Carli Bay and Orange Valley). This has disrupted daily life and, in some instances, separated families as parents send children to live with family members in safer areas. In Jamaica, research indicates that violent gang-related activity is increasingly commonplace in small fishing towns, such as Rocky Point, caught in the drugs-for-guns trade (Witbooi 2020; Robinson 2017; Fisher 2016). In South Africa, remote coastal communities are under siege by organised criminal gangs illegally accessing abalone off their shores (Isaacs and Witbooi 2019; de Greef and Raemaekers 2014).

Organised crime in the fisheries sector also has noticeable gendered implications. In South Africa, women in female-headed households have become accomplices to organised poaching operations, washing divers' wetsuits and storing their illegally harvested abalone in their refrigerators to earn money for basic necessities, subjecting them to criminal prosecution (Isaacs and Witbooi 2019). In Nigeria, where the combined effect of illegal fishing, climate change and pollution from oil companies threatens the livelihoods of coastal fishing communities, fishmongers—who are predominantly women—have in some instances been forced into prostitution to make ends meet (Okafor-Yarwood 2020, 2018), worsening the region's already high prevalence of HIV/AIDS (Okonko and Nnodim 2015; Udoh et al. 2009). In Mexico, the rapid growth of the illegal sea cucumber fishery on the Yucatán Peninsula, triggered by rising international demand, has driven dramatic social and ecological changes in the community of Río Lagartos (Kaplan-Hallama et al. 2017). In addition to creating new pressures on local environmental resources, the 'gold-rush' influx of new actors has weakened the community's social cohesion and sense of security, and fishers from outside the area have been associated with rising levels of local violence, prostitution and drug use (Kaplan-Hallama et al. 2017).

Given communities' central role in the supply chain of organised criminal networks, it may be useful to complement the law enforcement response with an approach that enables the community to play a preventative role (Isaacs and Witbooi 2019; Hübschle and Shearing 2018, 5; Hauck and Sweijd 1999). Communities can build their resistance to the infiltration of organised crime by strengthening their resilience (Felix 2017).

Women, who often hold powerful positions in fishing communities (albeit often unrecognised; see Matthews et al. 2012), can be prominent actors in this effort. This could be the case, for example, in Rocky Point, Jamaica, where women are the primary owners and managers of key community fishing assets (Livelihoods Report 2012).

2.3.2 Economic Impacts

Costs to Coastal States

Organised crime in fisheries can severely compromise the revenue base of coastal states. For instance, in the Gulf of Guinea large-scale illegal fishing is estimated to amount to 40–65 percent of the reported catch (Doumbouya et al. 2017; Agnew et al. 2009): the combined annual economic cost of large-scale illegal fishing to the Gambia, Guinea, Guinea-Bissau, Mauritania, Senegal and Sierra Leone is estimated to be $2.3 billion (Doumbouya et al. 2017; Ali 2015). In Guinea- Bissau alone, more than half of the industrial catch landed, valued at $260.7 million, is caught illegally. Only a third of the remaining catch is captured by the local economy through fishing fees and access agreements (Intchama et al. 2018, 9). Facing a similar predicament, Indonesia introduced a comprehensive and bold law enforcement and policy reform against fisheries crime. The reform has spurred national economic development and resulted in an increase of fish stocks from 7.31 million tonnes in 2014 to 9.93 million tonnes in 2015 and 12.54 million tonnes in 2016 (MMFA 2018, 23; Cabral et al. 2018). Catch landings by local coastal fishermen have also risen, and the resulting increase in their purchasing power has driven the economic growth of local fisheries. The reforms contributed to significantly improved tax revenue from the fisheries sector in 2018, amounting to 1.6 trillion rupiah ($113 million) (Indonesian Ministry of Finance 2019).

Piracy and armed robbery at sea also have noticeably reduced revenue generated by the fisheries sector in the Gulf of Guinea. In Nigeria, for instance, such crime has led to a drop in the number of licenced fee-paying industrial fishing vessels operating in local waters, thereby weakening the sector's contribution to gross domestic product (Okafor-Yarwood 2020). This echos past impacts: in 2008, in response to safety concerns, the Nigerian Trawler Owners Association recalled about 200 local fishing vessels to shore, impacting approximately 20,000 jobs and leading seafood prices to more than double (Onuoha 2012).

At an international level, a 2020 report indicates gross revenues of between $8.9 billion and $17.2 billion are annually redirected out of the legitimate market through illicit trade. Asia, Africa and South America account for approximately 85 percent of total catch losses to likely illicit trade globally. Africa is estimated to experience annual losses of between $7.6 billion and $13.9 billion and between $1.8 billion and $3.3 billion in economic and income impacts, respectively, due to the redirection of catches from legitimate to illicit seafood trade (Sumaila et al. 2020).

Costs to the Legitimate Industry

Legitimate businesses are burdened with the negative economic impacts of organised crime in fisheries.

Networks engaged in organised crime can significantly cut their costs and launder illicit gains, giving them an unfair advantage over legal operators, whom they can effectively push out of business. Russian authorities have warned against foreign companies taking control of local fishing companies and undercutting resident competitors (Krivoshapko 2017). In the north of Norway, the introduction of underpaid migrant workers in the foreign-flagged snow crab fleet led some Norwegian- registered snow crab companies to employ their own vulnerable migrants in violation of national crewing regulations (Dagbladet 2018a; Fenstadt and Kvile 2016).

Organised crime in the fisheries sector damages the reputation of the legitimate industry and fishing nations.

An example is the document fraud around shark fin exports in the Trinidad and Tobago fishing industry, as mentioned above. In a further example, in 2014 Trinidad and Tobago was cited by the Commission for the Conservation of Antarctic Marine Living Resources for trading in Patagonian toothfish, contrary to the region's fisheries management agreement. It was subsequently discovered that the trade documents attached to the Patagonian toothfish exports to Canada indicating Trinidad and Tobago as the country of origin were fraudulent (Republic of Trinidad and Tobago, Fisheries Division 2019).

Businesses outside the fishing industry may also be harmed by the rise in crime. In Jamaica violent crime, fuelled by the maritime smuggling of guns into the country, has led to a loss of business productivity (due to resulting death and injuries) and weakened investor confidence (Leslie 2010). In Trinidad and Tobago, the influx of drugs and illegal weapons by sea has led to reduced production and increased expense for security, with 85 percent of businesses spending the highest portion of their budgets on increased security in recent years (Sutton 2017). These effects are interwoven with the social impacts of organised crime in fisheries, outlined in the section above.

2.3.3 Environmental Impacts

Impact on Fish Stocks

Organised crime in the fisheries sector in the form of large-scale overfishing has been shown to sharply reduce commercially exploitable fish stocks. In 2009, a group of British and Canadian researchers published an estimate of the worldwide extent of illegal fishing between 2000 and 2003. They found that 18 percent of the global catch, valued at between $10 billion and $23.5 billion, was lost to either illegal or unreported fishing during this period (Agnew et al. 2009). An updated 2011–2014 estimate suggests that annual illegal and unreported marine fishing generates $15.5 billion to $36.4 billion in illicit profits (Global Financial Integrity 2017). A recent global study (Sumaila et al. 2020) estimates that between 7.7 and 14.0 million metric tonnes of unreported fish catches are potentially traded illicitly each year. Latest FAO figs. (2015 data) estimate that some 59.9 percent of the world's commercial fish stocks are now fully fished, with about a third of global fish stock overexploited (FAO 2018). As fish stocks decline, the resource becomes more valuable, which, in turn, attracts increasing involvement by transnational organised crime syndicates in the fisheries sector (UNDOC 2011).

Effective law enforcement resulting in successful prosecution of organised crime in the fisheries sector can dramatically strengthen the targeted stocks. An illustrative example is the rock lobster case described earlier. The successful prosecution of the criminal network involved contributed to the dramatic recovery of the south coast rock lobster.

Catch rates of the fishery, which had been subject to government regulation since the mid-1970s, declined by 5–10 percent per year from 1984 to 2000 despite the introduction of a total allowable catch in 1984. This was the period during which the criminal network operated. Following the arrest and prosecution of those involved, five consecutive years of increased catch rates were recorded between 2000–2001 and 2004–2005 (Johnston and Butterworth 2017).

Impact on the Marine Environment

Organised crime in fisheries can also harm the marine environment and associated ecosystems. In Nigeria, local fishers struggling to sustain their livelihoods are known to fish illegally near oil pipeline installations, which risks causing oil leaks and marine pollution (Okafor-Yarwood 2020, 2018). Piracy and armed robbery at sea in the broader Gulf of Guinea region can also lead to oil or chemical spills, through the use of weapons like rocket-propelled grenades to attack vessels and in the transfer of the targeted ship's cargo (IMB 2013). The use of gill nets in the illegal totoaba trade in Mexico has not only brought the vaquita porpoise, which is caught as by-catch, to the brink of extinction but has resulted in severe damage to the larger marine ecosystem of the Upper Gulf of California (Alvarado Martínez and Martínez 2018). Illegal dynamite (or 'blast') fishing, associated with explosives trafficking, off the Tanzanian coast is highly destructive to the marine habitat, including coral reefs, and reduces fish stocks, which has broader food security ramifications (IOC and FAO 2015; Galbraith 2015).

2.4 Addressing Organised Crime in Fisheries

2.4.1 Challenges

Globally, jurisdictions face a number of law enforcement challenges in identifying, investigating and successfully prosecuting organised crime in fisheries. Many of these are outlined in reports and outcome documents from expert group meetings and the International Symposiums on Fisheries Crime (e.g. CCPCJ 2017, 2016; UNODC 2017), underscoring the necessity of effective criminal law enforcement in addressing fisheries crime throughout the value chain. The 2017 report *Chasing Red Herrings* (NA-Fig 2017) highlights particular enforcement challenges arising from secrecy and the use of flags of convenience in the fishing industry.

Law enforcement faces a number of challenges in addressing organised crime in the fisheries sector:

- **Low national prioritisation of organised crime in fisheries at political and operational levels.** Law enforcement officers around the world have noted that limited budget and resources lead law enforcement agencies to prioritise investigation of cases perceived as important. The result is that '[i] n many countries, crime linked to the fisheries value chain will not be investigated because it is not seen as a major priority and it is difficult to investigate' (UNODC 2017, 28).
- **Lack of coordination between government departments and agencies nationally, regionally and transnationally**. Due to the global nature of the fishing industry, key actors are scattered across various jurisdictions, with those ultimately responsible for, and benefitting from, criminal activities often in different states from those where the activities are taking place. This can make it unclear which state has jurisdiction to prosecute the offences in question. Without a high degree of information-sharing and cooperation between law enforcement authorities, in particular cross-border mutual legal assistance (MLA), successful prosecution of fisheries crime is very difficult (UNODC 2017, 28–29; NA-Fig 2017, 66).
- **Inadequate criminal and criminal procedural legislative frameworks**. The failure to criminalise fisheries crime at the national level can make it impossible to investigate and prosecute fisheries crime effectively, a problem emphasised in numerous reports and outcome documents (e.g. NA-Fig 2017, 66; UNODC 2017, 14).
- **Lack of clarity of jurisdiction at sea and extraterritorial jurisdiction**. Most states have not adequately criminalised offences committed by their nationals onboard foreign fishing vessels at sea or passed legislation regarding offences onboard stateless vessels. The result is that fisheries crime at sea (beyond national waters) is often not investigated or prosecuted (NA-Fig 2017, 66).
- **Lack of at-sea enforcement**. Effective at-sea surveillance by patrol boats requires considerable infrastructure and resources to maintain effective control in large and often distant marine areas (UNODC 2011, 131). Many states that rely heavily on the fisheries sector have very limited maritime law enforcement capability; this is particularly true in the Global South.
- **Lack of law enforcement agency and criminal justice capacity, particularly around financial investigations**. Law enforcement officials may have insufficient capacity to identify various forms of fisheries crime and to subsequently investigate and successfully prosecute the offences. They may also lack the technical skills necessary to pursue financial investigations (UNODC 2011, 138; CCPCJ 2017, paras. 6, 23; UNODC 2019a, 49).
- **Lack of transparency in the fisheries sector and the financial sector.** The lack of accurate information about beneficial ownership of vessels and legal entities operating in the fishing sector, unreliable and out-of-date information on vessels' identities and global movements, including in relation to at-sea transhipments, and the use of flags of convenience frustrate investigations of

organised fisheries crime (UNODC 2011, 132, 137; CCPCJ 2017, para. 12; NA-Fig 2017). The ability of criminal networks to easily invest, disguise and launder the proceeds of their crimes in financial secrecy jurisdictions throughout the world, especially through the use of corporate structures like anonymous shell companies and tax havens, hampers investigators' ability to 'follow the money' and recover the proceeds of the crime and secure restitution (UNODC 2011; NA-Fig 2017).

2.4.2 Promising Practices

State administrations have numerous tools at their disposal to address organised crime. If employed correctly, these tools can significantly reduce the overall occurrence of organised crime. The complexity of organised crime in fisheries, the potential harm it may cause and the resources needed to combat it all suggest that any strategy should stress crime prevention. In this regard, identifying socio-economic drivers of criminal activities is key, as are crime disruption strategies and robust legislative frameworks that criminalise serious offences and attach sufficiently deterrent penalties. At the same time, where criminal networks have manifested themselves, it is important to identify effective means to address them, underpinned by robust cooperative criminal law enforcement and criminal procedural efforts.

FAO (2014) has acknowledged that 'the realities of corruption and organised crime [in fisheries] . . . need to be addressed through supplementary means extending beyond the realm of fisheries control and enforcement'. Legal tools developed to improve compliance in fisheries management should thus be seen as complementing a criminal justice enforcement approach to tackle criminal networks in the fishing sector. Evidence shows that the enforcement approach to 'prevent and control' organised crime cannot rely on the use of administrative sanctions alone, because criminals are able to absorb such penalties as part of their costs of doing business. For example, criminal operators select jurisdictions with low penalties, or totally avoid penalties by flying the flag of a state unable or unwilling to impose them. Likewise, the potential costs associated with vessel's being seized can be minimised by running a fleet of low-value vessels (de Coning 2016).

The following paragraphs detail five promising practices in addressing fisheries crime.

National-Level Inter-Agency Cooperation

The multitude of offences falling under the umbrella of 'fisheries crime' necessitates cooperation among a range of government agencies to identify, investigate and prosecute members of criminal networks. Various countries have introduced different types of cooperative enforcement models to address organised crime in fisheries.

Thailand employs a multidisciplinary approach to vessel inspections at the country's 31 'port-in, port-out' control centres to verify compliance with fishing and labour regulations. The teams include representatives from a range of agencies, including the Department of Fisheries; the Marine Department; the Department of Labour, Protection and Welfare; the Department of Employment; the Royal Thai Navy and the Marine Police. Most recently, a flying inspection team was added to increase the effectiveness of the control centres (MFA 2018).

In Indonesia, the Task Force to Combat Illegal Fishing (Task Force 115), established by presidential regulation, is a model of an integrated criminal justice mechanism to improve coordinated enforcement in combatting illegal fishing and fisheries crime cases with transnational organised elements. It operates as a 'single-roof' enforcement agency bringing together five enforcement agencies—the Ministry of Marine Affairs and Fisheries, the Navy, the Marine Police, the Coast Guard, and the Attorney General's Office—under the auspices of the Ministry of Marine Affairs and Fisheries. Task Force 115 undertakes a range of activities to ensure effective enforcement in fisheries, including case monitoring, management and assistance. Malaysia is currently also moving towards introducing a similar 'one-roof' enforcement agency to address maritime crime.

Norway established the Norwegian National Advisory Group on Fisheries Crime and IUU Fishing (Fiskeriforvaltningens Analysenettverk) in 2008. All relevant agencies, including the Coast Guard, the police, as well as fisheries, maritime, tax, customs and labour authorities meet regularly to discuss common cases.

The secretariat of the advisory group is housed in the Ministry of Trade, Industry and Fisheries and is involved in law and policy development on fisheries crime.

In Tanzania, the Multi-agency Task Team on environmental and wildlife crime (MATT) was launched in 2015. The MATT is led by the Ministry of Home Affairs and includes the Ministries of Livestock and Fisheries Development, the Ministry of Energy and Minerals, the Ministry of Natural Resources and the Tanzanian Police Force. Aimed at coordinating efforts and resources, the MATT targets individuals and criminal networks that control environmental and fisheries crime in the region and the illegal trade in wildlife (IOC and FAO 2015).

Regional and Global Cross-Border Cooperation

Regional and global cooperation also plays a vital role in enhancing the investigation of organised crime in fisheries, including through the use of MLA, INTERPOL tools and judicial requests to cooperate with other countries. Countries such as Indonesia and South Africa have used these tools to uncover cases of transnational organised crime in fisheries, and to facilitate prosecution of the offenders. Example cases highlighting the value of this collaboration include those of the *STS-50* and *Viking*, in which Indonesia invited a multilateral team of experts and INTERPOL to help facilitate information-sharing, analyses and possible prosecution of the offenders in various jurisdictions.

Law Reform

A number of jurisdictions have criminalised fisheries offences and attached deterrent penalties to facilitate engagement of the criminal law enforcement track and frustrate criminal operators' ability to factor fines into the cost of doing business. For example, the Ghanaian courts may, in certain circumstances, impose a maximum penalty of two years' imprisonment for the illegal export of fish under the terms of the 2002 Fisheries Act, and in South Africa violations of almost all the provisions of the 1998 Marine Living Resources Act amount to a criminal offence and are punishable by a fine of up to five million rand ($338,000). Norway follows a similar approach.

The criminalisation of other offences falling under the fisheries crime umbrella, along with sufficiently severe sanctions, including against corporations, has been implemented by various jurisdictions. Indonesian Law 25/2003 on the Crime of Money Laundering obliges banks and financial service providers to make information on suspicious financial transactions available based on which law enforcement officers have the power to request that the bank freeze the accounts of suspected money-laundering criminals (Husein 2014). Also particularly valuable is the enactment of organised crime legislation, such as South Africa's 1998 Prevention of Organised Crime Act, which criminalises racketeering and triggers asset forfeiture. The act is successfully employed in the prosecution of organised crime networks engaged in abalone trafficking. Legal measures to increase transparency in the fisheries sector are also valuable as they may facilitate identification and investigation of organised crime in the sector. In Taiwan, for example, the 2016 Act to Govern Investment in the Operation of Foreign-Flag Fishing Vessels aims at regulating Taiwanese nationals' involvement in the operation of foreign-flagged fishing vessels beyond national waters.

As cases of human rights abuse on fishing vessels increasingly come to light, various countries have introduced legislation to protect against these abuses, following the adoption of the ILO Work in Fishing Convention No. 188. Indonesia introduced regulations based on the three-pillared Ruggie Guiding Principles on Business and Human Rights (UN OHCHR 2011) implementing a certification system obliging Indonesian fishing companies and fishing vessels to protect fishers' human rights. In February 2019, Thailand also ratified the ILO Work in Fishing Convention No. 188 and is seeking to amending existing laws to comply with regulations on protecting workers onboard fishing vessels (Tavornmas 2019).

Capacity-Building and Skills Training in Criminal Justice Systems

Capacity-building activities are deemed important to broaden the knowledge and hone the skills of investigators and prosecutors in enforcement efforts against organised crime in the fisheries sector. Both Indonesia and Norway offer professional accredited training to strengthen the law enforcement capacity to detect and punish crimes throughout the fisheries value chain. The International FishFORCE Academy of Indonesia, at the Jakarta Centre for Law Enforcement facility in Semarang, was established in December 2016, while the Norwegian Police University College (2019) has offered modules on fisheries crime investigation to Norwegian law enforcement agencies since 2010. Particular emphasis should be given to enhancing the capacity to conduct financial investigations parallel to investigating the underlying offence where significant amounts of money are involved (UNODC 2019a).

Sensitisation of judges to cases of organised crime in the fisheries sector is also recognised as valuable. Most recently, in 2020, the Norwegian government launched the Blue Justice Initiative, which includes a focus on the capacity-building needs of developing countries to address organised crime in the fisheries sector (Blue Justice 2020).

Awareness-Raising

Given the transnational nature of organised crime in fisheries, the technical expertise of law enforcement agencies must be augmented by strong international networks built to enhance the timely and accurate gathering of information, as well as intelligence-led law enforcement efforts. International government organisations, such as UNODC and the INTERPOL Fisheries Crime Working Group, facilitate this, as do international processes such as the International Symposiums on Fisheries Crime (FishCRIME Symposiums), which, as of 2020, will be superseded by the Global Blue Justice Conferences.

Awareness of organised crime in the sector must also be raised among legitimate fishing businesses in order to minimise opportunities for criminal activities along the industry's retail and value chains. Case examples exposed in the media have helped increase public demand for improved sustainability and transparency of seafood production practice. For example, in 2014 The Guardian reported on an investigation that found that the world's largest Thailand-based prawn farmer was purchasing fishmeal to feed its prawns from some suppliers that owned, operated or bought from fishing vessels engaged in human trafficking for forced labour. These prawns were sold to the public in four of the world's top retailers (The Guardian 2014), raising questions about these businesses' ethical standards. *Corporate social responsibility* (CSR) as an umbrella term refers to the commitment of businesses to recognise their responsibility for the behaviour of their business partners (i.e. within their value chains) and for their impact on society and the natural environment (Blowfield and Frynas 2005, 503). An increased focus on CSR in the fishing industry could give fishing companies a tool to engage in activities that respond to civil society pressure in this regard (Packer et al. 2019). Civil society, in turn, can play a role in both influencing the substantive content of CSR practices and holding companies accountable for their implementation.

3 Concluding Thoughts

In reviewing relevant literature, international cases, reports and expert insights in order to produce this Blue Paper, the authors found ample anecdotal, scientific and case-based evidence of the many manifestations of organised crime in the fisheries sector and its multi- faceted negative impacts on society at large.

The paper shows that organised crime in the fisheries sector is widespread in the sense that it is not restricted to specific geographical locations but rather is found globally. That said, criminals will tend to seek out the world's most vulnerable regions as sites for their activities, and fisheries crime thus appears to most harm the coastal populations of states with the least resources to prevent and combat it.

There is, however, a knowledge deficit with regards to the scale of organised crime in the fisheries sector. To date no statistical data are publicly available estimating the extent of organised crime in the fisheries sector or mapping incidents of its location at a global level. Existing scientific output and data on criminality in the fisheries sector speak almost exclusively to illegal or unreported fishing, which does not take into account the range of criminal offences that occur throughout the fisheries value chain. Greater scientific and criminological knowledge is needed of the dynamics and scale of organised fisheries crime and the networks involved therein in order to identify, evaluate and implement the best measures to address the drivers of such crime.

As outlined in this Blue Paper, organised crime in the fisheries sector has the potential to severely undermine the premises for a sustainable ocean economy, with notable adverse social, economic and environmental implications. The problem is recognised as sufficiently severe to warrant states' mobilisation to take political action. The rate at which support of the Copenhagen Declaration is gaining momentum, particularly among states from the Global South, attests to states' increasing acknowledgement of the existence, extent and adverse impacts of organised crime in the fisheries sector. Further, states acknowledge that a failure to effectively address such crime will result in a widespread inability to meet SDG 16, among others, and ultimately to create a sustainable ocean economy. A next important step will be for states supporting the Copenhagen Declaration to identify practical measures to implement their political commitments.

This Blue Paper highlights the complexity of the underlying problem and suggests a number of 'opportunities for action' for states to address organised crime in fisheries. These suggestions confirm that an approach rooted in fisheries management alone cannot adequately respond to the criminal challenges identified in the fisheries sector. Also essential is the application of an intelligence-led, skills-based cooperative law enforcement response at a domestic level that is facilitated by enabling legal frameworks and increased transparency in the fisheries governance sector and associated financial systems at the global level.

4 Opportunities for Action

The UN General Assembly has noted with concern the existence of possible connections between international organised crime and illegal fishing and urged states to better understand the causes and methods of, and contributing factors to, these connections, bearing in mind the distinct legal regimes and remedies under international law applicable to illegal fishing and international organised crime (UNGA Resolution 63/112).

States have acted on the General Assembly's request, engaging in and supporting a number of initiatives aimed at increasing the knowledge base and understanding of the possible connections between organised crime and illegal fishing. These initiatives' findings, which are publicly available, reflect the General Assembly's instructions to respect the two distinct legal regimes that govern IUU fishing and transnational organised crime, respectively, according to the mandates of the corresponding two UN agencies, namey, the FAO and the UNODC.

Yet, with notable exceptions, the world community remains largely uninformed of the evidence, or even existence, of transnational organised crime in the global fishing industry as a distinct problem alongside global efforts to secure a sustainable fisheries resource.

Furthermore, states remain predominantly unaware of the most appropriate remedies and applicable legal regimes to address this problem, and how they differ from (yet are complimentary to) measures aimed at remedying fisheries management challenges. This lack of distinction between the problem of organised crime in fisheries (in effect a security and law enforcement problem), on the one hand, and IUU fishing (in effect a problem of unsustainable fishing practices), on the other, may lead states to continue making ill-informed decisions regarding the most suitable approaches to these two challenges, both separately and in concert, with the danger that neither will be adequately addressed.

The distinct natures of the two phenomena are particularly evident when organised crime in fisheries is examined within the context of other maritime crimes.

In February 2019 the UN Security Council heard national submissions highlighting the multifaceted nature of transnational organised crime at sea, including fisheries crime, and the threat it poses to international peace and security. The members underscored the Security Council's potential future role in addressing the problem of fisheries crime, while one permanent member of the Council expressed doubt that IUU fishing, or the degradation of the maritime environment, falls within the Council's power and prerogative (UNSC 2019). It is worth taking note of this point: It is not the primary objective of fisheries management and conservation bodies to address organised crime, and it is not the primary objective of peace and security bodies, like the Security Council, to address fisheries management and conservation. By respecting the distinct natures of organised crime in fisheries and IUU fishing, states will have a wider and complimentary set of tools at their disposal to address the security implications of organised crime in fisheries and the fisheries management implications of IUU fishing, respectively.

In order to meet the targets set by SDG 16 to significantly promote the rule of law, reduce illicit financial flows, combat all forms of organised crime, substantially reduce corruption and bribery, strengthen relevant national institutions and build capacity to combat crime, it is imperative that at a state level there be universal recognition of the security implications of organised crime in fisheries, of the need to address the challenges posed by the shadow blue economy and of the necessity of cooperation at all levels to enhance inter-agency and cross-border fisheries crime law enforcement. As SDG 16 is an enabling goal of, among others, SDG 14 on 'life below water', addressing organised crime in fisheries will impact states' ability to reach the targets set forth in SDG 14.

States are, however, moving towards increased understanding of the problem of organised crime in fisheries. In 2017, a Nordic political declaration on Transnational Organised Fisheries Crime was issued through the Nordic Council of Ministers (the Ålesund Declaration), and in 2018 ministers from nine countries adopted the Copenhagen Declaration, which is gaining traction. In both declarations, the ministers express their conviction 'that there is a need for the world community to recognize the existence of transnational organised crime in the global fishing industry'.

Only when all states share a joint understanding of the problem at hand can technical solutions to address the problem be implemented. To this end, the opportunities for action suggested below are divided into two consecutive stages (Box 16.1). In the first stage, outlined in Sect. 4.1, the opportunities for action is to work towards the political goal of a common understanding of organised crime in the global fishing industry. A political recognition of the problem is crucial in order to identify and implement more technical and practical opportunities for action to address organised crime in fisheries. In the second stage, outlined in Sect. 4.2, the opportunities for action focus on practical law enforcement tools to address organised crime in the fishing industry based on the promising practices detailed above.

Box 16.1 Summary of Two Stages of Action

1. Political Action: Develop a common understanding of transnational organised crime in the fisheries sector globally, and build political will to address the challenge cooperatively.
2. Practical Tools: Develop practical tools to strengthen law enforcement capacity through:
   - Strengthened national inter-agency cooperation
   - Effective cross-border law enforcement cooperation
   - Enabling legal frameworks
   - Skills training and capacity building
   - Community-based crime prevention strategies which incorporate a gendered approach
   - Engagement of civil society
   - Support of relevant research

4.1 Stage One: Develop a Common Understanding of Transnational Organised Crime in Fisheries

We offer the following opportunities for action:

- **All states should report to the UN General Assembly in response to the call made by UNGA Resolution 63/112 to examine connections between illegal fishing and organised crime in the fisheries sector.** This will facilitate establishment of a solid platform of knowledge about the manifestations of organised crime in the fisheries sector as it is experienced around the world.
- **UN Security Council members should raise the security implications of transnational organised crime in the fisheries sector** to encourage the development of a common understanding of the problem's security dimensions.
- **All states should formally support the 2018 International Declaration against Transnational**

Organised Crime in the Global Fishing Industry (the Copenhagen Declaration). Broad support for the declaration would be an important step towards developing a common understanding and awareness of the problem of organised crime in the fisheries sector and building the political will to more vigorously address it, which in turn would facilitate achievement of the SDGs.

- **All states should report annually on transnational organised crime in the fisheries sector to the UN Commission for Crime Prevention and Criminal Justice (CCPCJ)** to ensure widespread and continuous attention to the problem.
- **All states should participate in regular international knowledge- sharing forums** to share information on, and discuss challenges and opportunities arising from, cases of transitional organised crime in the fisheries sector worldwide. Outcome documents therefrom should be made publicly available.

4.2 Stage Two: Develop Practical Tools to Strengthen Law Enforcement Capacity to Address Organised Crime in the Fisheries Sector

Once there is a common understanding of organised crime in the fisheries sector, states, acting jointly and individually, should develop a number of practical tools to strengthen their criminal law enforcement capacity to address the problem. Together these tools should improve states' ability to prevent, detect and respond to organised crime in the fisheries sector.

We offer the following opportunities for action:

- **All governments should strengthen national inter-agency cooperation to address organised crime in the fisheries sector**. We recommend that states introduce national inter-agency models to facilitate and support coordinated criminal law enforcement efforts to prevent organised crime in the fisheries sector and identify and prosecute offenders. The sharing of relevant information across agencies should be facilitated by legislation in line with personal data protection principles (for European Union General Data Protection Regulations, for example, see European Commission 2019). The inter-agency body should have high-level political support, should ideally be established via legislative means and should have a clear mandate and permanence.
- **All governments should strengthen cross-border cooperative law enforcement efforts to identify, investigate and prosecute cases of transnational organised crime in the fisheries sector, including through mutual legal assistance**. We suggest that the tools available through international and regional networks and organisations, such as multilateral information-sharing and analysis mechanisms, be used to this end, as well as platforms for the secure exchange of financial intelligence, and that existing databases on organised crime, such as the UNODC's SHERLOC (2019) database, be augmented to also include fisheries. This will facilitate the sharing of information and intelligence and enhance the ability of law enforcement action to address organised crime in the fisheries sector.
- **All states should review their legal frameworks and implement reforms where needed**. The goal should be to criminalise and attach sufficiently deterrent penalties to all fisheries crime offences, introduce anti-corruption and anti–money laundering measures and make provision for asset recovery and forfeiture of the proceeds of crime. We recommend that states provide for the extra-territorial and extra-jurisdictional application of relevant laws (e.g. through a Lacey-type law) and for corporate criminal liability. States should expressly provide for the criminal procedural tool of mutual legal assistance. This will facilitate cross-border information-sharing, asset tracing, and evidence collection and will strengthen investigation and prosecution of cases. States should be encouraged to introduce measures aimed at increased transparency around, for instance, information on the true beneficial ownership of fishing vessels, fishing vessels' movement and licences, and fisheries access agreements. Further, states should be encouraged to support international legal frameworks aimed at reducing human rights abuses in the fishing industry and ensure that these legal frameworks are enacted and enforced at a national level. States should also aim to standardise their laws and penalties. It may be advantageous to consider establishing a fund to assist law enforcement agencies, similar to the Green Fund in Trinidad and Tobago, based on a levy from corporate taxes (Finance Act 91 of 2000, Part XIV).
- **All states should engage in skills training and capacity building for law enforcement officials in the criminal justice system from at-sea to trial**. This should include the development of skills around financial investigation and asset recovery and capacity to detect tax crime in the fisheries sector. Mentoring schemes could be beneficial in this regard. This will facilitate the identification, investigation and successfully prosecution of cases of organised crime in the fisheries sector.
- **All states should introduce community-based crime prevention strategies incorporating a gendered approach as appropriate**. This will strengthen the resilience of vulnerable coastal communities and their ability to respond to organised crime in the fisheries sector.

- **Civil society should engage with the fishing industry on corporate social responsibility for sustainable fisheries practices**. In response to increasing public demand for sustainable fisheries products and a transparent value chain, the global fisheries industry is increasingly harnessing CSR practices, which, in turn, help minimise the risk of criminal activities in the fisheries value and supply chain. Civil society should be encouraged to engage with the fishing industry towards the development of corresponding CSR standards.
- **All states should support research to understand the causes, nature, scale and impact of organised crime in fisheries**. This supports the UN General Assembly's call for states to increase knowledge and understanding of the links between illegal fishing and organised crime. Research outcomes should be made publicly available since they can inform the development of appropriate means to prevent organised crime in fisheries and strengthen the law enforcement response.

Acknowledgements The paper's technical reviewers, Teale Bondaroff, Alan Cole, Jorge Torre and Steve Trent, as well as its arbiter, Kristian Teleki, all provided helpful technical comments. Special thanks to Januar Dwi Putra for assisting Mas Achmad Santosa and Yunus Husein.

The authors also thank the World Resources Institute for providing support as the Ocean Panel Secretariat.

While our colleagues were very generous with their time and input, this report reflects the views of the authors alone. The authors thank Alex Martin for copyediting and Romain Warnault for design.

Appendix A

We, the Ministers of Faroe Islands, Ghana, Indonesia, Kiribati, Namibia, Norway, Palau, Solomon Island and Sri Lanka [1]: Encourage other Ministers to support this non-legally binding declaration.

Note the recommendations and the outcome of the second International Symposium on Fisheries Crime held in Yogyakarta, Indonesia 10–11 October 2016 which was published by the United Nations Office on Drugs and Crime at the occasion of the United Nations Commission on Crime Prevention and Criminal Justice during its twenty-sixth session in Vienna 22–26 May 2017.

Recognize that our countries are dependent on the sea and its resources and the opportunities it holds for the economy, food and well-being of our population and we are determined to support a healthy and thriving fishing industry that is based on fair competition and the sustainable use of the ocean.

Are committed to work towards the fulfilment of the UN Sustainable Development Goals particularly in relation to Goal 14 on 'Life Below Water' and Goal 16 on 'Peace, Justice and Strong Institutions'.

Are convinced that there is a need for the world community to recognize the existence of transnational organized crime in the global fishing industry and that this activity has a serious effect on the economy, distorts markets, harms the environment and undermines human rights.

Recognize that this transnational activity includes crimes committed through the whole fisheries supply and value chain which includes illegal fishing, corruption, tax and customs fraud, money laundering, embezzlement, document fraud and human trafficking.

Recognize further the inter-continental flow of illegal fish products, illicit money and human trafficking victims in transnational organized crime cases in the global fishing industry and that all regions of the world need to cooperate when investigating such acts.

Are convinced that inter-agency cooperation between relevant governmental agencies is essential at a national, regional and international level in order to prevent, combat and eradicate transnational organized crime in the global fishing industry.

Are also convinced that there is a need for international cooperation and that developing countries are particularly affected.

Recognize the particular vulnerability of small-island developing states and other Large Ocean Nations of the impact of transnational organized crime in the global fishing industry.

Are also convinced of the need for continuous support on the highest level and the necessity for awareness raising on these issues through events such as the International Symposiums on Fisheries Crime.

About the Authors

Lead Authors

Emma Witbooi is a Research Associate with the Nelson Mandela University in Port Elizabeth, South Africa, and Director of the PescaDOLUS International Fisheries Crime Research Network.

Kamal Deen-Ali is Executive Director of the Centre for Maritime Law & Security Africa in Accra, Ghana.

Mas Achmad Santosa was Coordinator of Special Staff in the Indonesian Presidential Task Force to Combat Illegal Fishing at the time of writing.

[1] The following countries have subsequently pledged their support to the Declaration: Benin, Chile, Costa Rica, Fiji, Greenland, Iceland, Liberia, Maldives, Marshall Islands, Mexico, Mozambique, Myanmar, Nauru, Philippines, São Tomè and Principe, Scotland, Seychelles, South Africa and Timor Leste. 1 Executive Summary

The ocean is a dominant feature of our planet, covering 70% of its surface and driving its climate and biosphere. The ocean sustains life on earth and yet is in peril from climate change.

However, while much of recent attention is focused on the problems that the ocean faces, the ocean is also a source of potential solutions and innovation. This report explores how the ocean, its coastal regions and economic activities can provide opportunities in the fight against climate change.

Highlights

- Until recently, the ocean was thought to be so large that its response to climate change was thought to be minimal; it has now taken centre stage in the impacts and solutions.
- Ocean-based mitigation options to reduce or sequester and store emissions offer significant potential to contribute to global efforts to limit global warming and for achieving the goals of the Paris Agreement.
- Ocean-based mitigation options could reduce global greenhouse gas (GHG) emissions by nearly 4 billion tonnes of carbon dioxide equivalent (CO_2e) per annum in 2030 and by more than 11 billion tonnes per annum in 2050, relative to projected business-as-usual (BAU) emissions. Reductions of this magnitude are larger than the emissions from all current coal fired power plants worldwide and more than China's total emissions in 2014.
- Ocean-based mitigation options could reduce the "emissions gap" (the difference between emissions expected if current trends and policies continue and emissions consistent with limiting global temperature increase) by up to 21% on a 1.5 °C pathway, and by about 25% on a 2.0 °C pathway, by 2050.
- This report considers five areas of ocean-based climate action to mitigate GHG emissions: ocean-based renewable energy; ocean-based transport; coastal and marine ecosystems; the ocean-based food system (wild capture fisheries, aquaculture, and shifting human diets towards food from the sea); and carbon storage in the seabed.
- Ocean-based renewable energy production currently offers the greatest potential for delivering clean energy and reducing GHG emissions, with the expansion of floating wind and solar facilities being exciting frontiers.
- When wider impacts on the environment and social well-being are considered, nature-based interventions—especially protection and restoration of mangroves, seagrass and salt marshes—offer the best combination of carbon mitigation and broader cobenefits.
- While innovation is required to improve many specific technologies and practices, four of the ocean-based climate action areas are ready to be implemented today (ocean-based renewable energy; ocean-based transport; coastal and marine ecosystems; the ocean-based food system). This could offer many cobenefits in terms of creating jobs, improving air quality and human health, and supporting livelihoods if implementation addresses trade-offs with sustainable development dimensions appropriately. The fifth, carbon storage in the seabed, has significant theoretical potential to divert carbon from the atmosphere, but it currently faces significant technical, economic, and sociopolitical challenges (e.g., environmental safety) that must be adequately explored prior to deployment at the scale required to make a substantive contribution to solving the climate problem.
- Ocean-based mitigation options must be accompanied by deep cuts in emissions across terrestrial GHG sources, including measures to phase out fossil fuels, create sustainable food systems, and increase carbon sequestration and storage in forests and other natural ecosystems.

1.1 Climate Change Threatens the Ocean

The world needs to move rapidly and systematically to reduce emissions of green house gases (GHGs) to the atmosphere if it is to avoid irreversible climate impacts (IPCC 2014; IPCC 2018). Greater efforts are essential to accelerate and scale decarbonisation of the economy and pursue a pathway to net-zero emissions by the middle of the century. The sooner widespread action begins, the more cost-effective it will be, and the greater the chance of avoiding the worst impacts of rapid human-driven climate change.

Following the findings of the IPCC Special Report on the implications of 1.5 °C warming above the preindustrial period (IPCC 2018), it is now abundantly clear that stronger action to mitigate GHG emissions is a global imperative that will require an inclusive approach across the whole of the global economy. To date, much of the attention has been directed to the role of terrestrial sources of emissions and sinks. The ocean and its coastal regions, however, offer a wide array of additional potential mitigation options.

The ocean plays a fundamental role in regulating global temperatures. Not only does the ocean absorb 93% of the *heat* trapped by rising anthropogenic carbon dioxide (CO_2), but it also absorbs approximately 25–30% of anthropogenic CO_2 *emissions* that would otherwise remain in the atmosphere and increase global warming. The ocean also produces around 50% of the oxygen on the planet through the photosynthetic activity of marine plants and algae.

The ocean's ability to contribute to these fundamentally important services, however, is at risk (IPCC 2019). Ocean warming and acidification (the latter being a direct result of the extra CO_2 dissolving into the ocean) are damaging marine ecosystems and compromising the ability of the ocean to provide food, livelihoods, and safe coastal living on which billions of people depend (IPCC 2014, 2018, 2019).

Efforts to protect the ocean and its vitally important ecosystems cannot be considered in isolation from the challenge of stabilising the global climate. To secure the long-term health of the ocean and the livelihoods and economies that depend on it, atmospheric concentrations of GHGs must be urgently reduced. This report outlines a suite of options for how the ocean and coastal regions can contribute to lowering projected emission trajectories and help achieve the temperature stabilisation goals established in the Paris Agreement on Climate Change (UNFCCC 2015).

1.2 The Ocean is a Major Part of the Climate Solution

Ocean-based mitigation options do not feature as prominently as they could in countries' nationally determined contributions (NDCs) or long-term low greenhouse gas emission development strategies under the Paris Agreement. This report presents a wide array of potential ocean-based mitigation options and provides detailed analysis of their potential contribution to closing the emissions gap in 2030 and 2050 (Box 17.1).

Box 17.1. Why the World Needs to "Close the Emissions Gap"

Each year, the United Nation's Emissions Gap Report compares where global greenhouse gas (GHG) emissions are headed with where they need to be if the world is to avoid the worst impacts of climate change. Scientists first collect the latest information on countries' climate commitments, expressed in their nationally determined contributions (NDCs), and calculate their projected emissions pathway. They then compare this pathway with the latest models on how warming could be limited to either 1.5 °C or 2.0 °C, the temperature goals to which countries committed under the Paris Agreement of December 2015, and the limits scientists say are necessary for preventing some of the worst climate change impacts. The most recent report (UNEP 2018) concludes that unless countries strengthen their ambition and cut 2030 emissions beyond the targets established in their current NDCs, exceeding a temperature rise of 1.5 °C "can no longer be avoided." And unless the emissions gap is closed by 2030, it is unlikely that warming can be held below 2.0 °C.

Source: Levin et al. (2018).

Five areas of ocean-based climate action are considered in this report:

- Ocean-based renewable energy, including offshore wind and other energy sources, such as wave and tidal power.
- Ocean-based transport, including freight and passenger shipping.
- Coastal and marine ecosystems, including protection and restoration of mangroves, salt marshes, seagrass beds, and seaweeds.
- Fisheries, aquaculture, and dietary shifts away from emission intensive land-based protein sources (e.g., red meat) towards low carbon ocean-based protein and other sources of nutrition.
- Carbon storage in the seabed.

Additional ocean-based carbon storage options, such as direct injection into the deep ocean, alkalinity addition, and iron fertilisation are discussed, but due to the current uncertainty regarding their viability and higher risk of adverse impact on the ocean, they have been excluded from the calculated mitigation potentials.

Offshore oil and gas drilling, although the most significant source of ocean-based CO_2 emissions, is not discussed in the report, as it has been comprehensively tackled by other reports and its tracjectory is clear.

Within each area, this report assesses the set of individual mitigation options that could be undertaken, along with the technology developments and policies required to advance implementation. These mitigation options are summarised in Fig. 17.1, along with their mitigation potential in 2050. We also examine current and future deployment scenarios and suggest research priorities to improve the feasibility and scale of each option. The inclusion of any particular mitigation option in this report does not imply endorsement.

This report concludes that actions across all five ocean-based climate action areas of intervention have the potential to reduce emissions by up to 4 billion tonnes of CO_2e per annum in 2030, and by more than 11 billion tonnes of CO_2e per annum in 2050, thereby making a significant contribution to closing the emissions gap in 2030 and 2050 as shown in Fig. 17.2. Table 17.1 shows the total mitigation potential (expressed as a range) for each of the intervention areas.

Figures 17.3 and 17.4 below show the emission reduction and/or sequestration potential of each area of ocean-based climate action, including individual mitigation options, for 2030 and 2050.

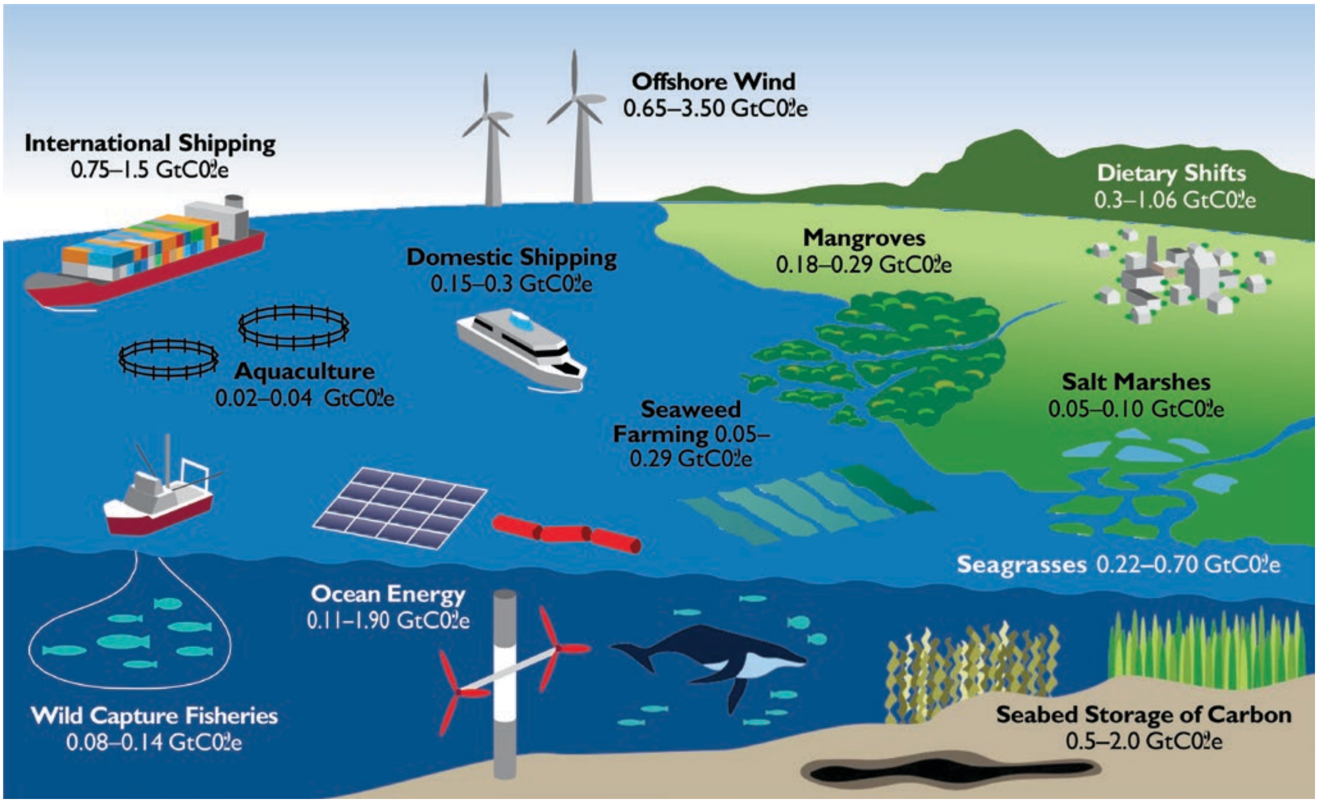

Fig. 17.1 Ocean-based mitigation options explored in this report and associated annual mitigation potential in 2050. (*Source: Authors*)

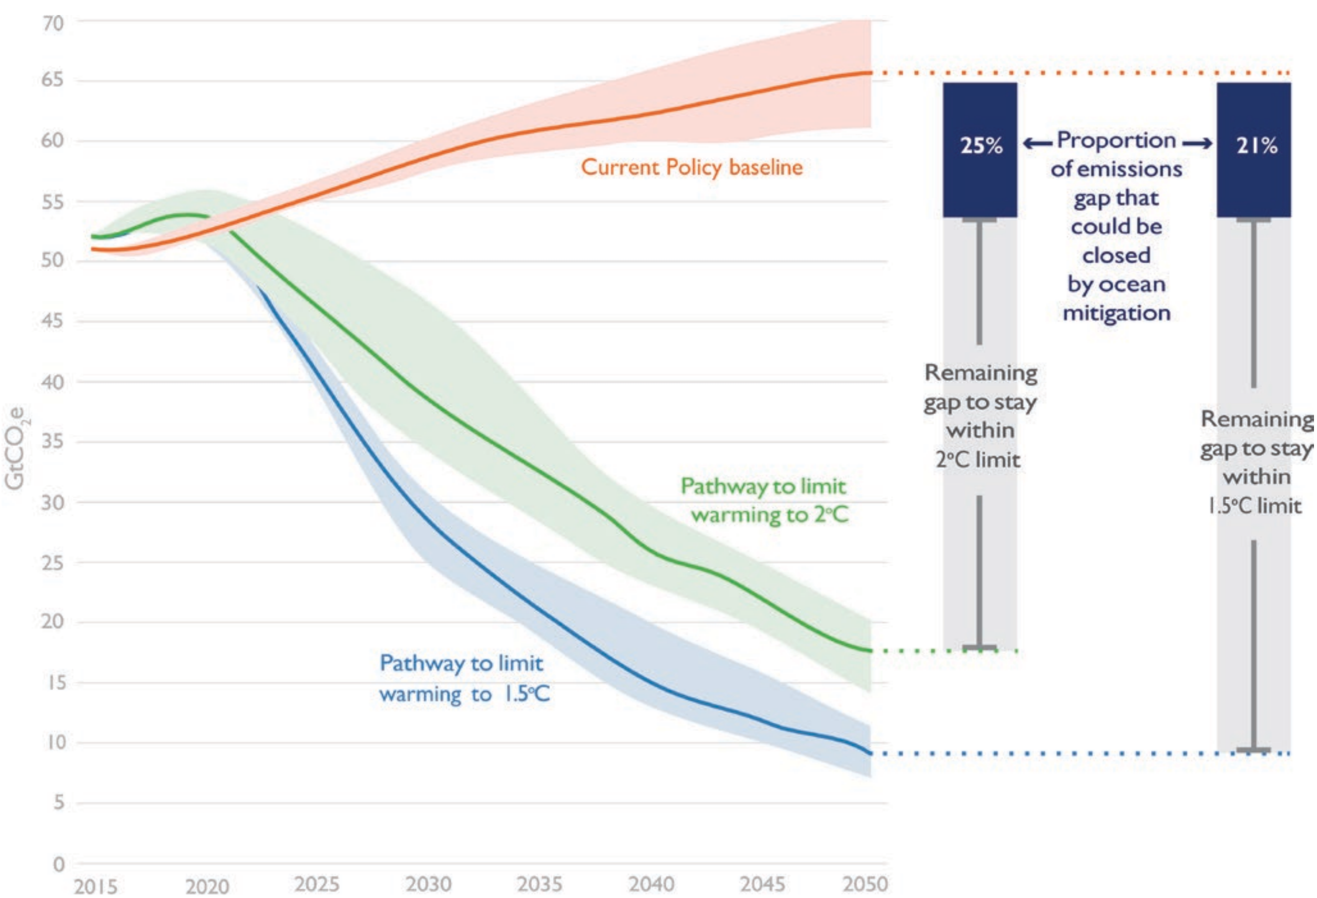

Fig. 17.2 Contribution of ocean-based mitigation options to closing the emissions gap in 2050. (*Source: Adapted from* UNEP (2018), Climate Action Tracker (2018))

Table 17.1 Summary of global mitigation potential offered by each area of ocean-based climate action

Areas of ocean-based climate action	2030 mitigation potential ($GtCO_2e$/year) (%)	2050 mitigation potential ($GtCO_2e$/year) (%)
1. Ocean-based renewable energy	0.18–0.25	0.76–5.40
2. Ocean-based transport	0.24 – 0.47	0.9 – 1.80
3. Coastal and marine ecosystems	0.32–0.89	0.50–1.38
4. Fisheries, aquaculture, and dietary shifts	0.34–0.94	0.48–1.24
5. Carbon storage in the seabed (action in this area requires further research prior to implementation at scale)	0.25–1.0	0.50–2.0
Total	**1.32–3.54**	**3.14–11.82**
Total percentage contribution to closing emissions gap (1.5 °C pathway)	4–12	6–21
Total percentage contribution to closing emissions gap (2 °C pathway)	7–19	7–25

1.3 Ocean-Based Mitigation Options

Scaling up ocean-based renewable energy (offshore floating and fixed wind installations, tidal and wave power), and decarbonising ocean-based transport offer some of largest mitigation potential in 2030 and 2050.

Utilising nature-based solutions, such as leveraging the ability of coastal and marine ecosystems to sequester and store carbon, also offer a sizable mitigation potential. Protection and restoration of these ecosystems provides valuable benefits by expanding sequestration and maintaining carbon stocks in soils and vegetation.

Restoration also yields cobenefits to local communities via other ecosystems services, such as providing habitat for fish; supplying food, fibre, and traditional medicines; and reducing the impact of storms during extreme weather events. Seaweed aquaculture offers significant potential for developing low-carbon alternatives for food, feed, and many other applications.

Storage of carbon in the seabed has enormous theoretical potential to divert carbon from the atmosphere, but it currently faces significant technical, economic, and sociopolitical challenges (e.g., environmental safety) that must be adequately explored prior to deployment at the scale presented in this report.

This report analyses the potential of seabed storage on the basis that it is the only ocean-based carbon, capture and storage (CCS) option that is currently being implemented at industrial scale (in Sleipner, Norway). However, given the technological, economic, social, and political barriers to implementing carbon storage in the seabed as a mitigation option, and the number of trade-offs and risks that must be reduced if ocean storage is to be widely used as a mitigation option, it is distinguished from the other four ocean-based

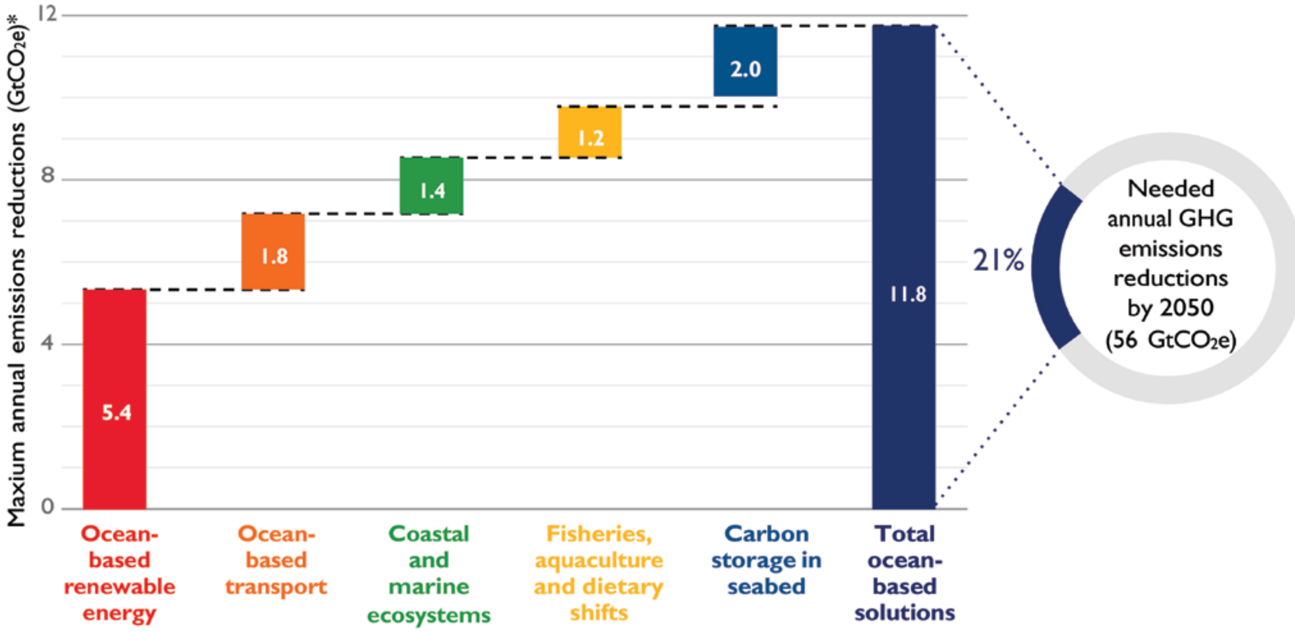

Fig. 17.4 Contribution of five ocean-based climate action areas to mitigating climate change in 2050 (maximum $GtCO_2e$). (*Notes: * To stay under a 1.5 °C change relative to pre-industrial levels. Source: Authors*)

Table 17.2 Potential of ocean-based climate action to contribute to current policy for closing the emissions gap in 2030 and 2050

	Annual emissions ($GtCO_2e$)			GAP		Total GHG mitigated $GtCO_2e$		% GAP closed: 1.5 °C		% GAP closed: 2.0 °C	
	Current policy	1.5 °C pathway	2.0 °C pathway	1.5 °C	2.0 °C	Min	Max	Min	Max	Min	Max
Today	52	52	52	0	0	0	0	0.0	0.0	0.0	0.0
2030	58	28	39	30	19	1.3	3.5	4	12	7	19
2050	65	9	18	56	47	3.1	11.8	6	21	7	25

Source: Authors

Note: Estimates are base on comparison between multiple scenarios for annual emissions in 2020, 2030, and 2050. For those year, we compare '1.5 °C', '2 °C' and the 'current policy' scenarios from UNEP (2018) *and calculate the mitigation needed to fill the 'gaps' between the 'current policy' and the '1.5 °C', '2 °C' respectively. 'Min' refers to conservative ocean based mitigation potential, while 'Max' represents higher (more ambitious) potential projected in this paper. The total ocean-based mitigation* (Table 17.2) *was compared to the gap at 2030, and that at 2050, generating the percentage of the gap mitigated by ocean-based mitigation of GHG emissions*

mitigation options as it has certain dimensions that cannot be implemented in the short-term.

It is important to note that this report looks at the mitigation potential of each area of intervention at a global level. Not all options will be available or appropriate for all countries. Countries vary not only in their physical attributes (e.g., not all countries have mangroves), but also in their economic and social profiles (some countries have major fishing industries; some are high consumers of red meat; others engage actively in maritime trade). Therefore, while ocean energy and transport offer higher mitigation potential than nature-based solutions at the global level, restoration of vegetated coastal habitats ("blue carbon ecosystems") may provide the most viable and -cost-effective opportunity for contributing to global efforts to reduce GHG emissions for some individual countries or regions. In addition, the presence or absence of enabling factors, such as carbon market, may influence decisions and priorities, changing the economic potential of the options outlined in this report (Table 17.2).

1.4 Wider Impacts of Ocean-based Climate Action

The IPCC Special Report on 1.5 °C scenarios integrated an assessment of wider impacts; however, the ocean was not addressed comprehensively as a sector within this impacts analysis. This report aims to address this major knowledge gap by evaluating four sustainable development dimensions where wider impacts—beyond avoided or reduced emissions—may be expected:

- Environment (impacts on marine and terrestrial biodiversity, water quality, land-use, coastal resilience, and adaptability of ecosystems and human settlements to climate change).
- Economy (impacts on employment, household incomes, economic growth, supply of clean energy innovation, profit/revenue generated by firms, and supply of clean energy).

- Society (impacts on human health outcomes, income inequality, quality of education, gender equity, poverty reduction, and food security targets).
- Governance (effective, transparent and strong institutions, participation in global governance, strong national institutions, global partnership for sustainable development, capacity building).

The assessment was based on a review of literature and reveals that, while ocean-based mitigation options have both cobenefits and trade-offs, the cobenefits far outweigh the trade-offs.

Positive environmental impacts include high biodiversity benefits to marine and terrestrial ecosystems, higher ecosystem services (improvement in fisheries productivity and coastal tourism), reduced risk of ocean acidification, increased coastal resilience, and reduction in withdrawal/usage of water. Economic impacts or cobenefits that are positive include opportunities created by spillover from new or improved technologies, new local employment opportunities, energy savings from improvement in the design of vessels, and economic growth driven by a growing ocean-based economy.

Positive social impacts or cobenefits include reduced morbidity and mortality due to improved local air quality, positive health impacts from shifting diets away from meat towards low-carbon ocean-based protein, enhanced global food security, potential to ensure greater gender parity as ocean-based industries expand, and improved income opportunities and livelihoods in coastal areas.

A number of negative effects or risks were identified when assessing the wider impacts of the mitigation measures on sustainable development, especially for the dimensions focusing on environment and society.

Policy design and implementation, along with contextual factors, play a key role in determining how mitigation options influence negative social outcomes. For example, mitigation options aimed at rebuilding fish stocks and other ocean biomass can negatively impact poverty reduction and employment targets and limit progress on food security targets in the short term.

Lack of effective stakeholder engagement on "blue carbon" restoration projects (including exclusion of local community representatives from key international decision-making events) limit their access to ocean spaces and can lead to negative outcomes for small-scale fishers who heavily rely on local ecosystems for jobs, nutritional needs, and economic sustainability. In these instances, well-planned mitigation measures that follow best governance practices, with strong engagement of communities, nongovernmental organisations (NGOs), and governments, are essential to avoid worsening of inequalities and creation of new social injustices.

Environmental trade-offs and risks include the damage that can be done to coastal ecosystems or marine species by unplanned growth in coastal aquaculture or renewable energy installations. Seabed carbon storage approaches, if deployed unwisely, could contribute to ocean acidification and damage ocean ecosystems by impacting chemical, physical, and ecological processes at a large scale. While some of these risks can be adequately addressed via stakeholder engagement, inclusive management policies, careful monitoring, and effective marine planning, others will require further research on their implications. In some instances, there will be a need for significant action on the part of governments to ensure that negative impacts are reduced or resolved. Concerted action to address these negative impacts will help enhance the net positive outcome.

When looking at the five ocean-based areas as a whole, coastal and marine ecosystems, fisheries and aquaculture, and ocean energy have a positive impact on the largest number of sustainable development dimensions. When looking at individual mitigation options within the five ocean-based areas, nature-based interventions (especially protection and restoration of mangroves, seagrass and salt marsh) and offshore wind energy positively impact the largest number of sustainable development dimensions. The analysis showed that all ocean-based mitigation options will need strong national institutions, engagement of business and industry, and community involvement and international cooperation to ensure their planned implementation maximises the positive impact and limits the negative impact on sustainable development dimensions. The results of this analysis is shown in Fig. 17.5.

1.5 Delivering the Mitigation Potential of the Ocean

There is a small, but important window of opportunity within which the "Current Policy" emissions trajectory can be directed towards a pathway that is consistent with achieving the 1.5 °C and 2.0 °C temperature goals set by the Paris Agreement. While much of the required emission reductions must come from deep cuts within terrestrial-based activities, including the use of fossil fuel, this report identifies major ocean-based opportunities that could play a critical role in the transition to a low-carbon future and safer climate.

Achieving the mitigation potential identified in this report will not be possible without significant investment in research and development. It will also be necessary to provide strong incentives to align financial flows with the needs of the mitigation action opportunities available. Governments must send policy signals. Table 17.3 summarises the policy, research, and technology priorities for the short and medium term to support action in each of the areas of ocean-based climate action examined in this report.

One of the first opportunities that governments will have to comprehensively integrate ocean-based mitigation options into national plans and strategies for climate change is the reconsideration and updating of NDCs in 2020. This is an extremely important moment, as emphasised by the IPCC (2018): the chances of "failing to reach 1.5 °C [will be] significantly increased if near-term ambition is not strengthened

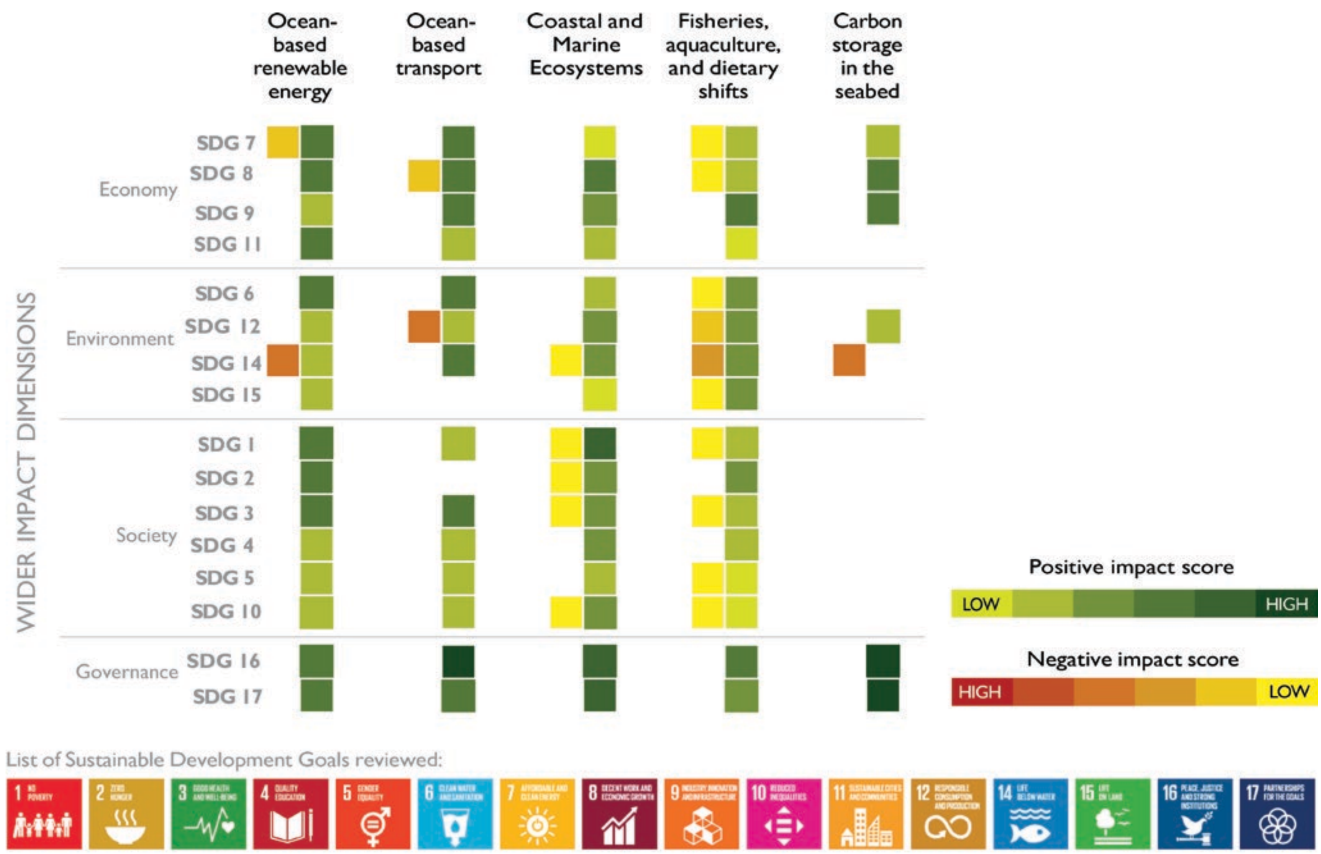

Fig. 17.5 Summary of wider impact of ocean-based interventions on sustainable development dimensions. (*Source: Authors. Notes: Wider-impact dimensions cover various sustainable development dimension indicators as well as 2030 Sustainable Development Goals (SDG). The figure shows the relative strength of the relationship between the ocean-based areas of interventions and the SDGs. The relationship between each ocean-based mitigation option and SDG is given a linkage score, positive scores shown by green boxes and negative scores shown by yellow/red boxes. Scores range from +3 (indivisible) to −3 (cancelling)* (Nilsson et al. 2016). *A zero score (no bar and no colour) means no impact was found in this review of the literature. For intervention areas where there is more than one mitigation option, an average of the linkage score is taken among the mitigation options in that area. Further information on the linkage scores and the associated confidence levels are provided in the Annex)*

Table 17.3 Short- and medium-term policy, research, and technology priorities necessary to deliver on mitigation potential of ocean-based climate action areas

	Ocean-based energy		
	Policy	Research	Technology
Short-term priorities (2020–2023)	• Undertake marine spatial planning • Develop national targets to increase the share of renewable energy in the national energy mix • Provide a stable economic and regulatory framework to stimulate investments in required infrastructure for an accelerated deployment of ocean-based energy systems	• Understand the impacts (positive and negative) of both fixed and floating offshore wind installations on marine biodiversity • Undertake a detailed mapping of global renewable energy resources and technical potential	• Advance storage capacity and design • Improve performance, reliability, and survivability, while reducing costs
Medium-term priorities (2023–2025)	• Develop strategic national roadmaps for zero-carbon economy in 2050 • Develop appropriate legislation and regulation	• Understand the potential benefits of co-location with other ocean-based industries (e.g., desalination plants and aquaculture) • Explore the potential for installing large scale floating solar installations at sea (under wave conditions) • Quantify the potential of ocean thermal energy conversion (OTEC)	• Advance technology that can move technologies into deeper water sites (e.g., development of floating offshore wind technologies) to open access to larger areas of energy resources

Table 17.3 (continued)

	Ocean-based energy		
	Policy	Research	Technology
	Ocean-based transport		
Short-term priorities (2020–2023)	• Redesign the energy efficiency design index (EEDI) formula to avoid vessels being suboptimised for the test only, to ensure that instead vessels are being optimised for minimised fuel consumption in real operation at sea • Adopt policy measures to go beyond Ship Energy Efficiency Management Plan (SEEMP) to incentivise the maximisation of operational efficiency of new and existing ships • Adopt policies that can reduce the broader GHG emissions of shipping instead of CO_2 only, including well-to-tank emissions (WTW) of ship fuels	• Identify and rectify of market and nonmarket barriers and failures to enable larger uptake of more energy-efficient technologies and cooperation patterns • Ensure continuous research on ship design, including hull forms and propulsion, with a focus on reducing energy usage per freight unit transported • Increase focus on utilisation of wind, waves, ocean currents, and sun to reduce use of externally provided energy, i.e., both the carbon and non-carbon-based fuels carried on board	• Develop the necessary high efficiency hull forms and propulsion methods • Develop and implement hybrid power systems, including combustion engines, fuel cells, and batteries technologies • Develop and implement wind assistance technologies • Develop more advanced weather routing systems to better utilise wind, waves, ocean currents, and tides to reduce the use of both carbon and non-carbon fuel carried on board
Medium-term priorities (2023–2025)	• Develop policy to enable the business case for the adoption of low and zero carbon fuels by shipping (e.g. a carbon price) • Commit to the timetable for shipping's transition to low- and zero-carbon fuels • Develop national incentives for decarbonising domestic transportation • Commit to decarbonisation of national energy systems faster or as fast as the transition in the international fleet	• Develop cost-effective production of low- and zero-carbon fuels, both from renewables and from carbon based in combination with carbon capture and storage (CCS) • Develop cost-efficient hybrid setups on seagoing vessels to utilise the best of combustion, fuel cells, and batteries to reduce fuel consumption and local pollution • Ensure safe storage and handling on ships and at the ship-shore interface of hydrogen/ammonia • Ensure safe and efficient use of hydrogen and ammonia in internal combustion engines and fuel cells	• Advance technologies for producing hydrogen, both from renewables and carbon-based fuels • Invest in technologies to store hydrogen (including cryogenic storage of liquid hydrogen, or carriers able to store at high-energy density) • Invest in fuel cells for conversion of future fuels into on-board electricity, and internal combustion engines designed to operate on hydrogen/ammonia
	Coastal and marine ecosystems		
Short-term priorities (2020–2023)	• Enhance protection measures for mangroves, seagrass, salt marsh, and seaweed beds to prevent any further losses due to human activities • Provide incentives for restoration of "blue carbon" ecosystems, through payments for ecosystem service schemes, such as carbon and nutrient trading credits • Include quantified nature-based solutions within nationally determined contributions (NDCs) and other relevant climate policies for mitigation and adaptation • Protect coral reefs as important and integrated coastal defence systems for ensuring the protection of coastal blue carbon ecosystems	• Undertake national-level mapping of blue carbon ecosystems • Address biophysical, social, and economic impediments to ecosystem restoration to develop restoration priorities, enhance incentives for restoration, and increase levels of success • Improve the IPCC guidance for seagrasses and other wetland ecosystems • Develop legal mechanisms for long-term preservation of blue carbon, especially in a changing climate • Understand the impacts of climate change on rates of carbon capture and storage, or the potential for restoration	• Advance biorefining techniques, allowing sequential extraction of seaweed products
Medium-term priorities (2023–2025)	• Enhance and adopt carbon accounting methodologies for mangroves, seagrasses and salt marsh within national GHG inventories (IPCC 2013) • Improve methods for monitoring mitigation benefits to enable accounting within national GHG inventories, and biennial transparency reports (BTRs)	• Undertake global-scale map of seaweed ecosystems • Develop IPCC-approved methodological guidance for seaweed ecosystems • Develop methods to fingerprint seaweed carbon beyond the habitat	• Develop and pilot offshore and multiuse sites, including seaweed aquaculture, in the open ocean

(continued)

Table 17.3 (continued)

	Ocean-based energy		
	Policy	Research	Technology
	Fisheries, aquaculture, and dietary shifts		
Short-term priorities (2020–2023)	• Eliminate harmful fisheries subsidies (SDG14.6) • Strengthen international tools to eliminate IUU fishing (SDG14.5) • Avoid the transport of fish by air • Reduce discards • Reduce and eliminate hydrochlorofluorocarbons (HCFCs) in refrigerants • Create incentives for shifting diets towards low-carbon protein (e.g., fish) and other food (e.g., seaweed) diets • Create incentives to improve fishery management • Create incentives for lower trophic- level aquaculture • Devise sustainable finance mechanisms for small-scale fishery transitions to sustainable fishing	• Develop disaggregated global data sets for GHG emissions from wild catch fisheries and marine aquaculture • Impacts of scaling marine aquaculture and associated sustainability considerations (e.g., low carbon and climate resilient, environmentally safe) • Enhance understanding of how climate change and ocean acidification will impact aquaculture and fisheries	• Extend surveillance technologies for tracking fishing in the ocean and along coastal areas
Medium-term priorities (2023–2025	• Create incentives to switch from high-carbon land-based sources of protein to low-carbon ocean-based sources • Improve fisheries management to focus on optimising biomass per harvest	• Explore potential impact of a carbon tax on red meat and other carbon intensive foods	• Develop and bring to scale high-technology digital aquaculture
	Seabed carbon storage		
Short-term priorities (2020–2023)	• Invest in pilot projects to further explore potential environmental impacts • Incentivise public/private partnerships	• Map global geophysical potential • Understand the impacts of long-lasting containment of CO_2 in a deep seafloor environment	• Few major technical advances are required as seabed storage is already deployed at industrial scale
Medium-term priorities (2023–2025)	• Develop national strategies and targets • Develop regulatory frameworks to ensure environmental impact assessments and associated precautions are put in place	• Understand the impacts of long-term storage on marine ecosystems • Explore the integrity of long-term storage technologies (leakage)	• Scale up technologies in ways that are economically feasible

Source: Authors

beyond the level implied by current NDCs.” Given the consequences of failing to limit global average temperature rise to 1.5 °C, or at least to “well below” 2.0 °C, it is of great importance that actions begin immediately.

2 Introduction

Efforts to protect the ocean and its vitally important ecosystems cannot be considered in isolation from the challenge of stabilising the global climate. To secure the long-term health of the ocean and the livelihoods and economies that depend on it, atmospheric concentrations of GHGs must be urgently reduced. This report outlines a suite of options for how the ocean and coastal regions can be a part of the solution set.

2.1 Climate Change Is a Key Threat to Ocean Systems

Climate change is one of the greatest challenges in history. The concentrations of atmospheric carbon dioxide (CO_2) and other greenhouse gases (GHGs) are increasing, causing rapid rates of warming on land and in the ocean. These changes are creating unprecedented challenges for natural and human systems (IPCC 2018). If unchecked, these changes will undermine and destabilise economies by driving increasingly unmanageable and dangerous impacts on the biosphere, human health, and global economies (Sumaila et al. 2019).

Prior to the industrial period (i.e., before ~1850), the global carbon cycle was in net balance, with CO_2-producing processes (e.g., respiration) being equal to CO_2-consuming processes such as photosynthesis and geochemical weathering. This balance resulted in the carbon cycle being relatively stable for thousands of years. Since the beginning of the industrial period, however, emissions of GHGs have grown rapidly as humanity felled forests, cleared land for agriculture, and began to exploit reservoirs of nutrients and gases such as oxygen (Hoegh-Guldberg et al. 2014; Pörtner et al. 2014).

The ability of humans to obtain food and livelihoods from the ocean is being degraded as a result of these changes. While the intention of this report is not to review comprehensively the impacts of climate change on the ocean, which has been done more extensively elsewhere (IPCC 2014, 2018, 2019), it notes that a few regions do show "positive" outcomes from climate change on a short-term basis, such as the increased biomass caught by high-latitude fisheries over recent decades (Sundby et al. 2016). The great majority of oceanic changes from polar to equatorial regions (and from deep to shallow areas) are, however, negative (IPCC 2014, 2018; Gattuso et al. 2018).

The Paris Agreement goals aim to keep "global average temperature to well below 2 °C above preindustrial levels and pursuing efforts to limit mean global temperature increase to 1.5 °C above preindustrial levels" (UNFCCC 2015).

The increased concentration of atmospheric CO_2 has resulted in ocean warming as well as ocean acidification, which is a consquence of the increased absorption of CO_2 by the ocean (IPCC 2014). Changes in the temperature and chemistry of the ocean have had serious impacts on a wide range of biological phenomena, including the survival, reproduction, and growth of marine organisms. There is considerable evidence that the ocean is also becoming more stratified, which is affecting the mixing of the water column, and consequently the availability of unoxidised carbon in fossil fuels. Rising concentrations of atmospheric CO_2 have already driven major changes to our planet. The global mean surface temperature (GMST) of the earth reached 1 °C above the preindustrial level in 2017 (IPCC 2018).

The evidence accumulated by the Intergovernmental Panel on Climate Change (IPCC) (IPCC 2014, 2018, 2019) suggests that the world will continue to face accelerating and life-threatening challenges if the GMST is not kept well below 2 °C above the preindustrial period (conditioned before ~1850). This science-based conclusion led to the explicit goals of the Paris Climate Agreement (UNFCCC 2015) and subsequently the IPCC special report on the implications of 1.5 °C warming above the preindustrial period (IPCC 2018).

The recent IPCC special report on 1.5 °C (IPCC 2018) concluded that there was still time to limit global temperature rise to the vicinity of 1.5 °C above preindustrial levels (IPCC 2018), if current efforts were escalated. This would require limiting further accumulated emissions of CO_2 after 2018, to approximately 420 gigatonnes of carbon dioxide equivalent ($GtCO_2$), which essentially gives the global community around 10 years at the current rate of annual emissions to bring fossil fuel emissions to net zero by mid-century (IPCC 2018). Significantly, however, limiting warming to 1.5 °C above preindustrial levels will require annual emissions of CO_2 to fall below zero by 2050 (i.e., "negative emissions") (IPCC 2018). Achieving this goal will require additional novel technologies for removing large amounts of CO_2 from the atmosphere.

2.2 The Ocean Is Part of the Solution to Climate Change

Attention has only recently been drawn to the possible role of the ocean, with its vast size and productivity, in mitigating CO_2. The ocean already plays a dominant role in the global carbon cycle and is responsible for taking up 25–30% of anthropogenic CO_2 released into the atmosphere.

While changes to the carbon cycle are creating daunting challenges for the ocean and the ocean-based economy, the ocean-based economy offers opportunities for mitigating GHG emissions and hence contributing to land-based efforts to fight climate change. While the focus on ocean and coastal-based solutions for mitigating climate change is increasing (e.g., IPCC 2014, 2018; Gattuso et al. 2018), a comprehensive analysis of ocean-based mitigation options and their potential to contribute to reducing atmospheric greenhouse gases has so far been limited.

This report addresses this analytical gap through a detailed analysis of the opportunities as well as the challenges associated with implementing a series of ocean-based mitigation options. Each option is considered in the context of its role as a key sink or source of CO_2 and other GHGs.

In particular, this report assesses the mitigation potential and associated impacts (cobenefits and trade-offs) of a series of options in five prominent ocean-based areas of intervention:

- Ocean-based renewable energy, including offshore wind and other energy sources, such as wave and tidal power.
- Ocean-based transport, including freight and passenger shipping.
- Coastal and marine ecosystems, including protection and restoration of mangroves, salt marshes, seagrass beds, and seaweeds, as well as aligned ecosystems such as coral reefs which are important coastal barriers to waves and storms.
- Fisheries, aquaculture, and dietary shifts away from emission intensive land-based protein sources (e.g., red meat) towards low carbon ocean-based protein and other sources of nutrition.
- Carbon storage in the seabed.

Table 17.4 describes each area of ocean-based climate action and its associated mitigation options.

2.3 Methodology

This report assesses each option in the context of "mitigation potentials" (Fig. 17.6). We explore the size of each potential, considering geophysical, technical, economic, and socio/political considerations that may affect their feasibility.

We identified mitigation options in each intervention area and assessed the scientific and research literature on the global contribution of each one to reducing atmospheric

Table 17.4 Mitigation options in five areas of ocean-based climate action

Area of action	Mitigation options	Description
Ocean-based renewable energy	Scaling up harnessing of offshore wind	Fixed and floating offshore wind turbine installations
	Scaling up use of ocean energy	Energy extracted from ocean waves, tides, currents, salinity, and temperature differences. Floating photovoltaic solar energy
Ocean-based transport	Reducing emissions from domestic shipping Reducing emissions from international shipping	Following the International Maritime Organization (IMO) definition: shipping between ports of the same country; includes ferries Following the IMO definition: shipping between ports of different countries. International shipping excludes military and fishing vessels; includes bulk carriers, oil tankers, and container ships
Coastal and marine ecosystems	Restoration of mangroves, salt marshes, and seagrass beds	Sequestration potential gained from the restoration of lost and degraded coastal ecosystems. Coastal wetland systems include mangroves, salt marshes, and seagrass beds, plus conservation and restoration of adjacent islands, reefs and mudflats to slow the rate of erosion of coastal wetlands
	Avoided anthropogenic loss and degradation of mangroves, salt marshes, and seagrass beds)	Preventing the release of the high levels of sequestered carbon in soils and vegetation of coastal wetlands by protecting these ecosystems and avoiding further degradation
	Upscaling of seaweed production via aquaculture	Sequestration potential through seaweed aquaculture, primarily via farmed seaweed products substituting for other products with higher GHG footprint, or new application with no or minimal footprint
	Restoration and protection of seaweed habitats	Sequestration potential from the restoration of degraded (and protection of) intact seaweed habitats
	End overexploitation of ocean biomass to support recovery of biodiversity and increase biomass	Role of marine mammals and fish stocks in the ocean carbon cycle, including death and sinking to the seabed floor
Fisheries, aquaculture, and dietary shifts	Reducing emissions from fishing vessels Reducing emissions from aquaculture Increasing share of ocean-based proteins (from fish and other marine life) in diets	Emissions from fuel use for inland, coastal, and deep-sea fishing (wild capture) Life-cycle emissions from aquaculture (including, if possible, supporting activities such as production of fish meal and fish oil) Switching emission intensive land-based sources of protein (notably beef and lamb) for low carbon ocean based sources of protein
Carbon storage in the seabed	CO_2 storage in the seabed	Geological storage offshore of captured CO_2 in the seabed

Fig. 17.6 Determining mitigation potential. (*Source: Authors. Note: While the geophysical scale of a mitigation opportunity may be large, each mitigation opportunity must be considered through technical (i.e., its feasibility) and economic (i.e., its cost) lenses, as well as for social and political considerations (i.e., do people want it). A high geophysical potential might exist, given a lack of technical, economic, or socio-political constraints. In reality, a much smaller amount of a mitigation potential tends to be available after these considerations*)

emissions in line with the goals of mean 1.5 °C and 2.0 °C pathways by 2030 and 2050. The year 2030 was chosen to highlight the potential benefits of including relevant ocean-based mitigation options in new or updated nationally determined contributions (NDCs) submitted by 2020. The year 2050 was chosen to highlight the possible contribution of ocean-based mitigation options to long-term strategies of reducing emissons to net zero by mid century (IPCC 2018).

GHG mitigation options in each intervention area were evaluated for their technical, economic, social, and political implications when deployed to reduce GHG emissions (in $GtCO_2e$) by 2030 and 2050. A lower and higher range was estimated in each case to assess how particular ocean-based mitigation options might be modified, or restrained, by other important issues (see the Sect. 1.4 for further details). This assessment also considered the implications for near-term United Nations Sustainable Development Goal (SDG) targets and indicators.

2.3.1 Underlying Assumptions and Approach

Because this report collates multiple analyses, the underlying assumptions and discussion will differ in some cases. Important examples include the size of future baseline emissions and assumptions about the costs of key technologies and inputs. These are discussed and outlined in more detail in subsequent sections of the report.

The following approach was applied to each ocean intervention area to ensure consistency and comparability:

- Identify the baseline emission projections for 2030 and 2050, based on literature review.
- Outline the mitigation options per intervention area that can be implemented by 2030 and by 2050 (including explicitly identified assumptions).
- Identify the range of abatement potential for each mitigation option in 2030 and 2050, either directly from the literature or through calculations based on available data in the literature.

The range of abatement potential estimates is presented to reflect uncertainties in the mitigation potential of both the intervention areas and at the global level.

2.3.2 Determining the Contribution of Ocean-Based Climate Action to Closing the Emissions Mitigation Gap

The calculated mitigation potential from each of the five ocean-based climate action areas were added together to produce a total GHG mitigation potential for the years 2030 and 2050. Each mitigation option was explored in the context of the contribution made to closing the emissions gap in 2030 and 2050 between the "Current Policy" (UNEP 2018) emissions pathway and pathways consistent with achieving the 1.5 °C and 2.0 °C goals of the Paris Agreement (UNFCCC 2015; IPCC 2018). The Current Policy pathway was chosen to reduce the potential for double counting and a median value was calculated from the high and low values provided in the Climate Action Tracker. The intervention areas and mitigation options that are discussed here are generally outside Current Policy and hence should be additional except for the chance of a very small overlap, which is accounted for in the ranges provided for each mitigation option.

The Current Policy trajectory is based on estimates of 2020 emissions that consider projected economic trends and Current Policy approaches (including policies at least through 2015), with estimates based on either official data or independent analysis (UNEP 2018). The pathways consistent with 1.5 °C and 2.0 °C above the preindustrial period were taken from mean values summarised from the scientific literature in the most recent UN Environment Programme Gap Report (UNEP 2018). The 1.5 °C trajectories reach an emissions peak around 2020, then rapidly fall to approximately 45% below 2010 levels by 2030 (to ~28 $GtCO_2e$/year), reaching close to net zero by 2050 (~0–9 $GtCO_2e$/year) (Fig. 17.7). Trajectories for 2.0 °C show emissions decline by approximately 25% by 2030 (to ~40 $GtCO_2e$/year) in most pathways (10–30% interquartile range), reaching net zero by around 2070 (2065–2080 interquartile range). In the case of the Current Policy pathway, GHG emissions will rise from ~50 $GtCO_2e$/year in 2020 to ~65 $GtCO_2e$/year by 2050 (UNEP 2018). These extrapolated levels of emissions under Current Policy are consistent with the projections of the IPCC (IPCC 2018).

3 Ocean-Based Renewable Energy

This section analyses the potential mitigation impact of using ocean-based renewable energy sources of power (e.g. offshore wind and energy extracted from waves and tides) to displace coal fired power plants.

Many technologies are currently being assessed for their ability to harvest renewable energy from the ocean.

Sources of power include offshore wind and energy extracted from waves and tides. Energy within the ocean can also be extracted from salinity and temperature gradients (e.g., by ocean thermal energy conversion [OTEC] or by heat pumps for heating and cooling). Lastly, floating solar photovoltaic (PV) systems are beginning to emerge in marine environments.

While the overall proportion of global electricity generation from ocean-based sources is currently less than 0.3% (IEA 2019), large projects are underway, and investments are being made in the full range of ocean-based energy options. These investments include promising options, such as floating PV panels (World Bank 2018) and strategies to meet sustainable energy demands of a growing blue economy. There is also potential to unlock co-location benefits with other offshore industries; for example, ocean-based energy could meet the increasing demand for energy-intense desalinated seawater (USDE 2019) or support marine aquaculture operations.

3.1 Mitigation Potential

Electricity and heat generation accounts for about 25% of global emissions (IPCC 2014). Mitigation opportunities include replacing fossil-based electricity supplies with renewable sources and electrification, and reducing demand from end-consumers in the transport, industry, and building sectors, and from desalination plants. Depending on the scale and pace of technological development, up to 75% of anthropogenic GHG emissions (excluding some emissions such as those from the agriculture sector and land clearing) in a business-as-usual (BAU) trajectory can be considered as the target for avoidance through electricity generation with renewable sources.

Thermal power plants (using coal, oil, or natural gas) and combustion engines can convert only a fraction of thermal energy into electricity or kinetic energy. Consequently, only a fraction (typically one-third) of primary energy supplied by fossil fuels has to be replaced by renewable sources (GEA

2012). Many thermal plants are also dependent on large volumes of freshwater for cooling. In addition, recent studies such as Grubler et al. (2018) show that extensive use of renewable energy in combination with energy efficiency measures could achieve global low energy demand (LED) scenarios without loss of welfare and well-being.

Renewable energy both from the ocean and from land is therefore well positioned to play an increasing role in sustainable development.

Gross electricity generation in 2050 is projected to be between 42,000 and 47,000 TWh (TWh = terawatt hours; 1 TWh/year corresponds to continuous delivery of a power of 0.114 gigawatts (GW)) (IEA 2017). The ocean offers abundant resources in excess of global energy demand, but economic constraints limit the contribution of energy generated offshore.

We consider two ocean-based renewable energy technologies—offshore wind (OSW) generation and other forms of ocean-based renewable energy (ORE), such as wave and tidal power. Estimates of the potential for electrical energy generated by OSW in 2050 are in the range of 650 to 3500 TWh/year. Estimates of potential from ORE technologies in 2050 are in the range 110 to 1900 TWh/year.

We find that if ocean-based renewable energy technologies displace coal-fired power plants, CO_2 emissions can be reduced by between 0.65 and 3.50 $GtCO_2e$/year in 2050 in the case of OSW, and by between 0.11 and 1.90 $GtCO_2e$/year in 2050 in the case of ORE. Total emission reductions would amount to 0.76 to 5.40 $GtCO_2e$/year in 2050.

Alternatively, if energy technologies with emissions equal to the present global mean for the electricity sector of 0.46 kg CO_2e/kWh were displaced, OSW could contribute a reduction of 0.30 to 1.61 $GtCO_2e$/year in 2050, and ORE could avoid 0.05 to 0.87 $GtCO_2e$/year in 2050.

This mitigation potential of ocean-based renewable energy generation is presented in Table 17.5.

3.2 Methodology

The GHG mitigation potential of ocean renewable energy sources is estimated on the basis of substituting fossil fuels used in electricity generation sources (Gattuso et al. 2018). Offshore wind, in particular, and other ocean-based renewable energy sources have theoretical potentials that are many times larger than present global electricity demand, and also larger than future energy demand, assuming full electrification (Bosch et al. 2018) (See Box 17.2). The more interesting challenge is the cost competitiveness of these technologies. Different assessments and estimates of future costs explain much of the range in potential emissions reduction contributions from offshore and ocean-based renewable energy (Box 17.2 and Table 17.6).

Several studies have included offshore wind and other ocean renewable energy technologies in scenarios projecting future energy demand and generation fuel mix. These studies span a range of future carbon emission scenarios for 2050 and are typically presented relative to a business-as-usual, control, or reference scenario. We reviewed 15 scenarios for 2050 in which ocean renewable energy technologies were considered (Table 17.6). Here, we present the future generation mix of ocean energy technologies associated with the low-emissions scenarios (2050 emissions ≤14 Gt), compiled from these studies.

The methodology used to produce the energy contribution potentials was to combine the range of scenarios summarised in Table 17.6 with the difference in CO_2 emissions between energy sources. We recognise that the future evolution of the energy mix, and therefore the substitution effect of ocean-based energy, will depend on a broader set of global development trends, including costs of technologies in other parts of the energy sector, such as hydrogen conversion technologies and energy efficiency.

Table 17.5 Mitigation potential of offshore wind and other ocean-based renewable energy technologies in 2030 and 2050

Ocean-based climate action area	Mitigation options	Description	2030 mitigation potential ($GtCO_2e$/year) (%)		2050 mitigation potential ($GtCO_2e$/year) (%)
Ocean-based renewable energy	Scaling up offshore wind	Fixed and floating offshore wind installations	Coal displacement	0.17–0.23	0.65–3.50
			Displacing current generation mix	0.08–0.11	0.30–1.61
	Scaling up other forms of ocean energy	Energy carried by ocean waves, currents, tides, salinity, and ocean temperature differences	Coal displacement	0.006–0.016	0.11–1.90
			Displacing current generation mix	0.003–0.007	0.05–0.87
Total			Coal displacement	**0.18–0.24**	**0.76–5.4**

Source: Author

Notes: To establish estimates of projected energy generation in 2030, we determined the Compound Annual Growth Rate (CAGR) between 2018 energy generation and projected 2050 energy generation (separate CAGR for OSW and ORE). The CAGR is assumed constant through 2050. The per annum CO_2 mitigation potential in 2030 and 2050 is then derived from the energy generation (see Sect. 3.2*). The lowest and highest values were used to calculate the range across "coal displacement" and "displacing current generation fuel mix" for 2030 and 2050. The range for "coal displacement" was chosen for the final totals*

Table 17.6 Summary of energy scenarios reviewed for ocean-based renewable energy

Scenario	OSW generation (TWH/year)	ORE generation (TWH/year)
2018 (30) (Bahar 2019)	53	1.2
2050 Reference (50) Same fraction as current, for assumed 2050 electricity demand of 50,000 TWh	112	2.5
2050 Drawdown Reference (50) (Project Drawdown 2019)	57.2	2.1
2050 IEA WEO 2009 (45) (IEA 2010)	555	25
2050 Teske (Reference (45) (Teske et al. 2011a, b)	805	25
2050 IEA RTS (40) (IEA 2017)	651	108

Table 17.7 Estimated life-cycle emissions of energy generation technologies

Energy technology	Lifecycle carbon emissions ($kgCO_2e$/kWh)	Lifecycle carbon emission relative to current mix (%)
Coal	1.0 (0.67–1.7)	217
Natural gas	0.476 (0.31–0.99)	103
Current mix	0.46	–
Solar PV	0.054 (0.019–0.2)	12
Concentrated solar power	0.025 (0.007–0.24)	5.4
Nuclear	0.016 (0.008–0.22)	3.5
Onshore wind	0.012 (0.002–0.088)	2.6
Offshore wind	0.012 (0.005–0.024)	2.6
Ocean	0.008 (0.002–0.022)	1.7

Source: OpenEI (2019)
Note: Bracketed values represent the range of reported emissions

By calculating mitigation potentials for substitution of coal and for substitution of an energy source with CO_2 emissions corresponding to the present global average, we expect to bracket a realistic range.

Ocean-based technologies offer a renewable energy solution with low life-cycle carbon emissions (Table 17.7). Ocean-based renewable energy technologies are thus able to displace emissions associated with fossil-based electricity generation. The greatest emissions mitigation is obtained when displacing high-emitting electricity-generating technologies such as coal, which accounts for approximately 38% of global electricity generation (IEA 2019). The use of ocean-based technologies has the potential to displace approximately 0.35–0.9 $kgCO_2e$/kWh electricity produced, depending on the source of electricity being displaced.

Box 17.2. Current Global Status of Implementation and Future Deployment

Current Global Status of Implementation

Offshore Wind Energy

By the end of 2018, the total installed global capacity of wind energy amounted to 564 GW, of which 23 GW was offshore (IRENA 2019a). Annual offshore electricity production amounted to about 77 TWh (IEA 2018).

Bottom-fixed wind turbines in shallow water depth (<40 m water depth) dominate. Deepwater, floating support structures are used in only one wind farm, a 0.03 GW wind farm off the east coast of Scotland. Much of the available information on offshore wind used in this report (in particular experience with costs) is taken from Europe, where the majority of offshore wind installations are located. However, it is anticipated that Asia, especially China, will significantly increase installed offshore wind capacity in coming years. The specific rate of growth is, however, difficult to assess.

Over the past decade, the cost per MWh installed power has fallen and the capacity factor (ratio between realised energy output and theoretical maximum output) of new installations has increased. High capacity factors of OSW installations are a notable advantage: the 2018 mean capacity factor for European offshore wind farms of 36% far exceeded that of European onshore wind farms (22%). The operation and maintenance (O&M) cost per produced

MWh is also expected to decline as turbines are designed to be more robust and better suited to the offshore environment. These factors contribute to reduced LCOE. Several other parameters are important when estimating the LCOE, including the connection between wind farms and the grid and the discount rate used in cost estimates. The increased size of turbines and wind farms, as well as the learning rate of the offshore wind industry, have all contributed to reduce LCOE. However, moving into deeper water and farther from shore has partly offset the cost reductions.

For projects commissioned in 2018, the average European LCOE was 134 US $/MWh. A project in China had an LCOE of US $105/MWh (IRENA 2019b). Contracts with record low costs, however, have been signed in the Netherlands (US $55/MWh to US $73/MWh), while the LCOE of a near-shore project in Denmark was US $65/MWh, excluding grid connection costs. No reliable data are available for floating systems, but for bottom-fixed systems, offshore wind without subsidies has proved cost-competitive with other electricity sources. This is the case even without a CO_2 tax, which would negatively impact competing power sources.

Other Ocean Renewable Energy

Estimated theoretical potentials for ocean renewable energy technologies (other than offshore wind) are listed below:

- **Tidal Range Energy**: The estimated global theoretical tidal range resource is around 25,880 TWh/year (constrained to regions with water depth of less than 30 m, and a reasonable threshold for energy output). Considering the logistical issues of operations in ice-covered regions, the global annual potential energy from tidal range technologies is approximately 6000 TWh, with 90% of this resource distributed across five countries (O'Neill et al. 2018).
- **Tidal Stream Energy**: The best estimates of the total global technical tidal stream energy resource is approximately 150 TWh/year, but the estimate is subject to high uncertainty (Yan 2015).
- **Wave Energy**: The total theoretical wave energy potential is estimated to be 32,000 TWh/year (Mørk et al. 2010), with estimates of the global technical potential ranging from 1750 TWh/year (Sims et al. 2007) to 5550 TWh/year (Krewitt et al. 2009).
- **Ocean Thermal Energy Conversion (OTEC)**: OTEC is currently limited to the tropical regions (±20° latitude). Estimates of the global theoretical energy resource range from 30,000 TWh/year to 90,000 TWh/year. Global technical resource estimates range from 44,000 TWh/year to 88,000 TWh/year (Lewis et al. 2011).
- **Salinity Gradient**: According to Alvarez-Silva et al. (2016) the theoretical global potential of power from utilizing the salinity gradient at the mouths of rivers worldwide has been estimated to be up to more than 15,000 TWh/year. Considering the river systems in more detail, 3600 TWh/year is more realistic. Accounting for extraction factors and other technical limitations, the globally technical extractable potential is estimated to be in the order of 625 TWh/year (Alvarez-Silva et al. 2016).
- **Floating solar PV systems**: Floating solar is presently in use predominently in water reservoirs and a small number of marine sites. Moving such systems to the ocean environment, the technical potential will depend upon the system's ability to operate in ocean waves. To ensure survival when facing extreme waves will drive the costs of the systems.

At the end of 2018, the total installed capacity of ocean energy technologies was 532.1 MWh (IRENA 2019a), consisting mainly of tidal barrage technology at two sites. Installed capacity in 2016 was 523.3 MWh, which generated 1023.3 GWh of electricity (IRENA 2019a), implying a mean capacity factor of 23% across the sector. Salinity gradient (energy available where freshwater meets salt water) and floating solar photovoltaic (PV) do not contribute significantly to installed capacity at present, but could contribute in future.

Estimates of LCOE are subject to a range of assumptions, including local conditions, which all affect costs. The estimated LCOE for wave energy is in the range of €330 to €630/MWh (IRENA 2014a). Tidal stream energy LCOE is currently in the range of €250 to €470/MWh (IRENA 2014b). At the current scale of deployment, LCOE of ocean thermal energy conversion is in the range of US $600 to US $940/MWh (IRENA 2014c).

Learning rates for ocean technologies are typically assumed to be around 15% (OES 2015), resulting in average LCOEs of €150 to €180/MWh for wave energy and of €200/MWh for tidal energy by 2030 (Cascajo et al. 2019; SI Ocean 2013). Due to the capital intensity of OTEC, interest and discount rates have a high impact on LCOE estimates for this technology. Economies of scale are expected to bring the LCOE into a range of US $70 to US $190/MWh for installed capacities exceeding 100 MWh (IRENA 2014c; OES 2015).

Future Deployment Scenarios (2030 and 2050)

Offshore Wind Energy

According to IEA (2017), offshore wind generation grew fivefold over the period 2010 to 2015 and is expected to double between 2015 and 2020. James and Ros (2015) estimated that Europe alone has a 4,000 GW potential for floating offshore wind in water depths above 60 m. This corresponds to about 15,000 TWh/year. National strategies in Europe, if implemented, sum to more than 70 GW of offshore wind capacity by 2030 (Ørsted 2019). The present offshore wind base is lower outside Europe, which increases the uncertainty of future scenarios. But a total installed capacity of 100 GW in Asia and 10 GW in the United States has been estimated for 2030 (GWEC 2017). Worldwide, offshore wind capacity could reach 120 GW in 2030 (GWEC 2017).

In 2018, the European Commission presented a strategic roadmap towards a zero-carbon economy in Europe by 2050 (European Commission 2018). The roadmap includes 70 GW of offshore wind in 2030, increasing to 600 GW in 2050, which corresponds to about 2300 TWh/year. To achieve this level of installed power, a significant scaling-up in the installation rates of offshore wind is needed. Floating offshore wind may be key.

Other Ocean Renewable Energy Technologies

Electricity generation from other ocean renewable energy technologies increased by an estimated 3%/year in 2018 (IEA 2019). This rate of growth is not on track to meet the IEA Sustainable Development Scenario (SDS) target for ocean technologies of 15 TWh/year in 2030 (IEA 2019), which would require an annual growth rate of 24%. The IEA SDS corresponds to an emissions target of approximately 25 $GtCO_2e$/year by 2030. By 2050, the projected power generation from ocean technologies is 108, 536, and 637 TWh/year for the IEA Reference Technology Scenario (RTS), 2 Degree Scenario (2DS), and Beyond 2 Degree Scenario (B2DS), respectively. The 2050 emissions associated with these three scenarios are 40.0, 13.0, and 4.7 $GtCO_2e$/year, respectively. This corresponds to annual growth rates of ocean technologies of 15, 21, and 22%, respectively.

3.3 Policy Interventions Needed to Realise Mitigation Potential

Offshore wind energy resources alone would be sufficient to cover more than the world's electricity demand in 2050. However, significant scaling-up in the rate of deployment is needed for offshore wind to become the significant player indicated by its potential. For other ocean-based renewable energy technologies, additional policy support is required for research and development to enable the scale efficiencies and cost reductions that come with commissioning larger commercial plants.

The levelised cost of energy (LCOE) of ocean-based renewable energy is dominated by investment costs. This means that measures related to project finance and tax regimes can be crucial. Defining the interface between the offshore plant and onshore grid, ownership, and the regulation of electricity markets can make a big difference.

Other policy interventions can also support greater uptake of ocean energy technologies:

- Development of incentives (e.g., carbon taxes and innovative power purchase agreements) that can encourage the expansion of ocean-based energy systems.
- Marine spatial planning should integrate the future role of offshore renewable energy with the many other activities affecting ocean and coastal areas. Development of appropriate legislation and regulation of ocean-based renewable energy to allow easier integration in national electricity grids is also required.
- Establishment of national targets and strategies to increase the share of ocean-based renewable energy in the national energy mix.
- Stable economic and regulatory framework to stimulate investments in required infrastructure for an accelerated deployment of ocean-based energy systems.

3.4 Technology Needs

Energy development needs access to larger areas where ocean energy resources can be harvested. Innovations that can move technologies into deeper water sites will be required, for example, development of floating offshore wind technologies.

Improving performance, reliability, and durability, while reducing costs, are the key challenges confronting all ocean energy technologies. Much is to be gained through continued and expanded support for innovation.

However, technology improvements must take account of environmental and social constraints that, if ignored, will undermine efforts to achieve a successful energy transition (Box 17.3).

3.5 Priority Areas for Further Research

Technology innovations need to be underpinned by a high-resolution assessment of global ocean energy resources, in terms of both geophysical and economical potential.

Research on integrating renewable energy projects with other coastal activities (e.g. coastal defense, food production and aquaculture) requires further investigation in order to maximise potential synergies and co-benefits associated with co-location.

Advancing further pilots and testing on the ability of floating solar PV panels at sea (under wave conditions) and further quantification this potential, along with that of Ocean Thermal Energy Conversion (OTEC).

Box 17.3. Wider Impacts Associated with Scaling Up Ocean-based Renewable Energy

Potential Cobenefits:

- Positive and long-term effects on ecosystems from offshore wind farm structures acting as artificial reefs.
- Human health benefits from reduced local air pollution in regions relying heavily on coal and oil to generate electricity
- Reduction in freshwater usage (overall) compared to generating power via fossil fuel.
- Job creation at regional and local levels, benefiting workers transitioning from declining fossil fuel industries. Total full-time employment in offshore wind in 2030 is estimated to be 435,000 (compared to about 38,000 in 2010) (OECD 2016).
- Potential to generate employment opportunities for women and promote greater gender equity in the rapidly growing industry

Potential Trade-Offs

- The spread of invasive species, noise pollution, and disturbances to marine species from vibration.
- Collision risks to birds and the presence of electromagnetic fields disrupting marine life and benthic habitats.
- Emerging offshore ocean energy (such as tidal barrage, tidal current, wave energy, and thermal gradient) are yet to be deployed commercially at scale. Tidal barrage installations can cause disruption to estuarine ecosystems.

For a full exploration of the wider impacts associated with ocean-based renewable energy, see the Sect. 1.4.

4 Ocean-Based Transport

This section analyses the potential mitigation impact of reducing emissions from domestic and international marine transport and shipping.

Current GHG emissions from global ocean transport (both international and domestic shipping of passengers and freight) are approximately 1 $GtCO_2e$ per year and represent around 3% of global anthropogenic CO_2 emissions (Buhaug et al. 2009; Smith et al. 2014). Long-term trends in shipping indicate a strong increase in demand and gradual improvement in energy efficiency. Since 1970, energy efficiency has improved by only about 1%/year (Lindstad et al. 2013; Lindstad and Eskeland 2018). If current trends continue, demand is likely to grow by 3%/year, which would lead to GHG emissions approximately doubling in 2050, to roughly 2 $GtCO_2e$, compared to 2010. This is in sharp contrast to what is needed to keep global temperature rise well below 2.0 °C and consistent with a 1.5 °C increase (IPCC 2013) and align with the goals of the Paris Agreement (UNFCCC 2015).

Shipping is a significant source of emissions with identifiable reduction pathways, but it is also an enabler of world trade and economic development. In 2018, the United Nations International Maritime Organization (IMO) adopted its Initial Strategy (Resolution MEPC.304). An objective of the strategy was to reduce shipping GHG emissions by at least 50% in absolute terms by 2050, relative to 2008 emission levels. Whilst the minimum reduction (50%) would see shipping's relative share of total GHG emissions grow significantly under most Paris-aligned scenarios, [1] the strategy leaves open the possibility of greater ambition, that is, to set a total GHG reduction target for 2050 that is well above the minimum 50%. A more ambitious target will likely be considered in the Revised Strategy due for finalisation by 2023.

The energy intensity and the absolute GHG emissions of ocean-based transport can be reduced in the following ways:

- Technical and operational interventions to reduce energy consumption per tonne transported (reduced energy intensity).
- Substitution of low- and zero-carbon fuels (e.g., hydrogen, ammonia, some biofuels) for diesel and bunker oil (reduced absolute emissions).

The 50% GHG reduction target set by the IMO might be achievable with technical and operational measures alone. Achieving a greater level of reduction by 2050—or the full phaseout of GHG emissions from shipping, as called for in the Initial Strategy's vision statement—will be possible only with the introduction of low- and zero-carbon fuels to replace fossil fuels. In practice, a rapid and cost-effective reduction in GHG emissions will require both technical and operational interventions and a swift transition to low- and zero-carbon fuels.

4.1 Mitigation Potential

Ocean-based transportation has the potential for a roughly 100% reduction in operational net GHG emissions by changing the way it stores and consumes energy on board:

Batteries could be used to store electricity, particularly in ships on the shortest voyages.

Low/zero carbon synthetic or "e" fuels could replace fossil fuels. Examples include renewable hydrogen, hydrogen-

[1] If shipping's emissions fall by 50% in absolute terms, to achieve the Paris Agreement temperature goals, other sectors will need to have fallen by more than 50% in absolute terms, and so shipping's relative share of total emissions will have grown.

based fuels such as ammonia, and fuels that have been post-processed with CO_2 to make hydrocarbons. These fuels differ from synthetic fuels made from gas or coal.

Biofuels could replace fossil fuels. However, it is commonly assumed that biofuels will have a limited role because of land and water constraints on sustainable supply and the fact that many biofuels are not, in fact, carbon-neutral (Searchinger et al. 2019).

Transitioning ocean shipping to more efficient and low- or zero-carbon fuels, and the mitigation potential in 2030 and 2050, is largely determined by the timescales needed to renew or retrofit the existing fleet and develop the infrastructure to use and supply these new energy sources.

Producing synthetic ("e") fuels, electricity, and bioenergy at volumes required by ocean-based transport will likely still have significant upstream emissions by 2030, and only a small subset of the fleet is likely to be "zero-carbon-fuels ready" by 2030. The mitigation potential in this time period is therefore mainly driven by the opportunity associated with energy efficiency maximisation. The upstream emissions and therefore the life-cycle (or well-to-wake) emissions for each of these pathways may remain significant until a broader transition to a zero-carbon energy system has been completed.

Nevertheless, if we assume that, by 2050, there will be a fully decarbonised land-side energy system associated with the production of shipping fuels, and that this is a timescale over which the whole ocean-based transport fleet could be "zero-carbon-fuels ready," there is a clear potential for 100% GHG reduction.

This mitigation potential is presented in Table 17.8.

4.2 Methodology

We use a business-as-usual (BAU) emissions trajectory out to 2050, based on an estimate of growth in demand for shipping. The BAU scenario used here is taken from the Third IMO GHG Study (Smith et al. 2014), where demand is estimated to align with IPCC scenario RCP 2.6 (Residual Concentration Pathway 2.6, which is approximately associated with a 2 °C temperature rise) and SSP 4 (Shared Socioeconomic Pathway 4, which assumes continued global inequality and increasing disparities in economic opportunity).

This BAU scenario applies existing IMO policy (including the Energy Efficiency Design Index (EEDI) and the Ship Energy Efficiency Management Plan (SEEMP) regulations) and estimates that total GHG emissions from international shipping will grow from about 800 Mt in 2012, to 1100 Mt in 2030, and to 1500 Mt in 2050. There is no projection for GHG emissions from domestic shipping in the Third IMO GHG Study, so we derive the domestic shipping BAU by applying the growth rates of international shipping to the 2012 domestic shipping inventory (taken from the Third IMO GHG Study).

Using the BAU scenario as a baseline level of emissions, the mitigation potential is quantified by applying a percentage reduction (defined below) to the emissions in both 2030 and 2050. The group of technologies that can mitigate domestic and international shipping emissions are similar, so the same percentage reduction is applied to both fleets.

To estimate mitigation potential in 2030, a 39% emissions reduction is assumed as the upper bound, taken from Bouman et al. (2017). This paper reviewed multiple papers and models to produce consensus estimates of the mitigation potential, both of individual mitigation options and the options in combination.

By 2030, the authors estimated that, relative to BAU, the median reduction potential across their surveyed literature was 39%. Of all the papers reviewed, the lowest estimate of emissions reduction potential by 2030 is 20%, this value is used to set the lower bound in the range of reduction potential. The mitigation potential in 2050 assumes a 100% emissions reduction at its upper bound. This is based on the assumption described in the preceding section that, if all vessels move to full use of nonfossil fuels from renewable feedstocks, then operational and upstream GHG emissions can be reduced to zero. The lower bound reduction potential is set at 50%, taken as the minimum interpretation of the IMO's objectives in the initial GHG reduction strategy.

The estimate of mitigation potential is thus based on a number of assumptions:

Table 17.8 Mitigation potential of ocean-based transport in 2030 and 2050

Ocean-based climate action area	Mitigation options	Description	2030 mitigation potential[a] ($GtCO_2e$/year)	2050 mitigation potential[b] ($GtCO_2e$/year)
Ocean-based transport	Reducing emissions from domestic shipping	Following the IMO definition: shipping between ports of the same country. Domestic shipping excludes military and fishing vessels, Includes ferries. This definition is consistent with the IPCC Guidelines 2006	0.04–0.07	0.15–0.3
	Reducing emissions from international shipping	Following the IMO definition: shipping between ports of different countries. International shipping excludes military and fishing vessels; includes bulk carriers, oil tankers and container ships. This definition is consistent with the IPCC Guidelines 2006	0.2–0.4	0.75–1.5
Total			**0.25–0.5**	**0.9–1.8**

Source: Authors

[a]Achieved predominantly through technical and operational interventions to reduce energy intensity per tonne transported

[b]Achieved predominantly through substitution of low- and zero-carbon fuels

- The speed of policy implementation to enable or require the shipping industry to invest in the necessary changes to fleet and infrastructure (in particular with respect to low- and zero-carbon sources). We assume that clear policies incentivising shipping's decarbonisation are in place by 2025. Later adoption of policy could jeopardise the achievement of these mitigation potentials in 2030 and 2050.
- The 2030 GHG reduction potential is estimated by aggregating savings across a large number of technological and operational efficiency interventions. [2] If savings are individually or collectively lower (or higher) because of currently unforeseen performance characteristics or interactions between the different interventions, then there could be a significant impact on the abatement potential achieved in 2030.
- The extent to which the wider energy system is decarbonised with sufficient supply of zero-carbon electricity to enable shipping fuels to be produced with zero emissions. We assume that the wider energy system has fully decarbonised by 2050 and that renewable hydrogen (zero carbon in production) is available in sufficient volumes. If that is not the case, then significant upstream emissions may still occur and offset some of the mitigation potential achieved through operational emission reductions.
- Demand growth is assumed to broadly follow the IMO's RCP 2.6 SSP 4 scenario. However, demand growth could be significantly higher or lower, with direct consequences for the BAU emissions and therefore (in proportion) the GHG mitigation potential of a fully decarbonised ocean transport industry.

4.3 Policy Interventions Required to Realise Mitigation Potential

The majority of the mitigation potential in ocean-based transportation is significantly influenced by one global body: the IMO. Domestic shipping is regulated by national governments, but often by flowing through IMO regulation. This section discusses interventions that can be undertaken by the IMO, national governments (including supranational organisations such as the European Union), and private sector organisations.

Private sector initiatives may be voluntary, shifting behaviour and removing existing barriers to decarbonisation, or mandated by national or global policy in due course.

The key actions needed are immediate improvements in energy efficiency to reduce fuel consumption, followed as quickly as possible by policy interventions that can incentivise shipping to transition away from fossil fuels, and private sector initiatives that enable adoption of low- and zero-carbon fuels. The following considerations are relevant:

- Cost-effective energy efficiency improvements can be made today, before the arrival of new fuels and their associated infrastructure.
- Current energy efficiency policy (IMO regulations on energy efficiency design index, EEDI) and energy efficiency management (SEEMP) are inadequate.
- EEDI has significant failures in its design (see section below), and ship energy efficiency management plan (SEEMP) is only a guideline, with no mandatory target.
- Energy efficiency improvements can reduce the impact on shipping and trade of moving to higher- cost low- and zero-carbon fuels.
- Policy needed to stimulate low- and zero-carbon fuels and support innovation may take longer to implement at IMO. In contrast, existing policy frameworks at IMO may be more easily and quickly used to drive improvements in energy efficiency and energy intensity.

4.4 International Maritime Organization Strategy for GHG Reduction

Emissions from the shipping and aviation industries were not explicitly included in the Paris Agreement. The expectation was that their respective UN agencies, IMO, and the International Civil Aviation Organization (ICAO), would lead on GHG-reduction efforts and develop global regulations. Another factor is that the majority of GHG emissions from shipping and aviation occur in international waters or airspace, and there is no obvious way to allocate national responsibilities for mitigation.

The IMO's Initial Strategy was adopted in 2018, partly as a clear statement of how IMO intended to fulfil its responsibility under global efforts to combat climate change. It is closely linked to the Paris Agreement both in terms of its mitigation goals and its adherence to the principle of Common but Differentiated Responsibilities and Respective Capabilities.

The IMO's Initial Strategy lays out three groupings of candidate policy interventions (short, medium, and long term), which, if effective, could realise most of ocean-based transport's mitigation potential. The IMO does not define the specific time frame corresponding to short, medium, and long term, or whether the time frames refer to a policy's design, adoption, or implementation. However, the time frames are understood to correspond approximately to implementation timescales of before 2023 (short), 2023 to late 2020s (medium), and 2030 onward (long). In practice to have good likelihood of meeting the IMO's objectives, clarity of policy direction is important and urgency of implementation is high (because of the long timescales of asset

[2] Bouman et al. (2017) presented the results of a review of nearly 150 studies, to provide a comprehensive meta-analysis of CO_2 emissions-reduction potentials and measures. They identified 22 types of measures for which reliable and comparable data are available in the peer-reviewed literature.

lives relative to decarbonisation objectives). For these reasons all policy recommendations are for the short and medium time frame only.). This report proposes a number of priority actions that IMO should undertake to maximise the potential for decarbonisation of ocean-based transport:

Short Term

Redesign of the EEDI formula so that it is fit for purpose (see section above) and addresses all in-service GHG emissions.

Adoption of policy measures that go beyond SEEMP to incentivise maximum operational efficiency of the existing and new fleet by no later than 2030.

Adoption of policy to reduce GHG emissions from shipping other than CO_2, in particular methane (CH_4) emissions associated with methane slip [3] and volatile organic compound (VOC) emissions associated with certain cargoes. To enable this, it will be necessary to develop CO_2 equivalent emission factors for all major fuel and machinery combinations on a tank-to-wake (TTW) basis, including for use in the redesigned EEDI formula.

Commitment to a timetable for shipping's transition to low- and zero-carbon fuels that will prompt early action and send a clear signal that investment should flow into fleets and related infrastructure.

Medium Term

Development of policy to measure, report, and verify well-to-tank (WTT) emissions for ship fuel and fuel supply chains.

A "medium-term" policy measure entering into force, no later than 2025, that strongly incentivises the adoption of low- and zero-carbon fuels by shipping. Options include the following:

A price on carbon (or GHG) emissions to simultaneously close the price gap between conventional and low- and zero-carbon fuels and enable competitive pricing for all options that reduce the GHG intensity of shipping. Revenues raised by such a measure should be disbursed to assist research, development, and demonstration (RD&D), and, if necessary, to address disproportionate negative impacts on vulnerable member states.

Standards that prescribe the carbon or GHG intensity of operation or the fuel used in ocean-based transport, whilst finding alternative (non-revenue disbursement) mechanisms to enable efforts on RD&D and address disproportionate negative impacts on vulnerable member states.

Box 17.4. International Maritime Organization's Existing Regulation: EEDI and SEEMP, and Their Limits and Challenges

The EEDI and SEEMP policies were first implemented in 2013 (IMO 2011; Psaraftis and Kontovas 2013). They target minimum performance requirements for ship design (EEDI), and recommendations for how energy efficiency could be managed in operation (SEEMP). A number of studies on trends in ship design efficiency during the early years of these regulations (Faber et al. 2016) show that many ships have performed far better than the EEDI requirements (i.e., their CO_2 emissions have been significantly lower than the required threshold). The implication is the requirement could have been more stringent (and recently the standards have been tightened and dates of alteration to phase 3 stringency brought forward for some ship types).

However, as the stringency of the regulation increases, so does the incentive to "game" the system. Ship design can be optimised to pass the short calm water trial in which EEDI is measured. Calm water trials bear little resemblance to normal operating conditions, where ships encounter strong winds and waves. Unless the EEDI is adjusted to include a performance threshold for rougher conditions, GHG emission targets will be set too low, and emissions could potentially increase (Lindstad et al. 2019). It is easy to make hull form modifications that improve calm water performance even of full-bodied "bulky" hulls. However, these modifications generally increase fuel consumption under real operating conditions. By contrast, hull forms optimised with respect to performance in realistic sea conditions cannot prove their worth when tested in calm water.

In addition, the regulation has no mechanism to ensure that the fuel used when ships are tested will also be used in operation, when a ship has multiple fuel options. A ship could complete its certification and trials using low-carbon fuel, gaining an excellent EEDI "score" but then switch to higher-carbon fuel in operation.

As EEDI is currently designed, the regulation influences only design specification. Experience in other sectors has shown that regulation that does not also incentivise efficiency in operation may not achieve the magnitude of savings expected from an extrapolation of the design efficiency standards. Studies specifically on EEDI have projected that it may contribute as little as 3% to actual operational CO_2 reduction (Smith et al. 2016).

The SEEMP regulation is mandatory in that a ship must be equipped with SEEMP documentation (i.e., an energy efficiency management plan), but there is no mandate for what must be specified within the documentation. As such, the regulation is a guideline and cannot be relied upon to overcome the known market barriers and failures and drive carbon intensity reduction in line with Paris Agreement and IMO objectives.

4.4.1 National Government Actions

Some governments have identified opportunities for economic benefit from emission reductions in the shipping sector (Bell et al. 2019) and have introduced incentives or other measures. For example, the United Kingdom has adopted the Clean Maritime Plan; several Scandinavian countries have set domestic shipping emission-reduction commitments; the Marshall Islands has included specific reductions for shipping emissions in its nationally determined contribution (NDC); China has shown leadership at the IMO on the topic of National Action Plans. The plans are initiatives, led through the IMO, that provide support for regional Maritime Technology Cooperation Centres and for shipping energy efficiency measures undertaken by 10 national governments within a Global Maritime Energy Efficiency Programme (GloMEEP).

Key elements in government actions taken to date include the following:

- Incentivising decarbonisation of domestic ocean-based transportation, if possible at a rate of transition faster than that achieved in the international fleet through IMO regulation. Domestic fleets are populated with smaller ships and therefore better suited to pilots and tests of fuels and technologies, which in turn can help to de-risk and reduce costs for larger, high seas, and ocean-based transportation.
- Enabling decarbonisation of national energy systems at least as fast as the rate of transition in the international fleet, and with sufficient additional energy supply capacity to meet a relevant proportion of the international fleet's energy demands.
- Providing national support for development of low- and zero-carbon energy production capacities, and storage and refuelling infrastructure in ports and harbours.
- Forming partnerships, particularly in support of small island developing states (SIDS) and least developed countries (LDCs) with significant domestic or regional shipping decarbonisation challenges, to work together on joint objectives.

4.4.2 Private Sector Actions

The private sector has traditionally led efforts to address shipping issues, such as safety and oil spill risks. While there are examples of such leadership in the areas of energy efficiency and decarbonisation (Scott et al. 2017), early initiatives have not matched the ambition of the Paris Agreement. In part, this is because earlier voluntary initiatives have stayed close to IMO policy, which remains conservative for fear of creating commercial disadvantages for its members and potentially reducing membership. Market barriers and failures inhibit action (Rehmatulla 2014), but where an opportunity aligns with wider stakeholder objectives, further action can be taken. Examples include the following:

- Further work to understand where market and nonmarket barriers and failures to decarbonisation occur and can be removed. For example, ensure that authorities setting rules in ports, fairways, and pilotage and sailing restrictions do not unnecessarily penalise ship length, given this is a low-cost means of reducing GHG intensity of shipping.
- As demonstrated in the Poseidon Principles (www.poseidonprinciples.org), encourage/regulate the financiers of shipping to be held more accountable for management of the long-run risks of shipping decarbonisation. This aligns with the increasing general prioritisation of finance to put a price on climate-change mitigation and adaptation-related risks. This can ensure that finance is no longer directed towards "standard" designs, which are optimised on cost at the expense of energy efficiency. It can ensure financing of a decarbonisation-aligned fleet that will avoid risks of asset stranding and maximise investment in the most efficient tonnage.
- Encourage/regulate the charterers of shipping to measure, report, and be held more accountable for operational GHG emissions for which they have responsibility (e.g., Scope 3 emissions). This can help address the lack of a clear market signal that ensures the energy efficiency and carbon intensity differential across the fleet is reflected in the prices paid by charterers, and which is needed to ensure that the shipowners have the full economic incentive to invest in solutions that achieve GHG reduction. This also ensures, in addition to policy on operational emissions, that where charterers have opportunities to contribute towards achieving GHG reduction, they seek to do so.

4.5 Technology Needs

The greatest need is to accelerate and scale up deployment of energy efficiency interventions. Many feasible solutions are ready to implement but are being adopted in low volumes because of market barriers and failures. These need to be overcome through effective national government and IMO policy (Rehmatulla 2014). Market barriers and failures present the main obstacle, but faster technological progress and implementation of demonstration projects have potential to produce greater understanding of performance benefits, performance improvement, and cost reduction (Lindstad et al.

2015; Lindstad and Bø 2018). Current promising but low-volume solutions include the following:

- Energy efficiency technologies (e.g., air lubrication, waste heat recovery, batteries (Lindstad et al. 2017b)) and hybrid engines (Lindstad and Bø 2018) that help smooth and manage demands for power from internal combustion engines and enable them to operate more optimally. Cold ironing (also known as "shore power") and digital solutions help enable operational efficiency improvements.
- Wind assistance technologies (kites, sails, and rotors that can directly harness renewable wind energy for propulsion).

There also remains a need to develop supply chains and technologies for the use of new low- and zero-carbon fuels on board. These are all at lower readiness level (LR and UMAS 2019) and unlikely to be feasible without significant incentives from IMO and national government policy, in addition to private sector action (LR and UMAS 2019). Specific technologies include the following:

- Electrolysers and equivalent as well as related technologies for producing hydrogen from electricity.
- Carbon capture and storage (for use with production of hydrogen from fossil feedstock).
- Storage technologies for hydrogen (including cryogenic storage of liquid hydrogen or carriers able to store at high-energy density).
- Fuel cells for conversion of future fuels into on-board electricity, and internal combustion engines designed to operate on hydrogen/ammonia.

4.6 Priority Areas for Further Research

Minimising energy consumption remains of high importance as the lowest-cost means of reducing emissions in the short term. It is now predominantly a function of implementing best practice in the design and operation of ships, and introducing sufficient policy incentives and private sector initiatives to overcome market barriers and failures that are currently preventing full adoption. The energy efficiency area represents a market opportunity if improved technologies become more widely deployed, but it will be a diminishing priority for further research.

Enabling the necessary switch to low- and zero-carbon fuels requires rapid progress in a number of areas (LR and UMAS 2019), both to confirm the most cost-effective transition pathway for shipping and to help reduce the costs of that pathway. Our recommended priorities focus on hydrogen and ammonia, even though other fuels are often considered for the future of ocean-based transport. Until a long-term solution has emerged, the interim "transition" steps that might be compatible with that solution (e.g., the fuels and their production pathways) will remain unclear.

Short-Term

- Cost-effective production of low-carbon hydrogen and ammonia from fossil fuel feedstocks in combination with carbon capture and storage.
- Safe storage and handling of hydrogen and ammonia on ships and at the ship-shore interface.
- Safe and efficient use of hydrogen and ammonia in large (e.g., 1 MW+) internal combustion engines and fuel cells.

Medium Term

- Cost-effective production of zero-carbon hydrogen/ammonia using renewable electricity and electrolysers.

These research areas represent large future market opportunities in terms of the provision of hardware and technology; production of future fuels; provision of services related to managing the design, implementation, and operation of assets; and ownership and operation of other related assets. Those opportunities are relevant to corporate and national interests and are especially important for countries with significant maritime or renewable fuel interests and an associated industrial strategy. Countries and corporate entities will need to proactively position themselves to capitalise on these opportunities.

Box 17.5. Wider Impacts Associated with Reducing Emissions from Ocean-based Transport

Potential Cobenefits:

- Reduction in seasonal "hotspots" of ocean acidification caused by strong acids formed from shipping emissions
- Beneficial impact on human health, particularly for people living in port cities and coastal communities, including from reduction in the sulphur content of fuel oil used by ships.
- Upgrade in technological capabilities in marine transport will bring efficiency.

Potential Trade-offs:

- Cost to industry of switching to alternative fuels will be high; however, increased costs are likely to have a marginal impact on the price of traded commodities

For a full exploration of the wider impacts associated with ocean-based transport, see the Sect. 1.4 of this report.

5 Coastal and Marine Ecosystems

This section analyses the potential mitigation impact of conserving and restoring coastal and marine ecosystems, including mangroves, salt marshes, seagrass beds, seaweed aquaculture, and marine fauna.

An overview of the current state of each ecosystem is provided below.

Mangroves, Salt Marshes, and Seagrass Beds

Mangroves, salt marshes, and seagrass beds are highly productive vegetated coastal ecosystems, which are referred to as "blue carbon" ecosystems, analogous to "green carbon" ecosystems on land (Nellemann et al. 2009). They are hotspots for carbon storage, with soil carbon sequestration rates per hectare up to 10 times larger than those of terrestrial ecosystems (Mcleod et al. 2011). Most of their carbon (50–90%) is stored within the soils where saltwater inundation slows decomposition of organic matter, leading to accumulation of extensive soil carbon stocks.

When these ecosystems are degraded and converted, carbon in their biomass and soils, which may have accumulated over hundreds or thousands of years, is oxidised and emitted back to the atmosphere in a matter of decades (Fig. 17.8). Thus, protection of blue carbon ecosystems offers an efficient pathway to avoid CO_2 emissions, particularly for nations with large areas of coastal vegetation and high rates of loss. For example, conversion of mangroves to aquaculture accounts for 10–20% of CO_2 emissions associated with land-use change in Indonesia (Murdiyarso et al. 2015).

Between 20 and 50% of global blue carbon ecosystems have already been converted or degraded, leading some analysts to conclude that restoring wetlands can offer 14% of the mitigation potential needed to hold global temperature to 2 °C above the preindustrial period (Griscom et al. 2017). Rates of mangrove loss have declined from 2.1%/year in the 1980s (Valiela et al. 2001) to 0.11%/year in the past decade (Global Panel on Agriculture and Food Systems for Nutrition 2017; Bunting et al. 2018), thanks to improved understanding, management, and restoration (Lee et al. 2019). However, mangrove areas still emit an estimated 0.007 $GtCO_2e$/year (Atwood et al. 2017).

Rates of loss and degradation of seagrass cover are between 2 and 7%/year, mainly due to pollution of coastal

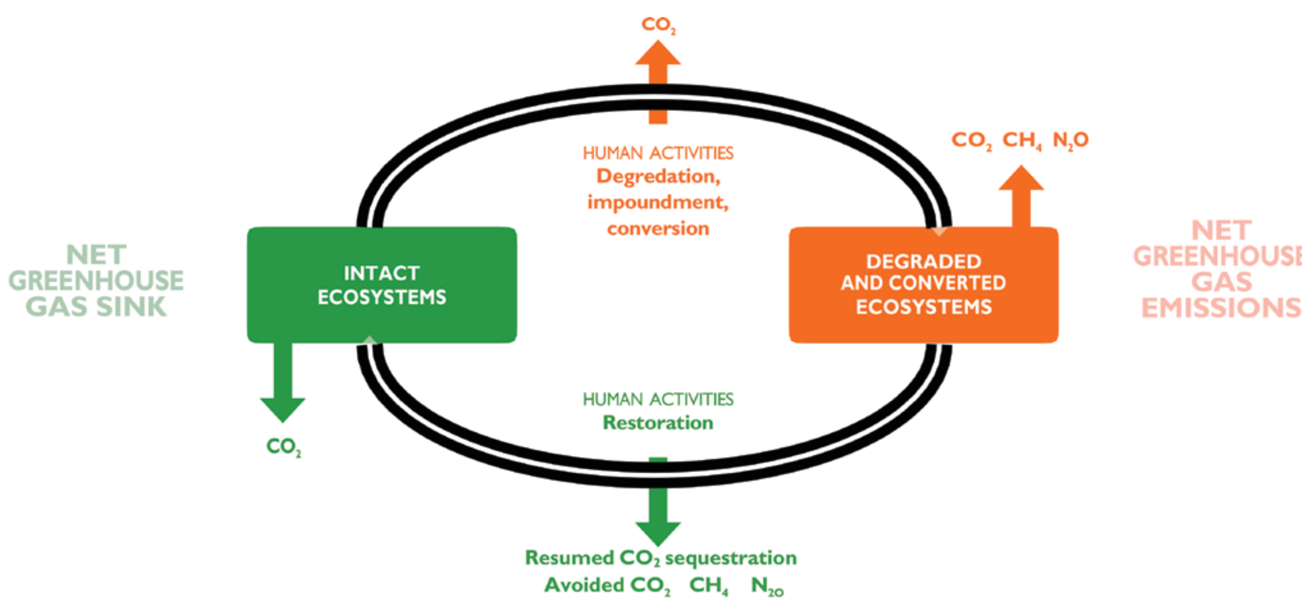

Fig. 17.8 The carbon cycle in coastal and marine ecosystems. (Source: Lovelock et al. (2017))

waters (Duarte et al. 2008; Waycott et al. 2009). Emissions are estimated at 0.05–0.33 $GtCO_2e$/year (Pendleton et al. 2012), although gains in cover have recently been observed in Europe (de los Santos et al. 2019). Global rates of salt marsh loss are uncertain (1–2%/year), but losses are estimated to be responsible for 0.02–0.24 $GtCO_2e$/year (Pendleton et al. 2012).

The area covered by blue carbon ecosystems is equivalent to only 1.5% of terrestrial forest cover, yet their loss and degradation are equivalent to 8.4% of CO_2 emissions from terrestrial deforestation because of their high carbon stocks per hectare (Griscom et al. 2017).

Seaweeds (Macroalgae)

Globally, the most extensive and productive coastal vegetated ecosystems are formed by seaweeds, which are a diverse group including brown algae (e.g., kelps), red algae, and green algae. Their areal extent is estimated—though with large uncertainty—to be 3.5 million km^2 of coastal regions (Krause-Jensen and Duarte 2016). Seaweeds are mainly attached to rocks or occasionally free-floating. They lack root structures that would sequester and trap soil carbon, which means that the climate mitigation value of wild seaweed habitats is largely through the export of organic carbon in plant biomass to sinks located in shelf sediments and in the deep ocean (Krause-Jensen and Duarte 2016).

Thus, the loss of seaweed habitats reduces carbon sequestration but does not result in emissions of CO_2 to the atmosphere from sediments below the habitats, as occurs in mangroves, salt marshes, or seagrass beds.

Globally, seaweed carbon sequestration is estimated to be 0.64 (range 0.22–0.98) $GtCO_2e$/year, representing 11% of annual global net seaweed primary production (Krause-Jensen and Duarte 2016). Recent studies also underline the large carbon export fluxes of seaweeds (Filbee-Dexter et al. 2018; Queirós et al. 2019; Ortega et al. 2019).

While there is no overall assessment of the global rate of change of seaweed habitats and the net area lost, it is estimated that kelps (brown canopy-forming seaweeds) have experienced a global average annual loss rate of approximately 0.018%/year over the past 50 years, with large geographic variability (Krumhansl et al. 2016; Wernberg et al. 2019).

Marine Fauna

Marine fauna (fish, marine mammals, invertebrates, etc.) influence the carbon cycle of the ocean through a range of processes, including consumption, respiration, and excretion. When marine fauna die, their biomass may sink to the deep ocean. In addition, their movement between habitats promotes mixing within the water column, contributing to increased phytoplankton production.

Marine fauna accumulate carbon in biomass through the food chain—starting with photosynthesizing plants that are consumed by animals, which in their turn are consumed. Although there are large data gaps, a first-order assessment estimates that 7 $GtCO_2e$ has accumulated within marine fauna biomass (Bar-On et al. 2018). However, the net carbon sequestration benefit from marine fauna, once allowance is made for respiration over the lifetime of the animal, respiration and carbon output from the species feeding on feces and carcasses prior to final burial in the seafloor, remains unclear.

Marine fauna activity can stimulate production by plants (Lapointe et al. 2014) and phytoplankton, leading to sequestration of 0.0007 $GtCO_2e$/year (Lavery et al. 2010). Populations of vertebrates are an important component of the carbon cycle in ocean ecosystems (Schmitz et al. 2018), including predators which can regulate grazers (Atwood et al. 2015) and should be given consideration when developing policies to secure nature-based carbon functions. However, there is currently insufficient data to estimate the global mitigation potential of protecting or restoring populations of fish and marine mammals to previous levels. Impacts of increased marine protected areas and fishery management practices on climate mitigation should be a priority research area.

5.1 Mitigation Potential

The mitigation potential of these coastal and marine ecosystems are examined by considering three mitigation options:

- Conserving and protecting blue carbon ecosystems, involving halting the loss and degradation of these ecosystems, thus avoiding direct land-use change emissions and additional emissions from alternative land use, such as agriculture.
- Restoration and expansion of degraded blue carbon ecosystems, involving rehabilitating the soil and associated organisms and thereby restoring their ability to sequester and store carbon.
- Expansion of seaweed (macroalgae) through aquaculture, to increase availability for alternative food, feed and fuel products to replace land-based options.

We estimate the total potential mitigation contribution from coastal and marine ecosystems as between 0.50 and 1.38 $GtCO_2e$/year by 2050. This estimate is similar to that of Gattuso et al. (2018), who estimated a cumulative mitigation of 95 $GtCO_2e$ by 2100 (a mitigation potential of 1.1 $GtCO_2e$/year by 2050). Due to lack of data, the estimated total mitigation contribution from marine and coastal ecosystems does not include the potentially significant mitigation effects associated with the conservation and restoration of wild seaweed or marine fauna. The greatest uncertainties in estimates concern ecosystem area and rates of change for seagrass and salt marshes. The estimated mitigation potential of conserving and restoring the marine ecosystems for which data are adequate (mangroves, seagrass beds, and salt marshes) along with the mitigation potential that could be achieved through avoided emissions by using seaweed as a food, feed or fuel replacement is summarised in Table 17.9.

Mangroves, Saltmarshes, and Seagrass Beds

Figure 17.9 shows the estimated mitigation potential of coastal and marine ecosystems via the two main pathways: (1) Protection and conservation of ecosystems avoids emissions of carbon that is currently stored in soils and vegetation, and (2) Restoration of ecosystems sequesters and stores carbon as vegetation grows.

Figure 17.10 compares the mitigation potential of land-based ecosystems to blue ecosystems. Although the mitigation potential of restoring green ecosystems, notably forests, is greater in total, the mitigation potential of blue ecosystems per unit area is very high.

Achieving high levels of mitigation through conservation and restoration is dependent on increased investment in protection, restoration, and enabling the expansion of ecosystem cover where sea level rise provides new opportunities. However, ambitious conservation and restoration targets must be considered within local socioeconomic contexts to prevent perverse outcomes (Herr et al. 2017; Lee et al. 2019; Lovelock et al. 2017).

Efforts to restore blue carbon ecosystems are growing in number, area, and success (Unsworth et al. 2018; Lee et al. 2019; Kuwae and Hori 2019), but are still relatively small scale in most instances. (An exception is the 589 km^2 of salt marsh restoration in the United States between 2006 and 2015 [Gittman et al. 2019]). Low-end estimates of mitigation likely to be achieved through restoration by 2050 are 0.2 $GtCO_2e$/year, reflecting limited restoration activities and success.

Estimates of CO_2 emissions associated with avoided anthropogenic degradation of mangrove, salt marsh, and seagrass ecosystems are sensitive to uncertainties in global cover and rates of loss, which is particularly the case for seagrass and wild seaweeds. Estimates of salt marsh area and losses of salt marsh area are also uncertain (Mcowen et al. 2017). Losses of mangrove ecosystems have slowed in the last decades, and thus emissions associated with their losses have also declined compared to those estimated by Pendleton et al. (2012).

Expansion of Seaweed Through Aquaculture

The protecting and restoration of wild seaweed habitats also holds potential for GHG emissions mitigation, but knowledge gaps are currently too large to estimate the potential contribution because the extent of lost macroalgal habitats that could be restored is unknown. Moreover, methods and success rates of restoration and protection measures (including sustainable harvest methods) need be explored and reviewed.

Table 17.9 Summary of mitigation potential from blue carbon ecosystems, 2030 and 2050

Ocean-based climate action area	Mitigation option	Description	Mitigation potential, 2030 ($GtCO_2e$/year)	Mitigation potential, 2050 ($GtCO_2e$/year)
Coastal and marine ecosystems	Conservation: potential mitigation from halting loss and degradation of ecosystems (avoided emissions)	Mangroves	0.02–0.04	0.02–0.04
		Salt marsh/tidal marsh	0.04–0.07	0.04–0.07
		Seagrasses	0.19–0.65	0.19–0.65
		Seaweeds	Knowledge gaps currently too large (see text)	Knowledge gaps currently too large (see text)
	Restoration: potential mitigation from restoring and rehabilitating ecosystems and organisms	Mangroves	0.05–0.08	0.16–0.25
		Salt marsh/tidal marsh	0.004–0.01	0.01–0.03
		Seagrasses	0.01–0.02	0.03–0.05
		Seaweeds	Knowledge gaps currently too large (see text)	Knowledge gaps currently too large (see text)
	Increased seaweed production via aquaculture		0.01–0.02	0.05–0.29
	End overexploitation of the ocean to support recovery of biodiversity and increase biomass		Knowledge gaps currently too large (see text)	Knowledge gaps currently too large (see text)
Total			**0.32–0.89**	**0.50–1.38**

Projections of mitigation from seaweed farming could reach 0.05–0.29 $GtCO_2e$/year by 2050. However, there are uncertainties in rates of expansion of the industry and the proportion of production that would be sequestered.

Scaling up seaweed production via aquaculture offers different potential mitigation pathways:

- Seaweed products might replace products with a higher CO_2 footprint, thereby avoiding emissions (rather than directly contributing to sequestration) in fields such as food, feed, fertilisers, nutraceuticals, biofuels, and bioplastics (World Bank 2016; Lehahn et al. 2016; Duarte et al. 2017). The extent of this mitigation pathway is currently not known.
- Addition of seaweeds to animal feeds might lead to reduced enteric methane emission from ruminants, a potential technology that is currently being explored and may substantially increase the mitigation potential of seaweeds (Machado et al. 2016). In vitro experiments have shown that the red alga, Asparagopsis taxiformis, can reduce methane emissions from ruminants by up to 99% when constituting 2% of the feed; and several other species, including common ones, show a potential methane reduction of 33–50% (Machado et al. 2016). However, this alga is not yet farmed, and many steps are required before large-scale mitigation can be achieved.
- Farmed seaweeds, similar to wild seaweeds, contribute to carbon sequestration through export of dissolved and particulate carbon to oceanic carbon sinks during the production phase (Zhang et al. 2012; Duarte et al. 2017).

This mitigation potential is presented in Table 17.9.

5.2 Methodology

Mangroves, Saltmarshes, and Seagrass Beds

Avoided emissions associated with halting ecosystem conversion were estimated from ecosystem aerial cover (km^2), mean carbon stocks in soils, and biomass per area from default emission factors (IPCC 2013), and estimated rates of loss (Table 17.10). The range of CO_2 sequestration potential per unit area for each ecosystem was calculated using default emission/removal factors from IPCC (2013). Our estimates are conservative because we do not include CO_2 emissions from previously degraded and converted ecosystems where soil carbon continues to emit CO_2 over time; these emissions may reach 0.7 $GtCO_2e$/year (Pendleton et al. 2012).

The range in potential mitigation that could be achieved through restoration of mangrove, salt marsh, and seagrass ecosystems varied with the level of effort and investment. We considered two scenarios: a moderate restoration effort recovering about 40% of historical ecosystem cover by 2050, which is consistent with Global Mangrove Alliance goals; and a much more aggressive scenario of complete restoration of pre-1980s cover. Restored areas would amount to 225,000 km^2 of mangroves (Valiela et al. 2001), 600,000 km^2 of seagrass (Mcleod et al. 2011), and doubling of the current area of salt marsh to 110,000 km^2 (Gittman et al. 2019). Mitigation benefits under these scenarios are likely conservative because avoided methane (CH_4) emissions from alternative land uses such as aquaculture and rice production could be substantial. Thirty percent of mangrove ecosystems in Southeast Asia have been converted to aquaculture and 22% to rice cultivation (Richards and Friess 2016). Both land uses can produce high nitrous oxide (N_2O) and CH_4 emissions (IPCC 2006, 2013, 2019).

Table 17.10 Global extent and loss rates of blue carbon ecosystems

Ecosystem	Areal cover (km^2)	Recent rates of loss (%/year)
Mangroves	138,000	0.11
Salt marshes	55,000	1–2
Seagrasses	325,000	2–7
Seaweeds	3,540,000	Not known

Seaweeds (Macroalgae)

To estimate the mitigation potential of seaweed farming by 2030 and 2050, two scenarios were considered (Table 17.9). The assumptions underlying the two scenarios are given below:

1. Seaweed farming develops at 8.3%/year (the current rate, calculated on the basis of the increase in the farmed and harvested production of green, red, and brown macroalgae between 2000 and 2017) (FAO 2018), 100% of production is assumed sequestered, and farming and processing are assumed CO_2-neutral. Conversion factors from wet weight to carbon are from Duarte et al. (2017).

   Average annual yield is 1000 tonnes dry weight/km^2 (current best practices) (World Bank 2016). Estimated production by 2030 (9.4 Mt dry weight/year, equivalent to 2.3 megatonnes of carbon/year [MtC/year)] and 2050 (49.3 Mt dry weight/year, equivalent to 12.2 MtC/year) would require an area of 9383 and 49,348 km^2, respectively. This represents 0.02 and 0.1%, respectively, of the global area suitable for macroalgal aquaculture (estimate based on suitable temperature and nutrient conditions, Froehlich et al. 2019).
2. Seaweed farming develops at 14%/year from 2013 onward (rate assumed in a scenario developed by the

World Bank (2016)), 100% of production is assumed sequestered, and farming and processing are assumed to be CO_2-neutral. Conversion factors from wet weight to carbon are from Duarte et al. (2017). Average annual yield is 1000 tonnes dry weight/km^2 (current best practices) (World Bank 2016), leading to production of 324 Mt dry weight/year, equivalent to carbon assimilation of 80 MtC/year by 2050.

We adopted the scenario of a 14% annual increase in production to provide an upper limit of the sequestration potential by 2030 and 2050, and we further assume that farming could proceed at this rate of increase without meeting constraints before 2050. An even higher production estimate of 10 billion tonnes dry weight/year was recently proposed (Lehahn et al. 2016), indicating that our estimated upper limit of seaweed production is not unrealistic.

The assumption that 100% of the seaweed harvest is sequestered is highly unlikely, as seaweeds are farmed for many other, and more economically profitable, purposes than carbon sequestration. Also, energy is required in the production process. However, carbon sequestration through export of the "nonseen production" during farming will contribute to the sequestration potential (Duarte et al. 2017). Recent estimates suggest that this export may constitute 60% of what is eventually harvested (Zhang et al. 2012). Assuming that 25% of the seaweed export is sequestered (Krause-Jensen et al. 2016), the projected seaweed aquaculture would have an associated sequestration of nonseen production of 0.0013–0.0027 $GtCO_2e$/year by 2030 and 0.0067–0.044 $GtCO_2e$/year by 2050.

To maximizes the mitigation benefit of seaweed farming, it is essential that farms do not harm wild blue carbon ecosystems (mangroves, seagrasses, saltmarshes, and seaweeds).

Conversely, sustainable seaweed farming may have the benefit of reducing the harvest of wild seaweeds.

Risks, Underlying Assumptions

Climate change is likely to have variable impacts on coastal marine ecosystems and their CO_2 mitigation potential (Fig. 17.11). Marine heat waves may adversely affect the mitigation contribution from seagrass beds and seaweeds (Arias-Ortiz et al. 2018; Wernberg et al. 2019). Warming may result in ecosystem losses at their equatorial distributional range limit (Wilson et al. 2019) and increases at the polar distribution range (Krause-Jensen and Duarte 2016; Marbà et al. 2018).

The area of mangroves and salt marshes may also be adversely affected by sea level rise in some regions (Lovelock et al. 2015) but could expand in others (Schuerch et al. 2018), increasing their mitigation benefits (Rog et al. 2017). Sea level rise will affect habitat areas for all coastal vegetated ecosystems, and thus their mitigation potential (Lovelock et al. 2015; Saunders et al. 2013; Schuerch et al. 2018). The impact of sea level rise on these ecosystems will be strongly influenced by human activity (e.g., sediment supply, land-use changes, population, and seawall defenses);

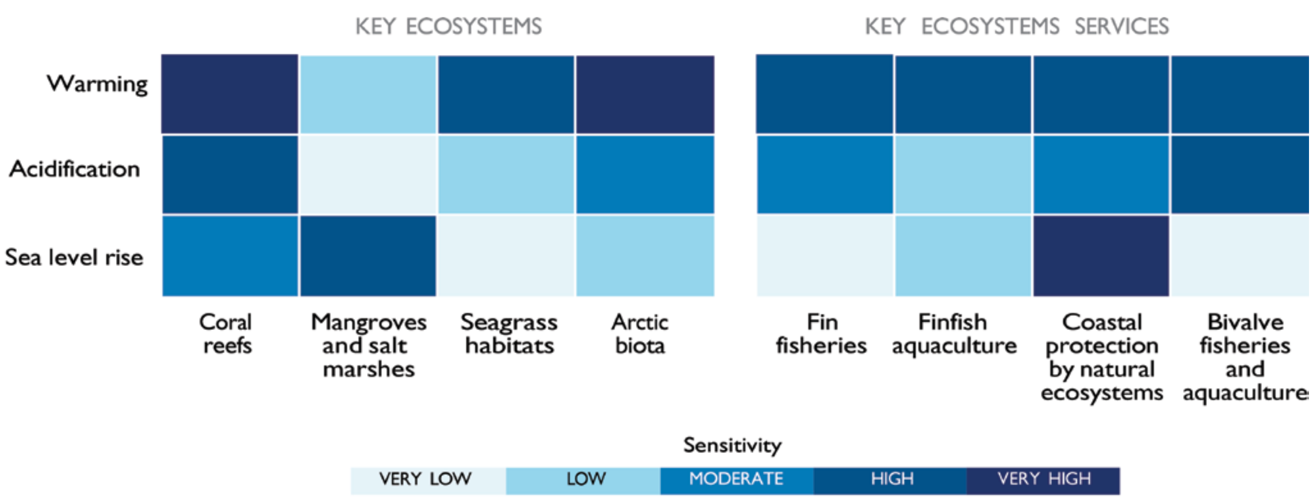

Fig. 17.11 The effects of climate change on coastal marine ecosystems will vary. (*Sources:* Gattuso et al. (2018))

the effects of climate change on adjacent ecosystems such as coral reefs (Saunders et al. 2013), mudflats or barrier islands; and GHG emissions from freshwater wetlands (Luo et al. 2019).

Extreme events could also reduce the effectiveness of restoration. While small-scale seaweed cultivation is considered low risk, a large-scale expansion of the industry requires greater understanding of impacts and the balance of environmental risks and benefits that seaweed cultivation projects can offer (Campbell et al. 2019).

In addition to climate change, marine and coastal ecosystems are also vulnerable to failure due to socio-economic factors, including inadequate and inappropriate incentives (Herr et al. 2017; Lee et al. 2019). Social safeguards, similar to those developed for forests, should be developed.

5.3 Policy Interventions Needed to Achieve Mitigation Potential

The following policy interventions are recommended to support the realisation of the mitigation potential outlined in this chapter:

Short Term:

- Enhance protection measures for mangroves, seagrass beds, salt marshes, and seaweed beds to prevent further losses due to human activities.
- Measures could include increasing the size and effectiveness of marine protected areas, but should also address underlying causes of loss, such as overexploitation, pollution, hydrological changes, and climate change impacts.
- Increase incentives for restoration of blue carbon ecosystems by paying for ecosystem service schemes, using mechanisms such as carbon and nutrient trading credits (Herr et al. 2017).
- Develop incentives for sustainable seaweed farming (Froehlich et al. 2019).
- Promote adoption of improved accounting for mangroves and salt marshes within national GHG inventories (IPCC 2013).
- Include blue carbon solutions in nationally determined contributions (NDCs) and other relevant climate policies for mitigation and adaptation (Herr and Landis 2016).
- Recognise the wider ecosystem services of these habitats beyond carbon sequestration and quantify their mitigation of coastal eutrophication and benefits for biodiversity, fisheries, coastal protection, fisheries and aquaculture, and their adaptation, to develop appropriate financial and regulatory incentive tools.
- Link conservation and restoration of mangroves, salt marshes, seagrass beds, and seaweeds to achieving the UN Sustainable Development Goals.
- Develop and implement social safeguards. Although restoration of blue carbon ecosystems provides important opportunities for mitigation, inadequate policies for restoration of mangroves for carbon could give rise to perverse outcomes (Friess et al. 2019a). Safeguards are required to ensure that, for example, restoration projects do not prevent local communities from accessing marine resources (McDermott et al. 2012).

Medium Term:

- Improve IPCC guidance for seagrass management and develop IPCC GHG inventory guidance for seaweed ecosystems.
- Improve methods for monitoring mitigation benefits to enable standardised accounting within national GHG inventories, and more comparable biennial transparency reports (BTRs).
- Increase the development of sustainable seaweed aquaculture globally.
- Increase investment in conservation and restoration of blue carbon ecosystems through innovative finance (insurance, debt swaps, taxes, and credits) and public-private partnerships.

5.4 Technology Needs

Restoration of mangroves and salt marshes is technically feasible at large scale (Lewis et al. 2011; Esteves and Williams 2017; Lee et al. 2019; Gittman et al. 2019).

Many constraints are imposed, however, by social and economic factors, including unclear land tenure, poverty, overexploitation, and lack of investment (Lee et al. 2019). Seagrass restoration at large scale faces significant technical impediments, for example, successful handling of and propagation from seagrass seeds (Statton et al. 2013). Successful seagrass restoration requires management of offsite factors, such as improvement of water quality (Unsworth et al. 2018).

Costs of restoration vary among ecosystems and among developed and developing economies (Bayraktarov et al. 2016). A review of costs per area of habitat revealed that marginal costs do not decline with increasing area of restoration projects, indicating that economies of scale have not yet been achieved. There are opportunities for improving methodologies, which could result in an increase in the scalability and effectiveness of restoration (Bayraktarov et al. 2016).

Seaweed farming is in operation in several countries, with more than 99% of production found in seven Asian countries (China, Indonesia, the Philippines, the Republic of Korea, the Democratic People's Republic of Korea, Japan, and Malaysia). Farms in the region vary from large industrial enterprises to smaller family-run businesses (World Bank

2016; Chopin 2017; FAO 2018). Currently, seaweed farming is not optimised for carbon sequestration or global large-scale production, as most of the production is for human consumption (FAO 2018).

Increasing the role of seaweed culture in mitigation will require a worldwide and sustainable expansion of the industry, of the sort that is underway in Canada (Chopin 2015) and Norway (Skjermo et al. 2014). Realising greater mitigation potential will also require the development of novel products, such as bioactive compounds and biomaterials.

Emerging biorefining techniques, with sequential extraction of products, are likely to markedly increase cost-effectiveness and scale of production (Chopin 2018a; Sadhukhan et al. 2019). The possibility also exists to develop more offshore, integrated multitrophic aquaculture, including seaweed aquaculture, in the open ocean (Buck et al. 2018).

5.5 Priority Areas for Further Research

Significant gaps exist in the knowledge base and practical application of ocean-based mitigation options.

Increasing efforts to produce national-level maps of blue carbon ecosystems would help monitor the success of restoration efforts and enable more accurate quantification of carbon sequestration in ecosystems under the full range of environmental conditions. This in turn would improve estimates of the likely impacts of restoration on mitigation potential. Building research capacity for an initial global-scale map of seaweed ecosystems would also contribute to improving available data, including developing IPCC-approved methodological guidance similar to that available for mangroves and salt marshes.

Research that explores the biophysical, social, and economic impediments to restoration, as well as enabling factors (e.g., value chain assessments), is needed to develop ecosystem restoration priorities, enhance incentives for restoration, and promote more successful restoration outcomes (Lee et al. 2019).

Relevant information would include assessments of the wider cobenefits of increasing seaweed area and carbon sequestration (Box 17.5), such as climate change adaptation, enhanced biodiversity, and improved ecosystem services (Krause-Jensen et al. 2018).

Deeper knowledge of the impacts of climate change is needed to more fully understand the risks to mitigation posed by climate change. The carbon sequestration and avoided emission benefits of ecosystem restoration are currently restricted to just a few sites, and more evidence is needed.

There is insufficient documentation on the global extent, production, carbon fluxes, and burial rates of the various groups of seaweeds. There is also insufficient information on how seaweeds respond—in terms of area and performance—to management efforts and methods that aim to restore and protect them, especially in the context of natural variability, human-caused stressors from local to global level, and climate change impacts. Methods to fingerprint seaweed carbon and other blue carbon sources beyond the habitat are also critical to link management action to carbon sequestration beyond the habitat, yet these methods remain poorly developed. Jurisdictional issues would also be a challenge to implementation.

The research agenda also must address the global potential for carbon sequestration through sustainable seaweed farming and processing and/or biorefining of seaweed products, circular management of nutrients, offshore production platforms, and the ecological impacts (positive and negative) of large-scale seaweed farming. Restoration of seaweed beds is developing, but, to the best of our knowledge, no reviews of methods and success rates are available.

Box 17.6. Wider Impacts Associated with Utilising Coastal and Marine Ecosystems for Carbon Sequestration and Storage

Potential Cobenefits:

- Increased climate change adaptation benefits from healthier coastal and marine ecosystems. Vegetated habitats protect coastal infrastructure and buffer acidification.
- Higher biodiversity benefits, with healthy marine and coastal ecosystems supporting a range of terrestrial and marine species.
- Provision of nutritious food through support of fisheries, plus other benefits, including traditional medicine by mangroves, salt marsh, sea grasses, and seaweeds for local communities.
- Higher ecosystem services (increase in fisheries productivity, coastal protection, and coastal tourism) from protected and restored mangroves, salt marsh, and sea grasses. Fair distribution of payments to local communities from restoration work could help meet decent work and economic growth targets.
- Integration of social and gender dimension into coastal and marine restoration work will increase its effectiveness.
- Expanding seaweed production contributes to meeting global food security targets, and offers a pathway to develop alternative food, feed, and fuels that do not require arable land. The farming also offers climate change adaptation benefits. The rapidly growing business has generated jobs, predominantly in developing and emerging economies.

Potential Trade-offs:

- Pushing forward blue carbon projects internationally, without considering social safeguards and demands of local small-scale fishers and other stakeholders who are heavily dependent on the resource for economic sustainability, can have unintentional negative consequences on societal well-being.
- Small-scale cultivation of seaweeds is considered low-risk. However, expansion of the industry will necessitate a more complete understanding of the scale-dependent changes and risks (facilitation of disease, alteration of population genetics, and wider alterations to the physiochemical environment).
- Mitigation options to recover ocean biomass can negatively impact poverty reduction and employment targets, and limit progress on food security targets in the short term.

For a full exploration of the wider impacts associated with coastal and marine ecosystems, see the Sect. 1.4.

6 Fisheries, Aquaculture, and Shifting Diets

This section analyses the potential mitigation impact of reducing the carbon footprint of ocean-derived food production (wild capture fisheries and aquaculture) and the potential reductions from shifting diets to include more low-carbon sources of ocean-based protein.

There are two principal ways in which ocean-based foods can contribute significantly to climate change mitigation. One seeks to reduce the carbon footprint of ocean-derived food production. For example, changing fuel sources in vessels and technological advances in production techniques can alter the emissions associated with seafood from both wild-caught fisheries and ocean-based aquaculture. The other seeks to identify emission reductions from potentially shifting more GHG-intensive diets to those that include more GHG-friendly seafood options, if those seafood options can be provided on a sustainable basis.

Different types of food, produced in different places by different means, can vary by more than an order of magnitude in the total GHGs they emit across their full life cycle. The composition of global diets, therefore, foods have the potential to play a significant role in these efforts if their production is sustainable. Food from the sea, produced using best practices, can (with some notable exceptions) have some of the lowest GHG emissions per unit of protein produced of all protein sources (González 2011; FAO 2013; Nijdam et al. 2012; Parker et al. 2018; Hallstrom et al. 2019). Increasing the fraction of ocean-based food in the global diet, and reducing the share of animal-based foods, would contribute significantly to climate change mitigation.

There are also opportunities for efficiency gains by reducing waste in the seafood supply chain (Springmann et al. 2018).

More than one-third (by weight) of all food that is produced is currently lost in the supply chain (Gustavsson et al. 2011), and even higher fractions may be lost in some seafood supply chains (Love et al. 2015).

The largest potential mitigation gains, however, are likely to be found in shifting diets away from terrestrial animal-based protein, particularly beef cows and other ruminants, towards plant- and ocean-based options that have been identified as having a lower carbon cost. The world's population continues to grow, and so does demand for food, although projections of food demand are highly uncertain. Rising affluence and the spread of "Western diets" is encouraging the consumption of more animal protein. These trends will continue to drive growth in GHG emissions unless dramatic changes occur in the scale and composition of foods that are selected for human consumption (Springmann et al. 2018).

Estimates of global food-related GHG emissions early in this century range from 4.6 to 13.7 billion tonnes of CO_2e (Tubiello et al. 2013; Smith et al. 2014; Poore and Nemecek 2018). By 2050, these emissions are projected to grow between 80 and 92% (summarised in Springmann et al. 2018). In addition to rising GHG emissions, the environmental consequences of producing ever-increasing quantities of food with the current dietary mix of species are projected to be severe in terms of water scarcity, soil degradation, and habitat loss, among others (Tilman and Clark 2014; Springmann et al. 2018). Without significant reductions in agricultural emissions, it will almost certainly be impossible to keep planetary warming constrained to 2 °C or less above preindustrial levels (Springmann et al. 2018).

Fortunately, there are several pathways that could collectively drive large emission reductions, and ocean has a major effect on global emissions (Poore and Nemecek 2018; Searchinger et al. 2019).

6.1 Mitigation Potential

We estimate that, with strategic policy and investment actions to change how seafood is provided and increase its share in the collective human diet, seafood could contribute potential mitigation of between 0.34 and 0.94 $GtCO_2e$ by 2030, and between 0.48 and 1.24 $GtCO_2e$ by 2050, relative to business-as-usual projections. Our estimates are explained more fully in the Sect. 6.2.

6.1.1 Reducing Emissions from Wild Capture Fisheries

Current fuel use and GHG emissions from global wild-capture fisheries up to 2011 were modelled by Parker et al. (2018). They estimated global fishing emissions in 2011 at 179 MtCOe, or 2.2 kg COe per live weight kilogram of landed fish and shellfish. Global fishing thus accounts for roughly 4% of global food system production emissions. Modelling was based on the aggregation and weighting of extant fuel-use data, specific to target species, gear, and/or fishing country, with corrections to account for upstream emissions from fuel production and transport, as well as non-fuel emissions from vessel construction, gear manufacture, refrigerant use, and other factors.

Reductions in emissions from wild-capture fisheries can be achieved in ways ranging from technological advances in engine efficiency or hull design to changes in skipper behaviour, such as speed reductions and willingness to fish in poor conditions. However, while technological changes, such as gear design and engine retrofits, have been demonstrated to influence fuel-use rates in individual vessels (e.g., Parente et al. 2008; Khaled et al. 2013; Latorre 2001), the effects of such changes at the fleet level are unclear and can be overshadowed by variation in stock abundance or structural changes to the fishery (Ziegler and Hornborg 2014; Farmery et al. 2014; Pascoe et al. 2012). A more consistently reliable driver of emissions within a fishery is catch per unit effort, reflecting both effort (e.g., days fished) and available biomass (Parker et al. 2017; Ziegler et al. 2016).

Our estimate of mitigation potential in this case is consequently focused on the potential for future changes in effort and landings, while acknowledging that technological and behavioural factors will play a role, either positively or negatively. Arnason et al. (2017) developed a future scenario to optimise the economic performance of global fisheries. Compared to wild capture landings in 2012, they estimated that, in theory, wild fish catch could increase by 13% by 2030, with significantly less fishing effort expended. Applying their effort and landings projections to Parker et al. (2017) emissions model, this increase in efficiency could reduce GHG emissions by a total of 81 $MtCO_2e$, or to roughly half of current fishing emissions (Table 17.10).

6.1.2 Reducing Emissions from Aquaculture

Global analyses of the complete GHG footprint of aquaculture are lacking, and many systems that make up a large portion of global production have not been sufficiently assessed. However, some clear patterns have emerged from the literature to date. In particular, the largest source of emissions in finfish and crustacean aquaculture is commonly the feed provided for their growth (Henriksson et al. 2012; Parker 2018; Pelletier et al. 2009; Pelletier and Tyedmers 2010; Robb et al. 2017). Minimizing the carbon profile of aquaculture feeds therefore can represent a substantial source of future emission reductions, or at least avoidance of emissions increases.

The composition of fish feeds varies greatly, especially across herbivorous, omnivorous, and carnivorous species (see the feed ingredients database: http://afid.seafdec.org.ph). Two of the key components of many feeds for omnivorous and carnivorous species have historically been fish meal and fish oils, which are products derived primarily from forage fish fisheries and increasingly from trimmings of other species during processing. These components promote vibrant fish growth and are also sources of key nutrients shown to have significant benefits for human health (Kris-Etherton et al. 2002).

There are active debates concerning the logic behind feeding wild fish to farmed fish rather than using the wild fish for direct human consumption (Naylor et al. 2000, 2009; Tacon and Metian 2008). In addition, the global supply of fish meal is now at a historical high and may be near biological limits (Costello et al. 2012). As a result, the continued growth of fed aquaculture has driven dramatic increases in the price of fish meal and incentivised reductions in the fish meal and fish oil content of many aquaculture feeds (McGrath et al. 2015; Rana et al. 2009).

To date, the primary replacements for fish meal have been soy and other agricultural crops, which often have high GHG emissions (Pelletier and Tyedmers 2007; McGrath et al. 2015). More recent substitutes for fish meals and oils include a range of livestock-derived inputs (e.g., blood, meat, and feather meal), which typically have even higher levels of GHG emissions (Parker 2018; Pelletier et al. 2009). Many of these substitutes, and particularly those derived from some crops, can have trade-offs in terms of fish and crustacean growth and health, especially for farmed predators. Consequently, efforts are now being made to identify new, highly nutritious, and ideally, low-impact feed sources.

Some of the most promising options are a variety of protein concentrates derived from a range of single cell organisms including yeast, bacteria, or microalgae (Sarker et al. 2018). Although the motivation for this innovation was to provide better quality feeds, one of the fortunate benefits is that some of these alternative feed inputs have significantly lower GHG emission intensities than soy-based protein (Couture et al. 2018). Other emerging feed alternatives, however, can have substantially higher emissions with few benefits relative to soy protein (Couture et al. 2018).

Because of the limited nature of fish meal and the reduction in fisheries that provide it, future aquafeeds will need to use alternative sources for meal and oil. Given current projections for aquaculture growth (SOFIA 2018), we estimate that targeting new low-emission alternatives as replacement feed components, rather than soy-based protein or other high-GHG sources, could avoid annual emissions from the industry by 16 $MtCO_2e$ by 2030 and 43 $MtCO_2e$ by 2050. If the pace of aquaculture growth increases further because of projected growth in demand (Waite et al. 2014), these emissions savings could increase by more than one-third. Since many options are emerging to replace the fish meal fraction in feeds, realising potential emissions cobenefits will require incentives. For example, a well-structured price on carbon, detailed full life-cycle assessments of emissions from new feeds, targeted investments, information, and certification campaigns would help prioritise low-emission feed options. If shifting demand (see below) drives even faster growth in aquaculture relative to other sources of animal protein, these savings could grow proportionately.

6.1.3 Reducing Emissions by Shifting Diets

Food will play an increasingly large role in future climate change mitigation efforts (Tilman et al. 2001, 2011; FAO 2013; Poore and Nemecek 2018; Springmann et al. 2018; Searchinger et al. 2019). GHG emissions from food systems are high, particularly from livestock production, and demand for animal-based food is projected to increase dramatically by 2050 (Searchinger et al. 2019). Since different foods vary widely in their embedded GHG emissions per unit of protein (Poore and Nemecek 2018), changes in the composition of future diets could greatly affect the emissions consequences of growth in demand (González et al. 2011).

If we look only at food system emissions of methane and nitrous oxides, which will not be affected by advances in low-emission energy sources, the business-as-usual scenario projects that GHG emissions will grow from 5.2 $GtCO_2e$ in 2010 to 9.7 $GtCO_2e$ in 2050 (Springmann et al. 2018). Of that projected growth, over 75% will come from projected growth in animal products.

The primary pathways for reducing these potential impacts are efficiency gains (e.g., reducing food loss and waste, feed conversion ratios, and growth periods for livestock) and dietary shifts in terms of food choices and levels of consumption.

Changing behaviour on a scale necessary to shift diets enough to materially affect projected GHG emissions is an immense challenge. One promising strategy is to incentivise lower consumption levels of particularly impactful foods (i.e., most animal-based products) (Poore and Nemecek 2018; Springmann et al. 2018) through education, but also through market mechanisms that increase the price of GHG-intensive foods. Another strategy targets people's self-interest and stresses the benefits of reduced animal food consumption for human health. There is a strong alignment between dietary changes that would improve human health and those that would benefit the environment (Tilman and Clark 2014).

Sustainable growth in seafood production and consumption, particularly from aquaculture, is at the core of these potential benefits. Such growth would necessitate improvements in ocean and coastal management to ensure that harvests can not only be increased, but also sustained. Springmann et al. (2018) suggest that an aggressive dietary shift at a global scale could reduce annual emissions by 4.7 $GtCO_2e$—more than offsetting projected growth of emissions under the business-as-usual scenario. Pathways to achieve such a scale of behaviour change are not clear. More conservatively, we estimate that two practical scenarios could achieve significant emission reductions—a carbon tax and aggressive health campaigns on diets and human health—leading to emission reductions of 0.24–0.84 $GtCO_2e$ by 2030 and 0.30–1.06 $GtCO_2e$ by 2050 (Table 17.11). Both scenarios would see the ocean playing a significantly larger and beneficial role in global food systems.

This mitigation potential is presented in Table 17.11.

Table 17.11 Summary of 2030 and 2050 mitigation potential by mitigation option

Ocean-based climate action area	Activity	Description	Mitigation potential, 2030 ($GtCO_2e$/year)	Mitigation potential, 2050 ($GtCO_2e$/year)
Fisheries, aquaculture and dietary shifts	Reducing emissions from wild capture fisheries	Emissions from fuel use for inland, coastal, and open ocean fishing (wild capture)	0.081	0.137
	Reducing emissions from aquaculture	Life-cycle emissions from aquaculture (new feeds to replace fish meal and soy-based proteins)	0.016	0.043

6.2 Methodology

This section describes our approach to estimating emission reductions that could be achieved by improving efficiency and yield in wild capture fisheries, improving performance of aquaculture, and shifting the dietary choices of consumers.

6.2.1 Wild Capture Fisheries

Reducing Emissions by Improving Fish Catch Efficiency

One basis for determining the extent to which effort relative to catch could be reduced worldwide is the modelling done by Arnason et al. (2017) in the *Sunken Billions* report. They estimated that an optimal economic scenario for the entire global fishing fleet would, relative to 2012, is likely to produce 13% more catch, using 56% as much effort (targeting maximum economic yield). While fuel use would not be perfectly correlated with effort in such a scenario, if we assume equal reductions in fuel use and effort, we can estimate the fuel use (and associated emissions) required to catch that future optimal harvest using the Parker et al. (2018) model. Our calculations assume a uniform change in landings and fuel use across all species groups and gear types, remodelled from Parker et al. (2018). This is likely an overly optimistic scenario, given the challenges to fisheries management globally, the uneven and insufficient implementation of effective management techniques, and the as yet unrealised recommendation of Arnason and colleagues to direct global fisheries towards their optimal future. Further, it fails to address technological and behavioural changes that may accompany changes in effort and landings, whether positive or negative.

The result of higher catches for less effort is roughly a halving of emissions intensity from 2.2 kg CO_2e per kg landed to 1.1 kg CO_2e. Total emissions from the global fishing industry would decline from 179 MtCO_2e to 98 MtCO_2e, a reduction of 81 MtCO_2e. These emission reductions could be achieved rapidly if countries adopt management reforms to align fishing effort with values appropriate for achieving maximum sustainable yields. Such a scenario would also eventually provide approximately 10% more fish and shellfish from the ocean than the current scenario (Parker et al. 2018) based on the suggested landings in Arnason et al. (2017), compared to the 2011 landings modelled by Parker et al. (2018). Such gains would occur gradually after the effort reductions, since they depend on the recovery of fish stocks.

Reducing Emissions by Increasing Fishery Yields

We estimate the additional protein provided by assuming an average flesh yield from live weight of 50% and protein content of 20%. This yields an additional 863 million kg of protein annually once stocks are rebuilt. While the degree to which that additional protein would be available to offset alternative animal protein sources would rely on numerous factors, we calculate the optimal case, assuming that all additional protein from fisheries replaces (does not add to) more emissions-intensive land-based protein sources.

We use pork to represent an average land-based protein (Poore and Nemecek 2018), as it has a middle-range emissions profile. If we assume the emissions from producing 100 g of protein from pork are 7.6 kg CO_2e (Poore and Nemecek 2018), compared to 1.1 kg CO_2e for average fish and shellfish, we derive a potential emissions offset of 6.5 kg CO_2e for every 100 g of additional fishery-sourced protein, or a total annual emissions reduction potential of 56.1 MtCO_2e by 2050 (Table 17.12).

The combined emissions reduction potential of global fisheries, assuming optimal effort to catch ratios from Arnason et al. (2017), and 100% substitution of available fish protein for average animal-based protein sources, is 137.1 MtCO_2e. Since these benefits require the inherent delay of population recovery of the fished stocks, we assume these added reductions are achievable by 2050.

6.2.2 Aquaculture

FAO projects that global aquaculture production will grow at an annual rate of 2.1% from 2017 to 2030 (SOFIA 2018), with annual production reaching 110 Mt by 2030. The Food and Agriculture Organization (FAO) does not currently project to 2050, but if we assume a similar annual growth rate of

Table 17.12 Projected emission reductions from improving fishing efficiency under two scenarios

Measure	Unit	2011 baseline	Optimal scenario
Fish landings	Million tonnes	81.1	89.7
Emissions from fishing	Million tonnes CO_2	179.0	98.0
Emissions intensity	CO_2e/kg fish landed	2.2	1.1
Additional harvest	Million tonnes	Not available	8.6
Additional protein	Million kg	Not available	863.0
CO_2e offset per 100 g protein	kg CO_2e	Not available	6.5
CO_2e reduction from substituting seafood for land-based protein	Million tonnes CO_2	Not available	56.1
CO_2e reduction from reduced fishing effort per unit catch	Million tonnes CO_2	Not available	81.0
Total CO_2e reduction from wild fisheries	Million tonnes CO_2	Not available	137.1

Sources: Authors (2011) baseline scenario from Parker et al. (2018). *Optimal scenario remodelled from effort and catch estimates in* Arnason et al. (2017)

approximately 2.0% from 2031 to 2050, total aquaculture production (excluding plants) would be approximately 163 Mt live weight in 2050—essentially double the 2017 production or an additional 80 Mt live weight.

The projected growth in aquaculture production could affect GHG emissions in two ways. Growth could influence the mix of animal proteins that is consumed. We address this issue below in the section on shifting diets. Secondly, constraints on the availability, and rising cost, of fish meal from wild fisheries, will mean that the fraction of fish meal in farmed fish diets will continue to decline. Fish meal is likely to be replaced primarily by agricultural products like soy and/or livestock by-products unless new alternative feeds are adopted. Fortunately, we have seen great innovation in the development of new protein-rich feed inputs.

Although the GHG emissions expected from many of these alternatives have not been thoroughly analysed, feeds derived from single-celled yeast and microalgae appear to have dramatically lower GHG emissions per unit of protein (Couture et al. 2018, unpublished) than alternatives like soy. If we assume that aquaculture production in 2050 is double what it is today and has a similar product mix (i.e., fed species versus shellfish, etc.), the use of new low-emission alternative feeds for the feed fraction that is currently fish meal would reduce projected feed-based emissions by more than 43 $MtCO_2e$ in 2050. At the extreme, if these alternative feeds provided all the required additional feeds needed to support projected aquaculture growth, emissions would be reduced by nearly 259 $MtCO_2e$ in 2050, relative to the emissions from a predominantly soy-based or emission-equivalent feed.

6.2.3 Dietary Shifts to Ocean Proteins

Conservative estimates focused only on methane and nitrous oxide emissions suggest that aggressive dietary changes could reduce global annual GHG emissions in 2050 by nearly 5 $GtCO_2e$, while simultaneously improving human health (Springmann et al. 2018; Willett et al. 2019). The challenge is to bring about significant behaviour change on the part of billions of people. To estimate what fraction of the potential gains from shifting diets might realistically be achievable, we examine the potential effects of two policy approaches—a carbon tax that applies to food systems and media campaigns focused on improving human health through diet.

Carbon taxes have been proposed as a market-based tool to reduce GHG emissions from livestock production systems.

In theory, a well-designed tax that encompasses more than just carbon emissions would make GHG-intensive food products, such as beef and lamb, relatively more expensive and steer consumers towards lower-carbon substitutes such as pork, seafood, chicken, or vegetable proteins. There are many practical and political challenges to designing and implementing GHG pricing in the agricultural sector. Several studies, however, have concluded that taxes could result in substantial reductions in GHG emissions (Tallard and Key 2012; Havlık et al. 2014; Wirsenius et al. 2010). Modelling suggests that a global price on methane emissions from livestock ranging from US \$15/tCO_2e to US \$100/tCO_2e would reduce methane emissions by 2.8% and 9.9%, respectively (Tallard and Key 2012). See also research in the previous section whereby the addition of some types of seaweed to livestock diets can lead to a large decline in methane emissions. After applying emissions intensities (Gerber et al. 2013) to forecasted production of terrestrial animal proteins in 2030 (Alexandratos and Bruinsma 2012), these reductions in livestock emissions would amount to 237–840 $MtCO_2e$/year. Extending this estimate out to 2050, these same percentage reductions in livestock emissions would lead to avoided emissions of 0.30–1.06 $GtCO_2e$/year, a portion of which will come from shifts to ocean-based proteins.

Shifting diets through media and educational campaigns the projected health benefits of reducing meat consumption are so large that GHG emissions mitigation could potentially be achieved as a cobenefit of behaviour change motivated by people's interest in their personal health (Willett et al. 2019). Numerous campaigns on other health-related issues provide insights on the magnitude of expected behaviour changes. In multiple meta-analyses (Snyder et al. 2004; Elder et al. 2004; Abroms and Maiboch 2008) on campaigns on seat belt use, smoking, cancer screening, alcohol use, and many other topics, the sobering result was that the observed effects were moderate—typically 15% or fewer people changed targeted behaviours. Lessons learned from past campaigns could help maximise the impacts of future campaigns on diets, but expectations for near-uniform adoption of behaviour change are clearly unrealistic. Applying the median (11%) and upper bound (15%) of these past experiences to the projected benefits of global adoption of a less-GHG–intensive diet (4.7 $GtCO_2e$ estimated by Springmann et al. 2018) suggests that effective campaigns focusing on health benefits of dietary change could potentially yield reductions between 0.52 and 0.71 $GtCO_2e$ by 2050.

6.3 Policy Interventions Required to Achieve Mitigation Potential

Achieving a level of efficiency gains in wild fisheries that would drive emission reductions requires more effective management of fisheries around the world. Several global analyses highlight where fisheries are working well and where there are needs for significant reforms (e.g., Arnason et al. 2009; Sumaila et al. 2012; Costello et al. 2016), and help identify which management practices are linked to success or failure in fisheries management (e.g., Keller et al. 2019; Evans et al. 2011; Allison et al. 2012; Barner et al. 2015; Lubchenco et al. 2016; Costello et al. 2016; Lester et al. 2017). The lessons of this rich literature are that there are robust solutions for a wide range of fisheries issues. Yet, the problems persist and grow. The challenge is to scale the successes more quickly than the problems grow. Achieving this goal requires national recognition of the nature of each country's fisheries challenges and the benefits of improved management (Box 17.7), and a concerted effort to draw on the lessons of others to drive more rapid change.

Significantly altering the behaviours of a broad section of society, even for actions that are both in the interest of the planet and of individual people, is surprisingly challenging. The two broad approaches of sending clear market signals via carbon or other food-related taxes that embed broader environmental and social costs of different food choices in prices, and motivating lifestyle changes need to be coupled. The two policy approaches, if synergistic, can help to realise greater GHG emissions mitigation.

6.4 Technology Needs

Unlike other categories in this assessment, the largest gains from changes in the global food system do not depend on the development of new technologies.

Rather, the benefits depend on scaling solutions globally that have already been demonstrated in specific places. Although this requires new innovative approaches, new market solutions, and new campaigns, it is not heavily dependent on new technological advances.

6.5 Priority Areas for Further Research

Data sources for GHG emissions from fisheries, both farmed and wild-caught, would better inform potential policy interventions.

Box 17.7. Wider Impacts Associated with Reducing Emissions from Fisheries and Aquaculture and Shifting Diets to Ocean-based Proteins

Potential Cobenefits:

- Even moderate shifts in diet from high meat consumption towards ocean-based protein have well-documented human health benefits.
- Moving to diets that are less dependent on animal products would slow the growth in demand for land and freshwater to support livestock agriculture.
- Growth of marine aquaculture will create jobs. Total direct employment in the industry is estimated to be 3.2 million in 2030 under business-as-usual projections (an increase of 1.1 million above 2010 levels) (OECD 2016).
- Innovations in developing fish meal substitutes and improving feed efficiency will be crucial to support a rapidly growing aquaculture industry and meet global food security targets.
- Replacing fish meal of future feeds with crops instead of animal by-products requires less water; reducing feed conversion ratio in aquaculture production decreases upstream water usage.
- Structural changes to fisheries that reduce fuel consumption will be economically beneficial.

Potential Trade-Offs:

- Offshore marine aquaculture is associated with multiple environmental challenges (such as eutrophication, disease, and risk of invasive species). These risks are also to some extent associated with land-based farming.
- Unplanned growth in shrimp aquaculture has caused widespread loss of mangrove ecosystems, leading to large CO_2 emissions, salinisation of soils and freshwater reserves, erosion, and loss of coastal resilience to flooding.
- Increased inclusion of terrestrial plant-based ingredients in fish feed for a growing aquaculture industry could lead to competition for land, causing social and environmental conflicts that may in turn affect the resilience of the global food system. However, the land and water demands of land-based agriculture, especially livestock production, are far greater on a unit output basis.

For a full exploration of the wider impacts associated with fisheries and aquaculture, see the Sect. 1.4.

7 Carbon Storage in the Seabed

This section analyses the potential mitigation impact of storing carbon in the seabed.

The ocean naturally contains nearly 150,000 $GtCO_2e$. This dwarfs the 2000 $GtCO_2e$ in the atmosphere and 7300 $GtCO_2e$ in the land-bqa biosphere. Each year, as a consequence of human activities, approximately 10 billion tonnes of CO_2, or about 25–30% of anthropogenic CO_2 emissions, enters the ocean (Global Carbon Project 2018). As a result, there is considerable theoretical potential to store CO_2 (once captured and compressed) in the ocean in ways that substantially reduce adverse environmental impacts relative to the environmental impacts that occur as a result of atmospheric release of CO_2 (GESAMP 2019).

However, any proposals for ocean-based carbon storage, including storage in the seabed, must be considered in light of the substantial risks to the ocean environment and its ecosystems (Kroeker et al. 2013; Gattuso et al. 2018; Pörtner et al. 2014) and the associated technical, economic, social, and political challenges. Options for ocean carbon storage differ, depending on whether the source CO_2 is concentrated, (e.g., captured from power plant flue gas) or diffuse (e.g. atmospheric CO_2). The options may also differ as to whether the stored CO_2 is concentrated (e.g., in storage reservoirs) or is to be diffused (e.g., mixed into deep ocean waters). The options also differ in the form in which the CO_2 is sourced (from power plants, the atmosphere, or biomass) and in which it is stored (as molecular CO_2, as ions with charge balanced by added alkalinity, or as organic carbon). Table 17.12 summarizes the options most often discussed for ocean-based carbon storage.

Note that vertical ocean pipes are not addressed in this document because the most reliable available science indicates that such pipes would bring carbon-enriched water up from the deep, and thus not be effective at storing carbon in the ocean (Dutreuil et al. 2009; Oschlies et al. 2010; Kwiatkowski et al. 2015). Furthermore, several studies have suggested that CO_2 extraction from seawater would be feasible at commercial scale; however, insufficient information is available to assess the feasibility and system-level effectiveness of these options. For example, Willauer et al. (2014) describe a CO_2-removal process that involves an effluent returned to the ocean with a pH of 6, with no consideration of how that effluent might affect the ocean environment.

The storage of highly concentrated and compressed CO_2 streams in the seabed is the only option that is currently deployed at industrial scale and is therefore the only option that has a reasonable likelihood of being deployed at large scale by 2030 and beyond. To date, sub seabed storage has been used only to facilitate the extraction of natural gas from the Norwegian coast. Thus, the net flux of carbon has been from the seafloor to the atmosphere, not the other way around. The process returns excess CO_2 back to the sub surface that comes up with the natural gas. If not for extracting the natural gas, the CO_2 have have remained in the sub surface. The rest of the options presented in Table 17.13 remain untested at an industrial scale.

All assessments of ocean-based carbon storage potential should therefore be greeted with considerabe caution. Further research is necessary to narrow the uncertainties and ensure informed decision-making about the viability of ocean-based carbon storage. As a result of the significant gaps in knowledge in terms of ability to scale the range of ocean-based storage options and the very real risks to ocean ecosystems, the only option that has been assessed in this report is seabed storage. The full range of options contained in Table 17.13 is discussed in Box 17.8 at the end of this section.

7.1 Mitigation Potential

Carbon capture and storage of CO_2 in the seabed requires that CO_2 be concentrated, compressed, and transported to the deep-water injection site. Based on a number of studies, Adams and Caldeira (2008) concluded that the costs for capture and compression from a fossil fuel power plant would be around US $20 to US $95 per tonne of CO_2 captured, and the cost of transportation approximately US $1 to US $10 per tonne of CO_2.

The cost of geological storage was estimated at US $0.5 to US $10.0 per tonne of CO_2 injected, and US $5 to US $30 per tonne of CO_2 (>1000 m).

Electricity generation accounts for about 25% of global GHG emissions (IPCC 2014) with up to 10% (or about 2.5% of the total) of electricity generation being located near enough to the ocean to make ocean disposal of power plant CO_2 economically feasible (IPCC 2005). Thus, the total potential for ocean-based carbon storage by seabed storage may be up to 2.5% of global CO_2 emissions. At 2018 global CO_2 emission rates, this would yield an estimated mitigation potential of 1 $GtCO_2e$. As it would be extremely difficult to retrofit most existing power plants with carbon capture and storage facilities and pipes to the deep ocean by 2030; the economic potential in 2030 is likely to be less by a factor of 10 (about 0.1 $GtCO_2e$).

By 2050, a greater fraction of the technical potential might be achieved and the environmental risks suitably understood and mitigated so that other ocean-based storage options might be developed, so it is conceivable that several billion tonnes of CO_2e could be stored in the ocean each year by 2050. However, this has not been included in our calculations for this report, given the degree of current uncertainty of the technical, environmental, social, and political feasibility of these additional options.

The first three options shown in Table 17.12 involve different forms of carbon capture and storage for coastal powerplants and as such should also be considered as interchangeable. Based on this, and the assumptions and limitations outlined above, it is possible to propose a total mitigation potential in 2030 of 0.25 to 1.0 $GtCO_2e$, and of 0.5 to 2.0 $GtCO_2e$ in 2050 (Table 17.14).

Table 17.13 CO_2 characteristics of storage options for deep sea and/or seabed storage

Option	CO_2 source	CO_2 storage reservoir	Initial CO_2 storage form	Technical readiness	Cost profile	Principal environmental concerns	Key references
CO_2 injection to seabed	Power plant	Geologic reservoirs beneath seafloor	Molecular CO_2	High to medium	High	Operational activities; leakage to ocean; impacts on deep sea ecosystems	SRCCS (2005)
CO_2 storage contained on top of the seafloor (CO_2 injection into CO_2 lakes or containment vessels)	Power plant	Reservoirs on seafloor separated from the ocean by physical or chemical barrier	Molecular CO_2	Low	High	Leakage to ocean; damage to seafloor; operational activities; impacts on deep sea ecosystems	SRCCS (2005), Palmer et al. (2007)
CO_2 injection into deep ocean	Power plant	Deep ocean	Molecular CO_2	High	High	Ocean acidification; leakage to atmosphere; operational activities; impacts on deep-sea ecosystems	SRCCS (2005)
Carbonate dissolution (CO_2 release to the ocean, buffered by dissolved carbonate minerals)	Power plant	Ocean	Bicarbonate ions	Medium	High	Possible contaminants; local impacts on ecosystems	SRCCS (2005), Rau and Caldeira (1999)
Alkalinity addition	Atmosphere	Ocean	Bicarbonate ions	Medium	High	Unintended ecosystem effects	SRCCS (2005)
Ocean fertilisation	Atmosphere	Ocean	Organic carbon	Low	Medium	Interference with marine ecosystems; ocean acidification; leakage to atmosphere	Williamson et al. (2012)

Source: Authors
Notes: "Power plant" is used to refer generically to concentrated CO_2 streams, and "Atmosphere" to diffuse sources. For technical readiness, "High" means could likely be accomplished within several years; "Medium" means no major technical barrier; "Low" means that there are substantial uncertainties regarding technical feasibility and/or geophysical effectiveness. For costs, "High" means comparable to carbon capture from power plants with geologic storage on land; "Medium" means lower, but still substantial, costs. These evaluations represent subjective assessments by the authors on the basis of available information. The "CO_2-storage reservoir" and "Initial storage forms" columns in Table 17.12 *indicate that in the case of some ocean storage options, the storage is isolated from the large volume of ocean seawater. In other options, the carbon is distributed through the ocean volume but primarily in forms that do not exchange with the atmosphere or cause ocean acidification. Lastly, some proposed options simply transfer molecular CO_2 to the deep ocean; in which case storage might not be permanent and would contribute to ocean acidification and impacts on marine organisms and ecosystems*

Table 17.14 Mitigation potential of carbon storage options in 2030 and 2050 ($GtCO_2e$)

Ocean-based climate action area	Mitigation option	Description	Mitigation potential, 2030 ($GtCO_2e$/year)	Mitigation potential, 2050 ($GtCO_2e$/year)
Seabed carbon storage	CO_2 storage in the seabed	Geological storage offshore of CO_2 below the seabed	0.25–1.00	0.5–2.0
Total			**0.25–1.00**	**0.5–2.0**

Source: Authors
Note: These values represent reasonable estimates of the lower and upper bounds of potential deployment rate in a highly aggressive mitigation scenario

7.2 Methodology

The physical potential of sub-seabed storage is thought to be very large, as there is an abundance of settings in which CO_2 could potentially be stored. The physical capacity of carbon storage in the marine environment has been estimated to exceed 10,000 Gt of CO_2 (36,000 $GtCO_2$) in the seafloor surrounding the contiguous United States alone (House et al. 2006). This is similar in magnitude to the total amount of the fossil fuel resource (IPCC 2014). More realistically, the capacity for storage in the seafloor will depend on costs of transport of CO_2 from the concentrated source, and the cost of emplacement in seabed geologic formations.

On the time frames considered here (2030–2050), seabed storage will be limited not by geophysical capacity, but rather by techno-economic and possibly sociopolitical factors.

Costs are somewhat higher than for land-based geologic carbon storage, but, even in the ocean case, the primary cost driver is the cost of separating and compressing the relatively pure CO_2 stream (SRCCS 2005). In the 1.5 °C stabilisation scenarios considered by the IPCC (2018), total carbon capture and storage amounts to year 2050 (cumulative) are typically about 100 $GtCO_2$, but range to over 400 $GtCO_2$ in some models. The corresponding magnitude for 2030 is of the order of several billion tonnes of CO_2.

If seabed storage were to comprise 30% of total carbon capture and storage, that would suggest an average rate of seabed carbon storage of the order of 1 $GtCO_2$/year. It is reasonable to presume that the most advantageous settings would be used first, so it is plausible that half of the average rate could be reached by 2030, approximately 0.5 $GtCO_2$/year. As a rough approximation of uncertainty, we halve and double these values.

7.3 Policy Interventions Needed to Achieve Mitigation Potential

Seabed storage would occur in territorial waters so the primary regulatory bodies would be national. The primary environmental concerns, if everything works as planned, involve local environmental disturbance from industrial operations. International implications arise related principally to the risk or event of failure.

Continuing to increase scientific understanding is essential if these technologies are to be used safely and without unintended consequences.

7.4 Technology Needs

Carbon storage in the seabed does not involve major technical advances and is an extension of activities that are already being carried out on land. Scaling up the technologies to match the scale of the problem, however, is a major challenge.

An exception, where technological advances are required, would be materials science questions relating to long-lasting containment of CO_2 in a deep seafloor environment. For the most part, noncost barriers primarily have to do with unintended environmental consequences, effectiveness, and verifiability, and not the state of technological development.

7.5 Priority Areas for Further Research

The primary barriers to use of the ocean as a carbon storage reservoir involve environmental concerns (Box 17.8). However, if done properly, some of these techniques could potentially isolate CO_2 away from both the atmosphere and the majority of ocean waters for millions of years.

Other techniques might have cobenefits, for instance, reducing associated impacts such as ocean acidification. On the other hand, seabed storage of CO_2 approaches, if deployed unwisely, could contribute to ocean acidification and damage ocean ecosystems by impacting chemical, physical, and ecological processes at a large scale.

Further research will help us understand the full implications of carbon storage options. Box 17.9 profiles the status of current knowledge for the other ocean-based carbon storage options not quantified in this report.

Box 17.8 Wider Impacts Associated with Options for Seabed Storage

Potential Cobenefits:

- Potential benefits in terms of direct job creation, as well as job retention in harder-to-abate sectors (e.g., heavy industries and fossil fuel based sectors) by allowing them to function with appropriate CCS infrastructure investment/development.

Potential Trade-Offs:

- Injection of CO_2 into submarine geological structures has the potential for CO_2 to leak back into the marine environment, affecting the health and function of marine organisms, especially with respect to the resulting localised ocean acidification. The gravity of the impacts at community level is unknown.
- Potentially serious impacts on little-understood deep-sea ecosystems, which are the largest habitat on the planet.

For a full exploration of the wider impacts associated with ocean-based transport, see the Sect. 1.4 of this report.

Box 17.9. Additional Ocean-Based Carbon Storage Options not Quantified in this Report

Containment of CO_2 on the Seafloor

Below about 3000 m depth, compressed CO_2 is denser than seawater and so will tend to sink or remain on the seafloor. This has led to the proposal that CO_2 might be stored in lakes on the seafloor (Shindo et al. 1993). However, in the absence of a physical or chemical barrier, such CO_2 lakes would be expected to dissolve into the overlying seawater (SRCCS 2005). Little work has gone into developing such barriers, although it has been estimated that the cost of creating a physical barrier would be small, perhaps as low as US $0.035 per tonne of CO_2 stored (Palmer et al. 2007). Because of the vastness of the seafloor, there is no practical constraint on the amount of CO_2 that could be stored in this way, and if concerns over physical integrity of the barrier and effects on the underlying seafloor can be addressed, the primary determinant of the scalability of this approach is likely to be the costs of producing a relatively pure CO_2 stream, and those of transporting and emplacing the captured CO_2 in these storage reservoirs.

Because containment of CO_2 on the seafloor has never been demonstrated for any substantial amount of time, the lower bound on the potential for this technology class must be regarded as zero. However, if demonstrated containment can prove cost-effective, the potential for containment storage on the seafloor could be as large as that estimated for sub-seabed storage.

Injection of CO_2 Into the Deep Ocean

Injection of CO_2 into the deep ocean is much simpler than storage beneath or on the seafloor. Deep-sea disposal and containment of CO_2, however, raises concerns about environmental effects (e.g., impacts of ocean acidification) and leakage back to the atmosphere. As noted above, most of the waste CO_2 released to the atmosphere by human activities will ultimately reside in the ocean. Therefore, placing CO_2 in the ocean instead of in the atmosphere could be expected to reduce the climatic consequences of CO_2 emission. It would also tend to reduce the amount of ocean acidification experienced in the ocean surface but at the cost of increased ocean acidification in the deep ocean. If the entire ocean were allowed to have the same pH change as the near-surface ocean (about 0.1 pH units), the ocean could store a total of about 2000 $GtCO_2$ (SRCCS 2005). Over one-quarter of this amount (GCP 2018) has already been absorbed from the atmosphere, leaving about 1500 $GtCO_2$ of storage capacity. If a pH change of 0.2 were deemed to be acceptable (corresponding to an atmospheric CO_2 concentration of about 600 parts per million [ppm]), the amount of remaining storage capacity would be about 3300 $GtCO_2$ (or roughly 10% of the estimated remaining fossil fuel resource).

Such changes in the chemistry of the ocean would be accompanied by a growing list of impacts on organisms, such as reef-building corals, seaweeds, invertebrates, and fish, among many others (Kroeker et al. 2013; Gattuso et al. 2018; Hoegh-Guldberg et al. 2014, 2018). In addition to decreasing the ability of organisms to maintain shells and skeletons, a wide variety of other impacts have been reported from disruptions of reproduction, gas exchange, and neural systems (Kroeker et al. 2013). Damage to deep-water ecosystems has been reported, and, though its extent has not been well documented, it is suspected to be large. These impacts have generated considerable concern about such fundamental changes to biological systems, especially given the long time (>10,000 years) it takes to reverse this change through the dissolution of carbonates and other processes (IPCC 2013).

Direct injection into the deep ocean is likely to be comparable to the cost of injecting CO_2 into the seabed. However, there is real concern about using the ocean waters as a waste disposal site for CO_2 from human industrial processes. Furthermore, storage of CO_2 freely dissolved in the deep ocean eventually exchanges with the atmosphere, so the isolation of CO_2 is not permanent. Therefore, it is far from certain that global political systems will encourage and credit deep-sea CO_2 injection. A reasonable estimate on the lower bound of conceivable deployment rate in a highly aggressive mitigation strategy would therefore range from zero to the rate estimated for seabed disposal.

Carbonate Dissolution

Most of the ocean acidification caused by adding CO_2 in the ocean will ultimately be neutralised over the longer term by the dissolution (and slower accumulation) of carbonate minerals on the seafloor, and from rock weathering products delivered to the ocean by rivers. Carbonate minerals will not dissolve in the surface ocean due to high levels of carbonate saturation (i.e., concentrations that are so high that they promote precipitation not dissolution). This fact led to the idea of using power plant flue gases to dissolve carbonate minerals, which would allow CO_2 to be stored in the ocean with little adverse impact on ocean pH or mineral saturation states in the ocean (Rau and Caldeira 1999; Caldeira and Rau 2000). About 2.5 tonnes of carbonate minerals would need to be dissolved, however, for each tonne of CO_2 stored in this way. This would require a huge and unprecedented mining infrastructure and would entail massive materials-handling costs and logistics.

The costs have been estimated to be lower than for injection of relatively pure CO_2 streams for cases in which the power plant is coastally located with access to carbonate mineral resources, because this approach does not require costly separation of CO_2 from power plant flue gases and subsequent pressurisation (Rau and Caldeira 1999). However, since such facilities have never been built, cost estimates must be regarded as speculative.

Regardless, such approaches would likely be cost-competitive only in locations where both carbonate minerals and CO_2 could be delivered to the ocean at low cost, which is likely to be the case for less than 10% of total power plant CO_2 emissions. Environmental concerns include the effects of a large scale-up of carbonate mineral mining and possible impacts on the marine environment of contaminants or incompletely dissolved particles.

Rau and Caldeira (1999) estimated that perhaps 10% of electricity production might be located suitably near carbonate minerals to make carbonate dissolution a cost-effective approach to carbon storage. However, there are environmental concerns about processing large amounts of seawater through carbonate reactors and using the ocean as a waste disposal site.

A plausible range for this approach might therefore be from 0 to 10% of the magnitude estimated for all of carbon capture and storage (IPCC 2018).

Alkalinity Addition

The acidity caused by CO_2 in the ocean, and the propensity of CO_2 to de-gas from the ocean to the atmosphere, can be reduced or eliminated by the addition of alkaline (also known as basic) minerals (Renforth and Henderson 2017). Addition of these minerals to the ocean (Kheshgi 1995) could result in the ocean absorbing additional CO_2 from the atmosphere (González and Ilyina 2016). Over 2.5 tonnes of rock would need to be mined and crushed to a fine powder (to overcome slow dissolution kinetics) for each tonne of CO_2 stored in the ocean in this manner. As with carbonate dissolution, this option raises concerns related to huge expansion of mining infrastructure (silicate rock mining might need to expand by three orders of magnitude) (González and Ilyina 2016). Further, many of the proposed silicate source rocks contain substantial amounts of heavy metals (Hartmann et al. 2013) and thus raise concerns about introduction of heavy metals into the marine environment. Because silicate rocks are abundant in Earth's crust, there is no practical physical constraint, but if applied at scale, such ocean CO_2 storage would represent "an unprecedented ocean biogeochemistry perturbation with unknown ecological consequences" (González and Ilyina 2016).

Renforth and Henderson (2017) estimate the potential for very ambitious rates of deployment: A 50 $MtCO_2$/year initial investment (roughly equivalent to the emissions of 10 of the largest cement plants in operation), followed by ramping up this capacity by about 7%/year, could achieve mitigation of 0.1 $GtCO_2$/year by 2020. If the same initial investment were ramped up by about 10%/year, mitigation could reach 1 $GtCO_2$/year. These might be considered plausible upper bounds. The lower bound must be considered zero, because it is not clear that the international community will accept adding large amounts of dissolved and/or particulate matter to the ocean as a climate mitigation strategy.

Ocean Fertilisation

Ocean fertilisation has been proposed as a means of transferring carbon from the atmosphere to the ocean. The basic idea is to add inorganic nutrients to the near-surface ocean, thereby stimulating biological production of organic matter. Some of this organic matter would sink to the deeper ocean, where it would be metabolised and dissolved in the deeper ocean waters. Some additional CO_2 would be absorbed from the atmosphere to replace the carbon that was removed by this additional biological activity. Some researchers have advocated fertilising the ocean with major nutrients that are often limiting, such as phosphate or nitrogen (Harrison 2017).

Because of the large amounts of nutrients involved, however, most of the focus has been on environments in which the major nutrients are abundant, but other minor nutrients such as iron limit marine productivity (Williamson et al. 2012). The efficacy of ocean fertilisation is reduced by shallow oxidation of sinking organic matter with the relatively rapid return of carbon to the surface ocean. This phenomenon has also attracted concern regarding the increased respiration rates stimulated by the additional organic carbon falling into the deep ocean, leading to decreased oxygen at depth and an increased risk of dead zones (Hoegh-Guldberg et al. 2014). Further, fertilisation with micronutrients utilises major nutrients that might otherwise have supported productivity elsewhere; some local increase in productivity may come at the expense of decreased productivity elsewhere at a later time.

The geophysical potential of ocean iron fertilisation has been estimated to be in the range of 0.25–0.75 $GtCO_2$e/year averaged over a 100-year period (Williamson et al. 2012). Small-scale experiments to date suggest that adding iron dramatically changes the composition of the phytoplankton, which in turn triggers changes in zooplankton, fishes, and other higher trophic species. Many of these consequences are little understood. Concerns regarding effectiveness, permanence, verification, and unintended consequences, combined with concerns about disposing of CO_2 in deeper ocean waters, mean that the lower bound on potential must be regarded as zero.

The geophysical potential of ocean fertilisation is estimated to be about 1.8 $GtCO_2$e/year. Plausibly, 10% of this geophysical potential could be achieved by 2030 and about half by 2050.

While the geophysical potential of ocean-based storage of captured CO_2 is large, the technical and economic mitigation potential is likely to be constrained by the technical challenges of making carbon capture and storage economically viable.

Some of these technologies are likely to be technically feasible and cost-effective. Given the importance of reducing the amount of excess CO_2 in the atmosphere and ocean, understanding the full set of the impact of these solutions on ecosystems, such as the deep sea, is critical.

8 Wider Impacts of Ocean-based Actions

This section presents analysis of the wider impacts (both positive and negative) of each of the five ocean-based intervention areas on the long-term Sustainable Development Dimensions and 2030 Sustainable Development Goals.

Increased efforts to reduce GHG emissions will affect multiple dimensions of long-term sustainable development, well-being, and governance in the form of cobenefits and trade-offs (IPCC 2018). Many interventions are likely to affect countries' ability to achieve targets established within the framework of the UN 2030 Sustainable Developmental Goals (SDGs). Taking these wider impacts into account can help provide a more informed and holistic picture of pursuing ocean-based climate solutions.

The IPCC Special Report on 1.5 °C scenarios integrated some of these wider impacts into its assessment of mitigation options; however, the ocean received relatively little attention. We address this major knowledge gap by focusing on four dimensions where wider impacts may be expected: the environment, the economy, society, and governance. These dimensions, their associated impact categories, and relevant UN SDGs are mapped in Table 17.15.

8.1 Methodology

Wider impacts are evaluated with a weighted scoring method and an associated assessment of confidence levels. Our method is based on a similar approach adopted in Chap. 5 of the IPCC 1.5 °C Special Report (Roy et al. 2018). Based on a review of the existing literature and expert judgment (Box 17.9), the performance of each ocean-based mitigation option was assessed within each of the wider-impact dimensions (Table 17.15). The impact was described, scored, and weighted based on the following factors:

- **Direction of impact:** The positive and/or negative direction of the impact of the mitigation option on the wider-impact dimensions and SDG goals was recorded. If a mitigation option was identified as having both a positive and negative impact, both were recorded. The net direction of impact was determined by the sum of the positive and negative impact scores.
- **Linkage score:** The strength of the relationship between the mitigation option and the indicator was scored. Scores range from +3 (indivisible) to −3 (cancelling), with a "zero" score indicating 'consistent', but with neither a positive nor negative impact (Nilsson et al. 2016). A zero score also indicates that no relevant literature was found during this review.
- **Confidence in assessment:** The confidence assessment was developed to reflect the robustness of the linkage scores. Confidence levels ranging from high to low were determined based on the level of evidence (number of studies and other articles) and level of agreement on the evidence presented in the literature. For each linkage score, an assessment of confidence was assigned, where increasing levels of evidence and degrees of agreement are correlated with increasing confidence (Mastrandrea et al. 2010).

Table 17.15 Wider impact dimensions explored in the report

Wider-impact dimensions	Associated impact categories	Links with near-term sustainable development goal targets and indicators
Environment	Impact on marine and terrestrial biodiversity, water quality, land use, and adaptability of ecosystems and human settlements to climate change	SDGs 6, 12, 14, 15
Economy	Impact on employment, household incomes, profits and/or revenues of firms, innovation, supply of clean energy, and economic growth	SDGs 7, 8, 9, 11
Society	Impact on human health outcomes, poverty reduction and food security targets, regional income inequality, quality of education, and gender equity	SDGs 1, 2, 3, 4, 5, and 10
Governance	Impact on national and local institutions, participation in global governance, global partnership for sustainable development, and capacity building	SDG 16 and 17

List of sustainable development goals reviewed:

Box 17.10. Literature Review Method and Types of Evidence Analysed

A two-step procedure was followed as part of a review of the literature on wider impact analysis. First, the databases Scopus and Google Scholar, and the search engine Google were used in a literature search using various combinations of keywords and short search strings such as "Ocean energy" AND "sustainability," "Ocean" AND "CCS," AND "sustainability." Second, the findings from the literature review were recorded and scored. Additional evidence was included based on feedback obtained through the expert review process. The types of evidence and number of studies are summarised in the table below. Please refer to Annex for further information on the scores and confidence assessments.

Types of literature	Description	Number
Case study	Case studies specific to countries or region	10
Experimental	Results based on experiments	11
Project-based	Results reported based on project-level impacts	2
Quantitative analysis	Studies that have employed econometric, graphical, or statistical tools to find the impact of any intervention. This includes meta-analysis, scenario analysis, spatial analysis, and other modelling assessments	46
Review paper	Studies that exclusively mention "review" in their objective or methods	16
Summary paper	This includes commentary, newspaper articles, discussion papers, policy briefs, and newsletters from international organisations	14
Website	Relevant information (such as examples of ongoing restoration programmes) provided on web pages owned and curated by international organisations	5
Report	Policy and analysis reports from international organisations, such as OECD, ETC, IRENA, FAO, IEA	31
Qualitative	Academic papers and reports that present qualitative discussion of the impact of policies and international agreements	4
Total number		**139**

8.2 General Findings of the Wider-Impacts Analysis

All mitigation options demonstrated both positive and negative impacts, with varying strengths, across the four wider-impact dimensions (Fig. 17.12). The headline messages can be broadly summarized as follows:

- All ocean-based mitigation options generate many cobenefits. Overall, cobenefits outweigh trade-offs and risks. However, these risks and trade-offs cannot be ignored, and concerted action to address negative impacts will help enhance net positive outcomes.
- Of the five ocean intervention areas, protecting and restoring coastal and marine ecosystems, fisheries and aquaculture, and ocean-based energy have a positive impact on the largest number of sustainable development dimensions. When looking at individual mitigation options, protection and restoration of vegetated coastal habitats (mangroves, salt marshes and seagrasses) and offshore renewable energy positively impact the largest number of sustainable development dimensions.
- Mitigation options were observed to have the strongest links with the social and economic dimensions, implying that implementing these options in a sustainable manner would result in benefits in terms of higher employment in ocean-based industries, gains from technology spillover, increase in revenues and profits to firms, improvement in livelihoods of local communities, better human health outcomes, contribution towards global food security targets, and potential to ensure greater gender parity as ocean-based industries expand.
- Protection and restoration of mangroves, salt marshes, and seagrasses has the highest number of and most strongly positive impacts on all the environmental dimensions assessed, indicating that there is potential to achieve many environmental cobenefits, including increased biodiversity-related services, coastal resilience, and climate change adaptation benefits.
- Trade-offs and risks are varied. Mitigation options aimed at recovering ocean biomass can negatively impact poverty reduction and employment targets and can limit progress on food security targets in the short term. Lack of community-level engagement on blue carbon restoration work can lead to negative outcomes for small-scale fishers who play a strategic role in providing jobs, supplying nutritional needs, and maintaining economic sustainability.
- Environmental risks include impacts on coastal ecosystems or marine species from unassessed growth in ocean-based activities. Shifting diets, fisheries, and aquaculture

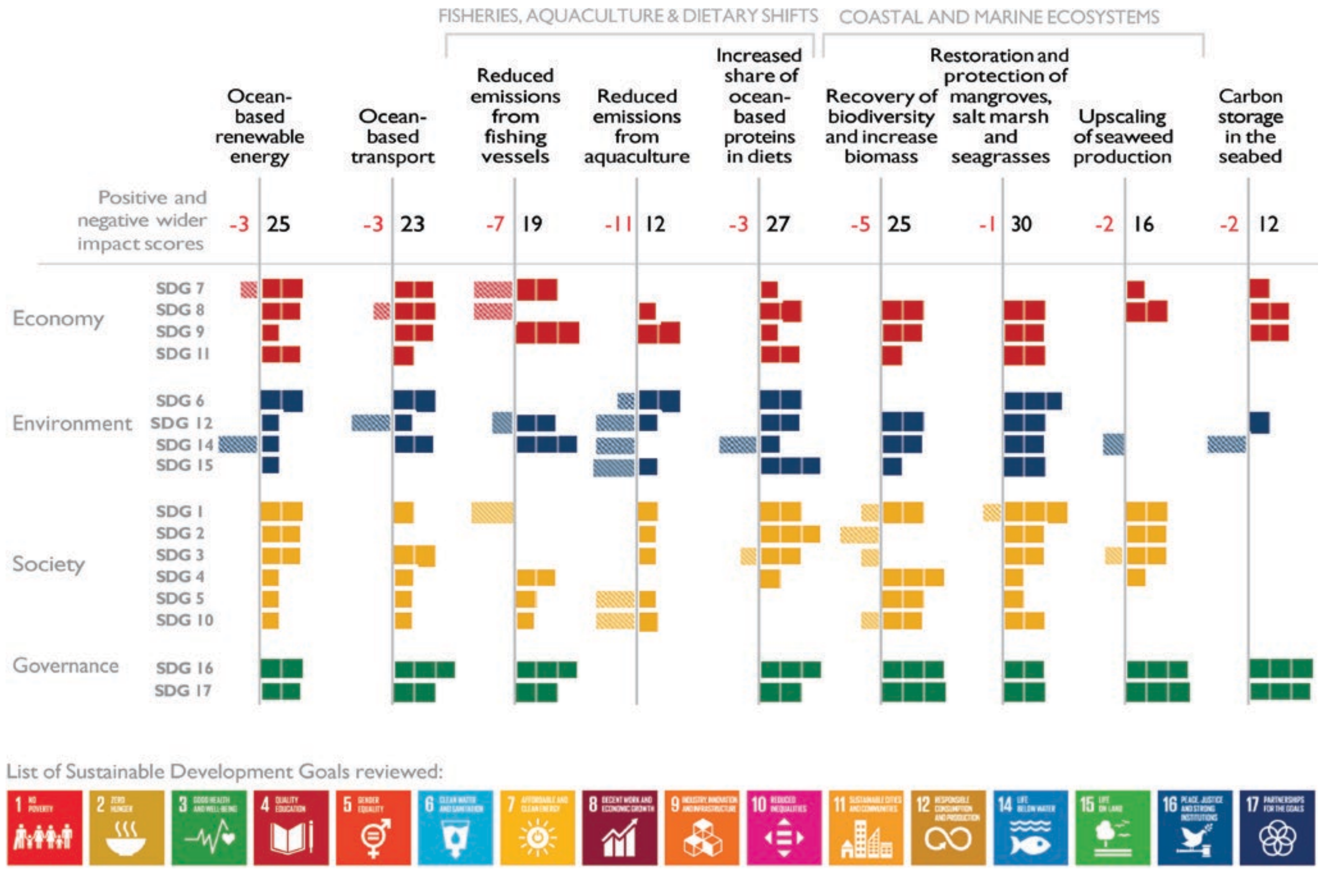

Fig. 17.12 Linkage scores of ocean-based interventions and selected mitigation options across the wider impact dimensions. (*Source: Authors. Notes: Wider-impact dimensions cover various sustainable development dimension as well as 2030 Sustainable Development Goals (SDG). The figure shows the relative strength of the relationship between a selected set of ocean-based mitigation options and the SDGs. For each mitigation option, the positive linkage score with a particular SDG (depicted with solid bars) is shown in the right-hand column and negative linkage score (depicted by shaded bars) in the left-hand column. Scores range from +3 (indivisible) to −3 (cancelling)* (Nilsson et al. 2016). *A zero score (no bar and no colour) means no impact was found in this review of the literature. Each colour represents a particular wider impact dimension: Red bars for economy (SDG 7, 8, 9, 11); blue bars for environment (SDG6, SDG12, SDG14, SDG15); yellow bars for society (SDG1, SDG2, SDG3, SDG4, SDG5, SDG10) and green bars for Governance (SDG 16, SDG 17). Further information on the linkage scores and the associated confidence levels are provided in the Annex)*

have a negative impact on the largest number of sustainable development dimensions.

- Some of these risks and trade-offs can be adequately addressed via stakeholder engagement, inclusive management policies, monitoring, and effective marine planning. Others will require further research on their implications and in some instances will call for significant action on the part of decision-makers and policy implementers to ensure that negative impacts are reduced.
- All ocean-based mitigation options will need strong national institutions; engagement by business, industry, and communities; and international cooperation to ensure their effective implementation.

8.3 Detailed Findings of the Wider-Impact Analysis

8.3.1 Ocean-Based Renewable Energy

Effective Marine Spatial Planning, in Combination with Emerging Ocean Energy Technologies, will Be Effective in Mitigating Biodiversity Loss from Ocean Energy Technologies and Reinforcing Biodiversity Cobenefits (High Confidence)

Offshore wind structures have positive and long-term effects on marine species because they provide new habitat in the form of artificial reefs and because fishing, mainly trawling, tend to be restricted in their vicinity (IRENA 2018a; Dinh and McKeogh 2018). In contrast to offshore oil and gas installations, there is little risk of pollution, and no need for the development of new sites in response to long-term exhaustion of the resource (Spalding and de Fontabert 2007). Risks of developing ocean-based energy include biological invasions, noise and disturbance vibrations to marine species, collisions between birds and wind turbine rotors, and the presence of electromagnetic fields that can disrupt marine life and benthic habitats (MERiFIC 2012; IRENA 2017; Langhamer 2012). However, studies have shown that most perceptions of environmental impacts from ocean-based renewable devices arise from uncertainty or lack of definitive data about the real impacts (Copping et al. 2016). While it is important to acknowledge all the impacts on the marine environment as ocean-based renewable industry develops, some of the perceived risks are likely to be small and can be avoided or mitigated (Copping et al. 2016). In the case of risks like collision with seabirds and impacts on migratory cetaceans, marine spatial planning appears to be appropriate mechanism to reduce risks to manageable levels (Best and Halpin 2019).

Ocean-Based Renewables will have a Positive Impact on Reducing Water Use Compared to Fossil Fuel–Based Technologies (Medium Confidence)

Offshore wind uses no water directly, and there should be an overall reduction in freshwater use compared to generating power from fossil fuels (Macknick et al. 2011). There is potential to develop ocean energy technologies for a range of purposes, including desalination for drinking water (OES 2011).

Replacing Fossil Fuels with Ocean-Based Renewable Energy Contributes to Positive Health Outcomes (Medium Confidence)

The health benefits of moving to ocean-based renewable energy for power generation would be significant, particularly for regions that rely more heavily on coal and oil to generate electricity. Offshore wind in the Mid-Atlantic region of the United States could produce health and climate benefits estimated at between US $54 and US $120 per MWh of generation, with the largest simulated facility (3000 MW off the coast of New Jersey) producing approximately US $690 million in benefits (Buonocore et al. 2016).

Expansion of Ocean-Based Renewable Energy has the Potential to Promote Gender Equity (Low Confidence)

A survey by IRENA revealed that women represent a higher proportion of full-time employees in the renewable energy industry, compared to their representation in the global oil and gas industry (IRENA 2019a, b, c, d). However, their participation is still low in science, technology, engineering, and mathematics (STEM) jobs compared to administrative jobs. Greater participation of women would allow the sector to unleash female talent while ensuring equitable distribution of socioeconomic opportunities (IRENA 2019a, b, c, d).

Expansion of Ocean-Based Renewable Energy Leads to Job Creation and Economic Growth (High Confidence)

Estimates predict direct full-time employment in offshore wind will be around 435,000 globally by 2030 (OECD 2016). Analysis by Ocean Energy Systems shows that deployment of other forms of ocean energy (tidal range, wave power, and ocean thermal energy) can provide significant benefits in terms of new jobs and additional investments (OES 2017). Ocean-based renewable energy has the potential to provide employment to coastal communities and will benefit workers transitioning from declining offshore fossil fuel industries (Poulsen and Lema 2017; IRENA 2018a, b; Scottish Enterprise n.d.). However, the net global impacts of ocean-based energy on jobs are uncertain.

Opportunities for Innovation Are Expected to Emerge with Expansion of Clean Ocean Energy, Promoting Scientific Research and Resulting in Upgraded Technological Capabilities (High Confidence)

The ocean-based energy industry has experienced rapid growth in installed capacity, ongoing improvements in costs and performance, and increased technological sophistication (IRENA 2018a, b). Innovations in clean ocean energy include the potential to be integrated into and codeveloped with algae-growing facilities and aquaculture farms, and the ability to provide emission-free and drought-resistant drinking water to larger municipalities along the coast (OES 2015; Dirks et al. 2018; Buck et al. 2018). These technologies simultaneously help reduce GHG emissions and increase energy security and diversity (Dinh and McKeogh 2019). Further, there is a trend towards locating offshore energy production to support the expansion of offshore aquaculture production. A number of projects worldwide have started to invest in technologies and system design needed to enable species farming in high-energy environments (Buck et al. 2018).

8.3.2 Ocean-Based Transport

Reducing Emissions from Shipping Vessels will Help Mitigate Ocean Acidification (Medium Confidence)

Strong acids formed from shipping emissions can produce seasonal "hotspots" of ocean acidification in ocean areas close to busy shipping lanes. Hotspots have negative effects on local marine ecology and commercially farmed seafood species (Hassellöv et al. 2013).

Cleaner Marine Shipping Fuels will Reinforce Positive Human Health Outcomes (High Confidence)

Reduced sulphur content of fuel oil used by ships will have beneficial impacts on human health, particularly the health of people living in port cities and coastal communities. Cleaner marine fuels are estimated to reduce premature mortality and morbidity by 34% and 54%, respectively. This represents a roughly 2.6% global reduction in cardiovascular and lung cancer deaths caused by small particulate matter ($PM_{2.5}$) and a roughly 3.6% global reduction in incidence of childhood asthma (Sofiev et al. 2018).

Mitigation Options to Reduce Emissions from Shipping Can Encourage Innovation and Upgrade the Technological Capabilities of the Sector (High Confidence)

Rapid development in power train technology will enable international maritime transport to use alternative and less-polluting fuels, such as hydrogen. The design of ships is being improved to enable them to move more quickly through water, while using less fuel. A complex array of internet-of-things sensors is being developed that will allow collection of data around tidal streams, wind strength, and visibility. This information can be used to reduce vessel waiting time, enable optimisation of routes, and support the concept of autonomous ships.

Reducing Emissions from Shipping Could Potentially Have a Marginal Impact on the Price of Internationally Traded Commodities (Medium Confidence)

While there could be efficiency and energy savings from better design of ships and route optimisation, the cost to the shipping industry of switching to alternative fuels will be high (ETC Mission Possible 2018; Kizielewiczm 2016; Sislian and Jaegler 2016). This could result in significant increases in voyage and freight costs. However, at least one study finds that these costs will have a marginal impact on the final product price of internationally traded commodities (ETC Mission Possible 2018).

8.3.3 Coastal and Marine Ecosystems

Vegetated Coastal and Habitats (Blue Carbon Ecosystems) Contribute to Climate Change Adaptation by Increasing Coastal Resilience and Reducing the Impact of Sea Level Rise (Very High Confidence) Mitigation Options that Help Recovery of Ocean Biomass Can Also Result in Climate Change Adaptation Benefits (High Confidence)

Vegetated coastal habitats reduce coastal flooding by slowing water flow rates and absorbing storm surges. They accrete vertically over time and thereby reduce the impacts of sea level rise and flooding (Duarte et al. 2013). Communities with more extensive mangrove forests experience significantly lower losses from exposure to cyclones than communities without mangroves (Hochard et al. 2019). Increased abundance of marine species is expected to enhance the productivity of surrounding areas, which can help buffer against climate impacts and increase their resilience (Gattuso et al. 2018).

Vegetated Coastal Habitats Offer High Biodiversity Benefits to Terrestrial and Marine Ecosystems, Including Fisheries (Very High Confidence)

Vegetated coastal habitats are used by a remarkable number of marine and terrestrial animals (Li et al. 2018; Rog et al. 2017), including species important for fisheries (Carrasquila Henao and Juanes 2017). Dense vegetated habitats buffer acidification as primary production creates high net pH (Kapsenberg and Cyronak 2019; Hendriks et al. 2014; Krause-Jensen et al. 2016; Wahl et al. 2018). Dense mangroves trap and stabilise sediments that buffer the effects of floodwaters and tidal movements, and are coming to be recognised as valuable natural systems that can play an important role in wastewater treatment systems (Ouyang and Guo 2016).

Integration of Social and Gender Considerations into Restoration Policy for Vegetated Coastal Habitats Can Promote Gender Equity and Educational Opportunities (Medium Confidence)

Local educational institutions and programmes spread awareness in communities about the ecological importance of mangrove forests and encourage community members to get involved in mangrove restoration efforts. Integrating social and gender considerations into restoration practice promotes effectiveness of restoration work (Broekhoven 2015; de la Torre-Castro 2019). Also, increasing women participation in decision-making and valuing the traditional and reproductive work of women in households will be important to ensure better governance and policy reform (Gissi et al. 2018; de la Torre-Castro 2019).

Restoring and Protecting Vegetated Coastal Habitats has the Potential to Create Jobs, Promote Economic Growth, and Enhance Research: Involvement of Small-Scale Fishers and Local Stakeholders Throughout the Decision-Making Process Is Crucial to Ensure Delivery of Net Positive Social Outcomes (High Confidence)

Blue carbon projects require development of good practice methods and monitoring (Needelman et al. 2018). Manuals have been developed that support project developers through the various phases of carbon project implementation, including feasibility and site selection, documentation, registration, implementation, and carbon asset management (Emmer et al. 2014). Job creation could follow successful restoration of coastal ecosystems; however, delivering jobs and other positive social outcomes are dependent on the participation of the affected communities throughout the policy development and implementation stages. Pushing forward blue carbon projects without social safeguards to consider demands from local small-scale fishers and other stakeholders who are heavily dependent on coastal resources for economic sustainability can have unintended negative consequences on societal well-being (Barbesgaard 2018; Bennett 2018; Friess et al. 2019a, b).

Seaweed Farming has Low Levels of Environmental Risks Identified for Small-Scale Cultivation Projects (High Confidence)

Seaweed farming may deliver a range of services and benefits and has the associated great advantage of not requiring arable land and irrigation (Duarte et al. 2017). The seaweed farming also offers climate change adaptation benefits (Duarte et al. 2017; Froehlich et al. 2019). However, while small-scale cultivation projects are considered low risk, expansion of the industry will require a more complete understanding of the scale-dependent changes to balance environmental risks and benefits (Campbell et al. 2019). Risks include spreading disease, changing population genetics, and altering the wider local physiochemical environment (Campbell et al. 2019). If not appropriately located, seaweed farms could also affect seagrass beds, and thereby disturb important flows of ecological goods and services (Eklöf et al. 2005). Spatial planning, ongoing monitoring, and proper management are key to mitigating these impacts.

Seaweed Production Can Lead to Job Creation, Economic Growth, and Enhanced Research (Medium Confidence): It Has a Potential Role in Providing Affordable Energy (Low Confidence)

The seaweed cultivation industry currently accounts for around 51% of total mariculture production and was valued at US $11.7 billion in 2016 (FAO 2018; Chopin 2018b). The rapidly expanding business is providing many jobs, predominantly in developing and emerging economies (Cottier-Cook et al. 2016). Seaweed biomass has potential as a source of various biofuels although it is evident that there are significant technological hurdles to be overcome before seaweed biofuel is viable in either energy or economic terms (Milledge et al. 2014).

Seaweed Farming and Restoring Wetlands Strengthen Capacity to Meet Food Security Targets (Medium Confidence): Healthy Mangroves Positively Impact Health Outcomes for Coastal Communities Through Provision of Food and Medicine to Local Residents (Medium Confidence)

Expansion of seaweed farming in several continents is contributing to global food security, supporting rural livelihoods, and alleviating poverty (Cottier-Cook et al. 2016). Healthy mangroves are important to human societies, providing a variety of ecological services that are critical to human livelihoods and food security, such as providing nursery grounds for important species, improving fisheries production, and filtering and detoxifing water (Ramsar Convention on Wetlands 2018). Mangroves are a direct source of food and traditional medicine for local inhabitants (Bandaranayake 1998).

Mitigation Options to Rebuild Ocean Biomass Can Contribute to Poverty Reduction (Low Confidence)

Marine protected areas have contributed to poverty reduction by improving fish catch, creating new jobs in tourism, strengthening local governance, benefitting human health, and enhancing women's opportunities (Leisher et al. 2007). Marine protected areas require monitoring and continuing study that will contribute to our ecological understanding of the ocean and promote scientific innovation (Nippon Foundation 2017).

Mitigation Options to Rebuild Ocean Biomass Can Also Negatively Impact Poverty Reduction and Employment Targets, and Can Limit Progress on Food Security Targets (Low Confidence)

Marine protection can have negative relationships with ending poverty and reducing inequalities (Singh et al. 2018). For example, ending overfishing and harmful fishing subsidies can conflict with targets related to youth employment if fleet capacity is reduced (Singh et al. 2018). These trade-offs may be avoided through stakeholder consultation and implementation. Conflicts may be temporary and, in the long term, potential increases in marine productivity could increase jobs and resources for people. Evidence shows that declines in fish catch pose risks of nutritional deficiency, especially in developing countries (Golden et al. 2016), and reforms to fishery management could dramatically improve overall fish abundance (compared to BAU) while increasing food security and profits (Costello et al. 2016). However, designating marine protected areas may restrict coastal people's access to local marine resources, which could limit progress on SDG targets associated with ending hunger (Singh et al. 2018).

8.3.4 Fisheries, Aquaculture, and Dietary Shifts

Aquaculture Can Present Numerous Societal and Environmental Challenges: Unplanned Aquaculture Expansion in Some Regions Has Negatively Impacted Other Coastal and Terrestrial Ecosystems (High Confidence)

Aquaculture is associated with multiple environmental impacts, such as eutrophication and spread of invasive species. Unplanned growth in shrimp aquaculture has led to the loss of mangrove ecosystems (Valiela et al. 2001; Richards and Friess 2017), which has in turn led to large CO_2 emissions (Murdiyarso et al. 2015), salinisation, erosion, and reduced coastal resilience (Hochard et al. 2019). Integration of mangroves into aquaculture landscapes may restore some ecosystem services (Hochard et al. 2019; Lee et al. 2019).

Improvement in Feed Conversion Ratio and Use of Plant-Based Ingredients in Aquaculture Feed Rather Than Animal By-Products to Meet The Demand of the Rapidly Growing Marine Aquaculture Sector Can Potentially Reduce Water Use (Medium Confidence)

Given the global supply of fishmeal may be near biological limits (Costello et al. 2012), ensuring that feed for a rapidly growing aquaculture sector comes from terrestrial crops or seaweeds rather than animal by-products would have a positive impact on water use. Reduction in feed conversion ratio in aquaculture production also reduces upstream water use. However, increased inclusion of terrestrial plant-based ingredients may lead to competition for land and water, causing social and environmental conflicts, which may in turn affect the resilience of the global food system (Pahlow et al. 2015; Pelletier et al. 2018; Troell et al. 2014; Blanchard et al. 2017; Malcorps et al. 2019). Many traditional crop-based substitutes are themselves carbon-intensive to produce; they can also adversely affect fish or crustacean growth and health, especially for farmed predator species. Consequently, there have been significant efforts in recent decades to identify new, highly nutritious, and, ideally, low-impact feed sources.

Reducing High Levels of Meat Consumption Among Some Populations and Substituting by Balanced Ocean-Based Protein Has Positive Human Health Benefits: The Overall Impact Depends on Whether Ocean-Based Protein Is Sourced from Sustainable Production Sources or From Indiscriminate Expansion of Aquaculture That Could Negatively Impact Coastal Ecosystems (High Confidence)

High consumption of saturated fats, present in a red meat–based diet, has been linked to cardiovascular disease and certain forms of cancer. Consuming ocean-based proteins, in moderate quantities, ensures a higher intake of bioactive compounds as well as micronutrients, fibre, and omega-3 fatty acids, all of which have well-documented health benefits (Tilman and Clark 2014; González Fischer and Garnett 2016; Simões-Wüst and Dagnelie 2019; Blas et al. 2019; Hollander et al. 2018; Oita et al. 2018). A significant shift from red meat among today's high consumers would dramatically reduce the land and water demands of livestock production (especially cows and sheep) (Poore and Nemecek 2018; Nijdam et al. 2012) and would also reduce the carbon emissions associated with land clearance for pasture (Searchinger et al. 2019).

Mitigation Options Related to Increasing Ocean-Based Protein in Diets and Reducing Emissions in Fisheries and Aquaculture Would Result in Job Creation and Savings for Households, and Encourage Technological Innovation (High Confidence)

The Organisation for Economic Co-operation and Development (OECD) estimates that employment in industrial-scale marine aquaculture will be 3.2 million in 2030, an increase of 1.1 million from 2010 levels. As fuel is a particularly high cost for fishers in developing countries (Lam et al. 2011), structural changes to fisheries that reduce fuel consumption will be economically beneficial. Innovations in developing fish meal substitutes and improving feed efficiency will be crucial to support a rapidly growing aquaculture sector.

8.3.5 Storing Carbon in the Seabed

There Are Large Uncertainties Regarding the Environmental Implications of Carbon Storage Options in the Ocean (High Confidence)

The discussion below does not capture the impacts of carbonate dissolution, alkalinity addition, or ocean fertilisation, which has not been quantified in this report due to the high degree of risk and relatively unknown impacts at this stage. It only considers the impacts of seabed carbon storage. For further information on the broader set of options and why they are not viable at this time, please refer to the Sect. 7.

The injection of CO_2 into submarine geological structures could potentially result in leakages of CO_2 back into the marine environment (Rastelli et al. 2016), affecting the health and function of marine organisms (Queirós et al. 2014). However, there is uncertainty about the gravity of the impacts of CO_2 leakage, especially at the species community level (Adams and Caldeira 2008). Recent evidence indicates that leakage can be reduced if storage sites are well chosen, and well managed and monitored (van der Zwaan and Gerlagh 2016). However, understanding the full range of impacts on ecosystems associated with these solutions is of critical importance. Scientific understanding must be advanced if these technologies are to be used safely and without unintended consequences.

Offshore Investments in Seabed Storage Can Lead to Job Creation, Economic Growth, and Innovation (Low Confidence)

Potential benefits in terms of direct job creation, as well as job retention in harder-to-abate sectors (e.g., heavy industries and fossil fuel based sectors) by allowing them to function with appropriate CCS infrastructure investment/development. A study estimated that carbon capture and storage investments in UK would lead to the creation or retention of 225,600 jobs and a cumulative £54 billion in gross value added (GVA) by 2060 (East Coast UK Carbon Capture and Storage Investment Study 2017).

Evidence indicates a strong need for policy innovation to kick-start carbon capture and storage infrastructure investment (Goldthorpe and Ahmed 2017).

The purpose of the analysis of the wider impacts of ocean-based interventions is to provide insight into the cobenefits as well as risks and trade-offs associated with specific mitigation actions. The approach used here aims to help policymakers evaluate the climate benefits in the context of multiple cobenefits and trade-offs that arise from implementing various ocean-based mitigation options. It is our hope that this report will enable discussion of the corrective measures that might be needed to alleviate unintended consequences of actions and avoid unnecessary risks and trade-offs. The analysis does not attempt a cost-benefit assessment of the mitigation options, which should be a key step in the implementation of any ocean-based mitigation option.

9 Conclusion

This report establishes the potentially significant role of the ocean in limiting global temperature rise, in line with the goals of the Paris Agreement on Climate Change. Analyses in this report reveal that ocean-based mitigation options can make a significant contribution to narrowing the emissions gap that lies between a pathway based on "Current Policy" and the desired pathway that would hold global warming to 1.5 °C above preindustrial levels. Ocean-based interventions could close up to 21% of the emissions gap by 2050. If the world pursues the less ambitious target of 2.0 °C, ocean-based interventions could close 25% of the emissions gap by 2050.

Many of the mitigation options presented in this report can be implemented now with technologies that are already available. To realise these benefits, however, will require significant steps over the coming years—especially with respect to clear policy signals from governments, as well as a greatly increased and targeted investment in research and development.

The options outlined in this report are important not only to support efforts to decarbonise the global economy in line with the goals of the Paris Agreement. They also offer an array of valuable cobenefits in terms of enhanced human health and well-being. In this regard, they contribute to improving the resilience of coastal communities and infrastructure, expanding jobs and economic opportunities, enhancing biodiversity, and strengthening food security. Many of these wider benefits are synergistic with and will support the achievement of the UN Sustainable Development Goals by 2030. However, risks of negative wider impacts cannot be ignored and require detailed attention in policy development, and project planning and implementation. This must be the responsibility of all involved stakeholders—governments, the private sector, researchers, project managers, and local communities.

When considering the political implications of this report, the message is clear. Bold political leadership and clear policy signals will be required to capitalise on the full potential of the solutions explored in this report, coupled with strong national institutions and international cooperation to ensure their effective implementation. Table 17.16 outlines the policy and research actions that must be established over the next 10 years if we are to make significant progress in closing the emissions gap and avoid a climate crisis.

Ultimately, the ocean, its coastal regions, and the economic activities they support should be a source of inspiration and hope in the fight against climate change. With the backdrop of a growing climate catastrophe, the timing of this report is critical, and there could not be a more compelling case for urgent action.

Table 17.16 Short- and medium-term policy, research, and technology priorities necessary to deliver on mitigation potential of ocean-based areas of intervention

	Ocean-based energy		
	Policy	Research	Technology
Short-term priorities (2020–2023)	• Undertake marine spatial planning • Develop national targets to increase the share of renewable energy in the national energy mix • Provide a stable economic and regulatory framework to stimulate investments in required infrastructure for an accelerated deployment of ocean-based energy systems	• Understand the impacts (positive and negative) of both fixed and floating offshore wind installations on marine biodiversity • Undertake a detailed mapping of global renewable energy resources and technical potential	• Advance storage capacity and design • Improve performance, reliability, and survivability, while reducing costs
Medium-term priorities (2023–2025)	• Develop strategic national roadmaps for zero-carbon economy in 2050 • Develop appropriate legislation and regulation	• Understand the potential benefits of co-location with other ocean-based industries (e.g., desalination plants and aquaculture) • Explore the potential for installing large scale floating solar installations at sea (under wave conditions) • Quantify the potential of ocean thermal energy conversion (OTEC)	• Advance technology that can move technologies into deeper water sites (e.g., development of floating offshore wind technologies) to open access to larger areas of energy resources
	Ocean-based transport		
Short-term priorities (2020–2023)	• Redesign the energy efficiency design index (EEDI) formula to avoid vessels being suboptimised for the test only, to ensure that instead vessels are being optimised for minimised fuel consumption in real operation at sea • Adopt policy measures to go beyond Ship Energy Efficiency Management Plan (SEEMP) to incentivise the maximisation of operational efficiency of new and existing ships • Adopt policies that can reduce the broader GHG emissions of shipping instead of CO_2 only, including well-to-tank emissions (WTW) of ship fuels	• Identify and rectify of market and nonmarket barriers and failures to enable larger uptake of more energy-efficient technologies and cooperation patterns • Ensure continuous research on ship design, including hull forms and propulsion, with a focus on reducing energy usage per freight unit transported • Increase focus on utilisation of wind, waves, ocean currents, and sun to reduce use of externally provided energy, i.e., both the carbon and non-carbon-based fuels carried on board	• Develop the necessary high efficiency hull forms and propulsion methods • Develop and implement hybrid power systems, including combustion engines, fuel cells, and batteries technologies • Develop and implement wind assistance technologies • Develop more advanced weather routing systems to better utilise wind, waves, ocean currents, and tides to reduce the use of both carbon and non-carbon fuel carried on board
Medium-term priorities (2023–2025)	• Develop policy to enable the business case for the adoption of low and zero carbon fuels by shipping (e.g. a carbon price) • Commit to the timetable for shipping's transition to low- and zero-carbon fuels • Develop national incentives for decarbonising domestic transportation • Commit to decarbonisation of national energy systems faster or as fast as the transition in the international fleet	• Develop cost-effective production of low- and zero-carbon fuels, both from renewables and from carbon based in combination with carbon capture and storage (CCS) • Develop cost-efficient hybrid setups on seagoing vessels to utilise the best of combustion, fuel cells, and batteries to reduce fuel consumption and local pollution • Ensure safe storage and handling on ships and at the ship-shore interface of hydrogen/ammonia • Ensure safe and efficient use of hydrogen and ammonia in internal combustion engines and fuel cells	• Advance technologies for producing hydrogen, both from renewables and carbon-based fuels • Invest in technologies to store hydrogen (including cryogenic storage of liquid hydrogen, or carriers able to store at high-energy density) • Invest in fuel cells for conversion of future fuels into on-board electricity, and internal combustion engines designed to operate on hydrogen/ammonia

Table 17.16 (continued)

	Ocean-based energy		
	Policy	Research	Technology
	Coastal and marine ecosystems		
Short-term priorities (2020–2023)	• Enhance protection measures for mangroves, seagrass, salt marsh, and seaweed beds to prevent any further losses due to human activities • Provide incentives for restoration of "blue carbon" ecosystems, through payments for ecosystem service schemes, such as carbon and nutrient trading credits • Include quantified nature-based solutions within nationally determined contributions (NDCs) and other relevant climate policies for mitigation and adaptation • Protect coral reefs as important and integrated coastal defence systems for ensuring the protection of coastal blue carbon ecosystems	• Undertake national-level mapping of blue carbon ecosystems • Address biophysical, social, and economic impediments to ecosystem restoration to develop restoration priorities, enhance incentives for restoration, and increase levels of success • Improve the IPCC guidance for seagrasses and other wetland ecosystems • Develop legal mechanisms for long-term preservation of blue carbon, especially in a changing climate • Understand the impacts of climate change on rates of carbon capture and storage, or the potential for restoration	• Advance biorefining techniques, allowing sequential extraction of seaweed products
Medium-term priorities (2023–2025)	• Enhance and adopt carbon accounting methodologies for mangroves, seagrasses and salt marsh within national GHG inventories (IPCC 2013) • Improve methods for monitoring mitigation benefits to enable accounting within national GHG inventories, and biennial transparency reports (BTRs)	• Undertake global-scale map of seaweed ecosystems • Develop IPCC-approved methodological guidance for seaweed ecosystems • Develop methods to fingerprint seaweed carbon beyond the habitat	• Develop and pilot offshore and multiuse sites, including seaweed aquaculture, in the open ocean
	Fisheries, aquaculture, and dietary shifts		
Short-term priorities (2020–2023)	• Eliminate harmful fisheries subsidies (SDG14.6) • Strengthen international tools to eliminate IUU fishing (SDG14.5) • Avoid the transport of fish by air • Reduce discards • Reduce and eliminate hydrochlorofluorocarbons (HCFCs) in refrigerants • Create incentives for shifting diets towards low-carbon protein (e.g., fish) and other food (e.g., seaweed) diets • Create incentives to improve fishery management • Create incentives for lower trophic- level aquaculture • Devise sustainable finance mechanisms for small-scale fishery transitions to sustainable fishing	• Develop disaggregated global data sets for GHG emissions from wild catch fisheries and marine aquaculture • Impacts of scaling marine aquaculture and associated sustainability considerations (e.g., low carbon and climate resilient, environmentally safe) • Enhance understanding of how climate change and ocean acidification will impact aquaculture and fisheries	• Extend surveillance technologies for tracking fishing in the ocean and along coastal areas
Medium-term priorities (2023–2025	• Create incentives to switch from high-carbon land-based sources of protein to low-carbon ocean-based sources • Improve fisheries management to focus on optimising biomass per harvest	• Explore potential impact of a carbon tax on red meat and other carbon intensive foods	• Develop and bring to scale high-technology digital aquaculture
	Seabed carbon storage		
Short-term priorities (2020–2023)	• Invest in pilot projects to further explore potential environmental impacts • Incentivise public/private partnerships	• Map global geophysical potential • Understand the impacts of long-lasting containment of CO_2 in a deep seafloor environment	• Few major technical advances are required as seabed storage is already deployed at industrial scale

(continued)

Table 17.16 (continued)

	Ocean-based energy		
	Policy	Research	Technology
Medium-term priorities (2023–2025)	• Develop national strategies and targets • Develop regulatory frameworks to ensure environmental impact assessments and associated precautions are put in place	• Understand the impacts of long-term storage on marine ecosystems • Explore the integrity of long-term storage technologies (leakage)	• Scale up technologies in ways that are economically feasible

1 Executive Summary

The ocean and its resources provide key ecosystem services and benefits that are crucial for human well-being and the prosperity of the global economy, but these services are at risk. The ocean's wide range of ecosystem services (including food, energy, recreational/ cultural services and trading/transport routes) is vital for the well-being of society. However, climate change, overfishing, pollution and a loss of biodiversity and coastal ecosystems are eroding the ability of the ocean to sustain livelihoods and prosperity.

Taking action to protect these ocean-based ecosystems and ensuring the environmental sustainability of ocean-based activities will produce health, environmental and ecological, and economic and social benefits to people and the planet. A key question for policymakers and funding agencies is how these benefits compare with the costs. This analysis aims to answer the question by building on several existing analyses and reports, including *The Ocean as a Solution to Climate Change: Five Opportunities for Action* (Hoegh-Guldberg et al. 2019) and *The Global Consultation Report of the Food and Land Use Coalition* (FOLU 2019).

Using both quantitative and qualitative methods, it demonstrates that ocean-based investments yield benefits to society in the long term, and these benefits substantially outweigh the costs.

This analysis is the first attempt to estimate the global net benefit and the B-C ratio over a 30-year time horizon (2020–2050) from implementing sustainable ocean-based interventions. It indicates the scale of benefits compared to the costs by focusing on four ocean-based policy interventions: conserving and restoring mangrove habitats, scaling up offshore wind production, decarbonising the international shipping sector and increasing the production of sustainably sourced ocean-based proteins (to ensure a healthy, balanced human diet by 2050). These interventions would contribute to global efforts to reduce greenhouse gas (GHG) emissions and move countries towards their Sustainable Development Goals and targets (Hoegh-Guldberg et al. 2019).

J. Lubchenco, P. M. Haugan (eds.), *The Blue Compendium*, https://doi.org/10.1007/978-3-031-16277-0_18

For each intervention area, the impact to reach a sustainable transformation pathway by 2050 is measured relative to a business-as-usual scenario. A B-C ratio is developed by dividing the present value of benefits in 2050 by the present value of costs. The categories of benefits assessed include health (such as a reduction in mortality and morbidity), environmental and ecological (such as benefits from higher biodiversity, reduced water usage and land-based conflicts, and coastal protection) and economic and social (such as increased business revenues, household income, jobs and food security). The categories of costs include costs to business (such as capital investments and increases in operational costs), costs to government (such as costs of regulations, research and development [R&D] expenditures, enforcement and monitoring costs) and costs to households (such as opportunity costs of forgone activities)**.** The benefit and cost estimates are partial estimates; impacts are monetarily quantified where possible and are qualitatively described when quantifiable data are absent.

2 Key Findings

The overall rate of return on investment (ROI) can be very high, with sustainable ocean-based investments yielding benefits at least five times greater than the costs. When assessing individual interventions, the average economic B-C ratio range between 3-to-1 and 12-to-1, and in some cases even higher. The B-C ratios were similar to key health interventions in developed and developing countries.[1] Specifically, investing $2.0–3.7 trillion globally across the four areas from 2020 to 2050 would generate $8.2–22.8 trillion in net benefits (average $15.5 trillion), implying a rate of ROI of 400–615%. The B-C ratios vary across sectors and interventions (Table 18.1; Fig. 18.1) as follows:

- **Every $1 invested in mangrove conservation and restoration generates a benefit of $3.** When assessing specific interventions, the B-C ratio for conservation is 88-to-1 and for restoration is 2-to-1. Three factors drive the difference in the B-C ratios: the higher cost of mangrove restoration (due to seeding and replanting), low survival rates following restoration and the lag in accrual of benefits from restoration. The total value of net benefits for mangrove restoration over 30 years ($97–150 billion) is higher than for conservation ($48–96 billion) because we assume the area of mangroves restored is 10 times that of the area conserved.[2]
- **Every $1 invested in scaling up global offshore wind production generates a benefit estimated at $2–17**, depending on the cost of offshore energy production and transmission and the types of generation that would be displaced.[3] The value of the ROI will increase as the costs for offshore wind energy generation fall because of improvement in technologies and actions to reduce integration costs.
- **Every $1 invested in decarbonising international shipping and reducing emissions to net zero is estimated to generate a return of $2–5.** The analysis assumed the significant capital expenditure to switch to zero-carbon emissions will happen after 2030, and limiting the analy-

Table 18.1 Summary of benefit-cost ratios for the four action areas in 2050

Action	Average benefit:cost ratio
Conserve and restore mangroves[a]	3:1
Decarbonise international shipping[b]	4:1
Increase production of sustainably sourced ocean-based proteins	10:1
Scale up offshore energy production[c]	12:1

Notes:
[a] *The ratio presented is the combined ratio for mangrove conservation and restoration. When assessing specific interventions, the benefit-cost ratio for conservation is estimated to be 88-to-1 and for restoration is 2-to-1*
[b] *The benefit-cost ratio estimated for decarbonising international shipping ranges from 2:1 to 5:1*
[c] *The benefit-cost ratio estimated for scaling up of global offshore wind production ranges from 2:1 to 17:1*
Source: Authors' calculations

[1] For example, the B-C ratio for double measles immunisation in Canada is estimated to be 2-to-1 to 4-to-1; for influenza vaccination in Italy, it is estimated at 4-to-1 to 12-to-1; for the meningitis prevention program in the Philippines, it is 8.4-to-1; and for the universal *Haemophilus influenzae* type B vaccination (starting at 2 months) in the United States, it is 3.4-to-1 to 5.4-to-1 (Bärnighausen et al. 2011; Colombo et al. 2006; Limcangco et al. 2001; Pelletier et al. 1998; Zhou et al. 2002).

[2] The conservation scenario assumes stopping the additional loss of mangroves whereas the restoration scenario assumes replanting large areas of mangroves already lost; that is we are doing more restoration in the scenarios analysed than conservation. The overall ratio of both conservation and restoration is calculated by adding the total present value benefits and costs of both measures. The very high restoration costs is the main factor driving the overall B-C ratio for both conservation and restoration.

[3] The return on investment for wind energy investments will vary depending on the specific generation technologies and costs in places where the offshore wind installations are located. On grids that have a high share of zero-carbon generation, including hydropower and nuclear energy, adding ocean energy will not decrease emissions significantly. Conversely, for grids with a high share of carbon-intensive generation, emission displacements could be significant.

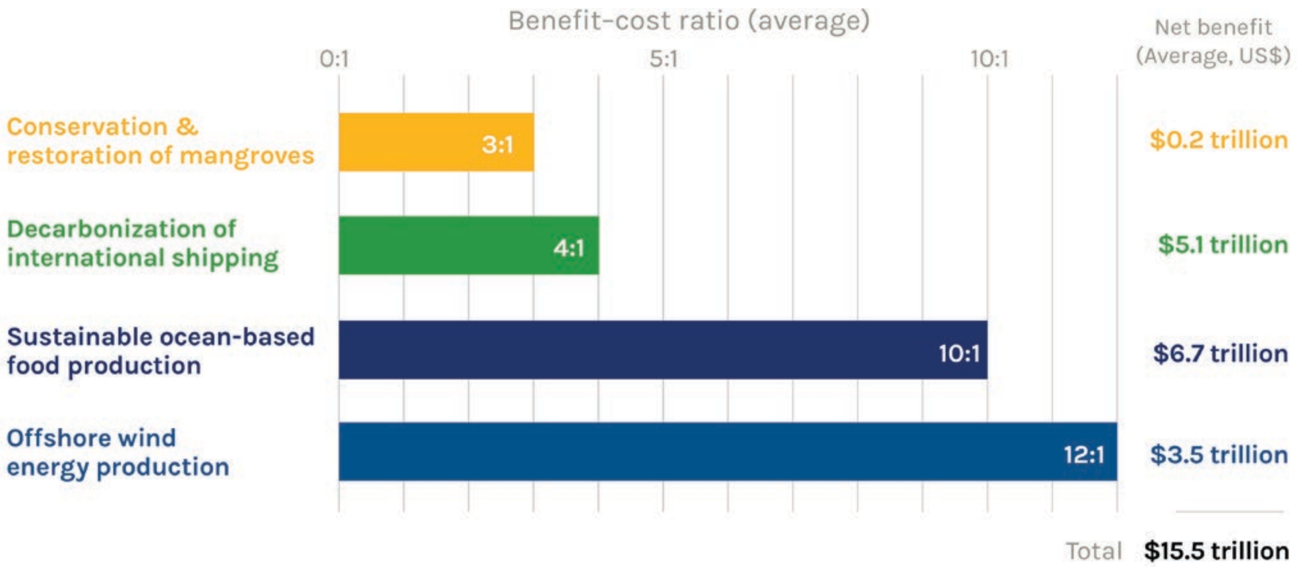

Fig. 18.1 Benefits significantly outweigh costs across sustainable ocean-based interventions, with average B-C ratio ranging between 3:1 and 12:1. *Note: Average benefit-cost (B-C) ratios have been rounded to the nearest integer and the net benefits value to the first decimal place. The B-C ratio for mangroves is the combined ratio for both conservation- and restoration-based interventions. The average net benefits represent the average net present value for investments and is calculated over a 30-year horizon (2020–2050). Source: Authors' calculations*

sis to 2050 captures only a portion of returns from these investments, which will continue beyond 2050.

- **Every $1 invested in increasing production of sustainably sourced ocean-based protein (to ensure a healthy, balanced diet by 2050) is estimated to yield $10 in benefits.** The increase in demand for ocean-based protein to provide a healthy diet for 9.7 billion people by 2050, which would replace a percentage of emission-intensive land-based protein sources, can be achieved by reforming wild-capture fisheries and by increasing the sustainable production of ocean-based aquaculture. Both measures will deliver benefits such as better health outcomes to consumers, higher revenues to fishers, lower GHG emissions mitigating the risks of climate damage, reduced land-based conflicts and lower water usage.

A number of impacts (both benefits and costs) have not yet been monetised, but they need to be considered by policymakers. These include the impact of GHG emissions on ocean acidification and the associated loss to biodiversity and commercial shellfish production; a potential increase in tourism revenues globally from restored mangroves; biodiversity benefits from healthier ecosystems; impacts on marine biodiversity from increasing the number of offshore wind farms; and distributional impacts of the benefits and costs on poorer communities. Given these nonmonetised impacts, the B-C ratios present a partial estimation of all benefits and costs that are likely to accrue as a result of such investments. These four examples are indicative of the relative scale of benefits compared to the costs. Further research and analysis to address these gaps will provide a more complete picture of the value of benefits versus costs.

Although data limitations prevented a full accounting of all benefits and costs, the results of the analyses suggest that taking actions to transform these sectors will generate a host of benefits that are much larger than the costs.[4] The results show that sustainable ocean-based investments yield benefits at least five times greater than the costs (Fig. 18.2), with minimum net returns of $8.2 trillion over 30 years. Better awareness of evidence of the possible ROI will help strengthen the economic case for action.

[4]For example, this is particularly true for the majority of ecosystem service benefits for mangroves that are not privately owned or traded, and hence their "value" is not reflected in price signals. We refrained from monetising some of the benefits due to the uncertainty of nonmarket valuation techniques. Further information is available in Sect. 18.5.1.

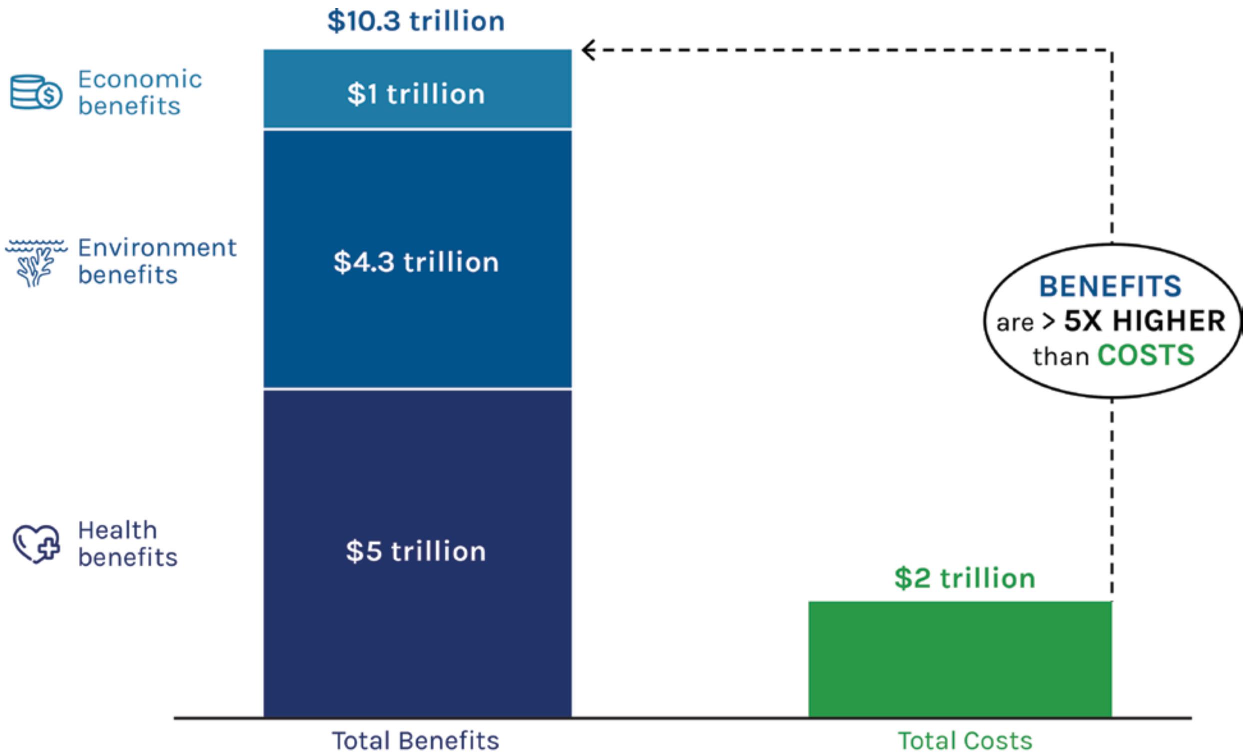

Fig. 18.2 Sustainable ocean investments yield benefits at least 5× higher than costs. *Note: The total benefits and costs in the figure present the lower-bound present value estimates to demonstrate the minimum scale of quantified net benefits. Source: Authors' calculations*

3 Introduction

The ocean's economic value is undisputed: it generates jobs that support millions of livelihoods, it supplies resources that have enabled decades of industrial growth, and its sea routes enable 90% of world trade (Fleming et al. 2014). The ocean's ecosystem services are vital for the well-being of society. For example, in some least-developed countries, fish protein accounts for more than 50% of animal protein intake (FAO 2018). Likewise, the ocean is reflected in many cultural practices, is manifest in inspirational art and provides recreational and aesthetic value to many (Fleming et al. 2014).

However, these services and benefits are at risk as the ocean faces pressures from enhanced economic activity, demands from a growing human population and uncertainty from a warmer, unstable climate.

Overfishing, pollution, climate change and loss of biodiversity are eroding the ability of the ocean to continue to sustain livelihoods and prosperity. The cumulative impact of human activities and climate change are likely to cause further ecosystem degradation or even collapse of ecosystems such as coral reefs, kelp forests and seagrasses (Halpern et al. 2019; IPCC 2019).

This analysis begins to estimate the benefits and costs of transitioning towards a sustainable ocean economy by focusing on four areas that represent key aspects of the ocean economy. It builds on *The Ocean as a Solution to Climate Change: Five Opportunities for Action* (Hoegh-Guldberg et al. 2019) and *The Global Consultation Report of the Food and Land Use Coalition* (FOLU 2019) and other analyses and reports to demonstrate that ocean-based investments can yield considerable economic benefits to society in the long term.

3.1 Scope of the Analysis

The High Level Panel for a Sustainable Ocean Economy (Ocean Panel) commissioned this benefit-cost analysis as an input to the deliberations of the Ocean Panel, serving to strengthen the evidence base of the forthcoming *Towards a Sustainable Ocean Economy* report and action agenda.

The Ocean Panel proposes that a sustainable ocean economy can simultaneously deliver on three dimensions. It can

- **Protect:** reduce greenhouse gas (GHG) emissions while safeguarding biodiversity;
- **Produce:** contribute to sustainably powering and feeding a planet of 9.7 billion people in 2050; and
- **Prosper:** create better jobs and support more equitable economic growth, household income and well-being.

To achieve this vision, it will be critical to take action to transform ocean-based sectors and ecosystems towards sustainability.

We indicate the scale of benefits compared to costs by focusing on specific policy interventions across one coastal ecosystem, mangroves, and the ocean-based sectors involved with offshore wind energy, international shipping and ocean-based protein from capture fisheries and mariculture (Table 18.2).

Although it was not possible to cover all potential interventions across these sectors, specific interventions were chosen to meet three criteria: achievement of the Ocean Panel's vision, contribution to the global efforts to reduce GHG emissions, and contribution to delivering countries' Sustainable Development Goals (SDGs) and targets (Hoegh-Guldberg et al. 2019).[5]

These are the four interventions analysed:

- Conserving and restoring mangrove habitats
- Scaling up offshore wind energy production
- Decarbonising the international shipping sector
- Increasing production of sustainably sourced ocean-based protein (to ensure a healthy, balanced diet by 2050)

This analysis is the first attempt to measure the global net benefit and benefit-cost (B-C) ratio of implementing ocean-based interventions over a 30-year horizon (2020–2050). While in the past, significant efforts have been made to assess the net positive benefits from protecting marine ecosystems and transforming ocean-based activities, they focused on particular measures, ecosystems and investments in particular regions or referred to assessments over shorter time periods. Consequently, the overall global benefits and costs of transitioning to a sustainable ocean economy across these four areas have not been generated in an aggregate form or included in global discussions. Building on existing literature, this working paper aims to address the knowledge gap by focusing on sustainable transformation pathway scenarios and by using both quantitative and qualitative methods.

Table 18.2 The four ocean-based areas analysed

Ocean-based sectors/ ecosystems	Specific actions
Mangrove coastal habitats	Conserve and restore mangrove coastal habitats
Ocean-based renewable energy	Scale up the production of offshore wind energy (fixed and floating wind installations)[a]
Ocean-based transport	Reduce emissions from international shipping with a target to reach net-zero emissions in 2050[b]
Ocean-based food production	Achieve a healthier balanced diet for 9.7 billion people by 2050 by switching a share of protein from emission-intensive land-based sources of protein (notably beef and lamb) to low-carbon sustainably produced ocean-based sources of protein[c]

Notes:
[a] *Based on the scenarios analysed, offshore energy will likely continue to dominate the generation potential of the ocean energy sector in 2050, accounting for 65% of the sector's potential* (Hoegh-Guldberg et al. 2019)
[b] *The analysis excludes military and fishing vessels and domestic transport and includes bulk carriers, oil tankers and container ships, which account for the majority of the emissions (55%) in the shipping sector* (Olmer et al. 2017)
[c] *Sustainable production involves reforming fisheries by 2050 and increasing the production of sustainable ocean-based aquaculture (fed and nonfed)*
Source: Authors

4 Methodology

This paper summarises the potential impact of investments in four ocean-based areas (see Table 18.2) over 30 years (2020–2050). By dividing the present value of benefits by the present value of costs, a B-C ratio for each sector is estimated (Box 18.1).

The assumptions used to derive the B-C ratio differ for each sector. They are discussed in detail in Sect. 18.5.

A generic analytical framework was applied to ensure consistency and comparability in analysing the impacts in each area:

- The ambition for each area was defined as the level of sustainability that would be achieved in 2050 with respect to an identified baseline scenario. The business-as-usual (BAU) and sustainable transformation pathway projections, based on scenarios modelled in *The Ocean as a Solution to Climate Change: Five Opportunities for Action* (Hoegh-Guldberg et al. 2019) and *The Global*

[5] Although the interventions selected are key to achieving the 2050 sustainable ocean economy vision, they do not represent an exhaustive list of actions that will be required to make such a transition. For example, this analysis does not look at the impacts of moving towards a sustainable coastal tourism sector, of reducing marine pollution, or of expanding the network of marine protected areas.

Consultation Report of the Food and Land Use Coalition (FOLU 2019), are described in Sect. 18.4.1.
- A range of benefits and costs were identified that would achieve the target state over 30 years. These impacts were quantified monetarily where possible and were described qualitatively where a lack of data did not allow for such quantification.
- Future benefits and costs were discounted using a rate of 3.5%. The discounted benefits and costs were summed over 30 years (2020–2050) to arrive at a present value of benefits and costs for 2050 (Box 18.1). All values are based on 2019 prices.
- For each area, a B-C ratio was developed by dividing the present value of benefits in 2050 by the present value of costs.
- The present value of benefits and costs were aggregated across the areas to provide an aggregate B-C ratio for 2050.

Box 18.1 Estimating the Benefit-Cost Ratio

The benefit-cost (B-C) ratio indicates the return from ocean-based investments in the four areas in 2050. A B-C ratio greater than 1 demonstrates that the returns from an investment will be higher than the costs estimated over the chosen time period.

$$B/C = \frac{\text{Present value of benefits}}{\text{Present value of costs}} = \frac{\text{Sum of discounted benefits over 30 years}}{\text{Sum of discounted costs over 30 years}} = \left[\frac{B_0}{(1+r)^0} + \ldots \frac{B_n}{(1+r)^n}\right] \div \left[\frac{C_0}{(1+r)^0} + \ldots \frac{C_n}{(1+r)^n}\right]$$

where n = year; B = benefits; C = costs; r = discount rate.

Discounting is used to compare benefits and costs occurring over different periods of time by converting them into present values. This is based on the concept that people prefer to receive goods and services now rather than later.[a] The discount rate used in the Green Book, also known as the social time preference rate, is based on two components: the 'time preference', which is the rate at which consumption and spending are discounted over time, assuming no change in per capita consumption, and the 'wealth effect', which reflects the expected growth in per capita consumption over time, where future consumption will be higher relative to current consumption and is expected to have a lower utility.[b]

Source: a, b HMT (2018).

The time frame of 2020–2050 provides enough time for measures to be implemented and environmental benefits to result. In addition, the year 2050 aligns with long-term strategies to reduce emissions to net zero by midcentury (IPCC 2018) and meet the 2050 biodiversity vision where biodiversity is valued, conserved and restored to sustain a healthy planet (Cooper 2018). The time frame also overlaps with the United Nations Decade of Ocean Science and delivery of the 2030 SDG.

We used a constant social discount rate of 3.5% for the analysis (HMT 2018). Views vary on the correct discount rate for climate policies as well as the extent to which rates differ between developing and developed countries.[6] Some economists give more weight to environmental benefits that occur in distant years and recommend a lower discount rate for intergenerational decisions or a 'hyperbolic' discount rate that declines over time (Hausker 2011). For example, the *Stern Review* recommends a declining social discount rate, with rates lower than 3% for investments beyond 30 years (Stern 2007). The review states, 'If the ethical judgement is that future generations count very little regardless of their consumption level then investments with mainly long-run pay-offs would not be favoured. In other words, if you care little about future generations you will care little about climate change. As we have argued that is not a position which has much foundation in ethics and which many would find unacceptable'.[7] To reflect the intertemporal consideration of resource values, we selected a lower social discount rate. Given that the appraisal period is 30 years (and no longer), we decided on a constant 3.5% social discount rate.[8]

[6] It is often argued that social discount rates are likely to be higher for developing countries because the social opportunity costs for capital is higher or the cost of borrowing capital tends to be higher. For example, the World Bank and the Asian Development Bank typically apply a real discount rate of 10–12% when evaluating projects in developing countries (Warusawitharana 2014).

[7] For example, the *Stern Review* recommends a declining social discount rate with rates lower than 3% for investments beyond 30 years (Stern 2007). The review states, 'If the ethical judgement is that future generations count very little regardless of their consumption level then investments with mainly long-run pay-offs would not be favoured. In other words, if you care little about future generations you will care little about climate change. As we have argued that is not a position which has much foundation in ethics and which many would find unacceptable'.

[8] Based on the recommendation of the *Stern Review*, the treasury for the United Kingdom recommends the use of a 3.5% discount rate for the first 30 years, followed by a declining rate until it reaches 1% for 301 years and beyond (Lowe 2008). It can be argued that a lower rate can be implemented in different ways if agreement to use a low rate is reached. For example, there could be two options: (1) a global agreement is reached so that investments on the ocean and coasts are evaluated with a low discount rate, but no country is required to act if its own internal discount rate is higher and the project does not pass its own internal return on investment criteria (unless international transfers change that balance), or (2) a global agreement is reached so that there are parallel evaluations—one with the low internationally agreed-upon discount rate and the other with the country's own rate for public investments.

Challenges related to carrying out a benefit-cost analysis of environmental measures include key benefit and cost omissions, ambiguity or uncertainty in assigning monetary benefits to nonmarket goods, difficulty in integrating distributional aspects,[9] and increased subjectivity for intangible benefits and costs. Although B-C ratio analyses or return on investment (ROI) studies at the global level are appealing, this approach has limitations. The biggest risk of global benefit-cost estimates is that they do not present the distribution of benefits and costs across developing and developed countries. Global B-C ratios do not reflect heterogeneity (due not only to the distribution of benefits and costs across the globe but also to differences in discount rates).

Consequently, the estimates should not be interpreted as giving an exact depiction of the flow of returns. They have been developed to indicate the scale of benefits relative to costs specific to the scenarios analysed for different activities. The analysis aims to stimulate timely discussion, influence ongoing debate on emerging sustainability issues and ensure that investments to obtain a sustainable ocean economy are not ignored in global discussions. The analysis does not attempt to show the regional variation of the benefits and costs. Conducting these assessments, which closely consider local factors, should be a key step when implementing ocean-based measures and regulations at local and national levels.

4.1 BAU and Sustainable Transformation Pathway Scenarios for 2050

The analysis aims to answer four key questions:

- If the rate of mangrove loss were halted and degraded mangrove areas were restored, what would be the benefits and costs to society?
- If the world decided to expand offshore wind energy generation (from 0.3% of total energy generation in 2020 to 2–7% of total future energy generation in 2050), what would be the benefits and costs to society?
- If the international shipping sector reduced its emissions to net zero, what would be the benefits and costs to society?
- If sustainable ocean-based food production increased (to meet the balanced diet requirements as advocated by the 2019 report by the EAT-*Lancet* Commission on Food, Planet, Health [Willett et al. 2019]), what would be the benefits and costs to society?

To answer these questions, we identified a sustainable transformation pathway scenario for 2050, then measured benefits and costs needed to achieve this pathway against a BAU scenario. The sustainable transformation pathway and BAU scenarios, taken from Hoegh-Guldberg et al. (2019) and the Food and Land Use Coalition (FOLU) report (2019), are summarised in Table 18.3. For most interventions, benefits are accrued over the long term but the investment costs occur up front.

4.2 Framework for Assessing Benefits

The four areas can yield three categories of benefits, which are discussed in more detail below:

- Health benefits from reducing environmental risks
- Environmental and ecological benefits from reduced environmental degradation (on land and in the ocean) and prevention of future temperature rise from climate change
- Economic and social benefits from stimulating economic activity and promoting sustainable development

Table 18.3 Business-as-usual and sustainable transformation pathway scenarios

Four actions	Business-as-usual (BAU) Scenario	Sustainable transformation pathway scenario
Conserve and restore mangroves	Blue carbon ecosystems continue to decline, but at decreasing rates. The rate of loss of mangroves globally is estimated at 0.11% per year.[a]	Mangrove conservation: The per year loss under BAU is halted completely.[b] Mangrove restoration: Two scenarios were considered: (1) a moderate restoration effort recovering 40% of the historical ecosystem cover by 2050 (consistent with global mangrove Alliance goals), and (2) an aggressive scenario of complete restoration of pre-1980s cover.[c]
Scale up offshore wind energy production	Worldwide installed offshore wind energy capacity in 2018 generated 77 terawatt hours (TWh) per year and accounted for less than 1% of world energy production.[d] The current energy technologies mix remains constant (and the share of offshore wind energy remains low) as energy production expands.	The total installation capacity for offshore wind energy is estimated to grow substantially by 2050. The offshore wind energy generation for 2050 is estimated at 650–3500 TWh per year.[e] Under this scenario, the energy mix will shift to a higher fraction of renewables to meet the future increase in energy demand.
Decarbonise international shipping	The total annual greenhouse gas (GHG) emissions from international shipping is estimated to grow from 800 megatonnes (Mt) in 2012, to 1100 Mt. in 2030 and to 1500 Mt. in 2050.[f]	Emissions in international shipping are reduced to net zero by 2050.[g]

(continued)

[9]In addition, the benefit-cost analysis does not apply any ‘equity weighting’ when aggregating benefits across countries or regions that have very different levels of wealth, thus giving relatively greater weight to the impacts of rich people relative to poor people.

Table 18.3 (continued)

Four actions	Business-as-usual (BAU) Scenario	Sustainable transformation pathway scenario
Increase ocean-based food production	• Fisheries continue to be overfished and global annual marine capture production declines in 2050 by 25%.[h] • Fed aquaculture (finfish) production remains at the 2020 level (11.7 million metric tonnes, or mmt) due to fishmeal constraints.[i] • Nonfed aquaculture (bivalve) continues to grow slowly to 28.5 mmt in 2050 due to lack of investments.[j]	• To meet healthy diet requirements in 2050, we need to double the current amount of ocean-based protein.[k] Part of this can be achieved by fisheries reform and the rest by increasing sustainable marine aquaculture production. • With global fisheries reform, annual marine capture production increases by 40% compared with baseline projections.[l] Fed finfish mariculture production increases to 22.4 mmt by 2050.[m] Bivalve production grows to 65.2 mmt in 2050.[n]

Notes: Total energy generation in 2018 was estimated to be 27,000 TWh/year; offshore wind contributed 0.3%
Sources: [a–g]*Hoegh-Guldberg et al.* (2019); [h]*Costello et al.* (2019); [i, j]*FOLU* (2019); [k]*Willett et al.* (2019); [l]*Costello et al.* (2019); [m, n]*FOLU* (2019)

4.2.1 Health Benefits

These include interventions such as scaling up ocean-based renewable energy production and decarbonising shipping to reduce GHG emissions. Indirect health-related cobenefits of reducing air pollutants include reduced mortality rates, improvements in productivity from improved well-being of workers,[10] lower absenteeism from school/work caused by reduced childhood asthma,[11] and reduced morbidity.

Measures that induce even moderate shifts in diet from high meat consumption towards ocean-based protein have well-documented human health benefits (Blas et al. 2019; González Fischer and Garnett 2016; Hollander et al. 2018; Oita et al. 2018; Simões-Wüst and Dagnelie 2019; Tilman and Clark 2014). Finally, healthy mangroves directly provide nutrition to local communities via enhanced fisheries and indirectly via increases in other ecosystem services (such as coastal protection and improvements in water quality) and by income-generating activities (such as timber for fuelwood, nontimber forest products like honey and medicines, and income from tourism.)[12]

Some health benefits cannot be quantified; thus, they have been described qualitatively. The monetary value of these benefits could be significant, and additional research is required to quantify them. The benefit assessed across most interventions is avoided health damage from increased GHG emissions, and it focuses specifically on the impacts of criteria pollutants (Box 18.2).

4.2.2 Environmental and Ecological Benefits

Direct climate change mitigation would be achieved by reducing GHGs and limiting global temperature rise to 1.5 °C. These impacts include avoided losses in activities that are counted in a country's gross domestic product, or GDP (such as agriculture, fisheries productivity,[13] tourism, manufacturing and services); avoided property damages from increased coastal flooding; and avoided noneconomic impacts that do not appear in GDP measures (such as the loss of natural habitats from increased ocean acidification and increased risks to human health from extreme temperatures, including heat stress). We use the social cost of carbon method to measure the environmental externalities caused by an increase in GHG emissions (Box 18.3). Biodiversity-related cobenefits include an increased abundance of marine wildlife, reduced noise and other disturbances that negatively impact marine species, and the natural treatment of pollution and waste. These benefits have a direct positive impact on the marine ecosystem and its organisms and indirectly contribute to societal well-being.

[10]Working in a highly polluted setting for a long period of time can affect your mood or disposition to work. Evidence shows statistically significant adverse output effects (resulting in lower productivity) from prolonged exposure to ambient particles (He et al. 2019).

[11]There is a link between shipping pollution and childhood asthma (Sofiev et al. 2018) that leads to children missing school and their parents missing work. The shipping sector analysis explores this in more detail.

[12]Tourism-based income can improve economic and social conditions in local communities; hence, it indirectly contributes to health benefits.

[13]Climate change can have a positive or negative impact on regional fisheries; overall, though, there will be a decline in fisheries productivity.

Box 18.2 A Description of Avoided Mortality Losses from Reduced Greenhouse Gas Emissions

The cobenefits of global greenhouse gas (GHG) reductions on air quality and human health are estimated using analysis from West et al. (2013), which found that the global average marginal cobenefits of avoided mortality were US $50–380 per tonne of carbon dioxide reduced ($65–490 in 2019 prices). The analysis used a global atmospheric model and consistent future scenarios via two mechanisms: reducing coemitted air pollutants and slowing climate change and its effect on air quality. The model accounts for the impacts of ozone as well as fine particulate matter ($PM_{2.5}$), international air pollution transport and changes in global ozone from methane, and the study evaluates future scenarios in which population susceptibility to air pollution and the economic 'value of statistical lives' grows.[a] The authors state that the cobenefits may be underestimated because they do not account for people younger than age 30 (including children and neonatal effects), and they do not account for the benefits of avoided morbidity outcomes (i.e., reduced output from lower productivity).

Note: [a]*The value of statistical life is based on the willingness (and ability) to pay for reducing the risk of death. Hence, the study estimates marginal cobenefits to be high in North America and Europe, reflecting higher incomes in the region. Overall, though, the marginal cobenefit is found to be highest in regions with largest population affected by air pollution.*

4.2.3 Economic and Social Benefits

Transitioning to a sustainable ocean economy can lead to higher productivity, efficiency gains and revenues. For example, reforming fisheries will lead to long-term revenues and profits from higher fisheries productivity (outweighing the short-term losses). Similar fisheries productivity benefits have been observed in restoring and maintaining healthy mangroves. Improving the productivity of resources will in turn help boost revenues to industry, contributing to a country's national income. In addition, driving innovation and technological advancement will increase efficiency gains and unleash unforeseen market opportunities (GCA 2019).

In addition, these investments will help countries meet their SDGs and targets (Hoegh-Guldberg et al. 2019).

This includes creating decent jobs (SDG 8.5), protecting vulnerable communities from climate-related disasters (SDG 1.5), reducing poverty by improving household income/livelihoods (SDGs 1.1 and 1.4) and helping countries achieve their food security targets (SDG 3.2).

Box 18.3 Measuring Climate Benefits Using the Social Cost of Carbon

Benefit-cost analysis assumes that society should reduce carbon dioxide (CO_2) emissions up to the point where the marginal cost of reducing a tonne of CO_2 is just equal to the marginal benefit of keeping that tonne out of the atmosphere. The social cost of carbon (SCC) measures the benefit of reducing carbon dioxide equivalent (CO_2e) emissions; that is, it represents the dollar value of the cost (i.e., damages) avoided by reducing CO_2e emissions by 1 tonne.[a]

The model used to deliver SCC values, the integrated assessment model, provides a range of estimates[b] because of the many factors (including the types of greenhouse gas emissions) analysed, the types of impacts (gross domestic product, or GDP, versus non-GDP) analysed,[c] the discount rates used and size of risk aversion of the population.[d]

The SCC value used in this analysis reflects the avoided costs from changes in net agricultural productivity, human health, loss from increased natural disasters and changes in energy system costs, such as reduced costs for heating and increased costs for air-conditioning.[e] To prevent double counting with estimated health benefits from a reduction in ozone and fine particulate matter ($PM_{2.5}$), we used the SCC value developed under the U.S. Environmental Protection Agency that focuses only on damage costs from increases in the level of carbon dioxide in the atmosphere. The damage costs for CO_2 was estimated, in 2007 prices, at US $42 in 2020 and rises to $69 in 2050. Because the SCC value used does not account for all the damage costs, the impacts quantified monetarily are underestimates.

Notes:

[a] *Hausker* (2011).

[b] *Based on a number of studies, SCC values range from $50 to $417 per tonne of CO_2e reduced* (BEIS 2019; ToI 2019).

[c] *Activities counted in a country's GDP, such as agriculture, fisheries productivity, tourism, manufacturing and services, would feature in a GDP measure whereas non-GDP measures would include noneconomic impacts, including the loss of natural habitats and increased risks to human health (from heat stress and other factors).*

[d] *Standard practice in benefit-cost analysis is to take a risk-neutral approach to uncertainties. In the real world, individuals and organisations of all types display risk aversion to catastrophic impacts* (Hausker 2011).

[e] *EPA* (2016).

4.3 Framework for Assessing Costs

The costs of transformation, relative to BAU, were assessed by examining a list of actions and measures that can be undertaken by the government and private sector to achieve targets such as restoring mangroves, reducing emissions, reforming fisheries and increasing sustainable ocean-based aquaculture production.

Examples of these types of costs are given below:

- **Costs to business** include capital investments; for example, building new offshore aquaculture farms, increasing offshore renewable energy, implementing technological improvements in shipping and increasing private research and development (R&D) expenditures.
- **Costs to government** include costs of regulations (on mangrove and fisheries conservation), public R&D expenditures and higher enforcement and monitoring costs (for mangroves and fisheries).
- **Costs to households** include temporary reductions in household income from fisheries reform and the forgone income from the alternative use of the mangrove area by shrimp farming and/or charcoal production if they are not protected (opportunity cost). The presence of positive private opportunity costs may be an economic barrier to the success of mangrove conservation because they represent a direct economic loss (or disincentive) to local communities that undertake mangrove conservation activities.

For some sectors, such as renewable energy production and ocean-based aquaculture, the private sector costs were estimated based on existing analytical projections of the state of the technology in 2030 and 2050, and we assumed reductions in future costs due to economies of scale and 'learning by doing' (Arrow 1962). If components of costs were not quantified—for example, the costs of implementing national regulations to ensure decarbonisation of the shipping sector have not been monetised—they are discussed qualitatively.

5 Assessing the Return on Investment for Four Sustainable Ocean Transformations: Scenarios, Assumptions, Methodology, Results

This section presents the scenarios, discusses the assumptions and methodology used to estimate the benefits and costs for each of the four areas examined and finally presents the net benefits and the B-C ratios.

5.1 Conserve and Restore Mangroves

5.1.1 Baseline, Sustainable Transformation Pathway and Target Scenarios

The assumptions about the BAU scenario and the sustainable transformation pathway needed to achieve the conservation and restoration targets by 2050 are informed by Hoegh-Guldberg et al. (2019).

5.1.2 The BAU Scenario

Although blue carbon ecosystems continue to decline, they do so at decreasing rates thanks to improved understanding, management and restoration (Lee et al. 2019). For instance, the rates of mangrove loss globally declined from 2.1% per year in the 1980s (Valiela et al. 2001) to 0.11% per year in the past decade (Bunting et al. 2018). The BAU scenario assumes the loss of mangroves continues at 0.11% per year until 2050. The sustainable transformation pathway builds from this base.

5.1.3 The Sustainable Transformation Pathway Scenario

The mitigation potential could be achieved via two pathways: conservation of ecosystems and restoration of ecosystems.

- **Conservation of mangroves.** The total area for mangroves conserved per year is estimated to be 15,000–30,000 hectares (ha) (see Table 18.4).[14] This scenario avoids emissions of carbon stored in soils and vegetation. The total potential GHG mitigation contribution is estimated to be 0.02–0.04 gigatonnes (Gt) of CO_2e per year (Hoegh-Guldberg et al. 2019).[15]
- **Restoration of mangroves.** Restoration sequesters and stores carbon as vegetation grows. In the Hoegh-Guldberg et al. (2019) study, the range of potential mitigation varied with the level of effort and investment. Two scenarios were considered: a moderate restoration effort recovering about 40% (184,000 ha per year) of the historical ecosystem cover by 2050 (consistent with Global Mangrove Alliance goals) and a more aggressivescenario of complete restoration (290,000 ha per year) of pre-1980s cover (Hoegh-Guldberg et al. 2019). The corresponding total GHG mitigation potential was estimated at 0.16 $GtCO_2$e per year to 0.25 $GtCO_2$e per year in 2050 (Hoegh-Guldberg et al. 2019). See Table 18.4.

[14]This is based on avoiding the current loss of mangroves per year under BAU (Hoegh-Guldberg et al. 2019).

[15]The range of CO_2 sequestration potential per unit area for each ecosystem was calculated using default emission/removal factors from the IPCC (2013).

Table 18.4 Conservation and restoration pathways for mangroves by 2050

	Conservation		Restoration	
	Moderate	Aggressive	Moderate	Aggressive
Hectares conserved or restored per year	15,000	30,000	184,000	290,000
GHG mitigation potential ($GtCO_2e$ per year)	0.02	0.04	0.16	0.25

Notes: GHG greenhouse gas, $GtCO_2e$ gigatonnes of carbon dioxide equivalent
Source: Hoegh-Guldberg et al. (2019)

The GHG emission mitigation estimates are likely conservative because they do not account for avoided methane (CH_4) and high nitrous oxide (N_2O) emissions from alternative land uses such as aquaculture and rice production (Hoegh-Guldberg et al. 2019). These emissions can be significant due to mangrove conversions to aquaculture or rice farming; for example, 30% of mangrove ecosystems in Southeast Asia have been converted to aquaculture and 22% to rice cultivation (Richards and Friess 2016). These GHG estimates from land use changes are excluded from the present analysis due to the lack of global data.

5.1.4 Assessment of Costs

Conservation Costs

For conservation, we estimated the cost of monitoring and maintaining the mangroves and the opportunity costs of the forgone net income from alternative use of the mangrove area (Table 18.5). For enforcement and monitoring costs, a global average cost estimate of maintaining marine protected areas was used as a proxy. For the second component, we looked at the opportunity costs for returns from shrimp farming, crab catching and charcoal production (see Table 18.5). Because it was unknown which activities might exist at which sites, we used the sum of the three to represent the higher estimate of the opportunity costs.

We estimated the annual global costs of conservation to be $28.8–57.5 million based on the per-hectare estimates in Table 18.5 and the additional area conserved by 2050.

These numbers are indicative of global costs. In reality, the actual costs might be lower or higher depending on the location and sizes of the protected areas.

Restoration Costs

Restoration is often needed when ecosystem degradation is reaching its ecological threshold and significant efforts are required for seeding and replanting mangrove species to restore it. The analysis uses the global restoration cost estimates reported in the Bayraktarov et al. (2016) study that

Table 18.5 Types of costs and data sources used to estimate the costs of mangrove conservation and restoration

Description of costs	Cost (US $/ha/year)	Adjusted 2019$	References
Monitoring and maintenance cost: Median cost covers the current marine protected area expenditure plus estimated shortfall[a]	27	40	Balmford et al. (2004)
Global restoration costs of mangroves	8961 (median)	9449	Bayraktarov et al. (2016)
Opportunity cost: Net economic returns from shrimp farming in Thailand	1078–1220	1873 (average)	Barbier (2007)
Opportunity cost: Net economic returns from charcoal production in northwestern Madagascar	4	5	Witt (2016)
Opportunity cost: Net economic returns from crab catching in northeastern Brazilb	12	16	Glaser and Diele (2004)

Notes: ha hectare
[a] *To assess the enforcement and monitoring costs, a global average cost estimate of marine protected areas was used as a proxy for the conservation costs for mangrove protection. Balmford et al. (2004) state that the total costs per unit area of running the marine protected areas in their sample varied enormously, with the sum of current expenditure plus estimated shortfall ranging from about $4 per square kilometre ($km^2$) per year to nearly $30 million/$km^2$/year (median, $2698/$km^2$/year or $27/ha). We use the median figure in our analysis. The costs of a protected-area system are divided into three categories: (1) recurrent management costs for existing areas, (2) systemwide expenses needed to support a network of protected areas and (3) costs of bringing new areas into the system*
[b] *At $13.50 per person/day × 4500 person days in a year over about 50 km^2 is about $12/ha/year*

conducted a meta-analysis and systematically reviewed 235 studies (with 954 observations), including projects that restored and rehabilitated mangroves and other vegetated coastal habitats in different world regions. They suggested a median cost per hectare of $8961 per year (2010 prices, converted to $9449 in 2019 prices). We assume the costs are two times higher ($18,997) if both operating and capital costs are included (Bayraktarov et al. 2016).

The opportunity cost for restoration is assumed to be the same as that of conservation, but the forgone benefits can occur only 5 years after the restoration efforts have been completed, assuming that once the coastal ecosystems have improved, these areas are again under the risk of being disturbed. The annual restoration costs are estimated to be $3.5–5.5 billion between 2020 and 2050.[16]

[16]The range is obtained by multiplying the median cost (point estimate) with the area of restoration (range).

Assessment of Benefits

Mangroves extend over 150,000 square kilometres (km^2), distributed across 123 countries (Beck et al. 2018).

They provide a wide array of market and nonmarket benefits, which are categorised below according to health, environmental and economic/social benefits. The range of benefits quantified includes coastal protection benefits, sequestration benefits and fisheries productivity benefits. Conserving and restoring mangroves will also increase other ecosystem services, which, in turn, will increase societal well-being, which we have discussed qualitatively.

In this study, we assumed that the benefits generated through mangrove restoration (such as coastal protection and fisheries productivity) will not accrue immediately following the restoration effort but rather after there has been improvement in the condition of the ecosystem. We assume this to be 5 years after the restoration/rehabilitation work begins (Burke and Ding 2016).[17] In addition, the probability of success for mangrove restoration is very low. Bayraktarov et al. (2016) estimate the median survival of restored mangroves, assessed only within the first 1–2 years after restoration, to be 51.3%. For the restoration scenarios, we multiply the benefits by the probability of success of restoration or the median survival rate.

5.2 Health Benefits

Mangroves are a direct source of food, fuelwood, fiber and traditional medicine for local inhabitants (Bandaranayake 1998; Chaigneau et al. 2019). They provide important opportunities for communities to generate incomes from tourism associated with recreational fishing and bird-watching that generate recreational and aesthetic value to visitors (Carnell et al. 2019). These livelihood, cultural and recreational benefits, while important to the physical and mental health and well-being of local communities as well as visitors (de Souza Queiroz et al. 2017; Pearson et al. 2019), have not yet been quantified. In some developing countries such as Kenya and Mozambique, mangrove medicine was used by coastal communities to cure stomach pains or headaches but did not have direct commercial value (Chaigneau et al. 2019).

5.3 Environmental Benefits

5.3.1 Protection from Storm Surges

The biggest benefits of mangroves are that they form a natural breakwater that limits the damage to property, economic disruption and loss of life caused by coastal flooding and storm surges, which become stronger and more frequent with climate change. The aerial roots, trunks and canopy of mangrove forests provide a strong protective barrier against winds, swell waves, storm surges, cyclones and tsunamis.

Studies indicate that incoming wave heights are reduced by 13–66% by a 100-m-wide mangrove belt, and by 50–100% by a 500-m-wide belt (World Bank 2016).

Protecting and restoring coastal and marine ecosystems can reduce the impacts of cyclones on an estimated 208 million individuals in 23 major mangrove-holding countries (Hochard et al. 2019).[18] A meta-analysis of 44 studies found a median value of $3604 per hectare per year for the coastal protection services (avoided property damage) provided by mangroves (Salem and Mercer 2012), which, when updated to 2019 prices, yield annual benefits of $60–120 million for conservation scenarios analysed, and $375–592 million for restoration scenarios analysed (Table 18.6).

5.3.2 Mitigation of Climate Change and Carbon Sequestration Benefits

Mangroves play an important role in sequestering carbon; hence, they can contribute towards mitigation solutions aimed at limiting temperature rise to 1.5 °C. The discounted climate benefits (calculated based on annual GHG emissions in Table 18.4) from reducing CO_2 emissions are estimated at $42–83 billion for conservation and $137–214 billion for restoration over 30 years.

5.3.3 Other Ecosystem Services

Mangroves also provide many ecosystem services, such as regulating water quality and reducing coastal erosion, that we have not been able to quantify (see Appendix 1).

5.4 Economic and Social Benefits

5.4.1 Commercial Fisheries

Although some estimates have been much higher [e.g., Aburto-Oropeza et al. (2008) estimated that protecting 1 ha of mangroves in California was associated with increased fish yields valued at $37,500 per year], we conservatively used $18,000 per hectare per year (de Groot et al. 2012), based on global meta-analysis, to assess the commercial value of fish yields associated with conserved or restored mangroves (Table 18.6). We estimate the global economic benefit from increased productivity of commercial fish spe-

[17]The time frame for generating these benefits will vary, and in some extreme cases, full development of the aboveground biomass will not be achieved for 20–30 years (Osland et al. 2012; Salmo et al. 2013).

[18]Countries receiving the largest benefits in avoided flood damage in absolute dollar terms include China, India, Mexico, the United States and Vietnam. The largest beneficiaries relative to the size of their economies include many low-income countries, such as Guinea, Mozambique and Sierra Leone (Beck et al. 2018).

Table 18.6 Benefits of mangrove conservation and restoration in avoided property damage and fisheries productivity

Type of benefit	Benefit (US $/ha/year)	Adjusted 2019$	References
Avoided property damage	3604	4000	Salem and Mercer (2012)
Fisheries productivity	18,000	19,980	de Groot et al. (2012)

Note: ha = hectare
Source: Authors' calculations

cies to be $300–600 million per year for the conservation scenarios and $1.9–3.0 billion per year for restoration scenarios.

5.4.2 Tourism

Although we have not been able to provide a global estimate on increases in tourism arising from the scenarios analysed, these are likely to be significant for some countries. Mangrove tourism and recreation is a multibillion-dollar industry (Spalding and Parrett 2019). For example, tourism associated with coral reefs and mangroves in Belize contributed an estimated $150–196 million (12–15% of GDP) to the national economy in 2007 (Cooper et al. 2009). These benefits are also further discussed in Appendix 1. While there will be a short-term dip in coastal tourism following the COVID-19 lockdown, this assessment focuses on benefits over a 30-year period. Over the longer term, we estimate these benefits will pick up as the global economy emerges out of the pandemic and economic crisis.

There is also a strong social angle in terms of the distribution of the benefits. For example, low-income communities are most reliant on mangroves for key ecosystem services (Box 18.4).

5.4.3 Estimated Benefits and Costs

We estimated the B-C ratio under two approaches. In the first approach, we estimated the ratio over 30 years (2020–2050) using present value benefits and costs. In the second approach, we calculated the B-C ratio per hectare.

B-C Ratio Using Present Value Approach

For every $1 invested in mangrove conservation and restoration, we get a return of $3. Net benefits for mangrove conservation are estimated at $48–96 billion and for restoration at $97–150 billion over 30 years (2020–2050). The value of net benefits for mangrove restoration is higher than conservation because we assumed the area of mangroves restored would be 10 times the area conserved (Table 18.7).

However, we find that conservation of mangroves yields significantly more returns per dollar invested than restoration. For every $1 invested in mangrove conservation, we get a return of $88 dollars for conservation, versus $2 for restoration.

Table 18.7 Net present value and benefit-cost ratios for mangrove conservation and restoration

Transformation areas	Net present value (US $, billions, 2019$, 2020–2050)	Benefit-cost ratio
Conservation of mangroves[a]	48–96	88:1
Restoration of mangroves[b]	97–150	2:1
Total	145–246	3:1

Notes:
[a] *Conservation of 15,000–30,000 ha per year based on halting annual loss of mangroves*
[b] *Based on 184,000 ha per year for a moderate effort to 290,000 ha per year for an aggressive estimate*
Source: Authors' calculations

B-C Ratio for a Hectare of Mangrove Restored/Conserved

We estimated the benefits for restoring 1 ha of mangrove to be $30,080 and for conservation $79,980. Based on the per hectare conservation and restoration costs in Table 18.5, we estimate the B-C ratio per hectare to be 2:1 for restoration and 48:1 for conservation.

Box 18.4 Mangroves Protect the Poorest Populations

Low-income communities rely heavily on mangroves for key ecosystem services. Over nearly 98 million people from 10 low- or lower-middle-income countries with major mangrove areas and a gross national income per capita less than US $4036 annually have suffered from cyclones.[a] This accounts for 50% of the global cyclone-affected population from 18 mangrove-holding countries. Poor coastal families are most vulnerable to natural disasters; hence, building ecosystem resilience to protect them from coastal flooding and cyclones will not only safeguard their valuable assets but also generate tremendous social benefits (e.g., feeling safe) that cannot be easily quantified monetarily.

Note: [a] *Hochard et al.* (2019).

For both of the approaches, the ROI for restoration is lower, first, because the cost of mangrove restoration is much higher than conservation due to the high costs of seeding and replanting; second, it takes time to accrue benefits from restoration since the plants need to regrow and restoration requires the right conditions to ensure a high survival rate (see caveats in Appendix 1).

The monetised benefits presented under both of the approaches exclude a number of ecosystem services provided by mangroves. Major ecosystem benefits such as erosion control, water management, nutritional benefits from fisheries supported by mangroves[19] and health benefits are excluded from the current assessment. This is mainly because our assessment relies on previous valuation studies or meta-analyses that either do not attribute a value to these particular services or provide a total value across a range of services but do not address double-counting issues. Other social benefits that are not accounted for include employment and the potential for livelihoods associated with sustainably harvesting timber and nontimber forest products. Taking into account these benefits will likely result in a higher ROI.

The results from both of the approaches show that both types of interventions yield significant benefits and are important to ensure a high ROI. To reverse the current trend of marine and coastal resource depletion and further halt the release of CO_2 emissions from marine resource degradation, significant investment will need to be made to transform the way coastal and marine ecosystems are being managed. They would need more reliable funding for management/enforcement and greater participation/diversification of opportunities dependent on these ecosystems, in addition to strong 'political will' to involve measures that alter the fundamental attributes of a system (including value systems; regulatory, legislative or bureaucratic regimes; financial institutions; and technological or biological systems) (Ellis and Tschakert 2019). These social and political investments are important and have not been valued in the analysis.

5.4.4 Data Limitations and Caveats

Data limitations prevented us from assessing other coastal ecosystems: salt marsh and seagrass beds. Some caveats are that the value of mangrove conservation or restoration varies by locality, the costs are higher in developed countries, and coastal development pressure is a big influence. See Appendix 1 for important caveats.

5.5 Scale Up Offshore Wind Energy Production

Currently, global electricity generation from all ocean-based energy sources is less than 0.3% of the total (IEA 2019a). The ocean energy sector has seen a dramatic increase in investments over the past decade and is expected to grow (European Commission 2018; Hoegh-Guldberg et al. 2019; WBG et al. 2018). Currently, most offshore installations are in Europe, but a significant increase is expected in Asia, especially China (Hoegh-Guldberg et al. 2019).

In assessing the impacts of expanding offshore wind energy generation, we do not advocate one renewable energy technology over another. Rather, we focus on the impact (positive and negative) of expanding offshore wind energy against a baseline where fossil fuel sources of electricity generation continue to dominate. We looked at how much it would cost to increase production of offshore wind energy to meet the energy generation potential proposed in Hoegh-Guldberg et al. (2019) and estimate the benefits to society from reductions in GHGs and water usage.

5.5.1 Baseline, Sustainable Transformation Pathway and Target Scenarios

Between 2000 and 2017, the cumulative installed capacity of offshore wind energy rose from 67 megawatts (MW) to 20 gigawatts (GW) (IRENA 2018a, b). In 2018, the total global capacity of wind energy was 564 GW, of which 23 GW were offshore. Offshore wind energy produced 77 terawatt hours (TWh) of electricity annually.[20]

By 2050, gross global electricity generation is projected to be between 42,000 and 47,000 (TWh) (IEA 2019a).

In reviewing 15 energy scenarios for 2050 that considered ocean renewable energy, Hoegh-Guldberg et al. (2019) concluded that the annual energy generation from offshore wind technologies would increase between 650 and 3500 TWh per year.[21] To assess the impact of this increase on GHG emissions, the authors made assumptions about what technologies offshore wind would displace. They looked at the impact on GHG emissions if

- Offshore wind technologies displaced coal; and
- Offshore wind technologies displaced the current (2018) energy-generation mix.

We used the second scenario, which projected that scaling up offshore wind energy could reduce GHG emissions by between 0.3 and 1.61 $GtCO_2e$ per year in 2050 (Hoegh-Guldberg et al. 2019). Hoegh-Guldberg et al. (2019) acknowledge that this is a simplistic approach and, in reality, the substitution effect of ocean-based energy will mainly impact certain grids with given energy mixes, which, in turn, depends on global trends, including technology costs.

5.5.2 Assessment of Costs

Offshore Wind Energy Generation Costs

We use the levelised cost of electricity (LCOE) to estimate the cost of additional offshore wind energy generation. The LCOE includes capital costs, fuel costs, fixed and variable

[19] It can be argued that the value of nutritional benefits is already embedded in the value of fish sold.

[20] Within offshore wind energy technologies, bottom-fixed water technologies dominate the current capacity of offshore wind energy.

[21] The authors based their estimation on several studies that have included offshore wind in scenarios projecting future energy mix. These include International Energy Agency scenarios, Bahar et al. (2019) and Teske et al. (2011). We assume a linear increase in energy generation from 2020 to 2050.

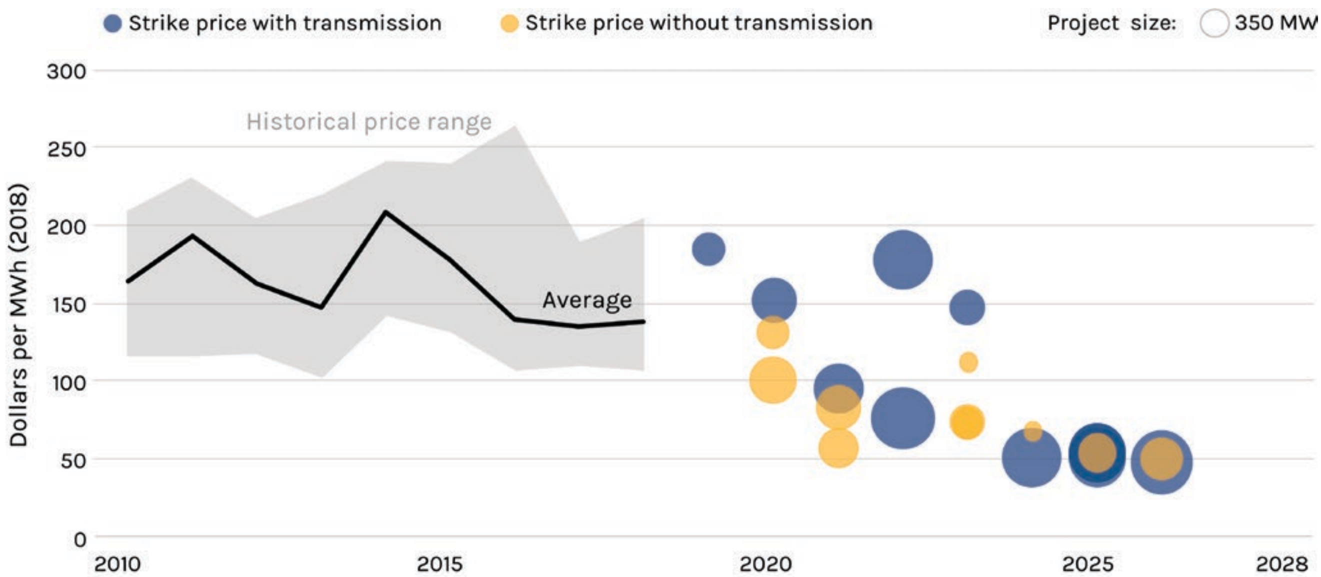

Fig. 18.3 Historical levelised cost of electricity generation of offshore wind and strike prices in recent auctions in Europe. Note: *MWh* megawatt-hour. Source: IEA (2019b)

operations and maintenance costs, financing cost and an assumed utilisation rate for each plant type (IEA 2015).

The LCOE for offshore wind power has declined since 2010 due to factors such as increased capacity from new installations (the ratio between realised energy output and theoretical maximum output), declining operational and maintenance costs due to improved turbine design (as they are made more robust for the offshore environment), improved capacity factors (linked to an increase in turbine size and hub height) and reduced transmission costs (Hoegh-Guldberg et al. 2019).

The global weighted-average LCOE of offshore wind projects commissioned in 2018 was estimated at $127–140 per megawatt-hour (MWh) based on the standard cost of capital representing full market risk (7% for developing countries and 7.5–8% for developed countries) (IEA 2019a; IRENA 2019). Improved financing terms could reduce the LCOE of offshore wind (IEA 2019a).

For example, applying a 4% weighted average of capital costs (WACC) to 2018 costs and performance parameters yields an offshore wind LCOE of about $100/MWh, which is 30% less than the LCOE derived from the standard WACC (7–8%) (IEA 2019b).

Declining recent strike prices[22] of offshore wind projects provide strong market signals of future cost reductions, indicating increased confidence from investors and setting the stage for low-cost financing opportunities for upcoming projects (Fig. 18.3). Analysis by the International Energy Agency (IEA) of auction strike prices shows costs could fall as low as $50/MWh (in some cases including transmission) for delivery in the mid-2020s (for example, a UK strike price of $51/MWh was seen in the September 2019 auction) (IEA 2019b).[23] Overall, evidence shows that with an economy of scale and learning curve effects, significant additional reductions in generation costs of offshore wind can be anticipated in subsequent years (IEA 2019b).

For floating offshore wind energy platforms, the LCOE may be higher because this is a less mature technology compared with the predominate bottom-fixed technology; it represents only 0.03 GW of the total of 23 GW of offshore power capacity. While cost reductions in the sector are expected due to rapidly advancing technology and market conditions enabling deployment to compete globally,[24] given the current low installation capacity of floating offshore wind facilities, it is difficult

[22]The strike price is a guaranteed price to be paid to wholesale generators of electricity.

[23]There is a risk that, depending on how auctions are designed, low bids may be associated with no delivery and/or renegotiations. For example, Welisch and Poudineh (2019) state that one-shot auctions and the lack of a nondelivery penalty clause increase the probability of speculative bidding and prevent bidders from learning and from utilising information efficiently.

[24]In 2015 the costs of floating offshore energy were estimated to range between $187/MWh and $316/MWh (IEA and NEA 2015), with predictions that costs would fall by 40% by 2030 due to rapidly advancing technology and market conditions that enable offshore wind deployment to compete globally. These cost declines are also reflected in recent studies. Previous National Renewable Energy Laboratory (NREL) studies estimated the LCOE for an offshore wind project in the Massachusetts wind energy area to be $77/MWh (Moné et al. 2016). Later NREL studies revised the LCOEs downward to $74/MWh by 2027 and $57/MWh by 2032 for floating offshore technologies in Maine (Musial et al. 2020). The recent technological and commercial improvements in the global industry are applicable to the turbine design, turbine scaling effects on the balance of station, lower financing terms and lower costs for the floating platform, array and export cables. Commercial-scale plant costs (in terms of dollars per kilowatt) modelled for the Aqua Ventus technology were found to be approximately five times lower than the pilot-scale demonstration project cost that was originally estimated at $300/MWh.

to predict its future global costs. That said, while the relative importance of floating wind power platforms will increase, we assume that within the next 30 years the majority of offshore wind installations will be bottom fixed; thus, for an overall cost estimate, we assume the LCOE figures will be close to that of the bottom-fixed installations.

For this analysis, we looked at two scenarios based on IEA cost projections (IEA 2019b):

- A **moderate scenario** based on a standard cost of capital financing representing full market risk (WACC is 7–8%). In this scenario, the global LCOE falls from $140/MWh in 2018 to less than $90/MWh in 2030 and close to $60/MWh in 2040.
- An **aggressive scenario** based on the same underlying technology costs and performance parameters as the moderate scenario, but which assumes low-cost financing (WACC of 4%). The global LCOE of offshore wind declines from $100/MWh in 2018 to $60/MWh in 2030 and to $45/MWh in 2040).

5.5.3 Offshore Wind System Integration Costs

The costs of integrating offshore power generation into the land-based electricity system include infrastructure costs (for expanding and adjusting the existing electricity infrastructure to feed in electricity production) and balancing costs (for handling deviations from planned production and extra costs for investments in reserves for handling power plant or transmission facility outages).

Offshore wind power requires an offshore grid as well as expanding the onshore transmission grid. The transmission or grid costs are closely tied to the regional regulations for connecting the project to the onshore grid (IEA 2019b). In 2015, the grid and balancing costs of integrating 50% of offshore wind power into the system were estimated at $43/MWh in 2019 prices (or €37/MWh) for offshore projects in Germany (Agora Energywiende 2015). These estimates were higher than the integration costs for photovoltaic (PV) solar and onshore wind ($5–20/MWh) because it costs more to connect with an offshore generation source. However, these costs are expected to decline as offshore wind projects increase and technologies improve. The average up-front cost to build an offshore wind project, including transmission costs, will drop by more than 40% over the next decade, according to the IEA. Such a drop would be due to innovation, economies of scale and supportive action to reduce costs by grid operators.[25]

[25]Wind corridors for onshore wind have helped to streamline the siting of transmission for multiple projects that allow multiple developers to share the cost. These innovations could help bring down costs.

Table 18.8 Levelised cost of electricity for conventional sources of energy, 2019

Type of energy source[a]	US $/MWH, 2019$ (3% discount factor)	US $/MWH, 2019$ (7% discount factor)
Conventional coal	71–103	72–152
Natural gas	67–146	83–110
Nuclear	28–70	41–111
Hydropower (seasonal)[b]	74	74

Notes: MWh megawatt-hour

[a] *Levelised cost of electricity generation (LCOE) estimates for coal, natural gas and nuclear are based on NEA and IEA (2015) country-level analysis of LCOE for the various technologies. The ranges show that the LCOEs will vary by location as each technology and each country faces a different set of risk profiles. Original estimates are converted from 2013 prices to 2019 prices using the Consumer Price Index inflation calculator*

[b] *LCOE estimates for hydropower are based on analysis of plants based in the United States (see Stacey and Taylor 2019). They calculate LCOE for new plants using EIA data (which used WACC of about 4%). They state that new plants have higher fixed costs and LCOE (than existing resources) as they begin their operational lives with a full burden of construction cost to recover*

Source: IEA and NEA (2015), Stacey and Taylor (2019)

For this analysis, we take a conservative approach and assume the grid and balancing cost is $43/MWh in 2020 and declines by 20% ($34/MWh) over 2030–2050.

5.5.4 Baseline Energy Generation Costs

In 2018, coal, gas, nuclear and hydropower accounted for 90% of the total electricity generation (IEA 2019a). We assume that, under the baseline scenario, demand for electricity will increase over 30 years (2020–2050) and additional investments in conventional sources of energy (mainly fossil fuels) will be made to meet the demand.

We analysed the LCOE of conventional sources of energy to estimate the current costs of energy generation in the baseline based on two discount factors (Table 18.8).

Based on the current energy mix and the discount factor, we estimate the global weighted average of LCOE in the baseline to be $86–94/MWh. We assume that by 2040 the LCOE will fall by 20% based on learning effects.

6 Additional Costs of Energy Generation from Offshore Wind

The following equation is used to calculate the additional costs of scaling up offshore wind production:

$$\text{Costs of offshore wind energy generation} = \text{offshore wind generation costs} + \text{offshore wind integration costs} - \text{baseline energy generation costs}$$

The total costs of scaling up offshore wind power are shown in Table 18.9, with the moderate scenario costing $250–884 billion and the aggressive scenario costing $97–420 billion.

6.1 Assessment of Benefits

Offshore wind energy can deliver a suite of health, environmental and ecological, and economic and social benefits.

6.1.1 Health Benefits

Due to its very low CO_2 emissions and negligible emissions of mercury, nitrogen dioxide and sulphur dioxide, as well as its 0 generation of solid or liquid waste, offshore wind energy production could have a positive impact on human health depending on what energy sources it displaces. Observational and modelling studies indicate that three million premature deaths are attributable to ambient air pollution and another 4.3 million to household pollution (WHO 2016). By multiplying the annual CO_2e emissions mitigation potential by the marginal cobenefits of avoided mortality (see Box 18.2), we estimate the total avoided damage costs (or discounted health benefits) from transitioning to offshore renewable energy at $0.15–4.4 trillion over 30 years (2020–2050).[26]

Table 18.9 Total costs of scaling up offshore wind production, 2020–2050

Scenarios	Description	Costs (US $, billions, 2019$)
Moderate	• Global LCOE falls from $140/MWh in 2018 to less than $90/MWh in 2030 and close to $60/MWh in 2040 • Integration costs: Grid and balancing costs are $43/MWh in 2020, declines by 20% over 2030–2050	250–884
Aggressive	• Global LCOE of offshore wind declines from $100/MWh to $60/MWh in 2030 and to $45/MWh in 2050 • Integration costs: Grid and balancing costs are $43/MWh in 2020, declines by 20% over 2030–2050	97–420

Source: Authors' calculations

6.1.2 Environmental and Ecological Benefits

Water Consumption Impacts

When estimating the impact of water usage for energy generation, we looked at water withdrawal and water consumption. Water withdrawal is the volume of water removed from a source, including water that is eventually returned to the same source; by definition, withdrawals are always greater than or equal to consumption (IEA 2016).[27] The type of cooling technology used mainly determines how much freshwater is withdrawn and ultimately consumed, although fuel mix, the power plant's role in the electricity system, turbine design and weather also influence the amount of water required (IEA 2016). Thermal power plants (coal, natural gas, oil, nuclear and geothermal) demand considerable amounts of water for cooling (IEA 2016) (Table 18.10). In contrast, studies show that wind systems require near zero water for energy generation and cooling (Macknick et al. 2011).

We estimate the water consumption to be 860–1315 gallons/MWh under the baseline. Using the true cost of water in terms of avoided damage to the environment, we estimate a range from $0.10 per cubic metre ($m^3$) in water-abundant

Table 18.10 Water consumption factors for nonrenewable technologies

Fuel type	Cooling type[a,b]	Water consumption (Gallons/MWH)
Nuclear	Tower, once-through, pond	269–672
Natural gas	Tower, once-through, pond, inlet	198–826
Coal	Tower, once-through, pond	103–942
PV solar	n/a	26
Offshore wind	n/a	0

Notes: MWh megawatt-hour, PV photovoltaic
[a] *Dry cooling is also an option that is not discussed here as it is expensive and has limited application*
[b] *Once-through cooling involves lower water consumption but higher water withdrawal than circulating cooling systems. In some jurisdictions (typically arid), once- through cooling is no longer permitted. However, we provide estimates of this technology to demonstrate a conservative water consumption scenario*
Source: Macknick et al. (2011)

[26]This is due to reduced criteria pollutants such as ozone and particulate matter (that are indirectly displaced).

[27]This analysis does not account for the impact of returning the water because it often gets returned at a different temperature, leading to thermal pollution.

areas to $15/m^3 in extremely water-scarce areas (Trucost 2013). We estimate the benefits (discounted) of achieving offshore energy transformation through water savings alone to be $1.3 billion to $1.4 trillion over 2020–2050.

Climate Impacts

We used the social cost of carbon method (see Box 18.3) to estimate the value of reductions in GHG emissions attributable to offshore wind at $344 billion to $1.4 trillion over 30 years.

Impacts on Biodiversity

Building more offshore wind farms could have both positive and negative impacts on biodiversity. The net impacts have not been quantified monetarily, and they would vary depending on the location of the offshore wind farm and the policies and measures to address negative impacts. Effective marine spatial planning, combined with emerging ocean energy technologies, can be effective in mitigating biodiversity loss from ocean energy technologies and reinforcing biodiversity cobenefits (Hoegh-Guldberg et al. 2019).

The risks of installing wind farms in the marine environment include biological invasions, noise and disturbing vibrations to marine species, collisions between birds and wind turbine rotors and the presence of electromagnetic fields that can disrupt marine life and benthic habitats (Langhamer 2012; Sotta 2012). However, studies have shown a gap between perceived risks and actual risks, and the former arise from uncertainty or lack of data about the real impacts (Copping et al. 2016). While it is important to acknowledge possible impacts, some of the actual risks are likely to be small and can be avoided or mitigated (Copping et al. 2016). For example, spatial planning appears to reduce risks, such as collisions with seabirds and impacts on migratory cetaceans, to manageable levels (Best and Halpin 2019). However, as wind energy expands into new areas, it could become more difficult to mitigate impacts.

Wind farms can have positive environmental impacts by serving as artificial reefs for many organisms (Hammar et al. 2016). In addition, the prohibition of bottom trawling near offshore wind farms for safety reasons eliminates the disturbance of fish, benthos and benthic habitats.

Evidence from Belgium and Norway suggests that in areas with a homogeneous seabed, wind farms may enhance diversity (Buhl-Mortensen et al. 2012; Degraer et al. 2012).

6.1.3 Economic and Social Benefits

This analysis does not monetise the impacts on jobs and livelihoods to the wider community, but it acknowledges them qualitatively. Offshore wind energy can create jobs: German and UK case studies state that offshore wind development is more labour-intensive than onshore wind development because of the greater challenges inherent in building and operating offshore farms in marine environments (BMWi 2018; IRENA 2018a). In Germany, the offshore segment accounted for 17% of total German wind employment in 2016, even though it represents no more than about 10% of the country's current total wind capacity. Estimates predict that direct full-time employment in offshore wind will be around 435,000 globally by 2030 (OECD 2016).[28] Similar analysis by Ocean Energy Systems shows that deployment of other forms of ocean energy (tidal range, wave power and ocean thermal energy) can also provide new jobs and additional investments (Huckerby et al. 2016).

However, the net global impact of the growth of the ocean-based energy on net jobs across the whole of the energy sector are less certain because the entire energy sector will transition to cleaner energy sources. Moving to cleaner energy will lead to job losses in the fossil fuel sector, though ocean-based renewable energy has the potential to benefit workers transitioning from declining offshore fossil fuel industries (IRENA 2018a; Poulsen and Lema 2017; Scottish Enterprise 2016), minimising the costs of transition and the risks of structural unemployment.

6.2 Estimated Benefits and Costs

We estimated the B-C ratio under two approaches.

In the first approach, we estimated the ratio over 30 years (2020–2050), where additional energy production is calculated for each year against the BAU scenario, using present value benefits and costs. In the second approach, we calculated the B-C ratio for one unit of energy produced.

6.2.1 B-C Ratio Using Present Value Approach

Table 18.11 shows the high and low benefit-cost ratios for the first approach—calculating additional energy production for each year against the BAU using present values benefits and costs.

On average, there is a net positive benefit from expanding offshore wind production. The net present value of benefits was estimated to be $253 billion to $6.8 trillion over 30 years.

Table 18.11 Net benefits from scaling up offshore wind energy and benefit-cost ratio

Action	Net present value; net benefit (US $, billions, 2020–2050)	Benefit-cost ratio (low)	Benefit-cost ratio (high)
Scale up offshore wind production	253–6849	2:1	17:1

Source: Authors' calculations

[28]This is an estimate of direct jobs, not including indirect or induced jobs, derived from the economic activity of an offshore wind farm.

Table 18.12 Benefit-cost ratio for offshore wind production under varying LCOE levels

Scenario	Benefit-cost ratio
Scenario 1: LCOE is US $140/MWh; integration costs are $43/MWh; baseline costs are $86–94/MWh	0.9:1–3:1
Scenario 2: LCOE is $60/MWh; integration costs are $43/MWh; baseline costs are $86–94/MWh	4:1–16:1
Scenario 3: LCOE is $45/MWh; integration costs are $30/MWh; baseline costs are $68–75/MWh	7:1–28:1

Note: LCOE levelised cost of electricity; MWh megawatt-hour
Source: Authors' calculations

The ROI in 2050 can be high, as shown by the B-C ratio of 2-to-1 to 17-to-1 in 2050.

6.2.2 B-C Ratio for a Unit of Energy Generation and Transmission

We estimated the benefits for production of one additional unit of energy to be $75–300/MWh. The B-C ratio varies mainly depending on the LCOE of offshore wind assumed. We examined three scenarios with different LCOE values and found B-C ratios between 0.9-to-1 and 28-to-1 (Table 18.12).

Both approaches show that the value of the ROI will increase as the costs of energy generation for offshore wind fall with improved technologies and as actions are taken to reduce integration costs. The estimates should be treated as partial because they do not include key impacts that are discussed qualitatively, such as impacts (positive and negative) on biodiversity and on jobs and livelihoods in coastal communities.

Data Limitations and Caveats

Data limitations and caveats are described in Appendix 2. They include potential risks to biodiversity, variations in GHG mitigation depending on the fuel mix in the local grid, variations in LCOE depending on local market conditions, and omitting financial benefits from water savings.

6.3 Decarbonise the International Shipping Sector

Shipping is a significant source of emissions with identifiable reduction pathways (Hoegh-Guldberg et al. 2019). The sector is responsible for approximately 1 $GtCO_2e$ per year and represents around 3% of global anthropogenic CO_2 emissions (Smith et al. 2015). Based on current trends, GHG emissions will double by 2050 to roughly 2 $GtCO_2e$, compared with 2010 (Hoegh-Guldberg et al. 2019). In 2018, the United Nations International Maritime Organization (IMO) adopted a resolution[29] to reduce GHG emissions from shipping by at least 50% by 2050, relative to 2008 emission levels. However, greater ambition is needed to keep global temperature rise under 2 °C to 1.5 °C (Hoegh-Guldberg et al. 2019; UNFCCC 2015).

6.3.1 Baseline, Sustainable Transformation Pathway and Target Scenarios

The sustainable transformation pathway focuses on decarbonising only the international shipping sector. Although there is potential to reduce emissions in both domestic and international shipping, we focused on international shipping, which accounts for 55% of the total emissions in the sector (Olmer et al. 2017). The following scenarios were considered from Hoegh-Guldberg et al. (2019).

Under the BAU scenario, it is estimated that total annual GHG emissions from international shipping will grow from 800 megatonnes (Mt) in 2012 to 1100 Mt. in 2030 to 1500 Mt. in 2050. The mitigation potential assumes a 20–39% emissions reduction in 2030 from a 2008 baseline, and in 2050, a 50–100% emissions reduction from the 2008 baseline emissions (Table 18.13).

The upper-bound emissions reduction for 2050 assumes that all vessels move to full use of nonfossil fuels from renewable feedstock. The lower bound is set at 50%, taken as the minimum interpretation of the IMO's objectives in the initial GHG reduction strategy (Hoegh-Guldberg et al. 2019).

6.3.2 Assessment of Costs

Because only a small subset of the fleet is likely to be 'zero-carbon-fuels ready' by 2030, we assume the mitigation potential for 2030 to be mainly driven by maximising energy efficiency (Hoegh-Guldberg et al. 2019). This includes technological measures that increase the energy efficiency of a ship, such as altering its weight (using lighter materials) or design (such as hull coatings and air lubrication to reduce friction), and other ways to reduce or recover energy (such as via propeller upgrades and heat recovery). These measures could result in fuel savings of up to 25% (ITF 2018). In addition, energy could be saved by changes in how ships—and, more broadly, maritime transport systems—are operated, such as changes in speed, ship-port interface and onshore power. Over the last few years, both slower speeds and larger ship sizes have contributed to a decrease in shipping emissions (ITF 2018).

Table 18.13 Greenhouse gas mitigation potential from decarbonising international shipping, 2030 and 2050

Action	2030 Mitigation potential ($GtCO_2e$/year)	2050 Mitigation potential ($GtCO_2e$/year)
Reduce emissions from international shipping	0.2–0.4	0.75–1.50

Note: $GtCO_2e$ gigatonnes of carbon dioxide equivalent
Source: Hoegh-Guldberg et al. (2019)

[29] See IMO (2018).

However, efficiency measures are ultimately limited by factors such as the efficiency of a propeller or an internal combustion engine that are impossible to improve beyond a certain point (IMarEST 2018). As those limits are approached, improvements have increasingly diminishing returns and become less cost-effective (IMarEST 2018). Hence, the cost of decarbonising international shipping is ultimately capped by the cost of switching to zero CO_2 emissions fuels and technologies (IMarEST 2018).

We refer to the IMarEST (2018) study to estimate the cost of GHG reduction in international shipping. The study assumes that significant absolute emissions reductions are achieved even at low marginal cost of carbon ($50/tonne) (IMarEST 2018).[30] The results from the same IMarEST (2018) model state that, depending on how prices evolve for renewable electricity in coming decades and other assumptions in the scenarios, a 70–100% absolute reduction in GHG emissions by 2050 can be achievable for a marginal abatement cost of $100–500/t$CO_2$e. By multiplying the cost per tCO_2e abated with the mitigation potential estimated in the Hoegh-Guldberg et al. (2019) study, we estimate the total costs (capital and operational) over 30 years to be $2.3 trillion to decarbonise shipping by 100%.[31]

6.3.3 Assessment of Benefits

The health, environmental and ecological, and economic and social benefits from the international shipping sector reducing its GHG emissions are summarised below.

Health Benefits

Reduced $PM_{2.5}$ from marine engine combustion mitigates ship-related premature mortality and morbidity (Sofiev et al. 2018). The annual avoided health damage cost to adults is calculated by multiplying the CO_2e emission mitigation potential by the average marginal cobenefits of avoided mortality (see Box 18.2). In addition to the impact on adult mortality, evidence shows that reducing shipping emissions will positively impact childhood morbidity by reducing childhood asthma (Sofiev et al. 2018). Based on the methodology outlined above for reducing adult mortality and for childhood asthma (see Appendix 3), we estimate the discounted cumulative health benefits from reducing emissions to be $1.3–9.8 trillion over 30 years (2020–2050).

Environmental and Ecological Benefits

Strong acids formed from shipping emissions can produce seasonal 'hot spots' of ocean acidification in areas close to busy shipping lanes. Hot spots harm local marine ecology and commercially farmed seafood species (Hassellöv et al. 2013). Reducing global GHG emissions, including shipping emissions, is critical to mitigating local and global ocean acidification.

A recent study found that lower trophic species such as bivalves were affected disproportionately due to the compounding effects of shifts in temperature, chlorophyll and ocean acidification. The commercial mollusc industry is estimated to lose over $100 billion by 2100 due to ocean acidification alone (Narita et al. 2012).

In addition, reducing ship speeds could positively impact marine mammals and other species. A 10% reduction in ship speed could reduce the total sound energy generated underwater by 40% and reduce the overall whale strike rate by 50% (Leaper 2019). Such measures would benefit marine species (including the whale population) globally, resulting in higher ecosystem service values (both recreational and nonuse values[32]) that will, in turn, improve human well-being. Because of uncertainty about the exact impact that measures to reduce GHG emissions would have on ocean acidification and noise, we have not been able to monetarily quantify these key impacts.

Reducing emissions in shipping will help avoid the most catastrophic impacts of climate change. We estimate the climate benefits (see Box 18.3) from reducing carbon emissions to be $0.8–1.6 trillion over 30 years.

Economic and Social Benefits

Estimates suggest that improved hull shape and materials, larger ships, drag reductions, hotel-load savings and better engines and propulsors, together with routing improvements, can deliver overall efficiency improvements of 30–55% (ETC 2018). The analysis indicates that reducing

[30] This is because of the assumption about the availability of bioenergy; in these scenarios, it is significant relative to international shipping's total demand for energy. In this modelling, bioenergy is assumed to enter the fuel mix as a substitute for fossil fuels and, therefore, is at the same price as the fossil fuel equivalent and is not dependent on additional carbon price to stimulate its take-up. For example, the study assumes that bioenergy enters the fuel mix as a substitute for fossil fuels at the same price as the fossil fuel equivalent (and is not dependent on additional carbon price to stimulate its take-up), the supply of bioenergy is 4.7 exajoules and there is a low price/capital cost of moving to future shipping energy sources, particularly electricity, biofuel, hydrogen and ammonia. The costs of investments increase (and, consequently, the B-C ratio decreases) if we assume a scenario where the cost of alternative fuel is higher.

[31] Our estimates reflect both operational costs and capital investments. It is, hence, higher than the cost estimate provided in the recent analysis by the University Maritime Advisory Services (UMAS) and the Energy Transitions Commission for the Getting to Zero Coalition (2019), which states that approximately up to $1.6 trillion 'capital investments' is needed between 2030 and 2050 to achieve the IMO target of reducing carbon emissions from shipping by 100% by 2050.

[32] Nonuse values (e.g., existence, bequest and option values) are the benefit values assigned to environmental goods that people have not used or do not intend to use. For example, the current generation can place a value on ensuring the availability of biodiversity and ecosystem functioning to future generations (bequest value).

a vessel's speed by 10% (e.g., from 20 knots to 18 knots) results in a 19% reduction in cargo-hauling fuel consumption after accounting for the reduced shipping speed and the associated loss in shipping time (Faber et al. 2012). These savings are already included in the cost calculations for 2030.

Estimated Benefits and Costs

Based on the methodology outlined above, we estimated that there are net benefits from making investments to decarbonise the shipping sector. The net discounted benefit (average) over 30 years (2020–2050) is estimated to be $1.2–9.1 trillion. The B-C ratio is estimated to be 2-to-1 to 5-to-1 in 2050 (Table 18.14).

6.3.4 Data Limitations and Caveats

Data limitations and caveats include a lack of consideration of the secondary impact on commodity prices and the impact of all cost reductions (technology change) in the future. For details, see Appendix 3.

6.4 Increase the Production of Sustainably Sourced Ocean-Based Proteins

The analysis for this section builds on the estimates provided in *The Global Consultation Report of the Food and Land Use Coalition* (FOLU 2019), the analysis of Costello et al. (2016) that looks at the return from global fisheries under contrasting management regimes, the analysis of Sumaila et al. (2012) that measures the net present value of rebuilding fish stocks over 50 years, and the analysis of Mangin et al. (2018) that compares the benefits from fisheries management against the costs for individual countries.

To determine the level of ocean-based protein production required to ensure a healthy, balanced human diet by 2050, we refer to the EAT-*Lancet* Commission report (Appendix 4; Willett et al. 2019), which states that the ocean will be required to produce 85–90 million metric tonnes (mmt) of edible-weight ocean protein annually by 2050. It is estimated that the world (freshwater and ocean) currently produces only half that amount (FOLU 2019; Willett et al. 2019).

Table 18.14 Net benefit from decarbonising international shipping and benefit-cost ratio

Action	Net benefit by 2050 (US $, billions, 2019$)	Benefit-cost ratio (low)	Benefit-cost ratio (high)
Decarbonise international shipping	1152–9050	2:1	5:1

Source: Authors' calculations

6.4.1 Baseline, Sustainable Transformation Pathway and Target Scenarios

The 2019 FOLU report looks at ocean-based production across three sectors: wild marine capture fisheries, ocean-based fed aquaculture (finfish) and ocean-based nonfed aquaculture (bivalves). The production scenarios under BAU and the sustainable transformation pathways are shown in Table 18.15. Production is measured in million metric tonnes live-weight equivalent. Broadly, the transformation scenarios for the sectors were modelled in terms of possibilities of expanded production.

- **Wild-capture fisheries.** Costello et al. (2016) and Sumaila et al. (2012) estimate fisheries management that aims to maximise long-term catch (maximum sustainable yield) could increase fisheries production up to 96–99 mmt. This is higher than the current catch (80 mmt) and the projected BAU catch in 2050 (67 mmt) (Costello et al. 2019).
- **Fed mariculture production.** In the BAU scenario, fishmeal and fish oil feed requirements remain at current levels due to the absence of large investments into improving feed efficiency, limiting the growth of fed aquaculture (FOLU 2019). Under the sustainable transformation pathway scenario, aquaculture fishmeal and fish oil feed requirements decrease by 50% by 2050, allowing increased production in fed aquaculture to be achieved via measures such as feed efficiency and alternative feed replacement (FOLU 2019).
- **Nonfed mariculture production.** In the sustainable transformation pathway scenario, policy incentives to boost the eating of low-carbon food increase bivalve/mol-

Table 18.15 The business-as-usual and sustainable transformation pathways

Type of ocean-based food production	Business-as-usual scenario	Sustainable transformation pathway scenario
Wild-capture fisheries (marine)	Global annual marine capture production will decline from 80 mmt in 2020 to 67 mmt in 2050[a]	Global annual marine capture production stabilises at 96–99 mmt[b] by 2050
Fed mariculture (finfish)	Fed mariculture production remains at the 2020 level of 11.2 mmt[c]	Fed mariculture production increases to 22.4 mmt by 2050[c]
Nonfed mariculture (bivalves)	Bivalve mariculture grows to 28.5 mmt in 2050 from 16.3 mmt in 2020[c]	Bivalve mariculture grows to 65.2 mmt in 2050[c]

Notes: mmt million metric tonnes
[a] *Costello et al.* (2019)
[b] *Costello et al.* (2016, 2019); *Sumaila et al.* (2012); *this refers to the higher estimates of the Sumaila et al. optimal catch range under reform*
[c] *FOLU* (2019)

lusc production and consumption to 4% per annum as opposed to the BAU average annual growth rate of 3.1% over the last 10 years (FOLU 2019).

6.4.2 Assessment of Costs

The analysis in this paper builds on the investment cost estimates and assumptions in *The Global Consultation Report of the Food and Land Use Coalition* (FOLU 2019), Sumaila et al. (2012) and Mangin et al. (2018).

Capture Fisheries Reform

Analysis by Mangin et al. (2018) estimates that under a fisheries reform scenario, annual global fisheries management costs would be $13–15 billion, whereas under BAU, the costs are estimated at $8 billion.[33] Sumaila et al. (2012) estimate that the amount governments need to invest to rebuild world fisheries is between $130 billion and $292 billion in present value over 50 years, with a mean of $203 billion.[34]

Nonfed and Fed Mariculture Production

- Additional bivalve production (compared with BAU) is estimated at an average cost of $605 per tonne (FOLU 2019).
- In the sustainable transformation pathway scenario, the capital costs for setting up fed mariculture farms are estimated at $157 million for offshore mariculture and $60 million for nearshore mariculture for 2020–2030 (FOLU 2019; O'Shea et al. 2019).[35] Between 2020 and 2030, it is assumed that 25% of the additional production will come from new capital expenditures to build these farms (FOLU 2019). After 2030, we assume that the cost of investment will fall by 15%. The capital costs will fall from $157 million to $133 million over 2031–2050. All increases in production beyond 2030 come from new farms.
- Because mariculture expansion is limited by shortages and the rising costs of fishmeal made from forage fish, we assume that fed mariculture expansion is possible over 30 years (2020–50) because of a 50% reduction in traditional fishmeal, with the gap filled by novel feed ingredients such as insects or algae.[36] Although these alternatives currently cost more than fishmeal,[37] we assume prices will decline with innovation and scaled-up production.
- Increasing the scale of fed mariculture and replacing fishmeal and fish oil with alternative fish feed will lead to a change in the variable costs of mariculture farms. To calculate the impact on variable costs, we assumed that, until 2030, the price of alternative feed would be twice the price of fishmeal and then, because of innovations, it would fall to equal the price of fishmeal in 2030–2050.
- Public and private R&D spending across food and land-use systems was assumed to grow from 0.07% GDP (2018) to 0.1% of GDP by 2030. FOLU analysis assumes 20% of the additional R&D spending on food and land-use systems ($197 billion over 2018–2030) is allocated to alternative fish feed, intensification impacts and the scaling up of innovative production methods such as multi-trophic mariculture and offshore mariculture. After 2030, we assumed the R&D expenditure in the food and land-use systems would continue to grow at the same rate[38] (reaching 0.13% of GDP in 2040 and 0.17% in 2050), and the proportion spent on ocean-based proteins would remain the same.
- Under the Organisation for Economic Co-operation and Development 2030 scenario, mariculture would employ

[33]The paper estimates a country-level B-C ratio for management improvements for 30 countries. It categorises landings in each country into three broad management categories: catch share, where managers and regulators set a scientifically determined catch limit on the amount of fish that can be caught using measures (e.g., community-based allocation, individual quotas, individual vessel quotas, individual transferable quotas, and territorial use rights for fisheries); strong catch controls, which include a broad range of management that can be classified as strong biological management without catch shares; and a broad 'other' category that consists of the rest of the fisheries referred to as open access. It focuses on three types of fisheries management costs: administration (or management), research and surveillance, and enforcement (Mangin et al. 2018).

[34]The estimated transition costs include the costs to society of reducing the current fishing effort to levels consistent with the maximum sustainable yield and the payments governments may decide to employ to adjust capital and labour to uses outside the fisheries sector (such as vessel buyback programs and alternative employment training initiatives for fishers).

[35]This is based on estimates that the average capital expenditure for a large-scale, high-tech farm is $6.50–20.00 per kg (O'Shea et al. 2019). The average production per farm is estimated to be 3000 tonnes/year (FOLU 2019).

[36]We estimated the increase in fishmeal and alternatives required under the sustainable transformation pathway scenario where mariculture increases to 22.4 t by 2050. The gap filled by novel alternatives and associated costs is calculated via the following steps. (1) We calculated the existing fishmeal requirements in the BAU using the feed conversion ratio (FCR) and fishmeal inclusion rate for salmon production. We use an FCR of 1.5 and a fishmeal inclusion rate of 25% (Konar et al. 2019). We assume the fishmeal inclusion rate decreases by 50% (to 13%) in the sustainable transformation pathway scenario. (2) We assumed that under the sustainable transformation pathway scenario, 50% of the fishmeal production (100 million t) will be replaced by alternative ingredients by 2050. (3) Finally, we used the current capital cost to produce feed ($1426/t) as a proxy to calculate the additional capital investment required to expand alternative feed (Suleiman and Rosentrater 2018). Using these steps, we estimated $145 billion in additional investments will be required in alternative feed to expand production to meet the gap caused by reducing traditional fishmeal usage.

[37]The fishmeal price in 2018 was approximately $1600/t.

[38]This reflects the gradual growth of R&D expenditure observed for the world over 2000–2010. For all countries within the Organisation for Economic Co-operation and Development, R&D expenditure grew from 2.1 to 2.4% in 2017.

three million farmers (OECD 2016). We assumed all mariculture farmers would receive training for sustainable production and improving feed efficiency ($450 per farmer [FOLU 2019]) over 2020–2050.

Based on these estimates and assumptions, the discounted costs are estimated to be $656 billion over 30 years (2020–2050).

6.4.3 Assessment of Benefits

Health Benefits

The real gain in health benefits is the potential to increase sustainable protein supplies by encouraging more fish consumption (produced via sustainable means) over other protein sources. This would reduce human mortality and morbidity from reduced GHG emissions (see below for the link between GHG emissions and animal-based proteins), increase healthier diets and reduce health costs from reduced pesticide and antimicrobial exposure. This is estimated to be approximately $170 billion in 2030 and $390 billion in 2050 (FOLU 2019).

Sustainable sourcing of ocean protein and micronutrients also helps diversify nutritious food supplies, particularly for poorer coastal communities that depend disproportionately on fish for their protein and micronutrient consumption. The distributional health benefits to poorer communities have not been analysed or quantified here.

Environmental and Ecological Benefits

Livestock production has high GHG emissions and requires extensive land use. The demand for animal- based protein is projected to increase even more quickly than overall food demand by 2050 due to increases in the world population and in incomes across the developing world (Searchinger et al. 2019). Since foods vary widely in their embedded land use and GHG emissions per unit of protein (Poore and Nemecek 2018), changes in the composition of future diets could greatly affect the emissions consequences of growth in protein demand (González Fischer and Garnett 2016). It is estimated that CH_4 and N_2O emissions in the BAU food system scenario will grow from 5.2 $GtCO_2e$ in 2010 to 9.7 $GtCO_2e$ in 2050 (Springmann et al. 2018). Of that projected growth, over 75% will come from projected growth in animal products (Hoegh-Guldberg et al. 2019).

Ocean-based proteins are substantially less carbon intensive than land-based animal proteins (especially beef and lamb), with farmed bivalves being particularly climate friendly (Hoegh-Guldberg et al. 2019).[39] Therefore, actions that shift diets towards ocean-based proteins can reduce pressure on land and also reduce emissions. Moving to diets that are less dependent on terrestrial animal products, especially beef and lamb, would also slow the growth in demand for freshwater to support livestock agriculture (Hoegh-Guldberg et al. 2019). The transition, if properly managed, could yield benefits of $330 billion in 2050 (FOLU 2019).

In addition, such diet shifts will reduce deforestation, the majority of which will be driven by clearing forests for future meat production and consumption. Searchinger et al. (2019) estimated that animal-based foods accounted for roughly two-thirds of agricultural production emissions in 2010 and more than three-quarters of agricultural land use. Under BAU, the analysis estimated that agriculture would expand by nearly 600 million ha (an area nearly twice the size of India), including the expansion of 400 million ha of pasturelands (Searchinger et al. 2019). The additional reduction in emissions from preventing deforestation has not been included in the estimated benefits.

6.4.4 Economic and Social Benefits

Reforming fisheries will result in an increase in revenues and profits to fishers in the long term. Costello et al. (2016) state that after all fisheries are optimally managed, it will take 10 years for stocks to recover and will result in $53 billion in fisheries profits against the BAU scenario. Sumaila et al. (2012) estimate that rebuilding world fisheries could increase profits from the current negative $13 billion to a positive $77 billion per year. Comparing these benefits to the cost of management, Sumaila et al. (2012) and Mangin et al. (2018) show that the cumulative benefits of sustainable management of fish stocks exceed the management costs. Sumaila et al. (2012) state that rebuilding fisheries stock will deliver a net gain (net present value) of between $600 billion and $1.4 trillion over 50 years, versus transition costs of $130–292 billion.[40]

Estimated Benefits and Costs

Based on key reports and papers, the benefits from increasing the share of sustainably produced ocean-based proteins in diets is estimated to be 10 times the costs (Table 18.16). Evidence indicates that while the global B-C ratio for fisheries management reform is about 9.2-to-1, the ratio is higher than 200 for some countries (Mangin et al. 2018). Sumaila

[39]This does not include farmed shrimp, which can be quite high in GHGs. However, salmon/marine fish and bivalves score well in terms of lower GHG emissions.

[40]The lower bound corresponds to 82 t of catch and the upper bound, 99 t, which is closer to the Costello et al. (2016) estimates. To be consistent, we used both cumulative benefit and cost estimates from Sumaila et al. (2012), which offer a scenario in which the optimal fish landings increase to 99 t when calculating the total net present value for increasing consumption of sustainably produced ocean based protein from capture fisheries, fed aquaculture and nonfed aquaculture. The net gains are present value estimates calculated using a 3% discount rate (Table 18.17).

Table 18.16 Net benefits from increasing the production of sustainably sourced ocean-based proteins and benefit-cost ratio

Action	Net benefit by 2050 (US $, billions, 2019$)	Benefit-cost ratio
Increase production of sustainably sourced ocean-based protein in diets	6678	10:1

Source: Authors' calculations based on estimates from FOLU (2019)*, Mangin et al.* (2018)*, Sumaila et al.* (2012)

et al. (2012) estimate the B-C ratio for rebuilding global fisheries to be as high as 7:1. The value of net benefits is estimated to be $6.7 trillion over 30 years; the total benefits are $7.4 trillion versus $769 billion total costs.[41]

Data Limitations and Caveats

The estimates do not fully take into account the effects of climate change and ocean acidification. We recognise that there are regional differences and that there are barriers to shifting diets. See Appendix 4 for more details.

7 Conclusion

The overall rate of ROI can be high, with the average B-C ratio ranging from 3-to-1 to 12-to-1 (Table 18.17), and in some cases, such as conservation of mangroves and fisheries reform (for particular countries), it can be much higher. Our research found that investing $2.0–3.7 trillion globally across the four areas from 2020 to 2050 could generate $8.2–22.8 trillion in net benefits.

Actions to transform these four areas will bring multiple benefits. The total monetised and discounted benefits are estimated at $10.3–26.5 trillion over 2020–2050.

Monetised benefits include health benefits, such as reduced mortality from improved air quality, reduced childhood asthma and improved health outcomes from dietary shifts towards sustainably produced ocean-based protein; environmental benefits, such as avoided property losses from coastal flooding, the prevention of land degradation and reduced water usage; and economic benefits, such as reduced production costs due to technological improvements and increased profits from higher fisheries productivity.

The total monetised and discounted costs are estimated to be $2.0–3.7 trillion over 2020–2050. The costs assessed include costs to business (capital costs to set up new infrastructure, R&D costs and increases in variable costs), costs to government (regulatory costs, monitoring costs and research costs) and costs to households (loss of forgone income).

[41] The B-C ratios vary across the countries and range from 1.7 up to 268, with a median of about 14 for catch share management (Mangin et al. 2018).

Table 18.17 Summary of benefit-cost ratios for the four action areas in 2050

Action	Average benefit-cost ratio
Conserve and restore mangroves[a]	3:1
Decarbonise international shipping[b]	4:1
Increase production of sustainably sourced ocean-based proteins	10:1
Scale up offshore energy production[c]	12:1

Notes:
[a] *The ratio presented is the combined ratio for mangrove conservation and restoration. When assessing specific interventions, the benefit-cost ratio for conservation is estimated to be 88:1 and for restoration 2:1*
[b] *The benefit-cost ratio estimated for decarbonising international shipping ranges from 2:1 to 5:1*
[c] *The benefit-cost ratio estimated for scaling up of global offshore wind energy production ranges from 2:1 to 17:1*
Source: Authors' calculations

A number of impacts (both benefits and costs) have not been monetised but are important and must be considered during the policy decision-making process. These include the following considerations:

- Reduced GHG emissions have a positive correlation with the reduced risk of ocean acidification. The measures assessed can positively impact lower trophic species such as bivalves, which are affected disproportionately due to the compounding effects of shifts in temperature, chlorophyll and ocean acidification.
- The tourism value of mangroves (and other coastal ecosystems) may increase over time as biomass and diversity increase within the protected areas.
- A number of ecosystem services from mangrove protection and restoration have not been quantified.

  For example, vegetated coastal habitats are used by a remarkable number of marine and terrestrial animals. Dense mangroves buffer ocean acidification and are becoming recognised as valuable natural systems that can help treat wastewater (Ouyang and Guo 2016).
- Measures to reduce emissions in shipping that involve lowering ship speeds reduce the total sound energy generated and overall whale strike rate and, hence, positively impact marine mammals and other species.
- The distributional impacts of the benefits and costs have not been measured. For example, poor coastal families are the most vulnerable in natural disasters, so building ecosystem resilience to protect them from coastal flooding and cyclones will not only safeguard their valuable assets but also generate tremendous social benefits (e.g., feeling safe) that cannot be easily monetised. The estimates also do not take into account the additional nutritional benefits to human health in terms of micronutrients, particularly in low- and middle-income countries.
- The analysis does not account for changes to the B-C ratio based on changes in the global physical risk profile associ-

ated with climate change. Often, the costs of climate change–related risks are underestimated, including the potential damage of weather-related shocks and sea level rise. If 'resilience' (e.g., through the integration of natural flood defences) is built into investments, then the benefits (e.g., of protective mangroves) could include a reduction in the cost of capital (due to improved risk-adjusted performance metrics) and/or reduced long-term operational expenses (e.g., through avoided losses and reduced maintenance costs).

Given that the B-C ratios in Table 18.17 are a partial estimate of all benefits and costs likely to accrue as a result of the specified investments, they should be treated as indicative to provide the relative scale of benefits from sustainable ocean-based investments compared with the costs. Further research and analysis to address gaps in quantifying benefits will help provide a more complete picture of their value versus their costs. The analysis does not attempt to show the regional variation of the costs and benefits, nor does it show the distribution of benefits and cost across society (especially focusing on the impact on vulnerable groups). Conducting these assessments should be a key step when implementing ocean-based policies and regulations.

Although data limitations prevented a full accounting of all benefits and costs, the results of the analyses suggest that taking the following actions to transform the ocean economy will generate a host of benefits that are larger in magnitude than the costs:

- **Conserving and restoring mangroves.** While the B-C ratio for restoration is lower than for conservation, both types of interventions yield significant benefits and, hence, are both important to ensure a high ROI. Protection measures to conserve these ecosystems should be enhanced along with measures that provide incentives for restoration (e.g., payment for ecosystem services schemes) (Hoegh-Guldberg et al. 2019).
- **Scaling up offshore wind energy production.** Scaling up offshore wind energy to replace fossil fuel–based sources of power generation will help deliver better local health outcomes, reduce risks of damages from climate change, create jobs and deliver immediate environmental benefits such as reduced water usage. Measures such as marine spatial planning is key to ensuring offshore wind technologies amplify these benefits as well as mitigate any environmental risks to habitats and marine species (Hoegh-Guldberg et al. 2019).
- **Decarbonising the international shipping sector.** Transitioning international shipping to net-zero emissions by 2050 will be costly, but these measures will be key to realising the estimated scale of benefits (health outcomes and environmental benefits), which substantially outweigh the costs.
- **Increasing the production of sustainably sourced ocean-based proteins**. Substantial gains in fisheries productivity can be achieved through better management of fish stocks, which eliminates overfishing, illegal and unregulated fishing and discards of nonmarketable fish. Sustainable marine aquaculture practices will also help meet the growing food demand. Technological innovation and adoption in breeding, production systems, disease control and environmental management will help improve mariculture's productivity and environmental performance (Waite et al. 2014). Encouraging innovation can make valuable contributions to the future scalability and lower prices of substitutes as forage fish resources become scarce (Konar et al. 2019). Incentives are required to shift diets towards low-carbon ocean-based proteins and away from high-carbon land-based sources of protein (Hoegh-Guldberg et al. 2019).

Acknowledgements The authors would like to thank the following people for their review, feedback and inputs: Juan Carlos Altamirano, Maximilian Bucher, Lauretta Burke, Linda Cornish, Diletta Giuliani, Craig Hanson, Peter Haugan, Norma Hutchinson, Catherine Lovelock, Sara MacLennan, Justin Mundy, Finn Gunnar Nielsen, Eliza Northrop, Linwood Pendleton, Alex Perera, Carlos Muñoz Pina, Tristan Smith, Mark Spalding, Michael Tlusty, Laura Malaguzzi Valeri, Adrien Vincent, Richard Waite, Jacqueline Wharton and Sophie Wood. While our colleagues were very generous with their time and input, this report reflects the views of the authors alone.

The authors would also like to acknowledge Maximilian Bucher for his valuable assistance, advice and contribution, especially in terms of providing essential data from *The Global Consultation Report of the Food and Land Use Coalition*, clarifying its underlying assumptions and suggesting modifications for the purposes of this study.

Thank you also to Mary Paden, Lauri Scherer, Carni Klirs and Rosie Ettenheim for providing administrative, editing and design support.

Appendix 1. Conservation and Restoration of Mangrove Habitats

Increasing Ecosystem Services from Mangrove Conservation and Restoration

Vegetated coastal habitats are used by a remarkable number of marine and terrestrial animals (Li et al. 2018; Rog et al. 2017). Dense mangroves trap and stabilise sediments that buffer the effects of floodwaters and tidal movements. They are becoming recognised as valuable natural systems that can play an important role in wastewater treatment systems (Ouyang and Guo 2016). The values of these ecosystem services can be significant, as demonstrated in Box 18.5, which provides a local example of the scale of these values for mangroves in Myanmar. While global value estimates of ecosystem services exist (i.e., Costanza et al. 1997, 2014; de Groot et al. 2012), many of these estimates are resulting from meta-analysis (i.e., analysis of analyses) rather than primary valuation studies. Hence, there have been concerns around the validity of using these values for simple benefit transfer without accounting for specific characteristics of the sites where ecosystem service value needs to be estimated (Himes-Cornell et al. 2018). We thus excluded them from the current B-C ratio analysis. However, as new primary valuation data become available, incorporating such benefits will improve marine decision-making.

Data Limitations and Caveats

- We excluded salt marshes and seagrasses from the calculation due to limited global data availability for both in terms of benefit assessment. During the literature review, only one study (Carnell et al. 2019) was found to assess the improvement in fisheries productivity through seagrass conservation, but the estimate is very local, pertaining only to Australia. Restoring salt marshes and seagrasses is found to be more expensive than restoring mangroves because most salt marsh and seagrass restoration efforts did not reach economy of scale.
- The actual conservation and restoration costs for mangroves might be lower or higher depending on the specific location, the sizes of the targeted areas and the measures used. Total restoration costs are up to 30 times cheaper in countries with developing economies (compared to Australia, European countries and the United States) (Bayraktarov et al. 2016).
- The analysis assumes a survival rate of 51.3% for the restored area, based on median survival rates provided by Bayraktarov et al. (2016). In reality, however, survival rates vary significantly between sites due to a few factors in play. First, the survival rate of mangroves is highly species-specific (Mitra et al. 2017). Second, a lack of incentives to engage local residents in the long-term management of restored areas is another reason for low survival rates (Hai et al. 2020). Addressing these factors will be key to improving restoration survival rates and achieving the scale of the benefits described in this study. Restoration efforts should follow a protocol that includes diagnosing the causes of the deterioration or deforestation of the mangroves, setting a baseline, planning restoration activities and long-term monitoring of the restoration project (Hai et al. 2020). Strong community participation in managing the ecosystem, including in the planning, implementation, management and monitoring, will be essential to ensure the success of restoration efforts.
- It is not yet understood how climate change will affect the productivity and resilience of coastal mangroves. In marine ecosystems, rising atmospheric CO_2 and climate change are associated with concurrent shifts in temperature, circulation, stratification, nutrient input, oxygen content and ocean acidification, with potentially wide-ranging biological effects (Doney et al. 2012). However, there is less confidence regarding the influence temperature will have on interactions among organisms, which is important for ecosystem productivities (Kennedy et al. 2002).
- The analysis does not account for the opportunity costs of coastal developments. The economic value of protecting and restoring coastal habitats, even when the necessary legal framework is in place, often loses out to the economic value of coastal development—even when sea level rise, storm surge and other risks are clearly present. To mitigate these risks, a better understanding of the drivers of degradation is needed, as are measures (policy and educational) that aim to change consumer/human behaviour and raise awareness of the benefits derived from nature-based solutions.
- Marine and coastal ecosystem conservation may result in short-term economic losses due to the forgone economic gains from any prohibited or reduced commercial fishing activities (opportunity costs). However, in the long term, this will help increase the productivity of fisheries in nearby fishing grounds through fish migration and reduce the risk of ecosystem collapse due to overfishing. The conservation benefits estimated are highly dependent on the annual carbon mitigation potential estimated by Hoegh-Guldberg et al. (2019) and the avoided risk of climate damages estimated using the social cost of carbon.

Box 18.5 The Economic Value of Key Mangrove Benefits in Myanmar

The values for ecosystem services of mangroves in Myanmar, as estimated by Estoque et al. (2018), illustrate the scale of the benefits that accrue to society from various ecosystem services.

In Myanmar, a mangrove's most valuable service is as a fish nursery (US $9122 per hectare [ha] per year) and as coastal protection from storm surges ($1369/ha/year). Recreational benefits are estimated at $476/ha/year. Mangroves also regulate water flow ($275/ ha/year) and water quality ($61/ha/year) (see Table 18.18).

Table 18.18 Value of mangroves in Myanmar

Ecosystem service	Valuation method	Value (2018US $/ha/year)
Wood-based energy and timber	Value of marketed and nonmarketed production	7.22
Coastal protection	Avoided expenditures on physical reclamation and replenishment	1369.28
Hazard mitigation	Costs of equivalent engineered storm protection defences	349.01
Regulation of water flow	Expenditures saved on alternative freshwater sources (alternative deep well and borehole drilling, piping)	275.25
Regulation of water quality	Reduced costs of wastewater treatment and sediment trapping	617.13
Mitigation of climate change	Potential value of carbon emissions reductions offsets sales	304.64
Maintenance of fisheries nursery populations and habitat	Contribution to on-site and off-site capture fisheries	9112.45
Recreation and experiential	Tourism expenditures and earnings	475.97
Cultural, amenity and aesthetics	Domestic and international visitor willingness to pay	28.46

8 **Appendix 2.** Scaling Up Offshore Wind Energy Production

Data Limitations and Caveats

Potential risks to biodiversity could arise or increase with the expansion of wind energy, especially as it moves farther from the coast. In such cases, it could be more difficult or costly to mitigate impacts on habitats and wider biodiversity.

- The types of generation displaced by ocean energy will depend on the specific generation technologies and costs in places where ocean energy is located. On grids that have a high share of zero-carbon generation, including hydropower and nuclear energy, adding ocean energy will not decrease emissions significantly. Conversely, for grids with a high share of carbon-intensive generation, emission displacements could be significant.
- The cost of building more offshore wind generation will vary depending on the supply chain and infrastructure available in each market. The investment required will be much higher for developing nations than for countries like Denmark that already have a wind power market.
- The analysis focuses solely on offshore wind energy generation because the projected future costs of other ocean renewable energy installations are subject to high uncertainty because energy development is still immature. Further analysis in this area will help provide a more holistic picture on the ROI for the ocean energy sector overall.
- Water-saving benefits are estimated based on the opportunity costs of water. Direct financial benefits are also associated with water savings, but we excluded them from the benefit assessment because local water prices vary greatly across countries.

Appendix 3. Decarbonising International Shipping

Estimating the Avoided Costs of Childhood Asthma

In schoolchildren, asthma leads to lost school days, which limits academic performance and has consequent psychological effects. Therefore, children with asthma have more indirect costs than older asthmatics, as the direct cost to parents is limited to missed workdays and other expenses. The total avoided costs from childhood asthma are estimated by summing the health care costs, the cost of school absenteeism and adult missed workdays. The following assumptions are made to derive the avoided costs from childhood asthma:

- Globally, 86 million children could suffer from asthma, based on the fact that 334 million people in the world have asthma and 26% of the world population is 14 years or younger (Global Asthma Network 2018).[42] Evidence-based regression analysis shows that 16% of these cases could be attributed to shipping (Sofiev et al. 2018), accounting for 14 million childhood asthma cases.
- Sofiev et al. (2018) states that childhood asthma morbidity due to shipping declines by 54%, from 14 million children affected in the BAU case to 6.4 million children in the 2020 Action case.[43] We assume these benefits are delivered in 2030 (i.e., when 54% of children suffering from asthma are asthma free). We assume a 100% reduction of GHG emissions in shipping will reduce childhood morbidity cases (attributable to shipping) by 100% (14 million).
- The average missed days is estimated to be 6.4 days per child (Nunes et al. 2017; Ojeda and Sanz de Burgoa 2013), and we assume at least one adult loses that many days of work per year to care for the child. The value of additional days lost attributable to asthma per year was $301 for each worker and $93 for each student (Nunes et al. 2017).

[42] Without adjusting for the higher prevalence for asthma among young and old persons.

[43] The 2020 Action assumes on-time implementation of the IMO's 0.5% low-sulphur fuel standard.

- The average annual health financial costs to government for treating pediatric asthma is estimated to range from $3076 to $13,612 per child in the United States (Perry et al. 2019). We take this as a proxy of the global health care cost to treat the illness.

Data Limitations and Caveats

- The analysis does not incorporate all potential cost reductions from innovation and increased R&D efforts. In this respect, the model is conservative because these factors would be expected to reduce technology capital costs. The analysis does not account for additional infrastructure investments such as safe storage and handling of hydrogen/ammonia at the ship-to-shore interface.
- The costs of investments increase (and consequently B-C ratio decreases) if we assume a scenario where the cost of alternative fuel is higher.
- The analysis does not compare the carbon impact of ship transportation versus air transportation. Investment in cleaner ships to meet demands from a growing economy will lead to a lower carbon footprint solution for global trade and travel (versus ground or air transport of goods and people).
- The analysis is static and does not analyse the secondary or indirect impacts following the shipping sector transitioning to a low-fuel economy. Although switching to cleaner fuel will impose costs to the shipping industry, the overall impacts on the economy will depend on how the firms absorb the increase in costs and, thus, are relatively uncertain. Being faced with higher cost, the industry could transfer part of the impacts to the price of final commodities (more likely if they are price inelastic), produce more local product, or reduce profit margins, which would lead to lower future capital investment until the industry's market equilibrium returns. The overall impact on consumers and households will depend on which of these impacts dominate, and by what extent. In most developed economies, impacts are expected to be negligible, and there are policy options for managing impacts in especially vulnerable and/or disproportionately impacted countries.

Appendix 4. Increasing the Production of Sustainably Sourced Ocean-Based Proteins

Data Limitations and Caveats

- The report by the EAT-*Lancet* Commission has set out scientific targets for healthy diets that will optimise human health (Willett et al. 2019). By its own admission, the report did not have the scope to fully analyse fishing and mariculture systems globally. Therefore, while some estimates were included on recommended fish intake, more detailed analysis is needed. EAT, along with other partners,[44] is supporting further work to expand scientific understanding of the role of ocean-based protein for planetary health and human well-being. This research, referred to as the Blue Food Assessment, aims to outline pathways for a transformation to sustainable and healthy blue food for all people on the planet, now and into the future. Analysis has focused on marine food production, but a greater understanding of aquatic food production as a whole (including freshwater fisheries and aquaculture)[45] is needed to evaluate the benefits and costs of aquatic food to human health and the environment. Those working on the Blue Food Assessment have recognised this and aim to incorporate it into the analysis.
- The fisheries reform scenarios are optimistic and assume optimal fisheries management everywhere, which may not be achievable in reality. In addition, the impacts of climate change, such as warming sea temperatures, on fish stocks and their movements have not been fully taken into account in this paper because they are difficult to model and cost. The authors recognise that impacts on production could be significant in some regions.
- The projections do not incorporate the potential impacts of ocean acidification on fish and fisheries. There is a lack of sufficient understanding of the capacity for marine organisms to adapt through acclimation as well as transgenerational and evolutionary adaptation (Gaylord et al. 2015; Munday 2014; Munday et al. 2013) to reliably predict ocean acidification impacts on marine populations and ecosystems (FAO 2018).
- The FOLU (2019) analysis states that the benefits are the difference between the global hidden costs under the better future and current trends scenarios. It provides an indicative estimate of the potential benefits accruing to the global economy from following the better future development path relative to remaining on the current trajectory. For the aquaculture sector the FOLU does not estimate the increase in revenues from production or direct benefit in terms of value added to GDP (which is accounted for under the fisheries reform scenario); rather, it is a reduction in the size of the externalities currently stemming from food and land use.

[44] Partners include the Food and Agriculture Organization, Friends of Ocean Action, Stanford Center for Ocean Solutions, Stockholm Resilience Centre, World Economic Forum and World Resources Institute.

[45] Currently, the majority of aquaculture production is inland or freshwater, which constitutes 64% of the total global aquaculture production, and the proportion is likely to be higher in Asia (FAO 2018).

- There are many barriers to shifting diets away from emission-intensive land-based sources of protein such as beef and lamb.[46] Consumer purchases are typically based on habit and unconscious mental processing rather than on rational, informed decisions (Ranganathan et al. 2016). Factors such as price, taste and quality tend to be more important than sustainability in purchasing decisions (Ranganathan et al. 2016). The costs of policy measures and business practices—such as private/public procurement, marketing and campaigning costs or sending clear market signals via carbon taxes or changes in subsidies—to enable a change in diet have not been estimated in this analysis. Several assumptions have been used to estimate the costs; hence, these should be treated with caution.
- The estimates do not take into account the additional nutritional benefits to human health in terms of micronutrients, not just protein, particularly in low- and middle-income countries. Ocean-based food production provides food security during extreme events (e.g., heavy rainfall and hurricanes) when the supply of land-based food sources is affected and limited.
- The average B-C ratio calculated here hides the regional and local variances that will occur in aquatic food production. These variances are likely to impact the livelihoods of smaller-scale fishers and farmers the most, and they often have the lowest resilience to changes in capture/farming levels.

About the Authors

Manaswita Konar is the Lead Ocean Economist at the World Resources Institute's Sustainable Ocean Initiative. Contact: Manaswita.Konar@wri.org.

Helen Ding is an Environmental Economist at the World Resources Institute. Contact: Helen.Ding@wri.org.

About WRI

World Resources Institute is a global research organization that turns big ideas into action at the nexus of environment, economic opportunity, and human well-being.

[46]Reducing consumption of animal-based foods should not be a goal for people who are underconsuming. Animal-based foods provide a concentrated source of some vitamins and minerals that are particularly valuable to young children in developing countries whose diets are otherwise poor (Ranganathan et al. 2016).

Our Challenge

Natural resources are at the foundation of economic opportunity and human well-being. But today, we are depleting Earth's resources at rates that are not sustainable, endangering economies and people's lives. People depend on clean water, fertile land, healthy forests, and a stable climate. Livable cities and clean energy are essential for a sustainable planet. We must address these urgent, global challenges this decade.

Our Vision

We envision an equitable and prosperous planet driven by the wise management of natural resources. We aspire to create a world where the actions of government, business, and communities combine to eliminate poverty and sustain the natural environment for all people.

Our Approach

Count It

We start with data. We conduct independent research and draw on the latest technology to develop new insights and recommendations. Our rigorous analysis identifies risks, unveils opportunities, and informs smart strategies. We focus our efforts on influential and emerging economies where the future of sustainability will be determined.

Change It

We use our research to influence government policies, business strategies, and civil society action. We test projects with communities, companies, and government agencies to build a strong evidence base. Then, we work with partners to deliver change on the ground that alleviates poverty and strengthens society. We hold ourselves accountable to ensure our outcomes will be bold and enduring.

Scale It

We don't think small. Once tested, we work with partners to adopt and expand our efforts regionally and globally. We engage with decision-makers to carry out our ideas and elevate our impact. We measure success through government and business actions that improve people's lives and sustain a healthy environment.

A Sustainable and Equitable Blue Recovery to the COVID-19 Crisis

19

Eliza Northrop, Manaswita Konar, Nicola Frost, and Elizabeth Hollaway

Highlights

- With a longer-term vision and the right actions, the COVID-19 pandemic can mark the beginning of a new type of global and societal cooperation in building a sustainable ocean economy.
- The pandemic has had deep and wide-reaching consequences for people around the world, resulting in a crisis that has led to significant loss of human life, increasing food and nutritional insecurity and poverty, and affecting almost all areas of the global economy.
- The ocean economy, which contributes upwards of US $1.5 trillion in value added to the global economy has been particularly hard hit by the pandemic. Significant revenue losses have been felt across coastal and marine tourism, fisheries and aquaculture, and the global shipping industries. Hundreds of millions of jobs have been affected, with disproportionate impacts for developing and small island nations and already vulnerable coastal communities.
- The linkages between ocean-based sectors and land-based economies mean that the pandemic's impacts flow beyond these individual sectors, with economic and social repercussions across the entire economy. A sustainable and equitable recovery is critical not just for those who live or work near the coasts but for the well-being and resilience of societies and economies at large. Despite the significance of the impacts, only a limited number of investments through stimulus and recovery packages are currently directed towards affected ocean workers, coastal communities and the sustainable rebuilding of the ocean economy.
- Furthermore, many response measures have the potential to reverse progress made to date on ocean sustainability and exacerbate the existing threats to ocean health, undermining the myriad non-monetary benefits provided by the ocean which are essential to human well-being and prosperous societies, and the ability of the ocean to continue to be a workplace, a source of income, livelihoods and nutritional food for billions of people worldwide.
- Investment through recovery and stimulus packages represents a crucial lever for accelerating the shift from business as usual to a more sustainable future that delivers on global targets under the 2030 Agenda for Sustainable Development, the Convention on Biological Diversity and the Paris Agreement.
- Humanity is at a critical crossroads. Stimulus which locks in high-emitting, high-polluting and inequitable development pathways now will have catastrophic implications for ocean health, the global climate emergency, economic resilience, human health and prosperity.
- The strategic investment of recovery and stimulus funds into the ocean economy offers an untapped opportunity to support job creation and economic diversification and relief in the short term. Such investments can also accelerate the sustainable and equitable growth of ocean industries, thereby securing the long-term health and resilience of the ocean and ocean economy and the myriad benefits that it provides to humanity.
- This report proposes a set of five priority opportunities for governments to consider for the immediate investment of stimulus funds to support a 'sustainable and equitable blue recovery' from the COVID-19 crisis. These mutually beneficial, no-regrets 'blue stimulus' opportunities, identified on the basis of criteria, are particularly relevant at this time for their potential to deliver short-term economic, social (health) and environmental benefits for affected communities and sectors, while building longer-term social, economic and ecological resilience:

  - Invest in coastal and marine ecosystem restoration and protection.
  - Invest in sewerage and wastewater infrastructure for coastal communities.
  - Invest in sustainable community-led non-fed marine aquaculture (mariculture) (e.g. shellfish and seaweed).
  - Incentivise zero-emission marine transport.
  - Incentivise sustainable ocean-based renewable energy.
- As evidenced by the stimulus response to the 2008–2009 global financial crisis, not all investments will be directed at measures capable of providing job creation in the short term. Instead, much of the investment will be used to lay the foundation for long-term recovery through systemic transitions to improve the efficiency and cost-effectiveness of the economy and initiating large infrastructure projects that will yield benefits over the next 10–30 years.

  This report proposes a set of additional opportunities that are more systemic and oriented towards using this critical juncture to sustainably reset the ocean economy. This will enable the accelerated transition of ocean industries towards smarter, sustainable practices that conserve marine ecosystems, promote human well-being and build social and economic resilience to future shocks.
- Maximising the use of financial mechanisms (e.g. debt restructure and financial grants) offers an unprecedented opportunity to incentivise sustainable recovery efforts and avoid a roll-back in advances already made in sustainable fisheries management, marine conservation and ocean data.
- Heightened awareness of the importance of coordinated and evidence-based global action to shared challenges, and rapid shifts towards new technologies and working practices as evidenced during the COVID-19 crisis, may create new opportunities for advancing the 2030 Agenda for Sustainable Development and the Paris Agreement.
- The urgency cannot be overstated. As the world continues to battle the health crisis, millions are without incomes to provide for themselves and their families. They need a job and a lifeline, for right now and for the future. Policymakers and financial decision-makers must consider the potential of the ocean economy's role in social and economic recovery and ensure that the ocean economy rebuilds to be more sustainable, equitable and resilient—as this is key to our global prosperity and well-being.

1 Introduction

A healthy ocean is the foundation for prosperous, healthy and vibrant economies. There is an unprecedented opportunity, through global stimulus and recovery responses to the COVID-19 crisis, to reset and rebuild economic activities in ways that will ensure a more sustainable, equitable and resilient ocean economy fit for everyone's future. This report provides a roadmap to achieve this vision.

1.1 Context

The COVID-19 pandemic has caused an unprecedented human health crisis around the world, resulting in significant loss of life. Emergency measures introduced to curb the extent of the virus have led to severe restrictions on human mobility, economic activities and services, affecting large swathes of the economy and resulting in widespread unemployment and impacts on people's livelihoods, well-being and wider health (Xu and Joyce 2020).

The resulting global economic downturn is expected to exceed the one experienced during the 2008–2009 global financial crisis (Bluedorn and Chen 2020). The global economy is projected to contract by 4.9–6% in 2020 (IMF 2020a), the largest economic dip since the global depression of the 1930s (OECD 2020c). Gross domestic product (GDP) is expected to shrink in nearly every country in 2020, although with significant variation reflecting differing national circumstances.

As economic projections have been revised downwards, unemployment has continued to rise. Worldwide, some 300 million full-time jobs could be lost, and nearly 450 million companies are facing the risk of serious disruption (ILO 2020c), reducing local incomes, tax revenues and foreign exchange earnings. Early evidence suggests that groups that were economically most vulnerable before the pandemic will experience the greatest impacts, exacerbating existing inequalities within society (UN DESA 2020a). Globally, the COVID-19 pandemic may force as many as 100 million people into extreme poverty and could double the number of people facing acute hunger, to 265 million people by the end of 2020 (Anthem 2020).

Before the pandemic, ocean-based industries such as fishing, energy, shipping and marine and coastal tourism had been conservatively estimated to contribute 2.5% of world gross value added, a value that was predicted to double by 2030 (OECD 2016).

As of 2010, these ocean-based industries contributed some 31 million direct full-time jobs (OECD 2016). This figure is significantly higher when jobs provided through informal or artisanal employment are included. For example, upper estimates in 2011 suggest that the fisheries sector alone provides the equivalent of 237 million full-time jobs when small-scale fisheries and artisanal employment are also considered (Teh and Sumaila 2013). The ocean also connects cities and countries around the world, driving economic activity and trade for the more than a third of the global population that lives within 100 km of the sea (Kummu et al. 2016). Most of the world's megacities are located in the coastal zone.

A healthy ocean not only underpins the global economy but also provides myriad non-monetary benefits alongside essential goods and services that are vital for healthy human societies, including regulating the global climate, offering a storehouse of compounds key for fighting disease (Blasiak et al. 2020) and providing natural infrastructure to protect against storm surges, flooding and coastal erosion. Fish and fish products are among the most highly traded foods in the world, supplying a critical source of animal protein, micronutrients and omega-3 fatty acids, particularly in low-income, food-deficit countries and small island developing states (SIDS) (FAO 2020a).

The pandemic has significantly disrupted ocean sectors and global supply chains. These ocean industries do not operate in isolation from one another, or from the ocean environment of which they are part (OECD 2016). This has led to cascading and interrelated impacts across the ocean economy, marine ecosystems and society.

Fiscal measures announced in response to the COVID-19 crisis by G20 nations are already three times greater than those made available during the 2008–2009 financial crisis. More is expected as the focus shifts from emergency spending to recovery investments. The UN secretary general, António Guterres, has called for a coordinated approach to social and economic recovery from the pandemic, a response that does not lose sight of the parallel threat to the global community posed by the climate emergency. Leaders from business and civil society alike are advocating for this unprecedented situation to be used as a catalyst for a cleaner, greener and more resilient future (Harrabin 2020).

The actions that governments and financial institutions take now to repair and rebuild the global economy will chart the course of economic growth and sustainability for many years to come. Although the nature of the investments themselves might have a short-term focus, their impact will be felt over the medium to long term. It is therefore important to avoid locking in high-emitting, high-polluting and inequitable pathways that limit the ability to build sustainable and resilient economic systems. Investment through recovery and stimulus packages represents a crucial lever for accelerating the shift from business as usual to a more sustainable future that delivers on global targets under the 2030 Agenda for Sustainable Development, the Convention on Biological Diversity and the Paris Agreement.

While the solutions will differ from one country to another, humanity has a unique opportunity to reboot economic activities in a way that is more firmly in service of society and restores planetary health for future generations. A healthy ocean is essential in the quest for a sustainable and prosperous future, and it will be an important ally in rebuilding national and global economies from the impacts of COVID-19 and lifting communities out of poverty. Cumulative impacts to ocean health resulting from unsustainable development, overexploitation of natural resources, pollution and climate change are, however, already causing rapid changes across ocean ecosystems, undermining the ocean's ability to continue to provide vital benefits and services to the global economy and humanity. A transformational shift is needed in the relationship between humanity and the ocean, in acknowledgement of its material and non-material values and importance, to ensure that the solutions pursued in response to the COVID-19 crisis do not further undermine ocean health or the future opportunities associated with the growth of a sustainable ocean economy.

The importance of green stimulus to maintain advances towards a greener economy has been recognised by some governments, yet few have recognised the role that 'blue' stimulus opportunities could also provide in supporting advances to meet environmental and climate change challenges. This report considers this gap between the impacts and responses and offers a set of high-level guiding principles for governments and financial institutions to consider as a first step towards ensuing a sustainable blue recovery to COVID-19. It also supports the notion that a 'blue' recovery is a 'green' recovery and vice versa—the decision to ensure a sustainable blue recovery does not come at the expense of a green recovery—they should go hand in hand and cover the full land-to-ocean interface of activities.

Early indications suggest that society may emerge from this crisis to be less cooperative and effective (Sachs et al. 2020). However, with a longer-term vision and the right actions, the pandemic can mark the beginning of a new type of global and societal cooperation in building towards a sustainable ocean economy—which for the purposes of this report is described as the sustainable use of ocean resources (produce) in ways that preserve the health, function and resilience of ocean ecosystems and associated services (protect) and improve livelihoods and jobs (prosper). Given the importance of the ocean as a workplace and a source of income, livelihoods and nutritional food for billions of people worldwide, the importance of resetting the ocean economy on a sustainable and just path so as to reduce vulnerability to future shocks, restore resilience in natural systems and redress existing inequalities must not be overlooked.

1.2 About This Report

1.2.1 Scope

This report aims to provide a holistic assessment of the impact (economic, social and environmental) that COVID-19 has had on the ocean economy. Section 2 considers the emerging impacts on the ocean economy and early responses to the crisis by governments, financial institutions, industry, intergovernmental organisations (IOs) and non-governmental organisations (NGOs). In considering the impacts, it looks at six key sectors—marine and coastal tourism, fisheries, marine aquaculture (mariculture), shipping, energy and marine conservation—as well as how these impacts are interconnected across the ocean economy as a whole. Recognising that this crisis continues to evolve, these impacts represent a snapshot in time but can still offer important lessons on the scope and degree to which recovery measures must take into account ocean-based sectors, workers and affected communities, and the health of the ecosystems upon which these industries depend.

Section 3 provides a roadmap for a 'sustainable and equitable blue recovery' predicated on three mutually reinforcing elements—effective protection of ocean ecosystems, sustainable production and equitable prosperity. It outlines

- high-level guiding principles for ensuring a 'sustainable and equitable blue recovery' to aid governments as they consider the nature of their recovery after COVID-19 (Sect. 3.1);
- 'blue stimulus' opportunities that are ripe for the immediate investment of stimulus funding and which can deliver short-term economic benefits to affected communities or sectors while also providing longer-term social and environmental benefits (Sect. 3.2);
- 'blue transformations' opportunities, which through more systemic or longer-term policy reform can accelerate the transition towards a sustainable ocean economy in order to secure economic recovery, resilience and prosperity over the longer term (Sect. 3.3); and
- 'blue conditionality' opportunities associated with financial grants and debt relief which can advance key reforms in areas such as sustainable fisheries management and monitoring and enforcement of protected areas (Sect. 3.4).

1.2.2 Approach

The report relies on real-time analysis of impacts of the COVID-19 crisis presented in published reports, working papers and blog posts to help provide an aggregated picture of the resulting economic, social and environmental impacts of COVID-19 on the ocean economy (Sect. 2.1). The COVID-19 response measures (Sect. 2.2) are based on systematic review of the policy response reports from international organisations (such as the International Monetary Fund and World Bank), think tanks, consultancies, academic institutions and national government websites. Both the impacts and response measures are rapidly evolving landscapes and, as such, these sections are not intended to provide a comprehensive overview of the status quo.

The opportunities for investment of stimulus funding identified in Sect. 3 are based on an extensive literature review and set of criteria to identify priorities that respond to the needs of governments and communities now, but which also help catalyse progress towards a sustainable ocean economy. These criteria were selected through literature review, and through expert input from bilateral and multilateral funders and government representatives involved in the design of recovery and stimulus packages. The opportunities highlighted in Sect. 3 of this report are not exhaustive of what will be required to fully transition to a sustainable ocean economy. There is already extensive literature on the solutions and opportunities for action to build a sustainable ocean economy that should be referred to in conjunction with this report—which focuses on the particular economic challenges and opportunities facing governments at this time. Annex 2 offers a summary of relevant literature.

The report draws on publicly available information (including news articles, expert opinion pieces, peer reviewed reports, academic studies and project-specific case studies) to identify potential (short- and long-term) economic, social and environmental benefits for the priority areas of action and interventions identified.

The figures included are offered as proof points and illustrative examples, not as conclusive statements or guarantees. For numbers of potential job creation, many of the estimates presented in the report are based on range of studies, including ones that use input–output (I-O) models to derive job numbers, which have their limitations[1]. The benefits (economic, social or environmental) that may accrue as a result of a particular policy decision or financial investment will be specific to the location, economy and population they relate to.

While it is beyond the scope of this particular assessment, the value of new analysis in these areas—particularly an assessment of the direct and indirect employment opportunities associated with transitioning to a sustainable ocean economy—is well recognised and encouraged to inform decisions that relate to the ocean's contribution to socioeconomic development.

In generating this report, the authors engaged with the 14 offices of the heads of state and government represented on the High Level Panel for a Sustainable Ocean Economy (www.oceanpanel.org) to gather real-time information on country impacts, response measures and priorities, and the relevance and feasibility of interventions for these diverse geographies and economies. This report is, however, an independent input to the Ocean Panel process and does not reflect the views of the Ocean Panel members.

2 Emerging Impacts and Early Responses

Jobs and sectors in the ocean economy and already vulnerable coastal communities have been hard hit by the COVID-19 crisis with significant revenue losses felt across coastal and marine tourism, fisheries and aquaculture, and the shipping industry. The linkages between ocean-based sectors and land-based economies mean that these impacts flow beyond these individual sectors to have economic and social repercussions across the entire economy. Only a small proportion of COVID-19 stimulus packages account for the impacts suffered by coastal communities and workers in the ocean economy and an even smaller subset focuses on transitioning to a sustainable ocean economy.

[1] *I-O analyses can portray the linkages between sectors well, based on industry-level accounts. However, they have several weaknesses, including the assumption of fixed prices (prices do not change when demand for a good, service, or input changes), fixed ratios of labour to other factors of production and fixed sectoral share of GDP over time.*

2.1 Emerging Impacts on the Ocean Economy

This assessment focuses on the impact that the crisis is having across six ocean-based sectors. We consider three categories of impacts (Table 19.1):

- **Economic impact** measures the impact on output, jobs, revenue, future investment targets and productivity of ocean-based sectors.
- **Social impact** identifies vulnerable groups (such as women, workers in the informal sector, young workers and Indigenous community members), poorer communities or low-skilled essential workers who face higher health risks due to limited access to healthcare and are disproportionately affected due to job losses and loss of livelihoods.
- **Environmental impact** assesses the benefits and harms to ocean health arising from a range of factors including reduced intensity of ocean-based economic activities, roll-back of environmental policies, changes in societal behaviours (e.g. increased use of e-commerce shipping, disposable personal protective equipment [PPE] and single-use plastics) and reduction in private sector funding for conservation.

2.1.1 Economic Impact

The ocean economy was projected to double by 2030, but this growth potential has been curtailed by COVID-19 (Richens and Koehring 2020; OECD 2016). Significant revenue losses have been experienced across most ocean-based sectors, with coastal and marine tourism being the hardest hit (UNCTAD 2020b). Across these sectors—in particular coastal tourism, shipping, fisheries and aquaculture—we see a significant loss in revenues, risks of high job losses and reduced appetite for future investment (Table 19.1).

With a decline in international tourist arrivals, the coastal tourism sector has seen a sharp drop in revenue, putting hundreds of millions of direct tourism jobs at risk[2].

Seafood sectors (both wild fisheries and aquaculture) have been affected by a fall in aggregate demand for seafood due to the closure of restaurants and supply chain disruptions (FAO 2020b; UNCTAD 2020b). Slowed demand has negatively affected maritime shipping, the cruise sector and shipbuilding.

[2] *Ocean tourism before COVID-19 was directly valued at US $390 billion globally and comprises a significant portion of many nations' GDP (OECD 2016).*

Table 19.1 Summary of impacts across ocean-based sectors and ecosystems

Sectors	Economic impact	Social impact	Environmental impact
Coastal and marine tourism	● The loss in gross value added is estimated to be up to US $2.1 trillion for the whole of the tourism sector, with 100 million jobs at risk (UNCTAD 2020b) ● Coastal regions are expected to be the most affected, and the cumulative reduction in gross domestic product (GDP) from April to June is estimated be between €9.7 billion to €24.9 billion for areas in Europe alone (OECD 2020b) ● Small island developing states have seen a decline in tourism receipts of 25%, resulting in a $7.4 billion loss (or a 7.3% fall in GDP) (Coke-Hamilton 2020) ● For the Caribbean, analysis estimates job losses to be 1.4 million to two million and losses to the tourism sector to be $27 billion to $44 billion (WTTC 2020) ● Recovery is estimated to take a minimum of 10 months to 2 years after the pandemic, and longer for smaller economies reliant on tourist arrivals from a few developed economies (UNCTAD 2020b)	● Small and medium enterprises, autonomous workers and workers from vulnerable communities, who constitute 80% of the coastal tourism sector workforce, have been hard hit by the reduced flow of income ● Seafarers from the cruise industry have been badly affected due to suspension of cruise operations and quarantining of workers and passengers (ILO 2020a; UNCTAD 2020b) ● Unemployment is significantly higher in the Pacific islands and Caribbean, which rely more on tourism revenues (ILO 2020a) ● Women are likely to be most affected by job losses in the tourism sector (based on the proportion of women employed in low-skilled jobs in the sector)	● The reduction in tourism revenues could have a knock-on impact on conservation and restoration efforts (MPA News 2009) ● The reduction in tourism activities provides a temporary respite to reef ecosystems (Zakai and Chadwick-Furman 2002)
Marine transport	● The cancellation of shipping is estimated to be causing revenue losses of $1.9 billion for the carriers (World Maritime News 2020) ● The outbreak is costing the liner segment of the global shipping industry around $350 million a week in lost volume (ICS 2020a; Paris 2020) ● With 384 sailings cancelled, the first half of 2020 could see a 25% reduction in shipping, with a 10% annual fall in 2020 (World Maritime News 2020). For all ships, departures in the first week of April 2020 were down 20% compared to 2019, while the decrease in container-ship departures was 29% (Heiland and Ulltveit-Moe 2020) ● The shipbuilding sector has sustained a major blow from production halts, temporary layoffs and liquidity issues—particularly in the European Union ● The drop in demand for new ships may lead to reductions in shipyard activity	● Travel restrictions and grounded airplanes make crew changeover impossible, leading to repeated contract extensions. About 200,000 seafarers have overrun their contracts and another 200,000 are now waiting to get on board (ICS 2020b). This is putting the personal safety, physical and mental health of seafarers at risk (IMO 2020; ILO 2020a; UNGC 2020a; ICS 2020a) and could lead to maritime accidents ● Seafarers stuck at sea due to crew change restrictions are prevented from reuniting with families (UNGC 2020a; IMO 2020; ILO 2020a) ● Crew members are often denied medical treatment by foreign authorities during the quarantine period (ICS 2020b; IMO 2020)	● Short-term environmental benefit might be observed due to lower transport demand ● Due to weak markets, several shipping companies are now considering scrapping excess tonnage (NSA 2020a). This could present an opportunity to get rid of older and more polluting tonnage ● Although the shipping sector's capacity to invest in more environmentally friendly technologies has been reduced (ECSA 2020), there is still a strong drive towards decarbonisation, as seen in recent announcements from the industry (NSA 2020b; Mærsk 2020; CMA CGM 2020) ● COVID-19 has curtailed the ability of the International Maritime Organization to have physical meetings, which may lead to delays in the adoption of regulations necessary to achieve environmental targets and a reduction in ambition among governments (long-term risk) ● An increase in loss and waste throughout the seafood supply chain as a result of an increase in quarantine paperwork and reduced personnel at the docks (Saumweber et al. 2020)

Table 19.1 (continued)

Sectors	Economic impact	Social impact	Environmental impact
Wild capture fisheries	● Global fishing activity has dropped by 10% since 11 March (Clavelle 2020)[a]. The impact has been even more significant for small-scale fishers (Campbell et al. 2020) ● Sales and prices have fallen for premium seafood products generally sold to restaurants, such as lobster, crabs, scallops and wild salmon (Saumweber et al. 2020) ● Export-oriented fisheries have seen a vast reduction in demand (particularly from Asia, the United States and Europe) as well as port closures, lost access to cold storage and cessation of shipping and air freight (Orlowski 2020) ● Demand has increased for non-perishable compared to fresh seafood (UNCTAD 2020b)	● Female employment may benefit from the production shift towards female-intensive occupations such as preserving and freezing (UNCTAD 2020b) ● The reduced demand, limited accessibility of markets and collapsed prices of some fisheries have restricted small-scale fishers' ability to pursue their livelihoods and food security ● Women working in the processing sector may be more likely to lose their jobs due to the sector's tendency to offer temporary and lower-paid positions without social protection benefits (Orlowski 2020; The Fish Site 2020) ● Gender-based violence may increase (Harper et al. 2020) ● Fishing communities may become 'hotspots' for rapid infection due to the migratory nature of fishers and the frequency of international visitors (FAO 2020a) ● Probable major disruptions to regionally important tuna industry in the Pacific islands will impact national access to tuna, with resulting economic consequences (Farrell et al. 2020) ● Local processing of tuna may be disrupted, and shortages of imported processed and packaged foods are possible (tinned foods). SMEs in this sector could be particularly affected (Farrell et al. 2020)	● A decline in fishing pressure, particularly by legal industrial fleets, could allow fish stocks with more resilient life histories to recover (Bennett et al. 2020) ● Illegal, unreported and unregulated and (IUU) fishing may increase due to the suspension of observer programs and fishing patrols ● Increased pressure on supply chains, due to port closures and restricted access, may lead to harder-to-regulate practices such as increased transshipment of fish at sea. Such activities are more likely to be associated with illicit fishing and human rights violations (Saumweber et al. 2020) ● The sustainability of stocks may be compromised by the extension of fishing seasons and the halting of stock assessment surveys (Carr 2020) ● Negotiations on fisheries subsidies at the World Trade Organization have been forced onto a slower track (GSI 2020)
Aquaculture	● Production may be affected by the disruption in the supply of feed or input, transportation and labour shortages ● Specialty aquaculture products like shellfish (e.g. lobster, shrimp and oysters) are hardest hit by restaurant closures (FAO 2020b) ● Flight cancellation has directly affected trade in some high-end fresh products that are transported by air (FAO 2020b) ● The sale of prepackaged, frozen or canned fish and fish products has increased in the short term due to panic buying. However, these industries may not be able to continue supplying the market if the raw material (such as feed) is not available (Aquafeed 2020)	● COVID-19 outbreaks have occurred among seafood process workers in Ghana, the United States and elsewhere, as well as in other animal processing plants (Love et al. 2020) ● Women, who comprise a disproportionate share of temporary and casual workers, face the highest risk of losing their jobs due to falling business revenues (Holmyard 2020) ● Women working or shopping in vendor markets are at greater risk of infection, since these locations have limited sanitation and hygiene facilities (FAO 2020a)	● Delays in trade are forcing fish farmers to sit on stocks of live fish for prolonged periods, increasing demand for fishmeal and fish oil containing aquafeed (FAO 2020a). This could increase pressure on forage fisheries that are pre-dominantly used for aquafeed production
Ocean-based renewable energy	● Offshore wind energy has seen significant growth during COVID-19 (reNews 2020) ● The forecast for offshore wind remains unchanged for 2021, as most projects are already financed and under construction (IEA 2020a). Beyond 2021, the industry might be affected due to permitting and other approval delays caused by COVID-19	● It is difficult to get specialised personnel on board offshore energy platforms or into ports to undertake operations, maintenance and repair, leading to increased risks to health and safety (UNGC 2020a; IMCA 2020) ● Though this is hard to disaggregate by sector or technology, some analysis shows that there could be regional job losses in the clean energy sector (Jordon 2020)[b]	● Falling energy demand means sharp reductions in the growth of installed wind, solar and battery capacity in 2020, with effects lingering into 2021 (Eckhouse and Martin 2020)[c] ● However, offshore wind investment has more than made up for a slowdown in investment in onshore wind and solar farm projects after the outbreak of COVID-19 (Ambrose 2020)[d]

(continued)

Table 19.1 (continued)

Sectors	Economic impact	Social impact	Environmental impact
Marine conservation	🔴 Reduced revenues from tourism have affected the functioning of some conservation organisations that relied on ecotourism for funding. This has forced these organisations to reduce costs, including by reducing staff engaged in monitoring (Riedmiller 2020)	🔴 Locals and Indigenous communities have turned to hunting and fishing for food security (due to job and income loss), rather than relying on food commodities sold in the markets (Bowlin 2020). In some instances, this could affect the conservation of nearshore reefs close to urban areas 🟢 Nature-based solutions for marine ecosystems, such as the protection of mangroves, are receiving increased attention for their contribution to global efforts like the Sustainable Development Goals and the Paris Agreement, for their co-benefits of protecting and restoring coastal ecosystems to strengthen food security and for their provision of sustainable 'goods and services' that improve social, economic and ecological resilience to climate change and COVID-19	🟢 Marine ecosystems (e.g. coral reefs) may benefit from the reduced physical impact of tourism activities and reduced sewage from hotels and restaurants. Polyethylene terephthalate bottle consumption may be reduced by the cancellation of mass events, tourism and travel (Circulate Capital and GA-Circular 2020) 🔴 Poaching and IUU fishing may increase due to roll-back of environmental protection measures (Kroner 2020). Other impacts may include reversion to unsustainable practices such as destructive fishing or mangrove clearing 🔴 Environmental deregulation measures include extension of the fishing season, opening of marine protected areas to fishing (SUBPESCA 2020a, b, c; Carey y Cía 2020), reassignment of new artisanal fishing quotas and rollover of uncaught quota (Australian Government 2020b) 🔴 The temporary roll-back on plastic bans may become permanent, which is likely to increase plastics in the ocean (Leonard and Mallos 2020)[e]. Marine plastic pollution in the ocean has increased due to the worker shortages in the informal waste sector, lack of demand for recycled plastics and lack of proper disposal of medical items such as masks

🔴 Negative impacts, 🟠 Positive impacts, 🟢 No/neutral impacts

[a] These figures primarily represent changes in activity for the world's industrial fleet—fishing vessels over 24 m—and do not fully capture the impacts on small-scale fisheries

[b] 15% of the U.S. total clean energy workforce could be lost over the coming months (more than half a million jobs) due to COVID-19. In March alone, more than 106,000 renewable energy and energy efficiency jobs were lost in the country (Jordan 2020)

[c] 2020 global solar and energy storage installations are expected to drop nearly 20% compared to pre-COVID-19 projections (Energy Choice Coalition 2020)

[d] Bloomberg New Energy Finance believes that offshore wind projects are taking off despite the global economic gloom in part due to a two-thirds fall in cost since 2012 and a rush in China to finance and build offshore wind projects before the government's subsidy regime expires at the end of 2021

[e] Several governments, such as that of the Indian state of Tamil Nadu, have suspended bans on single-use plastic bottles and bags in retail trade (Peszko 2020). The United Kingdom has suspended the plastic bag charge for online deliveries, with Scotland delaying the introduction of a packaging deposit-return scheme (Peszko 2020)

A potential decline in renewable electricity capacity for onshore wind energy and solar farm projects is forecast due to factors such as supply chain disruption, lockdown measures, emerging financing challenges and decreased energy demand (IEA 2020a). The share of renewables in the electricity supply has increased, as their output is largely unaffected by demand[3]. Demand has fallen for all other sources of electricity, including coal, gas and nuclear power (IEA 2020b). However, increased offshore wind capacity in 2020 has more than made up for a slowdown in investments (across other renewable technologies) after the outbreak of COVID-19 (IEA 2020a). There is some uncertainty in growth projections for the offshore wind sector beyond 2021, due to permitting and other approval delays caused by COVID-19. In addition, the sectors' interconnectedness amplifies the impacts discussed across the ocean economy (Box 19.1 and Fig. 19.1).

[3] *However, renewable sources (mainly wind and solar) saw their share of electricity substantially increase during COVID-19. For example, in less than 10 weeks, the United States increased its renewable energy consumption by nearly 40% and India by 45%. The ongoing increase in renewable energy into the grid results from a mixture of past policies, regulations, incentives and innovations embedded in the power sectors of many forward-thinking countries (Mojarro 2020).*

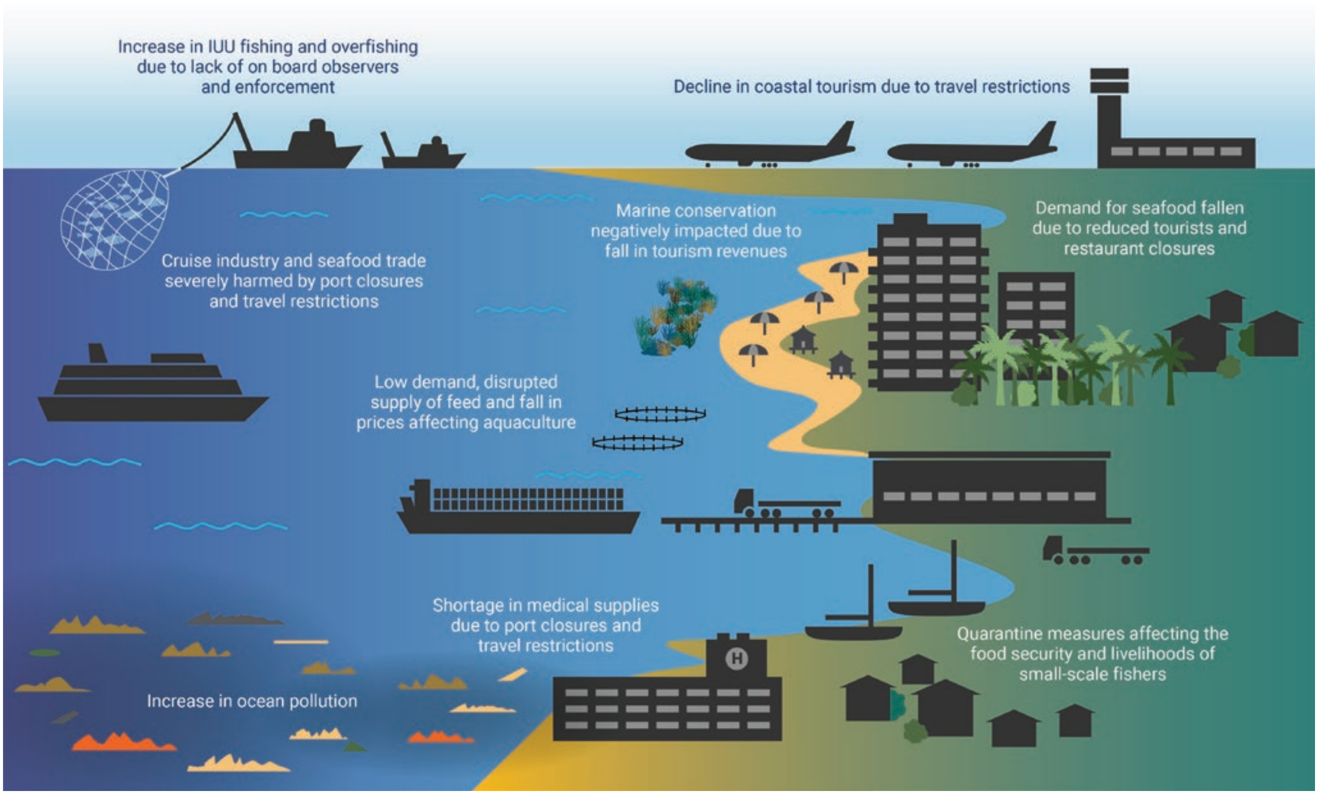

Fig. 19.1 Interwoven impacts across the ocean. (*Source: Authors*)

Box 19.1 Interwoven Impacts Across the Ocean Economy and the Rest of the Sectors

There are strong interconnections between ocean sectors and land-based economies. For example, fisheries and aquaculture provide employment to many communities and are vital for the food security of both coastal and inland communities[a]. The global maritime shipping industry carries around 90% of traded goods. In coastal areas, the tourism sector is the biggest contributor to local, regional and national GDP. Because of these interconnections and linkages between ocean-based sectors and land-based economies, impacts of COVID-19 flow beyond these individual sectors with amplified consequences for the entire economy. Some examples of the transmission of impacts across sectors are discussed below.

Disruption to maritime shipping and port services has negative consequences for the seafood, agriculture, energy, health and tourism sectors.

- Delays for fishing vessels in ports are associated with increased risk of higher seafood waste (Saumweber et al. 2020).
- Port closures (or restricted access to ports) in some countries may have increased the use of transshipment—the transfer of fish and supplies from one vessel to another in open waters—which is more likely to be associated with illegal, unreported and unregulated (IUU) fishing and human rights violations.
- Port closures and travel restrictions also severely harm the global cruise tourism industry, leaving many tourists and seafarers unable to disembark from vessels and replacement crews unable to join their ships.
- The ability of the shipping sector to provide undisrupted service to transport food, energy and other essentials, such as medical supplies, across the continents will play a critical role in overcoming this pandemic.

The aquaculture sector and its ancillary business supply chains face setbacks due to international trade delays, restaurant and hotel closures, and reduction in fishing effort.

- Lockdown restrictions on fishing operations have disrupted the production of fishmeal and fish oil (FMFO) from wild caught fisheries, with negative consequences for the aquaculture sector that is dependent on this input as feed (FAO 2020b).
- At the same time, trade delays are leading to higher unsold volumes of farmed live fish, resulting in higher feeding costs for the aquaculture sector. The risk of

fish mortality is also increased, especially in situations where key inputs are in low supply (such as FMFO requirements) (FAO 2020b).
- Reduced tourist visits caused by lockdown measures have heavily disrupted demand for seafood from the hotel and restaurant industry, particularly for high-value species such as lobster and prawn, reinforcing the interdependencies between the tourism, fisheries and aquaculture sectors (UN 2020c).

Ocean conservation and research have decreased as a result of falling tourism revenues, lost livelihoods in coastal communities and increased ocean pollution.

- In some locations, particularly low- and middle-income countries, fewer tourist visits and reduced availability of associated revenues have curtailed the availability of funding for fisheries management and marine conservation measures (Greenfield and Muiruri 2020).
- Coastal fisheries and reefs are also facing greater pressure, as local communities are turning back to traditional fishing as a food source—driven by a loss of income from tourism (Vyawahare 2020). This can be exacerbated when people return to their home communities from urban areas (Hockings et al. 2020).
- The work of ocean research vessels has been impaired by port closures and quarantine restrictions, with knock-on effects for ocean science and climate studies, such as the Alfred Wegener Research Institute Polarstern expedition, although some privately funded research missions have continued (e.g. Walsh Challenger Deep dive).
- Increased production and use of single-use plastic (such as for e-commerce shipping, grocery delivery, additional food layer protection, masks, gloves and other personal protective equipment) have increased plastic pollution in the ocean, since these items often are not properly disposed of (Tenenbaum 2020). Ocean pollution also has increased due to disruption of land-based waste collection and recycling facilities during COVID-19, especially in South and East Asia[b].

Reduced access to markets for small-scale fishers weakens the food security of entire local communities.

- Reduced inland ferry services and quarantine measures have restricted the ability of many small-scale fishers to access local markets, sell their harvest and contribute to the local economy and the food security of their community.

[a] *Fish accounted for about 17% of animal protein consumed by the global population (FAO 2020c).*

[b] *With recycling not recognised as an essential service in many countries, less than 20% of recyclers operated during the lockdowns in Vietnam, India and the Philippines, while in Thailand and Indonesia it was less than 60%, significantly curtailing waste collection in cities (Circulate Capital and GA-Circular 2020). Critical workers in the value chain lost jobs and income to support their families. The migration of workers in these countries (from urban to rural areas) has also reduced waste collection and recycling. For example, in India, 70–80% of informal sector waste workers have left cities for their hometowns (Circulate Capital and GA-Circular 2020). As a result, no waste-picking has been occurring in landfills and dumping grounds for India's five largest cities.*

2.1.2 Social Impact

Assessments of social impacts show that the COVID-19 crisis has disproportionately harmed a number of vulnerable groups, including women employed in temporary jobs, low-skilled workers, small-scale fishers and businesses, Indigenous community members and younger workers.

Women represent the majority of the workforce in the ocean economy sectors hardest hit by the crisis—about 50% of workers in the seafood sector[4], 70% in aquaculture, 80–90% in the post-harvest sector of small-scale fisheries[5] and 54% in tourism (Holmyard 2020; UNWTO 2019; Monfort 2015; World Bank 2012; OECD 2015). As businesses lose revenue, many will reduce their costs by laying off workers, starting with the temporary and casual jobs disproportionally occupied by women (Holmyard 2020) (Box 19.2)[6]. The shipping industry (including the cruise sector) has been particularly badly affected due to the suspension of cruise operations and quarantining of workers (ILO 2020a; UNCTAD 2020b), with seafarers' physical and mental well-being at risk.

The reduced demand, limited accessibility of markets and collapsed prices of some fisheries have curtailed small-scale fishers' ability to pursue their livelihoods. Indigenous communities are particularly at risk as they may have reduced immunity and limited access to healthcare (UN DESA

[4] *When considering fisheries, aquaculture, seafood processing and all related services.*

[5] *Of the 120 million people who work in the capture fisheries and post-harvest sectors, 47% are women. If the People's Republic of China is excluded, the share of women fishers and fish workers approaches 60% (World Bank 2012).*

[6] *Other systemic barriers such as gender-based violence and lack of access to finance and credit further contribute to the impacts faced by women when they are laid off work. In addition, in many countries women tend to have more work at home, raising children and taking care of the elderly and the sick. An increase in domestic violence and conflict within households could increase food insecurity for vulnerable groups (Farrell et al. 2020).*

2020a)[7]. These groups also face risks of lost livelihoods resulting from the economic crisis, as many are employed in the informal sector or engaged in seasonal work (such as tourism), in which they do not receive social protection benefits[8]. As for all sectors, young people, low-skilled workers and informal workers across the ocean-based economy have been disproportionately affected by the COVID-19 crisis (ILO 2018, 2020c; World Bank 2020a)[9].

Across the seafood supply chain, the social and financial resilience of small businesses (including ones that are family owned or whose workers are self-employed) is being weakened by labour shortages and low demand (Resilience 2020).

The severity of the impacts also varies across countries, with the economies of small island developing states (SIDS) facing higher economic risk (Table 19.1 and Box 19.2) given their small economic base, high degree of openness and extreme dependence on the economic performance of a few developed economies (UN 2020a; WTTC 2020).

The crisis has had some positive social consequences at a community level, such as stronger ties within communities, as demonstrated by many instances of food-sharing (Table 19.1), and by examples of community- run savings clubs to improve social and financial resilience in fishing-dependent communities throughout the Philippines (Arquiza 2019; Polo 2020)[10]. However, social cohesion and trust in authorities has also declined in some communities due to poor crisis management at all government levels.

[7] *The impact of COVID-19 on Indigenous elders has cultural implications for their communities, as elders play a key role in keeping and transmitting Indigenous traditional knowledge, culture and practices. These include conservation of biodiversity, upholding traditions and customs, leading community gatherings and ceremonies, and serving as custodians of customary law and governance (UN DESA 2020a).*

[8] *Indigenous people account for almost 19% of the extreme poor, irrespective of the region and residence in rural or urban areas and even across international borders. They are custodians of a wealth of traditional knowledge and practices, languages and culture, which includes time- tested responses to crises (UN DESA 2020a).*

[9] *More than 61% of the world's employed population—2 billion people—earn their livelihoods in the informal sector. These workers lack the right to social protection benefits and schemes. Some of the low-skill workers in these sectors are migrant workers. The combination of the decline in economic activity, travel restrictions and lack of social protection in many migrant hubs induces such low-skilled migrants to seek to return home. However, back home returnees continue to face challenges, including lack of employment opportunities, limited access to social safety nets, large debts accumulated to finance migration (costs that would have been paid with higher incomes earned at the destination), loss of remittances from abroad and even discrimination by community members fearful that migrants may transmit COVID-19.Young people face multiple shocks from the COVID 19 crisis, including job loss, disruption to education and training, and increased challenges to entering the labour market. A large proportion of young workers are employed in the hard-hit sectors (including tourism), and almost 77% of the world's young workers are in informal jobs (compared to around 60% of workers aged 25 and above) (ILO 2020c).*

[10] *Women make up the majority of members in savings clubs (~70%) and help fishing households pivot from quick spending to long-term financial planning. This change in behaviour can powerfully affect the long-term strategy behind coastal fisheries conservation and the goal of ending overfishing. The savings clubs have already proved to be a fast, secure and communal way to ensure food security for the community during the COVID-19 lockdowns.*

Box 19.2 Tourism Impact in Small Island Developing States

Due to the economic crisis caused by COVID-19, small island developing states (SIDS) as a whole have seen a 25% decline in tourism receipts, resulting in a US $7.4 billion or 7.3% fall in GDP (Coke-Hamilton 2020)[a]. The gross domestic product (GDP) of the Bahamas and Palau is expected to shrink by 8% or more, making the current crisis the worst in recorded history, while the drop in GDP could reach 16% in the Maldives and Seychelles (Coke-Hamilton 2020; UN DESA 2020b). High external debt, low foreign reserves and volatile capital flows have increased the severity of the pandemic's economic consequences for many SIDS (Coke-Hamilton 2020). This has had a severe impact on both direct and indirect employment (Coke-Hamilton 2020). In the Pacific and Caribbean islands, which rely heavily on tourism, hotels and resorts have been badly affected. For example, the Fiji Hotel and Tourism Association reports that 279 hotels and resorts have closed since the outbreak, with 25,000 workers losing their jobs (ILO 2020b).

Impact on women in tourism

In 20 of 28 SIDS, women constitute more than half of those employed in the accommodation and food services sectors, the core economic activities related to tourism. Women in this sector and in these countries are also more likely than other women to own small and medium businesses. Given the female-intensive nature of employment in tourism, especially in low-skilled activities, women in SIDS are more likely than men to lose their jobs. Businesses may also choose to lower wages or shift workers to informal or part-time work, worsening the already unclear terms of employment in tourism. In addition, women face higher barriers to access business credit. In the absence of targeted policies, this means women entrepreneurs in tourism face a higher risk of bankruptcy than their male counterparts (Zarrilli and Aydiner-Avsar 2020).

[a] *According to the World Development Indicator database, tourism provides more than 50% of export revenue in 20 SIDS and more than 30% in 29 SIDS (Zarrilli and Aydiner-Avsar 2020).*

2.1.3 Environmental Impact

Overfishing, pollution and biodiversity loss were eroding the ocean's ability to sustain livelihoods before COVID-19. The pandemic is likely to intensify the severity of these threats to the ocean. Decreased presence of law enforcement, a slowdown in key international negotiations (such as talks on fisheries subsidies at the World Trade Organization) and the roll-back of environmental regulation are likely to compromise ocean sustainability. For example, suspension of observer programs and fishing patrols may be leading to an increase in IUU fishing (Thomson 2020; CFFA CAPE 2020). Similarly, roll-back measures such as reassignment of new artisanal fishing quotas and rollover of uncaught quota have been reintroduced, which could reverse progress made in fish stock recovery (Australian Government 2020b). However, the policy response varies greatly from one country to the next and across levels of government[11]. Declining tourism revenue is also weakening conservation and restoration efforts, especially in cases where ecotourism provides the revenue stream for monitoring, data-gathering, conservation, certification and environmental education (see Box 19.3). Table 19.1 gives details of these impacts.

In addition, COVID-19 has had a temporary impact on efforts to ensure the sustainable transition of ocean-based sectors[12]. However, the ambition to have a carbon-neutral fleet by 2050 is still active, as demonstrated in the Norwegian Shipowners' Association climate strategy, the net-zero announcement by CMA CGM, the Mærsk Foundation donation to set up a new green technology research institute, as well as a number of large-scale projects involving energy companies (such as the partnership by Ørsted, Mærsk and others) to produce green methanol for shipping (NSA 2020b; Mærsk 2020; CMA CGM 2020)[13].

While the decline of ocean-based activities, such as fishing[14] and ocean-based tourism[15], has offered temporary relief to marine ecosystems, over the coming months the combined effects of increased food insecurity, reduced presence of law enforcement bodies and economic recession could prevent the environmental benefits of decreased commercial maritime activities from being fully realised (Torgler et al. 2020)[16].

Box 19.3 Decline in Funding for Marine Conservation Due to Loss of Tourism Revenue

In many cases, governments use revenue from marine tourism to fund marine research and conservation efforts (Wilson and Tisdell 2003) and undertake monitoring and protection activities in marine protected areas. For example, in the Philippines' Tubbataha Reefs Natural Park, tourism revenues make up over half of the conservation budget needed to protect areas from illegal fisheries (UNESCO 2020). However, as the main tourism season (normally April and May) coincided with the strictest quarantine restrictions during the COVID-19 period, tourism revenues in Tubbataha have dropped sharply.

With the decline in tourism revenues during COVID-19, some sites have turned to crowdfunding, online donations and government grants (where available) to meet the funding gaps. In some cases, private foundations have stepped in to compensate for reduced revenue from tourism and endowments. However, these funding sources are unlikely to be sustained. Others have had to reduce surveillance and/or downscale restoration programmes, leading to an increase in fishing pressure. For example, in Seychelles, Fiji, Indonesia, the Philippines and Hawaii, there are reports of increasing fishing pressure in marine protected and conserved areas, which is encouraged by a reduced management presence (Hockings et al. 2020).

[11] *For example, while we see the roll-back of many national-level environmental policies, some local-level governance approaches have used consultation to institute recovery plans for fisheries and aquaculture. One example is the virtual consultation by the Philippine Council for Agriculture and Fisheries with relevant stakeholders and government officials specifically to discuss issues confronting the fishery and aquaculture sector amid COVID-19 (PCAF 2020).*

[12] *A survey of its members performed by the European Community Shipowners' Associations revealed that COVID-19 may negatively affect efforts to decarbonise the shipping industry (ESCA 2020). Responding to a general question about investments in reduction of greenhouse gas emissions, 44% of respondents to the survey said it will no longer be possible to return to the investments planned prior to the pandemic. Only 26% of respondents to the survey thought they would return to the same level of investments, whereas 30% thought the investments would still happen, but to a lesser extent (ESCA 2020).*

[13] *Since decarbonisation of shipping is a full value chain endeavour, effort towards this transition should not be limited the shipping companies.*

[14] *The lockdown and labour shortages have resulted in a decrease in global fishing activity of nearly 10% (Clavelle 2020). In some regions this could provide temporary relief to recovering fish populations and some possible benefits for small-scale fisheries in the longer run (Jigeesh 2020; John 2020).*

[15] *A potential positive outcome for marine ecosystems as a result of the decline in tourism activities (e.g. reef trampling, anchor damage, etc.) is less sewage from tourist centres (Zakai and Chadwick-Furman 2002).*

[16] *Emissions reductions caused by economic downturns tend to be temporary—and can lead to emissions growth as economies attempt to get back on track. After the global financial crisis of 2008, for example, global CO2 emissions from fossil fuel combustion and cement production grew 5.9% in 2010, more than offsetting the 1.4% decrease in 2009.*

2.2 Emerging Responses

This section summarises the government policy responses announced thus far to absorb and react to COVID-19 disruptions to the ocean economy and the actions taken by development banks, international organisations (IOs), non-governmental organisations (NGOs) and the private sector to transition towards a sustainable ocean economy.

2.2.1 National Governments

Rapid Emergency Response

To date, response packages from governments have amounted to approximately US $10 trillion globally (IMF 2020a)[17]. As a part of the immediate response, governments have prioritised saving lives and protecting livelihoods, with money channelled directly to households and those on the frontlines of the pandemic. For the ocean economy, this means protecting vulnerable coastal communities dependent on marine natural resources, ocean economy workers, small and large-scale businesses, and ensuring that supply chains remain open for delivery of essential goods (Box 19.4).

Box 19.4 Economic Relief for Ocean Economy Workers and Businesses

A number of measures were introduced by countries to support workers, vulnerable groups and small businesses. Some governments, such as those of the United Kingdom and Canada, along with the EU Commission, have also classified ocean workers as 'key workers', thereby giving them right to movement (EU Commission 2020d; UK Government 2020; Government of Canada 2020).

The list below is not exhaustive but provides examples of support measures directed towards income protection and the welfare of ocean-economy workers.

- **Coastal tourism** Measures include extension of loans and credit to businesses, wage subsidy to workers, financial relief to businesses such as loan consolidation and term extension, increased promotion of tourism and strengthened regional cooperation to boost tourism (e.g. by the Association of Southeast Asian Nations) (Office of the Prime Minister, Canada 2020; KPMG 2020).
- **Marine transport** Staff (especially onshore) have been covered by general wage support schemes in many countries. A number of countries have agreed to new international measures to open up foreign borders for seafarers and increase the number of commercial flights to expedite repatriation following an international crew change summit (Chambers 2020a)[a]. There have also been a number of government support measures and bailouts for maritime companies.
- **Wild capture fisheries** Measures include grants and financial compensation for workers and small- scale businesses and enterprises (in the harvesting, processing and artisanal fishing sector), increased state aid (European Commission 2020b), online training programmes, provision of new fishing equipment, refrigeration transport service for seafood caught by artisanal fisher organisations (e.g. a pilot programme in Chile), provision of loans at subsidised interest rates, waiver of government fees associated with licenses, rollover of quota and deferral of income tax for small businesses (SUBPESCA 2020d; IKI 2020). The European Union also provides a US $1.2 billion guarantee from the EU budget to the European Investment Bank so that it can incentivise European banks and mobilise about $9.3 billion of working capital financing for small and medium enterprises in the fisheries, aquaculture and seafood services sectors (European Commission 2020b).
- **Aquaculture** Measures include income support to workers, increased funding to double community-based aquaculture production and loans or credits to seafood processors (EU Commission 2020a). In addition, the EU Commission, in response to stakeholders' requests, adopted new measures for the aquaculture sector, including support to farmers for temporary suspension of production, and support to producers for private storage of aquaculture products.

[a] *The 13 countries to agree this are Denmark, France, Germany, Greece, Indonesia, the Netherlands, Norway, the Philippines, Saudi Arabia, Singapore, the United Arab Emirates, the United Kingdom and the United States, all of whom now recognise seafarers as key workers.*

[17] *The majority of the $10 trillion constitutes rapid emergency response for the short term and focuses on mostly fiscal measures and regulatory or deregulatory measures.*

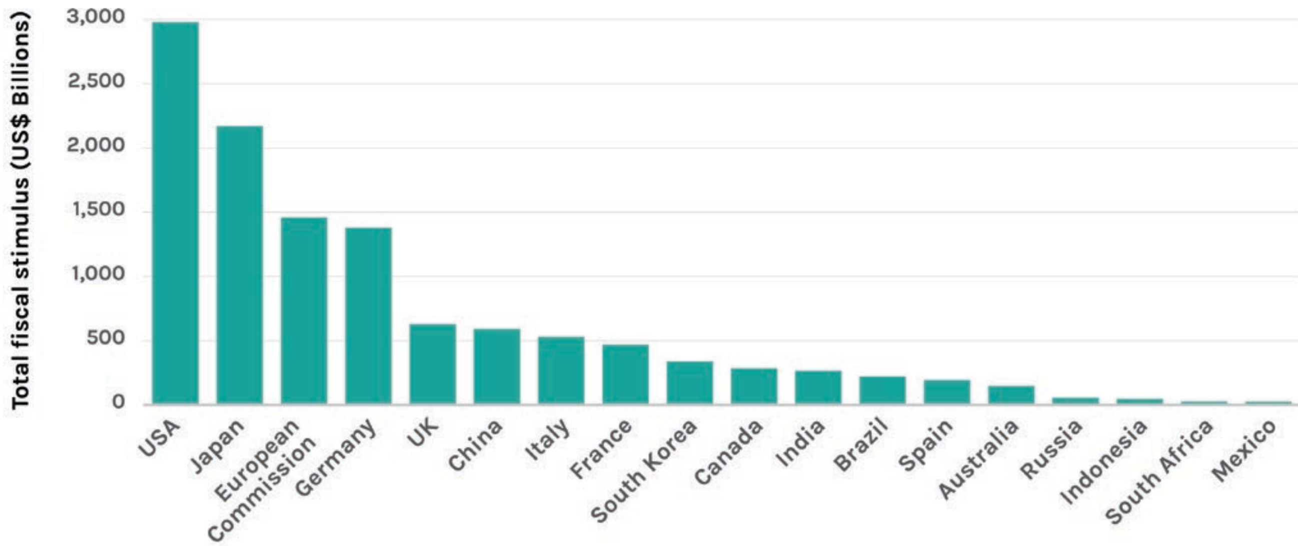

Fig. 19.2 Announced COVID response fiscal stimulus package by country. (*Note: Assumes the proposed 'Next Generation EU' recovery package is implemented in full. Source: Vivid Economics Data*)

Long-Term Recovery Response Measures

The second phase of response from national governments will be aimed at measures to promote longer-term economic recovery and resilience. Analysis from McKinsey shows that G20 nations have announced fiscal measures averaging 11% of GDP, which is estimated to be three times the response to the 2008–9 financial crisis (McKinsey 2020). The United States has announced the largest fiscal stimulus package, followed by Japan and the European Union (Fig. 19.2). Some countries, such as Italy, have said they will commit up to 40% of GDP to their economic stimulus packages (McKinsey 2020)[18].

So far, 30% of economic stimulus packages are going to sectors that currently have high environmental impact (Vivid Economics 2020)[19]. Within the 30%, it is estimated that the majority of the spending will have a predominantly brown impact without conditionality for performance improvements in these sectors[20]. Some of these 'brown' measures include unrestricted support to sectors that have proved to be environmentally harmful in the past and also include rollback on various environmental regulations implemented to deliver better environmental outcomes. For example, both the transport and industry sectors have been hit hard by the crisis and are receiving substantial support from governments. Another source estimated that more than half a trillion dollars worldwide—$509 billion (£395 billion)—is to be poured into high-carbon industries, with no conditions to ensure that they reduce their carbon output (Harvey 2020)[21]. In contrast, only about $12.3 billion is to go towards low-carbon industries, such as renewable energy, and a further $18.5 billion is intended for high-carbon industries provided they achieve climate targets (Harvey 2020).

Some of these interventions target the ocean economy and even fewer align with a transition towards a sustainable ocean economy (Table 19.2 and Sect. 2.3). At this stage, there is little information on how these high- level interventions and investments will be implemented and the degree to which they advance priorities for the sustainable ocean economy or undermine such progress.

Development Banks and Bilateral Development Aid

During the crisis, domestic resource mobilisation has decreased in low-income countries, and external private finance is projected to drop by US $700 billion in 2020, with significant capital flight as a compounding problem (OECD 2020d). Remittances are predicted to fall by 20% in 2020 (Ratha et al. 2020), and foreign direct investment is expected to decline 30–40% in 2020–2021 (UNCTAD 2020a). Given the uncertainty of domestic finance opportunities in many low- and middle-income countries and the volatility of private flows, the need for bilateral and multilateral finance is unparalleled.

[18] *Fiscal measures are likely to be just one aspect of the response measures—monetary measures will also be key in stimulating demand and much- needed liquidity in the market. Assessing the impact of these measures (such as quantitative easing measures) on the ocean economy is beyond the scope of the analysis.*

[19] *Economic stimulus packages encompass a range of fiscal mechanisms, including bailouts and loans. In defining the amount of stimulus flowing through to sectors with a high environmental impact, the index has removed any measures which are purely devised to provide income support to workers (e.g. furlough or income protection programmes).*

[20] *Estimated by Vivid Economics (2020) based on the 14 of 18 countries it evaluates in its study. Brown orientation of these countries' stimulus funding based on (1) the scale of funds flowing into environmentally intensive sectors, (2) the existing green orientation of those sectors and (3) the efforts which steer stimulus toward (or away from) pro-environmental recovery.*

[21] *Specific stimulus packages include, for example, bailout measures of the aviation industry without green conditionality, subsidies for fossil fuel vehicles and an easing of permits for coal mining.*

Table 19.2 Examples of blue stimulus packages announced by selected countries

Country	Selected blue stimulus packages
Australia	At a sub-national government level, the Victoria government package includes A$129 million for the Department of the Environment, for upgrading public land facilities, supporting solar and water infrastructure and addressing erosion and flood risk in marine and coastal areas (Victoria State Government 2020). The Queensland government has committed to provide A$17 million to create a renewable energy training facility as well as a A$8.93 million boost to national parks (including key coastal and marine parks), to provide visitor infrastructure upgrades and enhancements to reenergise nature-based tourism (Queensland Government 2020)
Canada	New assistance amounting to US $62.5 million will be provided to the fish and seafood processing sector through the Canadian Seafood Stabilization Fund, and US $75 million is set aside for emissions reduction in offshore oil and gas. Funding of US $469.4 million will be used to establish the new Fish Harvester Benefit and the new Fish Harvester Grant. The program is designed to work within the unique pay structures and seasonal nature of the fishing sector. The program is open for applications from 24 August to 21 September 2020 (Fisheries and Oceans Canada 2020)
Finland	The supplementary budget of €5.5 billion contains a package of measures supporting the recovery and revitalisation of the economy with a sustainable focus • €13.1 million for state-run rehabilitation of nature sites and the development of nature tourism • €53 million for projects involving green areas, water services and forest conservation. Funding is also proposed for the rehabilitation of local recreation areas • €20.75 million for innovation support for shipbuilding • €5 million for vessel design work in a project to replace three present offshore patrol vessels with vessels capable of responding to oil and chemical spills The previously agreed national climate fund will be capitalised by €300 million. The fund will focus on combatting climate change, promoting digitalisation and boosting low-carbon operations in manufacturing industries (Finnish Government 2020)
European Union	For climate targets, the Green Deal sets aside about €225 billion (US $190 billion) for the recovery fund and €322 billion (US $280 billion) for the 2021–27 budget. Specific detail on the climate policies is not provided. The Euro- pean Union will report annually on its climate expenditure[a] The targets proposed by the European Commission in the Communication on the Farm to Fork strategy (Green Deal on food system) include reduction the use of fertilisers and pesticides, which cause marine pollution As part of green legislation, the European Commission's Environment Committee voted to include CO_2 emissions from the maritime sector in the EU Emissions Trading System (ETS), with a new target of 40% CO_2 reduction by 2030 (EU Parliament 2020) The Environment Committee also called for an 'Ocean Fund' for the period from 2023 to 2030, financed by revenues from auctioning allowances under the ETS, to make ships more energy efficient and to support green infrastructure
Germany	The International Climate Initiative will spend €68 million (US $58 million) to support 29 projects (in 25 countries) responding to COVID; building future economic, social and ecological resilience; and seeking to prevent a new pandemic. The initiative aims to expand the role of green hydrogen as a part of modernising shipping programmes and helping the sector's transition towards decarbonisation (BMU 2020). Its mission is to invest in a sustainable recovery of the economy (including increasing climate resilience of the fishing sector) to contribute to climate change mitigation and the conservation of biodiversity (IKI 2020)
Italy	A state aid scheme worth €100 million (US $85 million) will support agriculture, fishing and aquaculture small and medium enterprises. The fund will provide aid to maintain their activities through state guarantees on investment and working capital loans and direct grants to provide support during the temporary cessation of fishing activities (EU Commission 2020b)
India	Rs 20,050 crore (US $2.7 billion) will be invested over the next five years to bring about a blue revolution through sustainable and responsible development of the fisheries sector
Jamaica	Grants totalling US $1.2 billion will be made available to businesses operating in the tourism and related sectors (KPMG 2020)
New Zealand	An NZ$1.1 billion (US $736 million) environmental jobs program will aim to create 11,000 jobs, include major investments in restoring wetlands
Norway	NOK3.6 billion (US $400 million) is budgeted to support green technology projects that would benefit offshore wind and low-emissions shipping (Nikel 2020). A 'green transition package' (US $384.5m) will be used to support a range of initiatives, including investments in hydrogen power and battery storage technology and building offshore wind infrastructure as Norway looks to reach the Paris Agreement target of limiting global temperature rise to less than 2 °C by 2050 (Casey 2020)
United States	Section 12005 of the Coronavirus Aid, Relief and Economic Security (CARES) Act allocates US $300 million in fisheries assistance funding to states, tribes and territories with coastal and marine fishery participants who have been negatively affected by COVID-19 (NOAA 2020)
Vietnam	An extension is proposed for wind energy projects (including offshore wind) until 31 December 2023 (more than two years beyond the current deadline of 1 November 2021), and a new solar power feed-in tariff (including floating solar energy projects) has been announced (Morris 2020)

Notes: The list of stimulus packages with a focus of blue sustainability is not exhaustive. Exchange rates: €1 = US $1.1842; NZ$1 = US $0.67; Rs1 = US $1.013; NOK1 = US $0.11

[a] The Green Deal consists of a €750 billion recovery fund and a €1.074 trillion EU budget for 2021–27. The amount of money set aside for climate targets, is set at 30%. The recovery fund alone would be the largest green stimulus in history. Specific detail on the climate policies is not provided, and the European Union will report annually on its climate expenditure

A number of multilateral development banks and international financial institutions have mobilised resources to counteract the economic crisis in the most vulnerable countries. For example, the International Monetary Fund (IMF), World Bank, Asian Development Bank and other regional partners are working together on approaches to assist countries in the Pacific overcome the challenges of the current crisis and position themselves for economic recovery (IMF 2020c)[22]. A number of SIDS would also be eligible to apply for short-term debt relief as a part of the IMF's Catastrophe Containment and Relief Trust (Coke-Hamilton 2020). As a part of building back better after COVID-19, the Asian Development Bank is working in cooperation with the UN Economic and Social Commission for Asia and the Pacific (ESCAP) on areas including gender inequality, climate change and ocean pollution (ANI 2020). Additionally, the African Development Bank (2020) has approved €225 million for a budget support loan for Egypt's electricity sector to bolster economic resilience and sustainability. These financial support measures would be in addition to several blue finance initiatives that were set up before the pandemic to achieve sustainable ocean health and governance. This includes the Asian Development Bank's (2019) commitment of US $5 billion (2019–2024) to expand its investments and technical assistance in ocean health and the blue economy; the World Bank's PROBLUE initiative that focuses on four pillars (fisheries and aquaculture; marine pollution; oceanic sectors and seascape management)[23]; and the European Investment Bank's commitment to more than double its lending to sustainable ocean projects, to €2.5 billion ($2.7 billion), over the next 5 years (Richens and Koehring 2020)[24]. However, blue measures still constitute a very small share of the response budget for development banks, and the role that blue recovery measures can play in responding to the crisis could more explicitly emphasized.

Bilateral aid and official lending to low- and middle-income countries from other countries can also make a big difference for the recovery. G20 nations have agreed to freeze bilateral government loan repayments for low-income countries until the end of the year as part of a plan to tackle the health and economic crises triggered by the pandemic and prevent a debt crunch in emerging markets[25] (Wheatley et al. 2020). New Zealand has pledged NZ$55 million in aid spending for Pacific island nations (Dreaver 2020). Similarly, Germany, through the International Climate Initiative, has invested in a number of sustainability projects in 25 countries in response to COVID-19 to build future economic, social and ecological resilience (IKI 2020). Overseas development assistance (ODA) has also played a key role by building health and social protection systems in developing countries, which are critical to countries' ability to respond to the COVID-19 crisis and are central to resilience and recovery (OECD 2020d). However, with several countries' budgets in turmoil, it is possible that the overall level of ODA could decline in 2020 (OECD 2020e)[26]. In addition, recent analysis by OECD shows that over the 2013-18 period a mere 0.8% of global ODA was allocated to support sustainable ocean economy and highly concentrated in three sectors—maritime transport, fisheries and marine protection (OECD 2020f). This suggests that more could be done to support a wider range of existing and new ocean-based sectors and thus foster greater economic diversification and resilience post pandemic (OECD 2020f).

International Organisations and Non-Governmental Organisations

The role of IOs and NGOs is vital in supporting local and national efforts to fight the pandemic. IOs are helping client countries to better address the impacts of this crisis, with a focus on empowering, protecting and prioritising the most vulnerable[27]. For example, the COVID-19 response offer of the UN Development Programme (UNDP) focuses on SIDS and aims to support long-term recovery efforts in these regions by helping them diversify (and sustainably expand ocean economy activities) as well as digitally transform to respond rapidly to crises[28].

---

[22] *The doubling of the IMF's emergency financing capacity means that up to $643 million could be made available immediately to the Pacific island economies.*

[23] *In fiscal 2019, PROBLUE received signed contributions of over US $50 million from five donor countries (development partners are in the process of signing for over $100 million). Actual funds received from donors totalled approximately $28.8 million. Because of the focus on operationalising the trust fund and preparing the February 2019 annual work plan, PROBLUE approved grants of $2 million, of which $600,000 were disbursed, as of fiscal year 2019. Grant amounts and disbursements are expected to accelerate significantly in fiscal year 2020. As of 30 June 2019, PROBLUE's total fund balance, taking into account actual funds received from donors, disbursements, commitments, and investment income, was just over $28 million.*

[24] *The bank expects to mobilise at least €5 billion in investments from private-sector companies and investors, among other partners (Richens and Koehring 2020).*

[25] *The moratorium on bilateral government debt repayments will begin on 1 May 2020. It will apply to the 76 countries that are eligible to receive assistance from the World Bank's International Development Association, which works with the poorest countries, as well as all nations defined as least developed countries by the United Nations. Eligible countries must be 'current' on any debt service payments to the IMF and the World Bank.*

[26] *The OECD calculates that if Development Assistance Committee members were to keep the same ODA to gross national income ratios as in 2019, total ODA could decline by $11 billion to $14 billion, depending on a single- or double-hit recession scenario on member countries' GDP.*

[27] *For more detail, see the UN COVID-19 response information at* https://www.un.org/en/coronavirus/information-un-system

[28] *The approach is to diversify and expand ocean economy activities and digital transformation to bolster governments' institutional capacities to respond rapidly to crises.*

Many IOs are working directly with industry associations to address the pandemic's short-term and long-term impacts on specific sectors. For example, industry groups, such as the International Chamber of Shipping and the International Association of Ports and Harbours, and UN organisations like the World Health Organization, the International Labour Organization and the International Maritime Organization, have already led an enormous effort to establish safety protocols for preventing and mitigating COVID-19 in vessels and ports, and have also come together to explore ways to safely facilitate crew changes from disembarkation to the airport (Henriksen and Selwyn 2020). The International Chamber of Shipping has led the creation of a 12-step plan for governments on how to undertake crew changes[29]. The UN Global Compact is calling for a coalition of willing governments to protect global ocean supply chains by classifying these workers as 'essential'; this includes offshore energy workers and fish farmers as well as seafarers (UNGC 2020a). The UN secretary general has called for bailouts of the shipping industry to be conditioned on alignment with the goals of the Paris Agreement (Chambers 2020b).

NGOs are working in partnership with multinational development banks and other financial institutions to address immediate needs whilst supporting a resilient, equitable and sustainable ocean economy. For example, the World Wildlife Fund is working to ensure continued monitoring and effective management of marine protected areas from the impacts of IUU fishing and other activities; advocating stimulus measures that promote clean energy and sustainable development; and making guidance available to cities dealing with high amounts of medical plastic waste (Plastic Cities 2020). Some NGOs are working with local fishers and women fish workers to connect catch to private households or local markets (e.g. restaurants), thereby supporting direct marketing of catches that would otherwise go unsold. For example, Rare is working with a fishing community in the Philippines to help manage its long- term finances (by setting up savings clubs), providing transportation for fishers (through engagement with government) and raising awareness about enforcing fish sanctuaries important for the long-term sustainability of community livelihoods (Polo 2020).

Private Investment

Some private sector companies are exerting pressure on governments to ensure that COVID-19 recovery is green and harnesses science-based targets. For instance, in May, a climate advocacy effort, backed by the United Nations and led by chief executive officers, saw 150 global corporations urge a net-zero recovery (UNGC 2020c). Private sector companies are also actively engaging in UN task forces to help with the global COVID-19 response[30].

Blended social and green finance has also grown due to mounting pressure on business to implement more sustainable business practices (Laidlaw 2020)[31]. Also, evidence that green/SDG funds are outperforming their peers during COVID-19 could make investment in ocean- related projects more attractive (Corporate Citizenship 2020). Banks and investors are also under pressure from stakeholders to allocate more funding for environment, social and governance (ESG) initiatives, and some investment firms have launched clean energy funds.

For example, the Southeast Asia Clean Energy Facility (SEACEF) is providing early-stage venture capital–type funding to get new clean energy projects off the ground in Southeast Asia (Nguyen 2020)[32]. However, there is some risk that ocean-based start-ups will face dwindling funds as private institutional investors have frozen their investment decisions (Runyon 2020). Lack of financing will likely cause some start-ups to stop their activity.

2.3 Gap Between Impacts and Response

An assessment of responses to COVID-19 from governments, the private sector, development banks and the 'third' (or voluntary) sector show that a limited number of investments are directed towards the ocean economy, and a small

[29] *A 'roadmap' was developed by a 'supply chain coalition led by industry and unions in cooperation with UN agencies' (ICS 2020c).*

[30] *For instance, cross-sectoral ocean companies are actively participating in the UN Global Compact Task Force, with aquaculture players such as Cermaq and Bakkafrost, maritime insurers such as Gard AS and maritime classification companies including Lloyd's Register and DNV GL.*

[31] *There has been gravitation towards a more blended sustainable approach and with considerations of environmental, social and governance factors. Social bond issuance for 2020 totalled US $11.58 billion as of 15 May, compared to just $6.24 billion in the same period of 2019, according to an International Capital Market Association analysis of the Environmental Finance database. Demand for sustainability bonds, something of a hybrid between green and social bonds, has also surged. It reached $25.62 billion in the year through 15 May, compared to $13.64 billion in the same period a year earlier. Green bond issuance, in contrast, has dropped sharply. It totalled $53.54 billion in 2020 as of 15 May, compared with $84.09 billion in the same period of 2019.*

[32] *The fund is supported by international climate foundations including Sea Change Foundation International, the Wellspring Climate Initiative, the High Tide Foundation, the Grantham Foundation, Bloomberg Philanthropies, the Packard Foundation and the Children's Investment Fund Foundation. The supporting global philanthropies have invested an initial $10 million in SEACEF, and are seeking to attract up to $40 million in additional capital. It is expected that every dollar of high-risk venture capital–type funding deployed by SEACEF will leverage up to 50 times more in follow-on investment in the clean energy portfolio across Southeast Asia—reaching more than $2.5 billion in assets—while cultivating the local ecosystem of developers to grow the market. The initial focus will be on Vietnam, the Philippines and Indonesia.*

subset focuses on transitioning to a sustainable ocean economy. Within the blue measures there has been more of a focus on short-term coping strategies to address the immediate impacts of the crisis, such as high unemployment, business insolvency and health risks faced by ocean economy workers. Shifting this focus to the development and implementation of longer-term resilience-building strategies will be key to preventing future shocks and responding to ongoing stressors, such as climate change and biodiversity loss. It is imperative that ocean activities and industries transition towards smarter, sustainable practices that conserve marine ecosystems and promote human well- being both now and into the future.

Based on an assessment of the gap between impacts and responses, we summarise below the consequent missing action or unintended impact on local economies and the health of the ocean.

To protect the livelihood of small-scale fisheries in the long term, it will be important to ensure that support policies from national governments do not encourage overfishing practices or IUU fishing that damage ocean ecosystems and deplete stocks. A number of measures have been introduced to promote the recovery of the sector and support the fishers (especially vulnerable groups) facing loss of livelihoods due to the crisis. However, while license fee waivers, measures to reduce input costs (through provision of loans at subsidised interest rates), deferrals and rollover of unused fishing quota are being used to support fishers by reducing fishing costs, this could lead to an environmental trade-off by incentivising overfishing[33]. Measures such as decommissioning schemes or payments for early retirement (e.g. the European Maritime and Fisheries Fund's allowing EU member states to pay fishers and aquaculture producers for a reduction or cessation in production) could reduce oversupply of fleets. However, whether such steps lead to longer-term reductions in fishing pressure and ultimately to healthier fish stocks will depend on whether they postpone fishing effort (OECD 2020d). Measures that incentivise sectors to move towards the sustainable management of fish stocks will be key for economic recovery and equitable prosperity in the long term. It will be important to ensure that support policies and investments do not encourage overfishing practices or IUU fishing that damage ocean ecosystems and compromise the sustainability of resources, putting future resilience at risk.

To help reduce seafood waste and meet long-term food security targets, continuity of investments facilitating the growth of sustainable mariculture will be key. Measures aimed at improving storage of mariculture and fisheries products will also deliver environmental benefits, reducing loss and waste of fish products across the supply chain. Growth of sustainable mariculture practices will be very important for food security, and investments in sustainable mariculture will require a substantial mobilisation of capital. A number of innovative practices are being developed in the sector to support its sustainable transition (including aquafeed alternatives, industrialisation of seaweed and bivalve farming). While some of these have been driven by private investments, financing from public bodies (such as the development banks and national governments) can help mobilise private capital by building confidence and reducing risk.

To help make up for declining tourism-based funding for ocean conservation, there is an immediate need for interventions that help protect vital and vulnerable marine ecosystems. While decreased tourism funding has led to an increase in alternative methods of funding for marine conservation (such as crowdfunding and donations from private foundations), these funding mechanisms are unlikely to be sustained. In addition, some marine sanctuaries have been opened to fishing, which can quickly erase the progress made on marine biodiversity recovery in these sites. The current protected area network is only receiving about one-third of the funding it needs to be effectively implemented and managed, and the shortfall is even greater in developing countries (Waldron et al. 2020). Expanding protection to at least 30% of the world's land and ocean and effectively managing it would require an average investment of US $140 billion annually and deliver a range of benefits to society that will outweigh the costs (Waldron et al. 2020)[34].

For the long-term resilience of the coastal tourism sector and protection against future climate change shocks, investment must go into restoring and protecting marine environments and uplifting local communities. Most emergency and recovery measures have aimed to provide income continuity for tourism workers and business continuity for small enterprises that otherwise would be unable to survive the crisis. The international community has also mobilised funds through multilateral development banks to counteract the economic crisis in the most vulnerable countries. However, much more needs to be done to stimulate demand and ensure the sector's long-term resilience once containment measures are lifted. Recovery following the crisis presents an opportunity to think about innovative measures where tourism businesses play an active role in uplifting local communities and protecting coastal and marine envi-

[33] *Input cost-reduction measures (such as the provision of fuel subsidies) tend to benefit larger fleets at the expense of small-scale fisheries.*

[34] *Waldron et al. (2020) state that this funding should come from a range of sources, including official development assistance, governments' domestic budgets, climate financing directed to nature-based solutions, philanthropies, corporations and new sources of revenue or savings through regulatory and subsidy changes.*

ronments. Policies and investments supporting structural transformation are needed to help build a low-carbon, less polluting, more sustainable and resilient coastal tourism economy. In addition, targeting recovery at diversification across a range of ocean activities to reduce dependency on the tourism sector will be key to building future resilience in Caribbean and Pacific islands.

To ensure the long-term viability of the marine transport sector, investment and regulation needs to create the right market incentives for a sustainable transition to zero-emission vessels. While the pandemic has curtailed the shipping sector's capacity to invest in more environmentally friendly technologies, industry is still leading a strong drive towards decarbonisation (NSA 2020b; Mærsk 2020; CMA CGM 2020). There is an important role for international organisations and governments to help keep the momentum by developing national and market incentives for decarbonising domestic and international transportation. This includes investment in green technologies, developing policy to enable the business case for the adoption by shipping of low- and zero-carbon fuels (e.g. a carbon price), develop national incentives for decarbonising domestic transportation and facilitating decarbonisation of national energy systems faster or as fast as the transition in the international fleet (Hoegh-Guldberg et al. 2019). Low-carbon domestic shipping and coastal marine transport can play a strong role in building coastal resilience. Shifting freight transport from road to waterways in emerging markets (like Africa, India or Latin America), where trucks alone are responsible for about 40% of transport emissions, can substantially reduce emissions and logistics costs (World Bank 2020b). Similarly, after the crisis key global partnerships will need to continue to support SIDS and least developed countries (LDCs) that face significant domestic or regional shipping decarbonisation challenges. Flexible port regulations based on screening and discretion will be needed to ensure the continuity of freight distribution and ferrying of food and essential goods so that supply chains are not hit by both low demand and supply bottlenecks (Heiland and Ulltveit-Moe 2020).

To accelerate deployment of ocean-based energy systems, a stable economic and regulatory environment will be needed to help stimulate investments in these growing sectors. The vast majority of the COVID-19 relief from governments so far supports carbon-intensive industries without requiring improvements. For long-term sustainability it will be important to shift towards a green-blue recovery, where government, businesses and investors can play a role in boosting clean investment, both by promoting low-carbon supply chains and by grasping the opportunities of clean energy markets (Mojarro 2020). Governments will need to play a key role in providing a stable economic and regulatory environment to help stimulate investments required for an accelerated deployment of ocean-based energy systems. Investment will also be needed to advance ocean renewable technologies beyond offshore wind to make them more economically attractive.

3 Roadmap for a Sustainable and Equitable Blue Recovery

Recovery and stimulus packages represent a unique opportunity to accelerate the shift to a sustainable ocean economy that delivers on global targets under the 2030 Agenda for Sustainable Development and the Paris Agreement. Mutually beneficial, no-regrets opportunities are ready to be implemented now to support affected communities and regions, while delivering significant social and environmental benefits. These opportunities respond to the immediate need for job creation in the short-term and offer opportunities for long-term economic growth and resilience. Governments can also utilise innovative financial mechanisms to incentivise progress and avoid rollbacks in progress.

The investments that governments and financial institutions make over the coming months and years will have long-term effects on the nature of economies and their resilience to future shocks. Efforts should be made now to avoid locking in high-emitting, high-polluting and inequitable pathways that limit the ability to build sustainable and resilient economic systems. Investment through recovery and stimulus packages represents a crucial lever for accelerating the shift from business as usual to a more sustainable future that delivers on global targets under the 2030 Agenda for Sustainable Development and the Paris Agreement.

The ocean economy can play a vital role in this transition, and in turn this transition will be critical to securing a sustainable ocean economy for the future. Using recovery and stimulus packages to invest in, and introduce, both short-term and longer-term policy reform for a sustainable ocean economy can provide short-term economic relief and recovery while delivering long-term societal benefits and building economic resilience to future shocks.

This report proposes that coastal and island nations have the opportunity to pursue a 'sustainable and equitable blue recovery'. We consider a 'sustainable and equitable blue recovery' to be one that advances a sustainable ocean economy predicated on three mutually reinforcing elements: effective protection of ocean ecosystems, sustainable production and equitable prosperity. A sustainable ocean economy should enable the growing global population to continue enjoying the innumerable benefits that the ocean provides.

To achieve this, it is imperative that ocean activities and industries transition towards smarter, sustainable practices that conserve marine ecosystems and promote human well-being both now and into the future.

This section of the report aims to provide a roadmap for a 'sustainable and equitable blue recovery' from the COVID-19 crisis.

First, it proposes a set of high-level guiding principles that act as a first step for ensuring a 'sustainable and equitable blue recovery'. These may be helpful for governments in their initial stages of planning on how to think about the nature of their recovery after COVID-19.

Second, it proposes a set of five priority opportunities that are ripe for immediate government investment through recovery and stimulus packages, what we call **'blue stimulus'** (Sect. 3.2). For each of these opportunities, we outline the economic (short- and long-term), social and environmental benefits to be gained from investment in this opportunity and then detail a set of potential interventions for governments based on their national circumstances. We identified these five priority opportunities based on a set of guiding principles outlined in Sect. 3.1.

Third, it proposes a set of additional opportunities that are more systemic in nature and oriented towards using this moment as a reset for the ocean economy to build long-term economic resilience to future shocks, what we call **'blue transformations'** (Sect. 3.3 and Annex 1). Not all these options necessarily provide the short-term economic benefits that the five priority opportunities do, but they are equally important for securing economic recovery, resilience and prosperity over the longer term. Governments that have the capacity to introduce more systemic and long-term policy reform at this time (in addition to taking action on the five priority areas) will find this longer list of additional interventions helpful.

Fourth, it looks at the potential role of financial grants and debt relief as an unprecedented opportunity to advance key reforms in areas such as sustainable fisheries management, monitoring and enforcement of protected areas and ocean data, what we call **'blue conditionality'** (Sect. 3.4).

The proposed opportunities and interventions outlined in this section are not intended to be exhaustive; they do not include everything that will be required to fully transition to a sustainable ocean economy. Resources aimed at providing the full suite of necessary interventions are contained in Annex 2 (Table 19.7). This report focuses on identifying the interventions most relevant at this unique point in time—recognising financial and capacity limitations that many countries have and the urgency of ensuring economic opportunities and health outcomes for their communities over the next few years as we recover from the COVID-19 crisis.

Each country will need to carefully evaluate the full set of interventions against its national priorities, circumstances, impacts and geography to ensure that the options pursued deliver the greatest benefit for its population.

3.1 Proposed Principles for a Sustainable and Equitable Blue Recovery

Given the gap between the impacts experienced by workers and sectors in the ocean economy and the early responses from governments and other stakeholders in their stimulus packages, decision-makers will need to better consider how to integrate the ocean and ocean economy into recovery measures.

This report proposes three high-level guiding principles[35]:

1. Actively advance (through direct investment or policy) projects and programs that contribute to building a long-term sustainable and equitable ocean economy.
2. Identify opportunities to make public finance and debt relief conditional on advancing core national priorities for a sustainable and equitable ocean economy.
3. Assess the impact of all interventions across sectors on the health of the ocean and ocean economy and either avoid investments that will detract from this long-term goal (e.g. high-emitting, polluting terrestrial and marine industries or inequitable practices) or minimise their impact through additional conditions or requirements.

Sections 3.2, 3.3 and 3.4 of this report provide a set of priorities for putting principles 1 and 2 into action.

The Sustainable Blue Economy Finance Principles provide a framework for implementing principle 3 (WWF 2018). These are voluntary principles that act as a framework to guide investment and development decisions. These principles complement existing frameworks in sustainable finance and recognise the importance of compliance, transparency and disclosure, as well as the specific challenges of investment in the context of the ocean. They are designed to support the Sustainable Development Goals (SDGs), in particular Goal 14 ('Conserve and sustainably use the oceans, seas and marine resources for sustainable development'). They are also designed to comply with the International Finance Corporation's Performance Standards and the European Investment Bank's Environmental and Social Principles and Standards (WWF 2018).

[35] *See also the UNGC Sustainable Ocean Principles for the private sector. They propose nine principles that cover three areas: ocean health and productivity; governance and engagement; and data and transparency (UNGC 2019).*

3.2 Five Priority Opportunities for a Blue Stimulus

Given the need for governments to respond to the immediate economic impacts experienced by most countries and coastal communities and the short-term priority of job creation and income protection, we can identify five priority opportunities ripe for immediate intervention by governments through recovery and stimulus efforts. These opportunities not only offer significant short-term job creation and income protection potential for affected communities but also offer long-term economic benefits in the form of catalysing sustainable ocean industries for the future and increasing resilience.

We identified these five priority opportunities through a literature review and expert input from government representatives involved in the design of recovery and stimulus packages and bilateral and multilateral funders (Fig. 19.3). We sought opportunities that provided the following:

- Short-term job creation (considering a match between the skills needed and those available in the local workforce) in the ocean sectors and communities affected by COVID-19 (European Commission 2020b)
- Ability to build long-term resilience to future shocks (considering improving human, natural and physical capital) (Hammer and Hallegatte 2020; OECD 2020e)
- Ability to directly respond to impacts suffered (e.g. economic, social or environmental) and support economic recovery in more than one sector

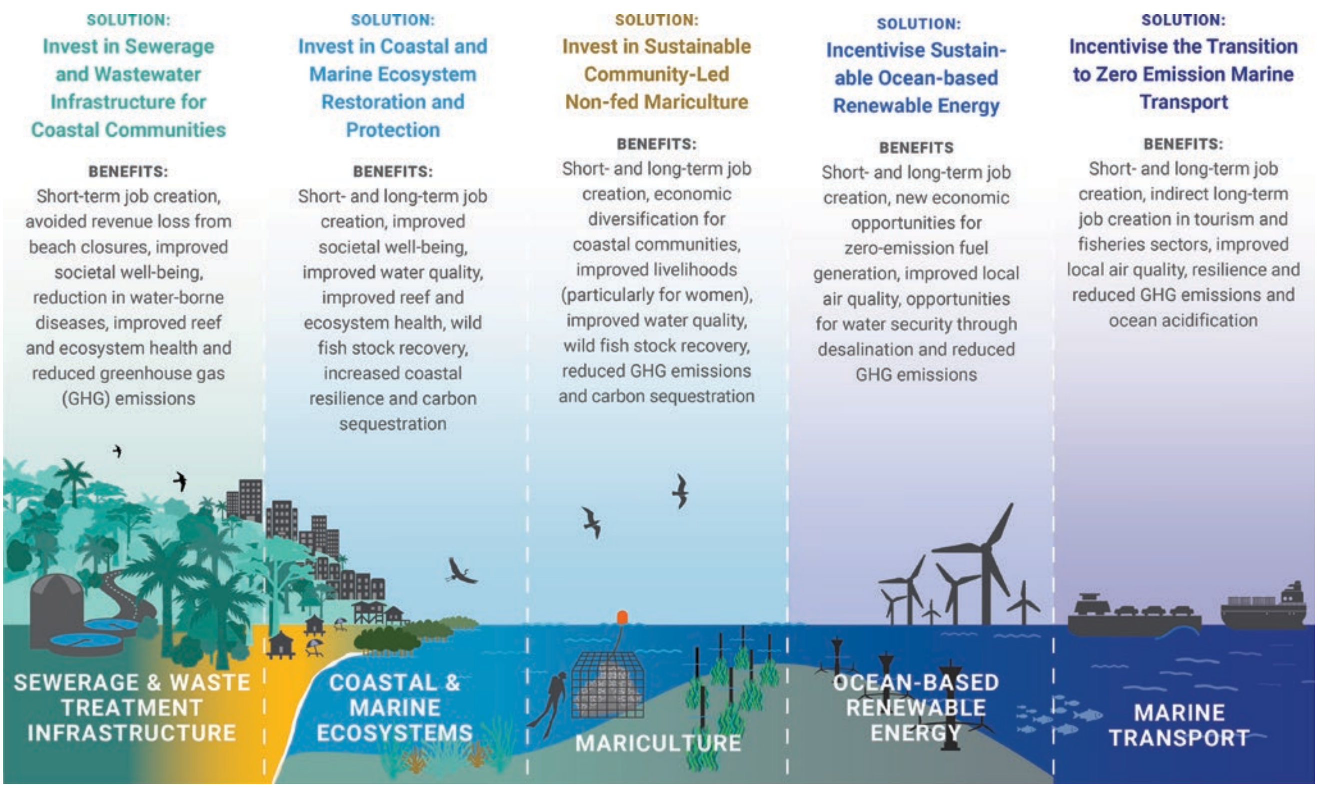

Fig. 19.3 Five priorities for ensuring a sustainable and equitable blue recovery to the COVID-19 crisis

- Ability to direct economic benefits to affected communities and vulnerable members of society (a people-centred approach) (UN 2020b)[36]
- Speed and feasibility of implementation (considering supply chain blockages and capacity of local communities) (Hepburn et al. 2020)[37]
- Ability to catalyse progress towards a long-term sustainable and equitable blue economy (Hepburn et al. 2020)
- Ability to deliver on international commitments such as the 2030 Agenda for Sustainable Development and the Paris Agreement (IMF 2020b)
- Relevance to multiple regions and economies (OECD 2020e)

In advancing a 'sustainable and equitable blue recovery' it will be important to make decisions in accordance with integrated and holistic long-term plans and strategies, so that investments are made in alignment with national priorities.

Such planning tools include integrated ocean management, integrated coastal zone management and marine spatial planning (MSP). Establishing MSP processes in addition to integrated ocean management will be essential to deal with the inherent variability of the ocean and a dynamic future shaped by climate change. Cohesive planning can facilitate optimal use and benefit from ocean resources by all users while streamlining management to improve governance and conservation of critical habitats[38]. Ideally, countries should develop a sustainable ocean economy plan that acts as a comprehensive strategy for advancing effective protection of ocean ecosystems, sustainable production and equitable prosperity.

[36] *The UN secretary general has stressed the need to ensure that national and local response and recovery plans identify and put in place targeted measures to address the disproportionate impact of the virus on certain groups and individuals, including migrants, displaced persons and refugees, people living in poverty, those without access to water and sanitation or adequate housing, people with disabilities, women, older people, LGBTI people, children and people in detention or institutions.*

[37] *Factors relevant to the design of economic recovery packages include the long-run economic multiplier, contributions to the productive asset base and national wealth, speed of implementation, affordability, simplicity, impact on inequality and various political considerations (Hepburn et al. 2020).*

[38] *The value of such planning instruments at times of economic hardship is illustrated by an MSP process in Massachusetts that led to a proposed optimum arrangement with associated value, calculated at preventing more than $1 million in losses to the incumbent fishery and whale- watching sectors and generating more than $10 billion in extra value to the energy sector (White et al. 2012).*

3.2.1 One: Invest in Coastal and Marine Ecosystem Restoration and Protection

Coastal and marine ecosystem restoration can broadly be defined as activities that are aimed at moving these ecosystems (mangroves, salt marshes, seagrasses, kelp and seaweed forests and reefs) to healthier states, often with the goal of increasing their ability to provide ecosystem services. This includes replanting coastal mangrove forests that have been degraded, reconstructing saltmarshes that have been lost to human development and enhancing the structural complexity of damaged reefs (both coral and shellfish). The potential benefits of restoration projects are higher—often significantly higher—than the costs, making such projects prime candidates for investment as part of recovery and stimulus packages (Bayraktarov et al. 2015).

Analysis indicates a potential net benefit of US $97 billion to $150 billion for mangrove restoration and $48 billion to $96 billion for mangrove conservation over 30 years (2020–50)[39]. This results in a benefit-cost ratio of 3:1 for both mangrove conservation and restoration (Konar and Ding 2020)[40].

Restoration of coastal and marine ecosystems has been identified as a priority due to its potential for job creation in the short term and significant potential in terms of avoided greenhouse gas (GHG) emissions. It is also a necessary precondition for protection and subsequent management and conservation efforts. Ensuring that ecosystems are placed under full or high protection and effective management is a critical element of a sustainable ocean economy and opportunities for countries to use debt for nature swaps as a means of expanding their marine areas under protection (see Box 19.7 below).

[39] *The total value of net benefits for mangrove restoration over 30 years is higher than for conservation because we assume the area of mangroves restored is 10 times that of the area conserved. The conservation scenario assumes stopping the additional loss of mangroves, whereas the restoration scenario assumes replanting large areas of mangroves already lost; that is why we are doing more restoration in the scenarios analysed than conservation. The overall ratio of both conservation and restoration is calculated by adding the total present value benefits and costs of both measures. The very high restoration costs are the main factor driving the overall benefit-cost ratio for both conservation and restoration.*

[40] *Konar and Ding's (2020) study estimates the benefit-cost ratio for mangrove conservation to be higher (88:1) than restoration (2:1) due to a number of factors: the higher cost of mangrove restoration (due to seeding and replanting), the low survival rates following restoration and the lag in accrual of benefits from restoration.*

SUPPORTING RECOVERY AND RESILIENCE IN THESE SECTORS:
Fisheries, Tourism, Marine Conservation and Infrastructure

SUPPORTING ACHIEVEMENT OF THESE SDGs:

Why Investment Makes Sense

Restoration of coastal and marine ecosystems provides short-term job creation in a number of industries at the local and regional level. Restoration works create jobs immediately through construction. Restoration projects extend to the full set of economic activities that contribute to restoration, from project planning, engineering and legal services, to intermediate suppliers of inputs, to on-the-ground earth-moving, forestry and landscaping firms that contribute to the ecological restoration process (BenDor et al. 2015). Restoration can include a full spectrum of jobs from all skill levels and technical backgrounds, including general trades, barge drivers, engineers, transportation, scientists and hatchery staff, oyster farmers and hydrologists. The economic benefits derived from coastal and marine restoration projects are not limited to direct jobs. However, much of the economic benefit is in uplift to the service and beneficiary industries associated with increased coastal productivity, including fishing, tourism, wastewater treatment and marine equipment and boat suppliers (Appeaning Addo et al. forthcoming)[41]. Other estimates for coastal and marine restoration works in the United States ranged from 15 to 33 jobs per $1 million, depending on the type of activity (removal of invasive species from coral reefs generated the most jobs), but the majority of projects fall within a range from 15 to 19 jobs per $1 million of expenditure (Edwards et al. 2013) (see Box 19.5 for more details). By comparison, investment of $1 million in traditional energy-intensive industries have been estimated at 14.4 jobs for road and bridge developments, 6.8 jobs for coal mining, 4.2 in nuclear and 5.2 jobs in oil and gas and 8.9 for offshore oil and gas (Hurowitz 2020; Pollin et al. 2009)[42]. These jobs can be created in rural areas, where poverty tends to be concentrated in low- and middle-income countries.

Box 19.5 Coastal Restoration in the United States

Following the 2008–2009 global financial crisis and expenditure under the American Recovery and Reinvestment Act (ARRA) of 2009, the National Oceanic and Atmospheric Administration (NOAA) estimated that coastal habitat restoration projects created, on average, 17 jobs per million dollars spent[a]. This is similar to other conservation industries such as parks and land conservation, but much higher than other traditional industries, including coal, gas and nuclear energy generation.

The study shows that the 50 ARRA projects administered by NOAA in the first year and half generated a total of 1409 jobs (Edwards et al. 2013). Many of these jobs were created in rural and regional coastal areas and offer a range of skilled and low-skilled positions, considerably enhancing economic opportunities in regional areas. Jobs were created for day labourers, administrative staff, barge operators, lawyers, accountants, engineers, helicopter pilots, fisherman, scientists, nursery workers and project managers. Longer-term employment can be created through the flow on benefits (uplift) created by an increase in productivity of coastal ecosystems and generation of wider ecosystem services benefits (for example, increased employment from improved productivity and higher tourism opportunities).

The median (global) restoration cost for all coastal ecosystems (mangroves, saltmarshes, seagrasses, coral reefs and oyster reefs) was estimated to be around $80,000 per hectare (Bayraktarov et al. 2015). Costs for restoration vary considerably within and between ecosystems and across countries (Bayraktarov et al. 2015)[b].

[41] *Estimates are based on Oregon's restoration project, and labour intensity will depend on local factors. The model used the economic impact modelling software IMPLAN 3.0 to describe the impacts from public investments in forest and watershed restoration. It was based on an input- output analysis to describe the patterns of trade and the degree to which goods and services are sold and purchased outside the state's economy. Based on the dependencies among different economic activities, input-output models can project the impact that changes in one sector will have on economic activity in other sectors of the economy.*

[42] *Multipliers were derived using IMPLAN 2.0 with 2007 data. Infrastructure multipliers and assumptions are presented in Pollin et al. (2009). The estimates are based on input-output models. Key limitations include the assumption of fixed prices (prices do not change when demand for a good, service, or input changes), fixed ratios of labour to other factors of production and fixed sectoral share of GDP over time.*

[a]*The model used to calculate these job numbers was the economic input/output software called IMPLAN (Impact Analyses and Planning) to estimate overall jobs and economic impacts. The economic data for IMPLAN come from the system of national accounts for the United States based on data collected by the U.S. Department of Commerce, the U.S. Bureau of Labor Statistics and other federal and state government agencies. Data are collected for 528 distinct producing industry sectors of the national economy corresponding to the Standard Industrial Categories. Industry sectors are classified on the basis of the primary commodity or service produced. Corresponding data sets are also produced for each county in the United States, allowing analyses at the county level and for geographic aggregations such as clusters of contiguous counties, individual states or groups of states.*

[b]*The median restoration cost per hectare for mangroves, seagrasses, oyster reefs, coral reefs and saltmarshes is estimated to be $8961, $106,782, $165,607 and $67,128, respectively. Total project costs—calculated for projects that included both capital and operating costs—for restoring seagrass, saltmarshes and oyster reefs were two to four times higher than the median.*

Healthy coastal and marine ecosystems under full or high protection and effective management can deliver long-term job creation and economic growth potential in ecotourism and artisanal fisheries. The protection and effective management of coastal and marine ecosystems through fully or highly marine protected areas (MPAs) (Carrasquila Henao and Juanes 2017) or other effective conservation-based measures (OECMs) can deliver long-term economic opportunities for coastal communities. Analysis has shown a benefit- cost ratio of between 3:1 and 20:1 of expanding the MPA network, meaning that every $1 invested returns up to $20 in benefits (WWF 2015). Analysis shows that expanding protected areas to cover 30% of the planet (terrestrial and ocean) would generate higher overall output (revenues) than non-expansion (an extra $64 billion to $454 billion per year by 2050). This would be in addition to economic benefits (avoided-loss value estimated to be $170 billion to $534 billion per year by 2050) (Waldron et al. 2020)[43]. In terms of direct job creation, coastal and marine ecosystems under protected area status generate demand for administration, conservation, management, monitoring, surveillance and scientific research jobs located in the local community. For example, for the Natura 2000 network (terrestrial and marine), every €1 billion of expenditure supports almost 30,000 jobs, with 60% of these on activities directly related to site management (e.g. designation, management, conservation actions, monitoring and research) (Mutafoglu et al. 2017). In addition, MPAs generate demand for other services, such as technology to improve surveillance and management (see Sect. 3.4 on how to digitise such efforts in a post-COVID-19 world) (EU Commission 2018). The restoration and protection of these ecosystems also directly improves the potential for ecotourism or the recovery and long-term viability of the coastal tourism sector. Studies have shown that ecotourism in marine protected areas provides 4–12 times greater economic returns than the economic returns from solely utilising the area for fishing (for example, A$5.5 billion annually and 53,800 full-time jobs in the Great Barrier Reef) (Deloitte 2017; Duarte et al. 2020). The port city of Xiamen, located on the west coast of the Taiwan Strait and one of the busiest ports in China, faced environmental degradation, sea-use conflicts and ineffective management. As a result of improving protection and advancing ecosystem restoration, the Chinese white dolphin population returned and tourist numbers increased from five million in 1996 to more than 100 million in 2019 (Winther et al. 2020). Industry has also been able to flourish, with year- on-year growth staying above 10%. New marine high-tech industries (biological pharmacy, science and education service, high-end equipment) have also grown (Winther et al. 2020). Roncin et al. (2008) summarise the impact of Southern European MPAs on local economies[44] and calculate the yearly local income related to services to non-resident recreational users to be €640,000/year per MPA and 15 yearly full-time equivalent jobs[45]. Lastly, MPAs and OECMs are critical tools to increase fisheries' productivity, maintain fish stock levels and thereby ensure ongoing economic opportunities for artisanal and commercial fisheries as well as provide local food security (Brander et al. 2015). In a meta-analysis looking at the role of biodiversity loss on ecosystem services, data showed that post-designation, levels of biodiversity of fully protected areas increased by an average of 23%, with large increases in fisheries' productivity in areas adjacent to the MPA (known as the spillover effect) (Halpern et al. 2010). Fisheries in medium- to high-decline gained the most from spillover from highly and fully protected MPAs (WWF 2015). Another study that looked at the combined economic benefits of MPAs found that both tour-

[43]*The financial estimates are for both terrestrial and marine protected areas. The economic estimates only refer to forests and mangroves.*

[44]*Empirical evidence is based on surveys with fishermen and divers (1,836 questionnaires).*

[45]*Estimates are based on local expenditures of non-resident recreational fishers and scuba divers only. Estimates would likely be higher if expenditure of all tourists were included.*

ism and neighbouring fishery profits increased within as little as five years after the reserve was established (Sala et al. 2013).

Healthy coastal and marine ecosystems deliver improved health, well-being and resilience for coastal communities. Restoration of these ecosystems can deliver significant benefits for improved food security for coastal communities (TNC 2013)[46], improved water quality (and the associated health benefits) and improved coastal recreation opportunities. Communities living in areas with more extensive mangrove forest experience significantly lower losses from exposure to cyclones than communities in coastal areas without mangroves (Hochard et al. 2019) and are more resilient to the effects of rising sea levels (Serrano et al. 2019). This is also true in communities bordering fringing reefs. Reef structures cause waves to break and reduce wave energy by an average of 97%, protecting the beach from possible erosion as well as reducing the number of people affected by annual flooding by more than 200,000 (Ferrario et al. 2014; Beck et al. 2018). Higher property values are associated with communities situated near restored and well-functioning coastal and marine ecosystems (Bark et al. 2009). Studies have shown that lower-income communities living in low-lying areas are the most vulnerable to natural disasters such as flood and coastal storm surges (Winsemius et al. 2018). Utilising restoration of coastal ecosystems in these areas can dramatically improve the quality of life of these communities. For example, following the 2004 floods in Bangladesh, poor households lost more than twice as much of their total income as non-poor households (Brouwer et al. 2007). Worldwide, low-income countries suffer 63% of all deaths from storms, including cyclones and hurricanes, even though they experienced just 12% of the global total of such events (CRED 2015). Coastal and marine ecosystem restoration and protection also offer opportunities for engagement, co-ownership and co-management with Indigenous communities and traditional owners—offering knowledge-sharing and capacity building for all stakeholders involved as well as the opportunity for revenue to be reinvested back in the local community (McLeod et al. 2018). Studies have shown that engagement of local communities in long-term restoration and protection is a key success factor, and lacking it is a major reason for failure (Hai et al. 2020; Suding et al. 2015). Inclusive planning processes for restoration activities have been shown to deliver a positive social impact and equitable benefits for communities.

[46] *In Mobile Bay, Alabama, \$3.5 million has been spent on efforts to successfully restore 5.9 km of oyster reefs that have reduced wave height and energy of average waves at the shoreline by 53–91%. The reefs have also produced 6,560 kilograms of seafood per year—a weight equivalent to half the total oysters harvested in Alabama in 2015.*

Coastal and marine ecosystems also have significant carbon sequestration potential and can provide valuable mitigation opportunities in addition to improving local water quality and enhanced biodiversity. Analysis estimates that restoration could deliver annual global emissions reductions of between 0.20 and 0.33 GtCO2e by 2050 (Hoegh-Guldberg et al. 2019), which is equivalent to taking approximately 4–7 million cars off the road annually[47]. The sequestration benefits from reducing CO_2 emissions are estimated at \$137 billion to \$214 billion for restoration over 30 years (Konar and Ding 2020). Coastal habitats are home to a number of marine and terrestrial animals (Li et al. 2018; Rog et al. 2016), including species important for fisheries (Carrasquila-Henao and Juanes 2017). These habitats buffer acidification (Kapsenberg and Cyronak 2019) and play an important role in wastewater treatment systems (Ouyang and Guo 2016). In addition, shellfish beds and reefs enhance habitat availability, benthic flora and marine organism populations. They act as nursery grounds for fish and other species (including crustacea), and their nutrients support the growth of seagrass and macroalgae (e.g. kelp) (Alleway et al. 2018; Hughes et al. 2018). Restoration of historic baselines in combination with bivalve mariculture can improve ecosystem health while providing a food source and employment (see Box 19.6). Bivalves are increasingly used to extract and convert pollution in the Baltic Sea (Petersen et al. 2020). In New York, the Billion Oysters Project aims to place 1 billion oysters in the harbour to help clean up its water while providing habitat for marine species, shielding shorelines from storm damage and engaging students and the local community (75 restaurants and 70 schools as of 2018) (Charlton 2019).

How These Benefits Can Be Achieved: Short-Term Interventions That Can Be Initiated Now as Part of Stimulus Spending and Recovery Measures

- **Commit public funding to a set number of restoration projects.** Direct public investment to 'shovel ready projects' (based on a set of criteria) through stimulus funding packages. See Box 19.5 for the example in the United States following the 2008–2009 financial crisis and Box 19.6 for an example of the suite of cross-sectoral benefits that can be derived from ecosystem restoration.
- **Establish national funds to mobilise private sector funding for large-scale restoration.** Initial public investment is used to attract impact investors and larger private sources of funding, including from philanthropy. The nature of the fund will need to depend on national circumstances. An example is the trust fund established for the

[47] *Based on the average emissions of a passenger vehicle being 4.6 metric tonnes per year, according to EPA (2018).*

tourist coast of Mexico's Yucatán peninsula. A tourist tax is channelled into the fund to pay for both routine reef maintenance, such as removing debris and replanting species, and bigger repairs after hurricanes.

- **Use debt-for-nature swaps or debt restructures.** Governments could consider including restoration and/or protection of coastal and marine ecosystems under fully or highly protected MPAs or OECMs as part of debt-restructuring negotiations and debt-for- nature swaps (see Box 19.7 for further details on debt- for-nature swaps).
- **Incentivise use of technologies such as remote electronic monitoring, and high-resolution vessel tracking and monitoring systems and collaborative approaches with small-scale fishing fleets to enhance outcomes for marine protected areas and fisheries management**. Increasingly, market considerations are a compelling reason for small-scale fishers to adopt monitoring systems. Gaining access to export markets would improve their incomes and help develop their local economies (INFOFISH International 2020). Governments could consider incentivising the use of remote electronic monitoring (REM) in key fisheries or working on collaborative partnerships to enhance data collection in protected areas (see Sect. 3.4 for additional ideas on conditional grants). REM data enable cross-verification of self-reported data and can confirm vessel compliance with regulations. This approach not only discourages violations because all activities are monitored but also gives legitimacy to self-reported catch. As an example of the potential benefits, providing 10% video review monitoring across the over-10-metre fleet throughout the United Kingdom would cost approximately £5 million. This equates to roughly a quarter of the money spent on more traditional systems, which deliver less than 1% at-sea coverage (WWF 2017). Inshore vessel monitoring systems can be undertaken by using inexpensive cellular 3G/GSM/GPRS networks rather than global satellites (see, e.g., AST 2019).
- **Ensure that the definition of 'infrastructure' includes hybrid green-grey infrastructure**. Ensure that investments targeted at stimulating large-scale coastal infrastructure projects enable the use of hybrid green-grey infrastructure approaches (e.g. the use of nature-based solutions such as living reefs or mangroves in conjunction with traditional concrete or non-living structures). These investments can include regulatory reform, procurement and tender agreements and definitions for bilateral aid. Hybrid solutions combine conservation and restoration of coastal ecosystems with conventional engineering and can offer enhanced levels of coastal protection while also delivering the key co-benefits associated with ecosystems.
- **Invest in blue carbon projects (restoration and conservation of coastal wetlands—mangroves, seagrasses and tidal marshes) and accelerate the associated policy and regulatory reform (inclusion in national GHG inventories, nationally determined contributions and market mechanisms)**. Blue carbon projects can bring sustainable carbon financing to the restoration and protection of coastal and marine ecosystems while at the same time contributing directly to a government's international commitment under the Paris Agreement. Carbon financing is also substantially more economically stable than tourism and other income streams. Sites must be carefully selected to meet the accounting requirements under the Paris Agreement, avoiding areas that are likely to be inundated by sea level rise. Blue carbon projects must also be advanced in conjunction with social safeguards to consider demands from local small-scale fishers and other stakeholders who are heavily dependent on coastal resources for economic sustainability (Barbesgaard 2018; Bennett 2018; Friess et al. 2019). Effective local engagement of stakeholders, ensuring their voice is heard, will be key for the success of these initiatives.

Box 19.6 Restoring Shellfish Reefs in Australia and the United States

In Australia, The Nature Conservancy, in partnership with state and Commonwealth governments, has embarked upon a national program to rebuild and restore Australia's lost shellfish reefs. Based on the results of existing pilot projects, scaling efforts to 60 reefs nationally will provide 850 new full-time jobs for local coastal communities, divert 7000 m^2 of shell waste from landfills, reduce coastal erosion and deliver the following annual benefits:

- 375 kg of new fish stocks, including high-value snapper, flathead and whiting
- Filtration of two billion litres of seawater (the equivalent of the annual water use of 21,000 Australians)
- Removal of 225 kg of nutrient pollution (nitrogen and phosphorous) in coastal areas (TNC 2020)

In 2011, the full suite of ecosystem services derived from natural oyster reefs in North America was conservatively estimated to be between US $5500 and $99,000 per hectare per annum, with recovery of their restoration costs in 2–14 years (Grabowski et al. 2012). These services include job creation and economic development, fish production, water filtration, coastal protection and providing habitat for many other marine species. The largest current initiative is the Chesapeake Bay Executive Order, which requires the oyster populations of 20 Chesapeake Bay tributaries to be restored by 2025. Three estuaries have been restored thus far, including 964 acres of restored reef at a projected total cost of $72.1 million[a]. The resulting harvested biomass has the potential to contribute millions of dollars in additional sales for commercial seafood harvesters. This would be in addition to a wide range of other ecosystem services from restoring the reef (such as water purification, nitrogen sequestration and water and biogeochemical cycling), which could help recoup the cost of investment (Knoche and Ihde 2018)[b].

[a] *This project focused on the first three tributaries in Maryland chosen for restoration: Harris Creek, the Little Choptank River and the Tred Avon River. The projected cost for achieving the total restoration acreage target was $72 million; actual costs incurred to this point have been $53 million.*

[b] *Knoche and Ihde (2018) used IMPLAN regional economic impact modelling software to calculate the economic effects for four key economic measures (output, labour income, value-added and employment). There are a number of limitations to using ecological and regional impact modelling studies. For example, the ecological model implicitly assumes that catchability is constant and also excludes key ecosystem services from oyster reefs. While the authors did not carry out a benefit-cost analysis per se, based on the estimates calculated and the missing value of the ecosystem services, we ascertain the benefits are likely to outweigh the cost of investment.*

Box 19.7 Debt-for-Nature Swaps to Advance Marine Protected Areas

Since 2008, when Seychelles defaulted on its national debt, the country has since sought ways to preserve its natural environment—the pillar of its economy and of its citizens' livelihoods—without endangering financial stability. In 2015, The Nature Conservancy and its impact investing unit, NatureVest, brokered a deal to restructure a portion of Seychelles' debt with a debt-for-nature swap. The deal allows the government to restructure the country's debt with a mix of investments and grants, in exchange for designating 30% of its exclusive economic zone (EEZ) as a marine protected area. The agreement frees capital streams and directs debt service payments to fund climate change adaptation and marine conservation activities that will improve the management of Seychelles' coastlines, coral reefs and mangroves. This is the first time this financing technique has been used for the marine environment (Thande 2018).

The designation of the 30% of the EEZ took place during the COVID-19 crisis, on 26 March 2020, and demonstrated the continued commitment of Seychelles to marine protection as a core aspect of its long-term strategy for economic sustainability (Statehouse 2020).

In 2018, the Republic of Seychelles complemented its debt restructure though the debt-for-nature swap by establishing the world's first sovereign blue bond. The blue bond was created in partnership with impact investors (private capital) and public multilateral bodies (the World Bank and Global Environment Facility) to finance the necessary shift to sustainable management and governance of fisheries in Seychelles. The beneficiaries of the proceeds of the blue bond will be local communities, civil society organisations and businesses who are seeking financing for activities that can support a transition to sustainable fisheries. The bond was issued with a ceiling value of US $15 million, with a maturity of 10 years. The World Bank provided support through a partial guarantee ($5 million), and the Global Environment Facility provided a concessional loan ($5 million), which will subsidise payment of the bond coupons. These credit enhancement instruments allowed for a reduction of the price of the bond by partially de-risking the investment of the impact investors, and by reducing the effective interest rate of 6.5% for Seychelles to 2.8% by subsidising the coupons (World Bank 2018).

Despite significant changes to national budgets and revenues as a result of the impacts suffered from COVID-19, the sovereign blue bond has continued to fund recovery efforts and economic diversification initiatives across Seychelles to aid in recovery efforts. This includes over $700,000 in grants for ocean conservation and management and $12 million to fund research and development for new economic opportunities.

Seychelles is also undertaking extensive mapping of its seagrass ecosystems, aiming to map the entire EEZ to enable inclusion of these ecosystems and the associated adaptation blue carbon benefits for inclusion in its nationally determined contribution (NDC) under the Paris Agreement to be submitted this year and a commitment towards integrating carbon accounting for the blue carbon ecosystems in the NDCs ahead using the Wetlands Supplement of the Intergovernmental Panel on Climate Change.

3.2.2 Two: Invest in Sewerage and Wastewater Infrastructure for Coastal Communities

Wastewater and sewage runoff into coastal waters (resulting in eutrophication and hypoxia) is a major contributor to human health issues, spreads water-borne diseases among coastal communities, contributes to the loss of local fish stocks (and therefore contributes to local food insecurity and loss of revenue for small-scale fishers), furthers the decline of coral (and therefore undermines opportunities for ecotourism) and results in costly beach closures for coastal communities and tourism (WWAP 2017)[48].

More than 80% of global wastewater flows are released without adequate treatment, with this figure as high as 95% in some least developed countries (ILO 2017). Much of this runoff comes from agricultural sources, where inefficient use of fertiliser and inadequate wastewater treatment leads to nitrogen and phosphorous loading in waterways and groundwater. Excess nitrogen and phosphorus often lead to eutrophication, harmful algal blooms and ocean hypoxia (UNEP et al. 2012). Even where treatment facilities exist, they may sometimes discharge untreated sewage into waterways and the ocean due to decayed infrastructure, facility malfunctions or heavy rainfall events that overwhelm systems using combined sewers and stormwater drains (Jambeck et al. 2020; Malik et al. 2015).

SUPPORTING RECOVERY AND RESILIENCE IN THESE SECTORS:
Tourism, Fisheries, Infrastructure, Marine Conservation, Health and Water

SUPPORTING ACHIEVEMENT OF THESE SDGs:

Over the last 30 years, wastewater and sewage runoff has cost the global economy an estimated \$200 billion to \$800 billion per year (UNDP 2012).

[48] *Bacteria use up oxygen in the water as they decompose the organic material in the wastewater, and the resulting lack of oxygen in the water kills the fish. The solids in sewage cause the water to appear dark and murky, which also affects the ability of fish to breathe and see around them.*

The estimated rates of return on water and sanitation investments are striking, with every \$1 invested in water, sanitation and hygiene having a potential return of \$3–34, depending on the region and technology involved (Hutton et al. 2004).

In the face of ever-growing demand for water, wastewater is increasingly seen as a reliable alternative source of water, shifting the paradigm of wastewater management from 'treatment and disposal' to 'reuse, recycle and resource recovery' and offering even greater benefits. In the context of a circular economy, whereby economic development is balanced with the protection of natural resources and environmental sustainability, wastewater represents a widely available and valuable resource (WWAP 2017).

Why Investment Makes Sense

The development of the infrastructure for sewage and wastewater treatment and reuse can offer immediate job opportunities for local communities in coastal areas. Analysis of stimulus packages in Latin America from the 2008–2009 financial crisis aimed at investment in public works found that investing \$1 billion in water supply and sanitation network expansion could result in the creation of up to 100,000 direct jobs annually (significantly higher than the same investment in coal- powered energy) (Schwartz et al. 2009)[49]. In the United States, investments in sustainable water practices are estimated to generate between 10 and 15 direct, indirect and induced jobs per \$1 million invested in alternative water supplies; between 5 and 20 direct, indirect and induced jobs per \$1 million invested in stormwater management; between 12 and 22 direct, indirect and induced jobs per \$1 million invested in urban conservation and efficiency; and between 10 and 72 direct, indirect and induced jobs per \$1 million invested in restoration and remediation (Pacific Institute 2013). Investing in green infrastructure, such as riparian buffers to address agricultural runoff, could also be a cost-efficient alternative to typical grey infrastructure. When compared to the creation of a new nitrate-removal facility, the planting of a riparian buffer offered a cost savings of up to \$29 million (Canning and Stillwell 2018). Reforms and incentives promoting recovery and reuse of wastewater (such

[49] *Note that Schwartz et al.'s (2009) study looks across multiple countries and projects aimed at water and sanitation. The figures provided in this report were for Columbia's expansion of its water supply and sanitation network. For the full details, including figures for other countries and types of investment, see Table 2 in Schwartz et al. (2009). The investment includes both water and sewage treatment. The direct employment- generation potential of an investment is thus highly sensitive to assumptions about wages, the division between skilled and unskilled workers, the sectoral allocation of the proposed program, the technology to be employed in each project and the potential crowding-out or substitution effects. Indirect job estimates are also highly sensitive to leakage created from the division between locally produced and imported inputs.*

as retrofitting homes and apartment buildings for composting, collection and reuse of human waste as fertiliser) are typically much more labour-intensive than current/traditional 'linear' municipal wastewater collection, treatment and disposal systems, leading to net job creation in both the private and public sectors. For example, as a result of concerted policy and investment, Israel now reuses 80% of its wastewater for agricultural production. This has led to a fivefold increase in the export of water technology, leading to a $2 billion industry between 2008 and 2013 (Hudson 2017).

Investment in sewage and wastewater treatment and reuse can avoid long-term costs (in terms of loss of biodiversity, tourism revenues and wider recreational benefits) as a result untreated wastewater being discharged into coastal waters. The longer-term economic benefits of investment in waste and sewerage infrastructure are twofold. First, clean coastal waters will bring economic benefits to communities and businesses that rely on tourism revenue. Cleaner waters and healthier coastal ecosystems offer additional opportunities for ecotourism and revenue-generating activities. Second, such investment avoids the economic loss suffered through inaction. The degradation of coral reefs due to pollution and overfishing caused the Caribbean to lose $95 million to $140 million per year in net revenue from coral reef–associated fisheries, $100 million to $300 million per year in reduced tourism revenue and $140 million to $420 million per year in reduced coastal protection (Burke et al. 2011)[50]. On a more local scale are the economic losses suffered by coastal business and tourism ventures from beach closures as a result of pollution. Furthermore, the integration of green infrastructure with traditional grey infrastructure for the recovery and reuse of wastewater has been shown to offer significant improvements and long-term economic savings for local authorities. In 2007, the city of Portland, Oregon, introduced a program to spur the use of green infrastructure for urban stormwater management. As a result, service providers installed permeable pavements and bioswales throughout the city, reducing peak flow by 80–94% in target areas. Estimates indicate the initial $9 million investment in green infrastructure has yielded a savings of $224 million in stormwater costs related to repairs and maintenance (EPA 2010). A review of the U.S. water and wastewater infrastructure estimated that meeting the nation's projected needs would require an additional investment of $82 billion per year for the next 10 years, but the review also found that this investment would result in over $220 billion in total annual economic activity, approximately 1.3 million jobs and productivity savings for U.S. businesses of approximately $94 billion a year[51] (Value of Water Campaign 2017).

Proper wastewater treatment and reuse facilities and sewerage infrastructure will improve the health of the local community, prevent future water-borne diseases, increase water security and reduce inequalities. Improved waste management has direct gender and social equity implications, and addressing this issue would also lead to improved social equity outcomes in associated communities (Satterthwaite et al. 2019). Targeted water investments may contribute to reaching growth and poverty alleviation goals more effectively (UN Water 2016). Globally, unsafe sanitation costs an estimated $223 billion a year in the form of high health costs and lost productivity and wages (WHO 2012). Investment in safe drinking water and basic sanitation could offer estimated economic returns of $3–34[52] globally for every $1 invested, with an overall estimated gain of 1.5% in global GDP (Hutton et al. 2004). These returns include both health benefits (such economic benefits from reduction in water-borne diseases) and non-health benefits (such as time savings associated with better access). Investment in small- scale projects providing access to safe water and basic sanitation in Africa could offer an estimated economic return of about $28.4 billion a year, or nearly 5% of the continent's GDP (UNESCO 2009). Improving employment is a good economic outcome; sound health and social equity outcomes are also important enabling conditions for resilient communities.

A reduction of untreated wastewater being discharged into coastal waters will improve local water quality and reduce stressors on coral reefs and coastal ecosystems, and reuse can offer climate-mitigation benefits.

Reducing the nutrient runoff will reduce a significant stressor on coral reefs and shellfish (especially bivalves that filter large quantities of water) resulting in improved and

[50] *The loss of economic value from degradation of reef goes beyond the estimated tourism revenue, as it includes both use value (e.g. recreational fishing, surfing or beach-going) and non-use values. Non-use value includes the value of preserving the ecosystem for future use either by an individual (option value) or by future generations (bequest values). In addition, there is existence value, which is unrelated to the use of the resource and represents the willingness to pay for the resource to exist (e.g. willingness to pay for the protection of a beach you will never visit). Non-use value is often difficult to quantify, and hence the economic losses tend to be larger than the market values estimated.*

[51] *If the water infrastructure gap is not addressed, businesses would face higher costs to procure water and wastewater services. These costs include operational and maintenance costs, higher water rates, costs of self-supply or costs of relocating to a better-served area.*

[52] *Returns are dependent on the region and technology used (Hutton et al. 2004). The benefits also refer to improving the quality of groundwater (which we use as a proxy). The estimates refer to the following intervention: halving the proportion of people who do not have access to improved water sources and improved sanitation facilities by 2015. 'Improved' water supply involved better access and protected water sources (e.g. stand post, borehole, protected spring or well, or collected rainwater). Improvement does not mean that the water is safe, but it is more accessible, and some measures are taken to protect the water source from contamination. 'Improved' sanitation, generally involving better access and safer disposal of excreta (septic tank, pour-flush, simple pit latrine, small bore sewer or ventilated improved pit latrine).*

more resilient coastal and marine ecosystems and improved local water quality. Energy from wastewater and sewage treatment can be recovered in the form of biogas, heating and cooling, and electricity generation. Technologies exist for on-site energy recovery through sludge and biosolids treatment processes integrated into wastewater treatment plants, allowing them to transition from major energy consumers to energy neutrality, or even to net energy producers. Energy recovery can also help facilities reduce operational costs and their carbon footprint, enabling increased revenue streams through carbon credits and carbon-trading programmes (WWAP 2017).

How These Benefits Can Be Achieved: Short-Term Interventions That Can Be Initiated Now as Part of Stimulus Spending and Recovery Measures

- **Commit public funding for decentralised, low-cost solutions and safe water reuse options in coastal areas.** Large-scale centralised wastewater treatment systems may no longer be the most viable option for urban water management in many countries. Decentralised wastewater treatment systems, serving individual or small groups of properties, allow for the recovery of nutrients and energy, save freshwater and help secure access to water in times of scarcity. It has been estimated that the investment costs for these treatment facilities represent only 20–50% of conventional treatment plants, with even lower operation and maintenance costs (in the range of 5–25% of those of conventional activated sludge treatment plants) (WWAP 2017).
- **Commit public funding for the development of services which can collect and transport sanitation waste for safe treatment.** This is often one of the main barriers to effective sanitation and can be a source of decent jobs for local and regional communities.
- **Establish a sustainable financing mechanism (e.g. a dedicated national fund) for sanitation.** A major barrier to improved and accessible sanitation facilities is low levels of public investment in the sanitation sector. The creation of an enabling framework and dedicated fund can attract both public and private sector funding and investment for resource mobilisation and guarantee the necessary funds at a national level for investment in the sector.
- **Incentivise management strategies such as implementing riparian buffers or reducing inefficient fertiliser use to reduce nutrient pollution.** Ecosystems can effectively provide economical wastewater treatment services, as long as these ecosystems are healthy, the pollutant load (and types of contaminants) in the effluent is regulated and the ecosystem's pollution assimilation capacity is not exceeded (WWAP 2017).

3.2.3 Three: Invest in Sustainable Community-Led Non-Fed Mariculture

Given the changing nature of the fisheries industry in a post-COVID-19 world and the increasing importance of ensuring local food security and economic diversification, investment in community-led non-fed marine aquaculture (mariculture) (e.g. shellfish and seaweed farming)[53] offers considerable opportunities. Non-fed mariculture has the greatest potential to contribute to food supply and make the global food system more resilient (Costello et al. 2019; SAPEA 2017; Duarte et al. 2009). Such mariculture requires no feed, fertiliser inputs, insecticides or antibiotics, and it requires less water and energy than fed aquaculture, making it a self-supporting system (Roberts et al. 2015; Suplicy 2018). The development of sustainable community-led mariculture could also provide local employment and strong ecosystem services in countries with climate-driven declines in capture fisheries (Costello et al. 2019).

Potentially 48 million km^2 of the world's ocean is suitable (based on nutrient availability and temperature) for seaweed cultivation[54]. These waters span 132 countries, of which only 37 are currently cultivating (Froehlich et al. 2019). In terms of bivalve production, Gentry et al. (2017) found that over 1.5 million km^2 (roughly the area of Mongolia or Iran) of marine habitat, spanning temperate and tropical regions, are suitable for bivalve production (e.g. oysters, mussels, clams) and that developing small suitable areas can result in high production volume (e.g. they found that developing just 1% of Indonesia's suitable area could produce over 3.9 billion individual bivalves).

Investment in sustainable community-led mariculture could protect and develop mariculture with the triple goal of producing high-quality protein, accelerating a shift towards sustainable food systems, and maintaining and restoring ocean ecosystem services.

[53] *Non-fed mariculture is for species that do not require human-derived feed inputs and instead extract resources from the surrounding environment (e.g. phytoplankton), primarily macroalgae and bivalves (e.g. oysters, mussels and scallops).*

[54] *We are not suggesting that all 48 million km2 be developed, as this would amount to large-scale cultivation that would not be compatible with a community-led approach and would likely result in unintended consequences through the disruption of coastal ecosystems and their functioning. We provide the area figure to show that potential is not limited to one region or a small group of countries.*

SUPPORTING RECOVERY AND RESILIENCE IN THESE SECTORS:
Fisheries and Aquaculture

SUPPORTING ACHIEVEMENT OF THESE SDGs:

Note that for some countries investment in developing sustainable feed alternatives for fed mariculture (e.g. finfish) might be a priority over investment in developing community-based non-fed mariculture (e.g. those countries that have very advanced fed mariculture industries, such as Norway and Chile). Important technological, nutritional and economic constraints remain to feed substitution, and many substitutes being explored are currently too expensive to incorporate in large-scale production (Naylor et al. 2009). As such, this has not been considered a priority applicable to multiple regions and economies to respond to the current economic crisis. Benefits associated with investment in research and development for alternative feed are explored in Annex 1.

Why Investment Makes Sense

Community-led non-fed mariculture creates jobs for local communities and requires comparatively less initial investment than larger-scale commercial mariculture. The potential for job creation is significant, predominantly in developing and emerging economies, with a focus on economic opportunity for women (see Box 19.8). In Indonesia, women play a significant role in seaweed farming, resulting in some women becoming the main household earner despite previously earning little income (Neish 2013). Women relatives of seaweed farmers were also found to be instrumental in tying seed (Valderrama et al. 2013). Seaweed farmers were shown between 2007 and 2009 to make up to $5000 per year, a 33% higher income than the national average ($3603) (Neish 2013). As of 2019, women made up 57% of the communities engaged in mabé pearl farming in Fiji, with sales ranging from F$735 to F$2200 (US $346–1038) per crop (Southgate et al. 2019).

Community-led non-fed mariculture can support long-term economic diversification for local communities. In addition to the direct benefits for local communities, seaweed mariculture offers a sustainable and low-carbon alternative for products such as biofuels (Jiang et al. 2016)[55] aquaculture and agriculture feedstocks, and plastic (Önen Cinar et al. 2020). The estimated value of micro-algae oil for people and animals from 500 million metric tonnes of seaweed is $23 billion (Bjerregaard et al. 2016). Extrapolating an estimate of 1 job per 10 dry tonnes of seaweed results in a potential direct employment of 50 million jobs; a standard seafood industry secondary-employment multiplier of 2:1 suggests 100 million jobs could be created overall (based on an estimate of 1 job created per 10 dry metric tonnes), roughly the number currently employed in marine capture fisheries (Bjerregaard et al. 2016)[56]. Bivalve mariculture offers significant opportunities for the creation of a green and circular local economy. Goods from provisioning services include meat, worth an estimated $23.9 billion as well as pearls, shell and poultry grit, with oyster shell being the most important, with a global potential worth of $5.2 billion (Olivier et al. 2020). Shells can be used as construction material, fertiliser, poultry grit and artistic products. Research on the potential of bivalves as medicinal and genetic resources is on the rise, looking at their bioactive peptides, proteins and metabolites for producing innovative pharmaceuticals and nutraceutical foods. Mussel byssus—highly resistant fibre that combines high extensibility and harness and is the only effective glue underwater—has particularly interesting potential applications in engineering, biological and biomedical fields, including in water-resistant adhesives, replacement of surgical sutures, bone protheses and fibre optics (Zhang et al. 2020; Guo et al. 2020).

The opportunity for community-led mariculture supports improved rural livelihoods, particularly for women, as well as cultural services for coastal communities. The expansion of seaweed farming in several continents is contributing to global food security, supporting rural livelihoods and alleviating poverty (Cottier-Cook et al. 2016). Some fast-growing species can be cultivated year-round, and yield per unit area can surpass that of terrestrial crops (Forster and

[55] *Marine algal biofuel is considered a promising solution for energy and environmental challenges. Macroalgal biomass has the potential for bypassing the shortcoming of first and second generation of biomass from food crop and lignocellulosic sources.*

[56] *Note that the micro-algae used as a replacement for fish oil are more likely to be cultivated in tanks in deserts with unlimited sun. All the recent big investments in fish oil substitutes have been in these kind of micro-algae, not ocean-grown macro-algae, where the promising segments are more those used for food, animal feed, fertilisers (biostimulants) and bioplastics.*

Radulovich 2015). Bivalve farming also provides many cultural services for communities and visitors, including links with the marine environment, a strong connection with cultural heritage and educational centres on ecosystems (Alleway et al. 2018; McLeod and McLeod 2019). A global assessment values the global, non-food bivalve mariculture services, including cultural services, at up to $6.47 billion per year—a figure recognised as an underestimate given existing data gaps (Olivier et al. 2020).

Increased community-led mariculture offers opportunities for GHG emissions reduction through the use of seaweed for alternative feed and fuel and promotion of oysters and mussels as a low-carbon alternative protein. Projections of annual global GHG emissions reductions from seaweed farming are between 0.05–0.29 $GtCO_2e$/year by 2050. This would be equivalent to taking approximately 1–6 million vehicles off the road every year[57]. However, there are uncertainties in rates of expansion of the industry and the proportion of production that would be sequestered (Hoegh-Guldberg et al. 2019). It is estimated that seaweed could create a carbon-neutral mariculture sector with just 14% of current seaweed production, with seaweed culturing at a regional level more feasible from a cost perspective, especially in areas with strong climate policy, such as California (Froehlich et al. 2019)[58]. The addition of seaweeds to animal feed to reduce enteric methane emissions from ruminants may substantially increase the mitigation potential of seaweeds (Kinley et al. 2016). Small-scale community seaweed farming projects are considered low-risk, but significant expansion would require a more complete understanding of how risks and benefits change as projects are scaled (Campbell et al. 2020), in addition to any potential trade-offs with other ecosystem values and uses. If not appropriately located, seaweed farms could also affect seagrass beds and other benthic habitats and thereby disturb the local ecology (Eklöf et al. 2005). Spatial planning, ongoing monitoring and proper management are key to mitigating these impacts and informing design of a system that promotes resilience, local empowerment and long-term conservation of marine and coastal ecosystems.

Bivalves contribute to the carbon cycle, serving as a carbon sink as their shells develop. In France, 250,000 metric tonnes of farmed shellfish (mainly oysters and mussels) sequester 9.2 metric tonnes of carbon each year, as much sequestration as is done by half of the Landes, the largest forest in the country (CNC n.d.). This benefit is not offset by carbon emissions associated with production, which remain low. Studies found that mussel farming has one of the lowest carbon footprints of any food production system, and may in fact have the lowest. It probably offers the best ratio of protein quality and climate and ecosystem benefits (SARF 2011; Suplicy 2018). Bivalve production could significantly contribute to promote low-carbon food systems and reduce meat production. A plate of mussels (approximately 500 grams in weight, which includes 150 grams of flesh) provides as much protein as two eggs and more iron than a piece of red meat while offering calcium, magnesium and daily needs in iodine (CNC n.d.). This comes with a very low environmental footprint compared to meat production (most comparisons look at beef and chicken production) and fisheries, in terms of carbon emissions, water use and non-renewable energy consumption (Alleway et al. 2018; Hughes et al. 2018; McLeod and McLeod 2019). In addition, bivalves function in a variety of ecosystems, such as estuaries, lagoons and coastal oceanic systems, while providing a multitude of services. As captured in Fig. 19.4, these include habitat and supporting, provisioning, regulating and cultural services. As filter feeders, bivalves purify water (up to 180 L—50 gallons—of water a day for an adult oyster, 25–30 L for a mussel) while treating waste (including hydrocarbons). This function enhances water clarity and helps control excessive phytoplankton blooms (Bricker et al. 2018; Alleway et al. 2018; Ferreira et al. 2018; Hughes et al. 2018; McLeod and McLeod 2019).

How These Benefits Can Be Achieved: Short-Term Interventions That Can Be Initiated Now as Part of Stimulus Spending and Recovery Measures

- **Feasibility studies and associated zoning (ideally guided by an integrated ocean management or marine spatial planning process)**. Spatial planning approaches in which biotic, abiotic and socioeconomic factors are considered could be used to identify where the positive effects of mariculture could be maximised (Alleway et al. 2018). This initial scoping work can also be a source of short-term job creation for local universities and scientists.

[57] *Based on the average emissions of a passenger vehicle being 4.6 metric tonnes per year, according to EPA (2018).*

[58] *Research has found that some fundamental and very significant hurdles remain to realising the potential contributions of seaweed cultivation at a global level. For example, the value of seaweed biomass needs to be improved, and the ecosystem services that seaweed farming can provide (such as in reducing coastal nutrient loads) need to be more fully considered. Additional considerations are environmental risks associated with climate change, pathogens, epibionts and grazers, as well as the preservation of the genetic diversity of cultivated seaweeds (Buschmann et al. 2017).*

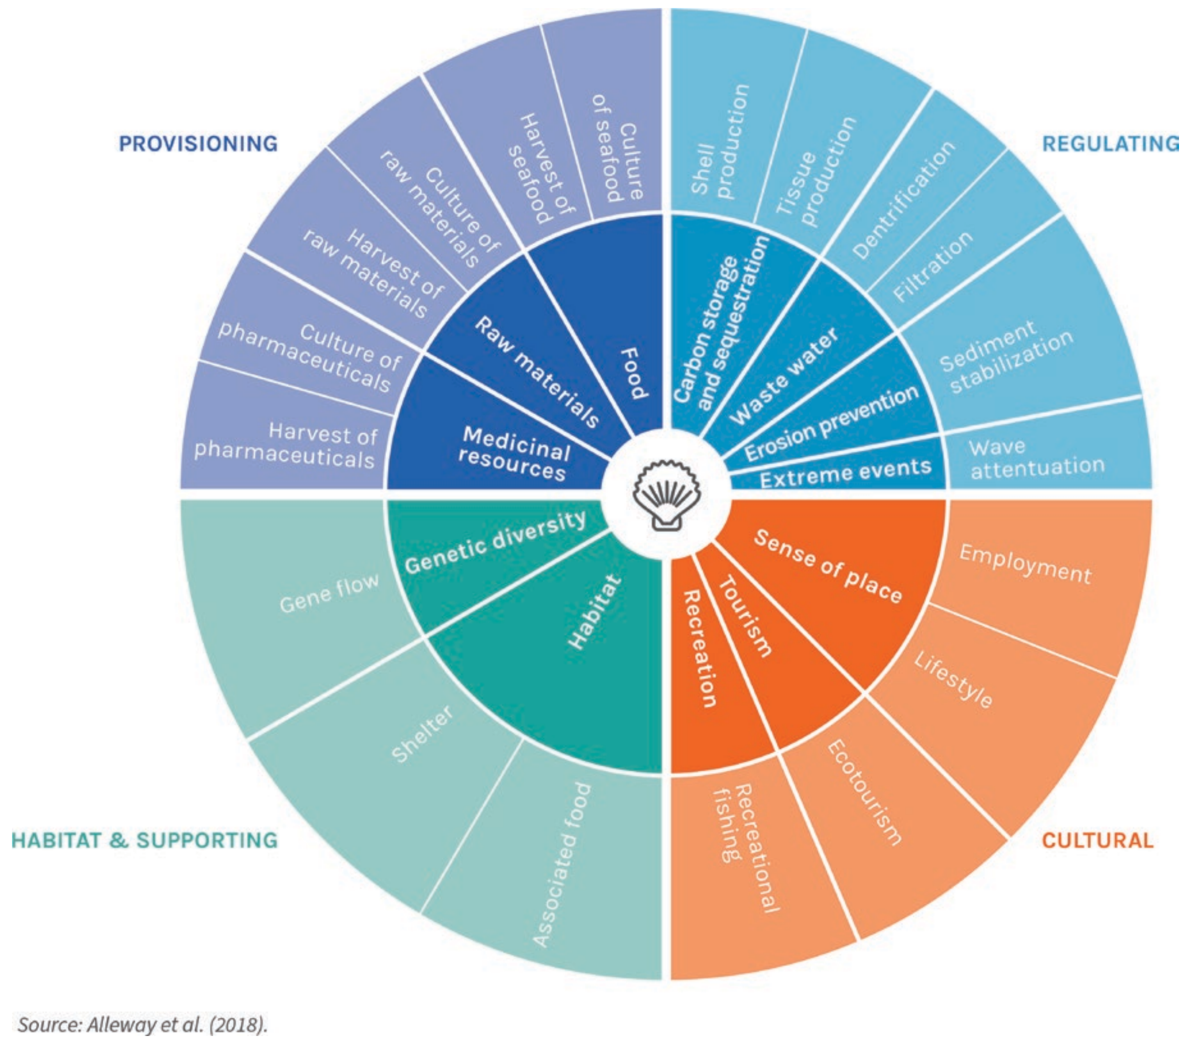

Fig. 19.4 Goods and services provided by shellfish mariculture

- **Streamlined and centralised permitting and regulatory processes.** The purpose of streamlined permitting is not to cut corners or skip necessary environmental impact assessments for new projects but rather to ensure that local communities and applicants can access and easily navigate the government process. Otherwise this process can be a significant barrier to communities' ability to initiate projects (even with funding).
- **Government grants and loans for new seaweed and/or bivalve farmers (including microloans).** The high upfront costs that these production systems involve represent a barrier for community- led projects in many countries (see Box 19.8 for an exploration of how the Kenyan government has helped stimulate the creation of community-led maricultural in partnership with the World Bank).
- Investment in communities of practice across different regions. With relatively small upfront investment, the capacity of small-scale and community-led initiatives can be accelerated by establishing regional communities of practice to share knowledge, experiences and best practice across the industry.
- **Creation of capacity-building and training programs for local communities.** These programs and opportunities could be prioritised for those communities most affected by reduced economic opportunities from tourism and lower demand from fisheries. See also Sect. 3.3 for recommendations on investment in research and development and skills-training programs for sustainable ocean industries.
- **Facilitation of cooperative and co-designed sites across multiple sectors and with the private sector.** Co-

designed initiatives could support development across a multitude of sectors (e.g. energy, transport, communication), to co-produce ecosystem services to support the needs and interests of multiple stakeholders (Outeiro et al. 2017). For example, offshore wind farms could provide a platform to which mariculture facilities could be attached, the operational costs of which might otherwise be prohibitive or the space and location required contested (Buck et al. 2018).

Box 19.8 Scaling Community Seaweed Farming in Kenya

Kenya started community seaweed farming in Kwale County on the South Coast in 2013, following feasibility studies undertaken by the Kenya Marine and Fisheries Research Institute. The initial funding was from a World Bank–funded project that targeted fishing communities along the Kenyan coast, but further funding has been provided by the Government of Kenya to build the farmers' capacity with the aim of developing the initiative into a robust industry to create jobs and income. The main objective of supporting the establishment of this new community-led industry was to offer an alternative livelihood to local fishing communities whose livelihoods had been challenged by reduced income due to the dwindling catches from artisanal fisheries. Importantly, it was also an intervention that specifically supported the creation of new jobs and economic opportunities for women—90% of seaweed farmers in Kenya are women.

To date, this support has resulted in the employment of approximately 400 seaweed farmers in Kwale County, each with his or her own individual farm generating income that flows directly to the farmer. For the women involved, this has meant financial independence from their husbands, with many using the income from their seaweed farms to educate their children up to the university level and constructing permanent houses.

The sale price of the dry seaweed is agreed upon with the buyers prior to the transactions, and plans are underway to have a contract between the farmers and the buyers. The seaweed farmers welfare group has also been registered as a cooperative to improve organisation and collective bargaining power. The Government of Kenya has provided additional support to the farmers to ensure effective post- harvest management, provision of farming implements, harvesting and storage facilities, value addition and marketing. The seaweed is also being used in local food products. Support is also being provided to diversify the farmers' income base through the development of soap and other cosmetic products, such as body creams, shampoos and hair treatment. To date, community-led seaweed farming has generated over 300 metric tonnes of dry seaweed that has generated over US $60,000 for the local village economies.

Some of the challenges faced in developing the initiative into a commercial entity include raising the level of production to volumes that make business sense to the potential investors and traders, particularly owing to the fact that the activity is a nontraditional economic activity, new to the farming communities. The difficulty of finding a reliable market for the produce, without economically feasible production volumes, affected the ability to reach scale. Extensive training of the communities has gotten more committed farmers and thus increased production volumes. The other major challenge has been extreme weather patterns, including very high temperatures followed by very heavy and extended rainfall, which resulted in massive die-off of seaweeds. This near complete loss of seaweed seed has been resolved by establishing new nurseries at the start of the favourable season (southeast monsoon) by bringing in seaweed from more sheltered sites.

As a result of the demonstrated socioeconomic benefits of community seaweed farming in Kwale County, and the engagement of a commercial seaweed buyer, Kenya is now looking to scale the industry along the South Coast and ultimately the rest of the coast. For Kenya, the immediate socioeconomic impact of investment in community seaweed farming makes it a priority intervention for economic recovery, as its relatively low investment, quick returns and broader social and environmental benefits make its uptake and scalability more feasible than other interventions.

Seaweed farming can be approached as integrated multi- trophic mariculture. Incorporating cages, bivalves and sea cucumbers optimises the productivity of a unit area of sea space and creates more employment. Additionally, seaweed helps clean coastal waters of excess nutrients that have been introduced through pollution and wastewater, making it the ideal crop for environmental sustainability.

The Government of Kenya is currently supporting the selection of further suitable sites and associated environmental impact assessment to scale the initiative.

Source: Information provided by the Government of Kenya, 2020.

3.2.4 Four: Incentivise Zero-Emission Marine Transport

Global supply chains rely on marine transport to move approximately 90% of global trade. Regional and intercontinental shipping constitutes the core of the global logistical system. At any given time 50,000 vessels and 1.2 million seafarers are in operation between ports in different parts of the world. Marine transport is also the mode of long-distance transport with the lowest carbon footprint and cost (WSC 2020).

The sustainability and viability of this industry is critical for ensuring the resilience of global populations to future shocks. During COVID-19 shipping has been responsible for transporting essential goods and services globally, from PPE to the core elements needed for the production of vaccines. In terms of domestic marine transport, it has been the only form of transport for food, health provisions and basic essentials between islands and atolls.

Despite its central role in ensuring that global supply lines remain open, the industry has faced a significant contraction (estimates of between 25 and 35% by the end of the year) (NSA 2020a) as global trade has dropped. Recovery offers an opportunity to scale investment in the future of this industry through supporting and incentivising industry to invest in the decarbonisation of its fleets. The average lifespan of a cargo vessel is 25–30 years. To enable these vessels to be aligned with the Paris Agreement requires upfront investment over the next few years to keep high-emitting ships and vessels from becoming stranded assets.

Marine transport is not limited to deep-water vessels and cargo shipping, however. Domestic fleets, including fishing and mariculture fleets, vessels that form national navies and coastal passenger transport make up large proportions of a country's transport footprint. Marine transport used in the tourism industry (cruise ships as well as coastal passenger fleets associated with hotels and resorts) stand to gain from early investment in their sustainability and decarbonisation.

An ancillary effect of the global contraction is an expected increase in vessel recycling, particularly for offshore and passenger ships (NSA 2020a). This provides the opportunity for government investment to not only support and incentivise investment in replacement fleets and retrofitting but also ensure environmentally sound and sustainable ship-recycling practices.

Regarding the economic, social and environmental net benefits, analysis shows that investments to decarbonise the international maritime shipping sector could deliver a net discounted benefit (average) over 30 years (2020–2050) of \$1.2 trillion to \$9 trillion (Konar and Ding 2020), with a benefit-cost ratio of 2:1 and 5:1 in 2050[59]. Similar figures are not yet available for domestic fleets.

Why Investment Makes Sense

Investment in the shipping industry to support efforts to retrofit or replace high-emitting vessels with low- or zero-emission vessels will protect jobs in the short term. Due to the contraction of the industry, market demand for new vessels is likely to decrease, threatening existing jobs. Government investment at this time would protect jobs and enable upskilling to support new zero-emission technologies. Supporting the replacement of domestic vessels with zero-carbon alternatives can create sustainable jobs, both by reducing domestic emissions and by preparing shipyards for future demand for zero-emission deep-sea vessels once demand picks up after COVID-19.

Investment now will yield long-term benefits for the industry as well as other sectors, including tourism, that rely on marine transport. Zero-emission coastal transport (e.g. passenger and car ferries) can be more cost-efficient to run than its high-emitting counterparts (European Commission 2018). Shifting the demand from oil to alternative fuels and battery propulsion can be a catalyst to scale the deployment of low-carbon fuels for the broader energy transition and unlocks the market for these fuels across a range of industries and other hard- to-abate sectors (Moore 2019). This is due to shipping's high level of fuel consumption, currently estimated to be around 250 million to 300 million metric tonnes every year, approximately 4% of the global oil demand (Christensen 2020). Decarbonising the shipping sector will increase confidence among suppliers of future fuels (e.g. hydrogen and ammonia) and offers opportunities for synergies with efforts to accelerate and scale the establishment of ocean-based renewable energy (see the preceding section). Annex 1 describes specific additional interventions that can target the establishment of these industries for alternative fuel generation.

Decarbonisation of marine transport, both international and domestic, offers significant health benefits for those on board the vessel as well as coastal communities and those living near or working at the port. Prior to cleaner ship fuels, ship-related health impacts included around 400,000 premature deaths from lung cancer and cardiovascular disease and around 14 million childhood asthma cases annually. Reduced PM2.5 from marine engine combustion mitigates ship-related premature mortality and morbidity (Sofiev et al. 2018). Based on this, analysis estimates the discounted cumulative health benefits from reducing emissions from marine transport to be \$1.3 trillion to \$9.8 trillion over 30 years (2020–2050) (Konar and Ding 2020).

[59] *The analysis excludes military and fishing vessels and domestic transport and includes bulk carriers, oil tankers and container ships, which account for the majority (55%) of emissions in the shipping sector (Olmer et al. 2017).*

SUPPORTING RECOVERY AND RESILIENCE IN THESE SECTORS:
Shipping, Energy, Transport and Tourism

SUPPORTING ACHIEVEMENT OF THESE SDGs:

Reducing GHG emissions from shipping vessels will help mitigate ocean acidification and contribute to domestic and global efforts to reduce GHG emissions. Ocean-based transportation could reduce operational net GHG emissions roughly 100% by changing the way it stores and consumes energy on board (e.g. use of batteries and zero-emission fuels such as hydrogen and ammonia). If the full suite of available technologies is employed, and zero-emission vessels are available for commercial use by 2030, global GHG emissions could be reduced by between 0.9 and 1.8 $GtCO_2e$/year in 2050 (Hoegh-Guldberg et al. 2019). This would be equivalent to taking 19–39 million cars off the road every year[60]. In terms of environmental benefits, the strong acids formed from shipping emissions can produce seasonal 'hotspots' of ocean acidification in ocean areas close to busy shipping lanes. Hotspots have negative effects on local marine ecology and commercially farmed seafood species (Hassellöv et al. 2013). Lastly, the shift to zero-emission vessels could reduce the noise impact on marine mammals. The effects of underwater noise from anthropogenic activities, including ships, on marine mammals includes behavioural responses, acoustic interference (i.e. masking), temporary or permanent shifts in hearing threshold, and stress (Erbe et al. 2019). Studies have shown that periods with a significant reduction in noise from ship traffic have been associated with a reduction in the stress of whale populations (Rolland et al. 2012). Moving to zero-emission vessels such as fuel cell and battery-powered could eliminate noise pollution (Reddy et al. 2019). Research also shows that this shift could be coupled with a 20% reduction in speeds, which would reduce underwater noise pollution by 66%, the chance of a fatal collision between a ship and a whale by 78% and CO_2 emissions by 24% (Seas at Risk 2019).

[60] *Based on the average emissions of a passenger vehicle being 4.6 metric tonnes per year, according to EPA (2018).*

How These Benefits Can Be Achieved: Short- Term Interventions That Can Be Initiated Now as Part of Stimulus Spending and Recovery Measures

- **Incentivise investment in upgrading coastal passenger transport (ferries) to zero-emission (battery- or hydrogen-powered) through subsidies, taxes and grants to the private sector**. Investing in coastal passenger transport offers immediate health benefits for coastal communities and new opportunities to stimulate ecotourism. It also improves the resilience of coastal communities that depend on these forms of transport (e.g. between islands and atolls).
- **Commit to use domestic fleets to pilot and test zero-emission fuels and technologies, which in turn can help to de-risk and reduce costs for larger, high-seas and ocean-based transportation**. Domestic fleets are populated with smaller ships and therefore better suited to small-scale and short-term pilots and tests. For many countries, the largest marine fleets are those of their navies, offering significant opportunities for domestic leadership and long-term economic resilience and benefits from early investment.
- **Incentivise private sector investment in replacement fleets and retrofitting by offering subsidies, tax cuts and government loans**. Support for the industry (both the shipping and tourism sectors) at this time can take the form of incentives for replacement and/or retrofitting (as appropriate given the nature of the vessel and availability of technology). Note that incentives should be targeted at incentivising zero-emission vessels and not low-carbon ones (e.g. running on liquefied natural gas), since the latter do not have long-term viability for the industry transition and would therefore be only a short-term investment requiring further investment in the future to facilitate the transition to hydrogen or ammonia.
- **As part of stimulus funding packages for infrastructure, allocate public investment to the development of low- and zero-carbon energy production capacities, and storage and refuelling infrastructure in ports and harbours**. Land-based measures will be critical to support the transition for marine transportation and ensure that a clear signal is sent to the private sector.
- **Invest in land-side grid infrastructure**. Lack of investment in land-based infrastructure to support zero-emission vessels is a common barrier. An example from Norway is a hybrid ferry operating between Norway and Sweden that was only able to operate at half its potential because the grid connection in Sweden was insufficient to recharge the batteries on the ferry.
- **Use bilateral aid to support regional partnerships, particularly in support of small island developing states (SIDS) and least developed countries (LDCs)**

with significant domestic or regional shipping- decarbonisation challenges, to work together on joint objectives. An example is the Pacific Blue Shipping Partnership, a joint initiative among Pacific nations and led by the Governments of Fiji and the Republic of the Marshall Islands. The partnership commits to zero-carbon domestic marine transport by 2050, with a 40% reduction by 2030 (MCST n.d.).

- **Require or establish environmentally sound and sustainable ship-recycling practices that provide decent jobs for local communities**. Ship recycling offers the most environmentally sustainable way of disposing of old vessels, with virtually every part of the hull and machine complex being reused or recycled as scrap metal. To do this properly, ships should be recycled at dry-dock ship-recycling facilities—not beached or exported to countries with weak regulatory systems. The nexus of ship-recycling yards, refurbishing shops, re-rolling mills, steel mills and second-hand shops creates a localised industry which can employ hundreds of thousands of people in semi-skilled and unskilled jobs.

3.2.5 Five: Incentivise Sustainable Ocean-Based Renewable Energy

What Investment Will Achieve

According to the International Energy Agency (IEA 2019a, b), global offshore wind power capacity is set to increase 15-fold over the next two decades, turning it into a $1 trillion business. Only using near-shore sites could supply more than the total amount of electricity consumed worldwide today[61], and moving further offshore into deeper waters (e.g. using floating turbines) could unlock enough potential to meet the world's total electricity demand 11 times over by 2040[62]. By 2050, the IEA forecasts that offshore wind could reach more than 1000 gigawatts (GW) of installed capacity. Expansion of offshore wind in line with these projections would put the global power sector on track for full decarbonisation and enable the production of zero-emission fuels (e.g. hydrogen and ammonia) to dramatically cut emissions from sectors such as shipping (IEA 2019a, b)[63]. Although less advanced, other forms of ocean-based renewable energy, such as tidal, wave, sea current and ocean thermal energy conversion, will be highly valuable for many geographies that lack the geophysical requirements to support offshore wind.

Stimulus funding could help fast-track private investment, resulting in job creation in the short term as well as long-term economic growth opportunities.

SUPPORTING RECOVERY AND RESILIENCE IN THESE SECTORS:
Energy, Shipping and Transport

SUPPORTING ACHIEVEMENT OF THESE SDGs:

However, such fast-tracking must not be done at the expense of the marine environment or lead to the use of shortcuts to environmental impact assessments.

Analysis shows that on average there is a net positive benefit from expanding the sector. The net present value of benefits is estimated to be $300 million to $6.8 trillion over 30 years for scaling offshore wind production. The return on investment in 2050 is significant, as shown by the benefit-cost ratio, estimated to be 2:1 to 17:1 in 2050 (Konar and Ding 2020). In terms of the benefit-cost ratio per unit of energy generation and transmission, analysis estimates the benefits to be $75–$300 per megawatt-hour (MWh) for 1 unit of additional energy production and the ratio range to be between 0.9:1 and 28:1 (Konar and Ding 2020). Estimates show that return on investment increases substantially as the

[61] *Offshore wind's technical potential is 3,000 terawatt-hours (TWh) per year for installations in water less than 60 metres deep and within 60 km of shore. Global electricity demand is currently 23,000 TWh (IEA 2019a, b).*

[62] *Offshore wind can generate electricity during all hours of the day and tends to produce more electricity in winter months in Europe, the United States and China, as well as during the monsoon season in India—providing higher value than that of its onshore counterparts and more stable over time than that of solar photovoltaics (PV) (IEA 2019a, b). Capacity factors for onshore wind farms in the European Union average 24%, with new farms reaching 30–35%. Offshore farms have a capacity factor averaging 38%, with new farms reaching 35–55% (an increase of more than 50%; IEA 2019b). Another advantage is size of turbines. A single 10 MW offshore wind turbine, operating at 60% capacity factor, will have output of 51 GWh/year. A solar farm with 25% capacity factor, to provide same amount of power, will require ~56,000 PV panels and occupy ~60 hectares of land. The analysts forecast a 60% reduction in the costs of turbines, foundation and installations by 2040 (IEA 2019b).*

[63] *These IEA projections are based on expansion in six key markets: Europe, China, the United States, South Korea, Japan and India. Europe, the current market pace-setter with 20 GW installed, is forecast to continue to lead the global pack for the next two decades, with expectations of some 130 GW turning offshore by this date—though China by this point is foreseen as having at least 110 GW online and being on track to outpace Europe's build-out by mid-century. The United States, meanwhile, is forecast to be in line for 'substantial growth' by 2040, with its fleet swelling to around 40 GW, while Korea, India and Japan would all see tens of GW of offshore wind turbines installed.*

costs of energy generation fall with improved technologies and as actions are taken to reduce integration costs.

Why Investment Makes Sense

Stimulating the creation or expansion of ocean-based renewable energy provides short-term job creation. In the early stages of exploring the feasibility of ocean- based renewable energy projects, jobs can be created for engineers, land and marine surveyors, energy specialists, researchers and providers of legal services (see Box 19.9 for an overview of the initial stages of development of Australia's first offshore wind farm). The opportunity for job creation is generally at the regional and local levels, but the extent of the breakdown will vary by region based on the nature of the wind, tide or wave resource, as well as on the supply chain and labour force. The IEA estimates that offshore wind creates about 1.2 construction jobs per $1 million invested (for both the construction and manufacturing phases) (IEA 2020a)[64]. In total, the development of a typical 500 MW offshore wind farm requires around 2.1 million person-days of work (IRENA 2019). Estimates in the United States vary from 6 to 44 jobs/MW during construction periods and 0.7 to 1.7 jobs/MW for the projects' ongoing operation (Tegen et al. 2015)[65]. The labour distribution is estimated as 1% for project planning, 59% for procurement and manufacturing, 0.1% for transport, 11% for installation and grid connection, 24% for operation and maintenance and 5% for decommissioning (IRENA 2019). A particular benefit of job creation through offshore wind is that the skills required may be similar to those in offshore oil and gas, enabling benefits to accrue directly to workers transitioning from declining fossil fuel industries (IRENA 2018; Scottish Enterprise 2016), which also minimises the costs of transition and the risks of structural unemployment. The expertise of workers and technicians in building support structures for offshore oil and gas sites, for example, could be leveraged when building foundations and substations for offshore wind turbines. Any such transition must ensure a transfer of benefits and comparable salary for comparable jobs and/or skill requirements, such as opportunities for union representation.

An established ocean-based renewable energy sector creates green jobs, economic diversification into zero-emission fuels and opportunities to co-locate and support other offshore industries. The long-term economic benefits associated with a new or expanded ocean-based renewable energy sector include new highly skilled jobs. The OECD estimates that by 2030 the total full-time employment in offshore wind will be 435,000 (OECD 2016)[66]. For offshore wind, an estimated 1 million new jobs will be created by 2050, with an estimated 0.45 million in construction and installation, 0.39 million in manufacturing and 0.17 million in ongoing operations and maintenance (IRENA 2019). For other ocean-based renewables, the sector could create 680,000 jobs by 2050 (OES 2017). The interaction of the offshore wind energy industry with other economic sectors creates the potential for economic diversification and the generation of additional revenue, through both supply chain activities and induced demand for goods and services (IRENA 2018). There is the potential to unlock co-location benefits with other offshore industries; for example, ocean-based renewable energy could meet the increasing demand for energy-intensive desalinated seawater or support mariculture operations. Investment in any form of renewable energy supports the achievement of energy security and independence from imported fossil fuels and associated price volatilities. Lastly, it also creates the opportunity for new green industries in terms of alternative fuel generation (e.g. hydrogen), which can serve as exports or inputs to decarbonisation of other sectors of the economy (such as marine transport). Education and training, however, must be attuned to emerging needs in the ocean renewable energy industry (see Annex 1).

Ocean-based renewable energy offers potential health benefits and desalination of drinking water in coastal communities facing water scarcity. The health benefits of moving to ocean-based renewable energy for power generation would be significant, particularly for regions that rely more heavily on coal and oil to generate electricity. Offshore wind in the Mid-Atlantic region of the United States could produce health and climate benefits estimated at between $54 and $120 per MWh of generation, with the largest simulated facility (3000 MW off the coast of New Jersey) producing approximately $690 million in benefits (Buonocore et al. 2016). There is potential to develop ocean energy technolo-

[64]*Wind power is less labour-intensive than PV solar. Onshore wind power projects create about 1 job in construction and 0.5 in manufacturing per $1 million invested. Offshore wind creates about one-fifth as many construction jobs but twice the number of manufacturing jobs per unit of investment.*

[65]*For the Southeast region, offshore wind energy development has the potential to support between 14 and 44 full-time equivalent (FTE) jobs/MW during construction periods and 1.6 and 1.7 FTE ongoing (operations phase) jobs/MW; in the Great Lakes, there could be between 6 and 27 FTE jobs/MW installed and 0.7 and 0.8 FTE jobs/MW for the projects' ongoing operation; in the Mid-Atlantic region during construction phases, we estimated a range of 12–30 FTE jobs/MW, and the average for ongoing jobs was 1.2 FTE jobs/MW. The Gulf of Mexico has the potential to support between 25 and 29 FTE jobs/MW during construction and 1.3 FTE jobs/MW on an ongoing basis, for operations and maintenance.*

[66]*Based on previous employment and capacity projections by the IEA (2014) and EWEA (2012), the OECD (2016) estimates that under a business-as- usual scenario, there will be an estimated 435,000 full-time jobs in the offshore wind industry by 2030. This estimate is based on the expectation that more countries will have multiple GW of wind power installed.*

gies for a range of purposes, including desalination for drinking water (OES 2011).

Increasing the share of renewable energy generation and reducing the use of fossil fuels will contribute to national and global efforts to reduce GHG emissions, but efforts to scale ocean-based renewable energy must be done in an environmentally sensitive manner to reduce the impact on marine mammals and ecosystems. If ocean-based renewable energy technologies displace the current energy generation mix, CO_2 emissions can be reduced by between 0.30 and 1.61 $GtCO_2e$/year in 2050 in the case of offshore wind (fixed and floating), and by between 0.05 and 0.87 $GtCO_2e$/year in 2050 in the case of ocean-based renewable energy (Hoegh-Guldberg et al. 2019)[67]. Total emission reductions would amount to 0.35 to 2.48 $GtCO_2e$/year in 2050 (Hoegh-Guldberg et al. 2019) which is equivalent to taking approximately 35–53 million cars off the road every year[68]. Based on the analysis on avoided damage costs to society from mitigating climate change, we estimate the environmental benefits (net benefit) of reducing greenhouse gases by scaling offshore wind energy generation to be $344 billion to $668 billion over 30 years (Konar and Ding 2020). This estimates the costs of displacing the current energy mix with offshore wind energy in line with the projections in Hoegh-Guldberg et al. (2019). Offshore wind uses no water directly, and there should be an overall reduction in freshwater use compared to generating power from fossil fuels (Macknick et al. 2012). Offshore wind structures have positive and long-term effects on marine species because they provide new habitat in the form of artificial reefs and because fishing, mainly trawling, tends to be restricted in their vicinity (IRENA 2018; Dinh and McKeogh 2019). The risks of installing energy operations in the marine environment include potential biological invasions, noise and disturbance vibrations for marine species, collisions between birds and wind turbine rotors, and the presence of electromagnetic fields that can disrupt marine life and benthic habitats (Sotta 2012; Langhamer 2012). However, studies have shown that there is a gap between the perceived and actual risks of these technologies, with the former arising from uncertainty or lack of definitive data about the real impacts (Copping et al. 2016). The most recent analysis has revealed that the potential impacts of ocean-based energy on marine life are likely small or undetectable (Copping and Hemery 2020). Effective marine spatial planning, in combination with emerging ocean energy technologies, will be effective in mitigating potential biodiversity loss and the risk of collision with seabirds and impacts on migratory cetaceans from ocean energy technologies and in reinforcing biodiversity co-benefits (Hoegh-Guldberg et al. 2019; Best and Halpin 2019). Efforts must also be made to expand renewable energy (both ocean-based and on land) in concert with efforts to improve the circular economy and reduce the reliance of renewable energy technology on rare minerals that would also undermine ocean health if mined from the seafloor (Haugan et al. 2020).

[67] *Note that higher figures were also calculated based on coal displacement. These can be found in the full report (Hoegh-Guldberg et al. 2019).*

[68] *Based on average emissions of 4.6 metric tonnes per year, according to EPA (2016).*

How These Benefits Can Be Achieved: Short-Term Interventions That Can Be Initiated Now as Part of Stimulus Spending and Recovery Measures

Investment in research, development and innovation will improve the technology and reduce costs but must be coupled with additional policy support to increase market visibility and investor security and enable the further cost reductions that come with commissioning larger commercial plants.

- **Streamlined permitting and clear and coordinated processes across government.** Traditionally, the time from inception to completion can be 8–12 years, with 5–7 years for project development and 3–5 years for construction (Veum et al. 2011). Long lead times are caused by lengthy permitting requirements involving multiple agencies and lack of clarity of areas available for ocean-based renewable energy (considering competing users of the marine environment) (Crouse et al. 2018; UK Government 2016). Reducing these obstacles would send a clear signal of intent and regulatory certainty to industry and enable the acceleration of private sector investment in this industry. Note that streamlining of permitting does not include a fast track or elimination of the need for environmental impact assessments or community and stakeholder engagement and participation in the planning and citing process.
- **National targets and frameworks for ocean energy.** As part of the European Green Deal, the European Commission is currently developing its Offshore Renewable Energy Strategy, which will outline targets for between 250 and 450 GW of offshore renewable energy installed capacity by 2050, or capacity to meet about 30% of Europe's energy demand (EU Commission 2020c). Achieving this target will require strong public-private partnerships and alignment with national climate policies, marine spatial planning policies and technology development frameworks. The United Kingdom has set a target for installed offshore wind energy of 40 GW by 2030; as part of this target the UK government will also be supporting the development of floating wind turbines. Germany has also approved the amendment to the Offshore Wind Act (WindSeeG) to reach 40 GW of offshore wind capacity by 2040.

- **Suitable financial support mechanisms (e.g. subsidies and guarantees) and revenue support to stimulate industry and avoid loss leaders.** A lack of financial support mechanisms (e.g. subsidies or guarantees), can drive up costs for industry and create roadblocks (Crouse et al. 2018; UK Government 2016). Governments could look to arrangements provided to stimulate early investment in land-based renewable energy, such as solar and wind subsidy schemes.
- **Investment in land-based grid updates and associated infrastructure.** The Netherlands government has published a roadmap for 2.5 GW of offshore wind by 2023 while also investing in a 700 MW offshore wind transformer platform to ensure that the land-based infrastructure is in place for private sector investment to support the achievement of the target.

Box 19.9 Establishing Australia's First Offshore Wind Farm

Star of the South Wind Farm is Australia's first offshore wind farm, paving the way for a new sustainable ocean industry for Australia[a]. A joint development by Australia's Offshore Energy and Copenhagen Infrastructure Partners, Star of the South could include up to 250 turbines, with a combined capacity of up to 2 GW. This could supply about one-fifth of Victoria's power needs and, through close proximity to demand centres along the Australian coast, could minimise the need for battery storage normally associated with land-based wind and solar.

Following the grant of an exploration license in March 2019 to investigate the technical feasibility of constructing wind turbines in the ocean off the south coast of Gippsland, Victoria, Star of the South is moving forward with marine surveys and engineering options in terms of land-based grid connections. It has partnered with Curtin University and Deakin University to assist with offshore site investigations, focusing on understanding marine mammals in the project area and undertaking the necessary seabird, seabed biodiversity and fish surveys. Both universities are working with RPS Australia Asia Pacific to collect data to inform the environmental assessments and the project's design. DHI has also joined the project by providing a 40-year hindcast of waves and currents that serves as input for moving further with the design phase (Skopljak 2020). Preliminary surveys also include mapping the seafloor, measuring water depths and identifying any buried infrastructure, such as cables.

In addition to the employment opportunities created through the above partnerships, the core development team for the project, all located locally in Melbourne, currently employs 35 people and is expected to grow to 50 by the end of 2020 (Parkinson 2020).

The Australian government has also begun developing a policy framework to underpin offshore wind development off its coasts, an initiative long called for by industry (Australian Government 2020a).

[a] *For more information on the project, see http://www.starofthesouth.com.au/.*

3.3 Additional Opportunities for a Blue Transformation

As evidenced by the 2008–2009 stimulus packages, not all investments will be directed at measures that create jobs in the short term. Instead, much of the investment will be used to lay the foundation for long-term recovery and resilience through systemic transitions to improve the efficiency and cost-effectiveness of our economy and by initiating large infrastructure projects that will yield benefits over the next 10–30 years.

Table 19.3 summarises a further set of opportunities for governments to consider to ensure a sustainable and equitable blue recovery from COVID-19 that will have long-lasting benefits for economic resilience and ocean health. These interventions, and their potential economic, social and environmental benefits, are detailed in full in Annex 1 (Tables 19.4, 19.5, and 19.6).

These interventions are organised in three categories:

1. Research and development to spur innovation and new technology
2. Regulatory reform to provide an enabling environment for a sustainable ocean economy
3. Public-private partnerships for a blue transition

Just as on land, these investments have the potential to dramatically alter the course of a country's transition to a sustainable economy that can provide long-term economic opportunities, improved health and food security, reduced emissions, enhanced biodiversity and ecosystem services

Table 19.3 Additional opportunities for a blue transformation

	Sector relevance	Economic benefits	Social benefits	Environmental benefits	SDGS
Research and development to spur innovation and new technology					
Invest in research and development, including pilot projects, to accelerate the development of sustainable and low-carbon alternative feed options for fed mariculture (e.g. finfish)	Fisheries	●	●	◍	2, 8, 9, 12, 13, 14
Invest in filling data gaps on national coastal and marine ecosystems through employment schemes for surveys, modelling and mapping	Tourism, Fisheries	◍	●	●	8, 12, 13, 14, 17
Invest in R&D and innovation grants to stimulate the development of new industries for generating alternative marine fuels, e.g. hydrogen and ammonia (invest in land-based infrastructure for fuel generation and supply chains as opposed to ship related investments)	Transport, Energy	●	○	◍	7, 8, 9, 12, 13, 14, 17
Establish blue economy skills-training and capacity-development programs in key ocean industries for affected communities and industries (e.g. ocean-based renewable energy, zero-emission vessels, GIS, ecotourism, restoration)	Tourism, Fisheries, Energy, Transport, Marine Conservation	◍	●	●	4, 7, 8, 9, 12, 13, 14, 17
Invest in research and development, including pilot projects, and incentivise emerging ocean-based renewables to accelerate their development	Energy, Transport, Mariculture	◍	◍	◍	7, 8, 9, 12, 13, 14
Regulatory reform to provide an enabling environment for a sustainable ocean economy					
Establish comprehensive integrated ocean management and marine spatial planning processes to balance marine users and spaces, competition for coastal resources and mitigate permitting and siting issues for sustainable ocean industries	Fisheries, Tourism, Energy, Shipping, Marine Conservation, Mariculture	●	◍	●	8, 12, 13, 14, 17
Initiate regulatory reform to promote best practice in climate-adaptive fisheries management, including through incentives for industry adoption in the form of taxes and subsidies	Fisheries	●	◍	●	2, 8, 12, 13, 14
Shift harmful subsidies to more sustainable and equitable uses, including supporting small-scale and artisanal fishing, ecotourism opportunities for local communities and management and monitoring of marine protected areas	Fisheries, Tourism, Marine Conservation	●	●	●	2, 8, 12, 14
Introduce levies or taxes to reinvest tourism revenue in local restoration and conservation efforts	Tourism, Fisheries, Marine Conservation	◍	◍	◍	8, 11, 12, 13, 14, 15
Integrate ocean accounts into national accounting frameworks, or develop satellite ocean accounts, to measure and monitor the impact of recovery measures on long-term sustainability of the ocean economy	Fisheries, Tourism, Transport, Energy, Marine Conservation, Infrastructure	●	○	◍	8, 9, 12, 13, 14, 17
Public/private partnerships for a blue transition					
Mobilise private sector investment in hybrid 'green/blue/grey' approaches (e.g. utilising living coastal infrastructure in traditional construction) for coastal infrastructure projects and ports through financial incentives such as tax exemptions and guarantees	Tourism, Fisheries, Marine Conservation	●	●	●	8, 9, 11, 13, 14, 15

(continued)

Table 19.3 (continued)

	Sector relevance	Economic benefits	Social benefits	Environmental benefits	SDGS
Invest in port authorities to transition to 'blue ports' and port reception facilities	Transport, Tourism, Energy, Infrastructure	Strong potential	Potential	Potential	3, 8, 9, 11, 13, 14, 17
Incentivise investment in cold storage capacity through access to affordable credit, government backed loans, duty-free imports of equipment and tax exemptions	Fisheries	Strong potential	Potential	Potential	2, 5, 8, 12, 14
Scale parametric insurance policies for blue natural capital in small island developing states, least developed countries and developing countries	Tourism, Fisheries, Marine Conservation	Potential	Minor potential	Potential	11, 13, 14, 15, 17
Stimulate sustainable and environmental sensitive mariculture (e.g. integrated multi-trophic aquaculture) through financial incentives such as tax exemptions and affordable credit, and government-backed loans	Fisheries, Mariculture	Potential	Minor potential	Potential	2, 8, 12, 13, 14

● Strong potential, ● Potential, ○ Minor potential

and improved resilience to climate impacts and other future shocks. For these additional opportunities, we sought ones that provided the following:

- Ability to build long-term resilience to future shocks (considering improving human, natural and physical capital) (Hammer and Hallegatte 2020; OECD 2020e)
- Ability to direct economic benefits to affected communities and vulnerable members of society (a people-centred approach) (UN 2020b)[69]
- Ability to catalyse progress towards a long-term sustainable and equitable blue economy (Hepburn et al. 2020)
- Ability to deliver on international commitments such as the 2030 Agenda for Sustainable Development and the Paris Agreement (IMF 2020b)
- Relevance to multiple regions and economies (OECD 2020e)

For each intervention, we identified the potential economic, social and environmental benefits based on existing literature. Note that for many of these interventions, no quantified benefits are yet available for the intervention level. The benefits highlighted are therefore intended to be a guide only and not prescriptive. As with any intervention, countries will need to go through a rigorous national process to fully quantify economic, social and environmental benefits given national or local circumstances.

[69] *The UN secretary general has stressed the need to ensure that national and local response and recovery plans identify and put in place targeted measures to address the disproportionate impact of the virus on certain groups and individuals, including migrants, displaced persons and refugees, people living in poverty, those without access to water and sanitation or adequate housing, people with disabilities, women, older people, LGBTI people, children and people in detention or institutions.*

3.4 Opportunities for Blue Conditionality to Avoid Roll-Backs in Progress

The provision of immediate relief packages and grants to the private sector brings with it the opportunity to incentivise recipients to implement measures central to the sustainable ocean economy agenda—but which might have been harder to incentivise or promote before COVID-19 without such finance or might be vulnerable to roll-backs as a result of decreased traditional revenue streams.

Although any form of 'blue condition' could be attached to a debt-relief agreement or government grant, we highlight two particular opportunities that take advantage of emerging and innovative technologies to avoid roll-backs in progress:

1. Digitalisation of the fishing industry to promote sustainable fisheries management and end illegal, unreported and unregulated (IUU) fishing.
2. Disclosure of ocean data to inform decision-making.

The above measures represent opportunities to advance long-standing agendas in terms of improving marine biodiversity, enhancing monitoring, ensuring fish stock recovery and responding to climate change. Both of them will have significant long-term benefits, improving ecotourism opportunities, enhancing the value of existing coastal tourism and improving the economic viability of artisanal and commercial fisheries.

In the short term such arrangements can provide immediate economic relief to the recipients (through the grant) and potential cost savings for the government.

3.4.1 Sustainable Fisheries Management Through Digitisation

Conditions aimed at fisheries reform and digitisation of the fishing industry offer the opportunity to make progress on long-standing fisheries governance agendas while also overcoming many of the short-term impacts of COVID-19 restrictions and revenue losses. These include the loss of on-board observers and reduced capacity for marine patrols to monitor and track fishing vessels for the purposes of reducing overfishing and IUU fishing. Traditionally, the burden for gathering such data has fallen on governments, but recovery efforts offer the opportunity to engage and empower the fishing industry itself to collect much of the data that underpin sustainable fisheries management.

The digitisation of the fishing industry would have other benefits in the face of COVID-19 and beyond fisheries governance. Traceability and data-sharing also enhances industry robustness and resilience by strengthening aquafeed supply chains, which have been curtailed during the COVID-19 crisis. Sharing data creates more robust supply chains for raw material. This can be achieved by making data on regional and sustainable raw materials sources available. Science-industry cooperation is vital for this process. Making these data available could also be a condition to strengthen the aquaculture industry (see the data-sharing and disclosure section below).

Consumers are also increasingly demanding more traceability, highlighting the added incentive for increased supply chain monitoring through digital tools. Creating alternative data-gathering mechanisms like apps empowers local fishers to take part in data-gathering while informing consumers. OurFish, developed by Rare, is one example of an app for local fishers to record and share their catch data digitally, creating a permanent digital log of sales, expenses and inventory. This app and the associated data also enable fishing communities to monitor the value, type and local amount of fish caught. The information can be made available to decision-makers in government and relevant stakeholder groups.

Examples of measures that could be attached to grants include requiring registration of vessels (relevant to small-scale and artisanal vessels); digital traceability—to increase transparency and strengthening monitoring, control and surveillance; and electronic monitoring and electronic reporting. Conditions can also target the publication of essential data, including vessel ownership and licenses (see the data-sharing and disclosure section below).

These industry-led measures could be supplemented by government investment in new artificial intelligence-powered electronic monitoring systems, enhanced drones and satellite data interpreted by machine learning. Such efforts will also dramatically improve the fishing industry's resilience to similar future shocks.

The potential economic impact of such measures is significant. Globally, between 8 and 14 million metric tonnes of unreported catches are traded illicitly yearly, resulting in gross revenues of $9 billion to $17 billion associated with these catches. This equates to an estimated loss (in annual economic impact) of $26 billion to $50 billion globally, while losses to countries' tax revenues are between $2 billion and $4 billion (U.R. Sumaila et al. 2020). What this means for a region is significant. For example, the Pacific experiences an estimated loss in gross revenues to the formal economy of $4.3 billion to $8.3 billion per year. These losses are substantially higher when we consider the economic impact ($10.8 billion to $21.1 billion per year), income impact ($2.8 billion to $5.4 billion per year) and tax revenue impact ($200 million–$1.6 billion per year) (Konar et al. 2019a). Furthermore, as a result of potential illicit trade in seafood, workers in the sector lose an estimated $6.8 billion to $13.3 billion in income annually (Sumaila et al. 2020).

The results of moving to digital systems, including electronic monitoring and reporting, will significantly improve information. Fishery management systems currently rely heavily on data from fishers' daily logbooks that include locations, amount of time spent fishing, how many fish were caught and how many and what kind of fish or other species were discarded. On-board observers have been the only option to validate these logbook data, but such efforts only cover a tiny fraction of global fishing activities—likely less than 2% (Michelin et al. 2018). In most instances, electronic monitoring systems can achieve monitoring goals more cost-effectively than human observers and can more easily scale to cover 100% of fishing activity. Also, electronic monitoring can provide transparency in the critical first link in a supply chain that is traceable from supply to plate, giving consumers confidence when purchasing premium-priced seafood that is labelled as 'sustainably harvested' (for an example of how this is being done in Jamaica, see Box 19.10).

Box 19.10 Jamaica's Focus on Improving Traceability and Monitoring of Wild Capture Fisheries

Jamaica's 17,000 artisanal fishers all received a one-time grant as part of Jamaica's initial rapid response to the impacts of COVID-19 on its fishing industry. These grants were to provide income support due to a drop in demand from Jamaica's tourist sector (the majority of Jamaica's fishing industry is oriented towards supplying high-end restaurants and resorts).

Jamaica has made long-standing efforts to restore its fish stocks through sustainable fisheries management and improved governance. The registration of artisanal fisherman has been a challenge.

Jamaica applied two main conditions to the grant: registration of the boat and mandatory GPS trackers. As a result of these conditions, Jamaica now has a much better understanding of the scale of small-scale fishing and has enabled a transition to digital information and tracking, two pillars of its existing commitment to sustainable fisheries management.

Source: Government of Jamaica.

Unsustainable fishing practices, including IUU fishing, threaten local livelihoods, exacerbate poverty and heighten food insecurity. Seizing the opportunity of relief packages to address this issue will have long-term economic benefits for countries and regions, helping to improve the resilience of these communities and their fishing industries (local, artisanal and commercial) for decades to come.

3.4.2 Improved Transparency and Decision-Making Through Ocean Data

Vast stores of unstructured data related to the ocean economy are currently stored by governments, researchers and industry (for legal, security or proprietary purposes), making them inaccessible and unusable to inform decision-making in either the public or private sector. These data should by default be made open and available through data-tagging, federated data networks (Brett et al. 2020). In support of SDG 14, the United Nations declared the 10-year period (2021–30) to be the UN Decade of Ocean Science for Sustainable Development (the Decade). The Decade is dedicated to providing a common framework to encourage stronger international cooperation that can better coordinate and integrate ocean data and research into the decision- making process of stakeholders.

Data on the ocean economy can spur incentives for innovation, new public-private instruments for investment and the creation of new business models as we adapt to our world's new realities after COVID-19. Increased data-sharing would also add resilience to ongoing COVID-19 challenges. Having active data streams is paramount for ocean resilience in facing up to COVID-19 and could contribute significantly to safer at-sea operations (e.g. through maritime track-and-trace systems using geofencing).

Conditions could include a requirement that private sector organisations and financial institutions disclose or improve the accessibility of such data. Such a condition would be comparable to those being advanced to improve environmental and climate disclosure as part of recovery packages (Office of the Prime Minister, Canada 2020).

Impactful requirements could include

- that all users of ocean resources such as fisheries, minerals, oil and gas or coastal land be required to make their environmental data available to the public (Leape et al. 2020);
- that domestic fisheries, fishing vessels, shipping and marine transport track their GHG emissions and report annually for inclusion in national GHG inventories in accordance with the relevant guidance of the Intergovernmental Panel on Climate Change;
- that fishing vessels use automatic identification systems and share essential data on fisheries, including vessel ownership, licenses and tracking for all fishing vessels (this is also relevant to fisheries reform, as identified above);
- that all data collected by defence and security agencies which can be shared without compromising national security be made publicly accessible (Leape et al. 2020); and

- that all financial institutions disclose whether their portfolios align with ocean sustainability. Companies based on, depending on or affecting the ocean should integrate relevant ocean-related risks and opportunities into corporate strategy, risk management and reporting[70].

In addition to conditions placed on financial grants to the private sector, governments should also provide support and training to develop appropriate data-gathering and processing capacities and systems in developing countries and coastal communities, to ensure that these nations and communities are not left behind.

4 Conclusion

The importance of the ocean to a sustainable future is too important to neglect at this great moment of resetting and rebuilding. The relevance of the ocean for global economic and social recovery and future prosperity must become part of global discourse, and a greater part of measures applied to respond to the economic and social impacts of the crisis.

The COVID-19 pandemic has severely impacted ocean industries and the livelihoods and food security of many millions of people. It has highlighted the significance of the ocean as a global workplace, its role in underpinning the modern economy and the inherent interdependencies between ocean sectors, the health of the ocean environment and human well-being.

How the world rebuilds from the COVID-19 crisis is of great importance for the ocean and climate. Early responses to promote economic recovery and protect industries from further losses have included large-scale investments in sectors previously shown to be harmful to the environment, alongside the easing of environmental safeguards. Such measures risk the future health and wealth of the ocean economy with impacts for food security, livelihoods and our shared prosperity, rolling back progress made towards mitigating global biodiversity loss and climate change. Governments and financial institutions need to immediately strengthen efforts to build environmental, social and economic resilience.

In tailoring support for those most affected by the COVID-19 pandemic, greater attention must be paid to the ocean economy and its many direct and indirect beneficiaries. A sustainable and equitable blue recovery is critical not just for those who live or work near the coasts but also for the well-being and resilience of societies and economies at large.

This report has identified specific opportunities for the immediate investment of stimulus and recovery funds that would lead to a more sustainable and resilient ocean economy. It also has highlighted opportunities to accelerate research on and development of future sustainable ocean industries and to transition emission- and pollution-intensive industries onto more sustainable pathways in order to reach their full economic growth potential.[71]

This report has highlighted that investment in the interventions necessary for a sustainable and equitable blue recovery will benefit other land-based sectors, including human health, technology, agriculture, supply chains and tourism.

The demonstrated interdependencies between the different ocean sectors, which has exacerbated the impacts of COVID-19 on individual industries, make a strong case for greater integration and collaboration among sectors, as a complement to traditional sectoral management, both in recovery efforts and long-term operations. Ecosystem-based, integrated ocean management and other related holistic and knowledge-based approaches to planning and managing the multitude of uses and users of ocean spaces offer an important framework to ensure that ocean industries can rebuild in a mutually reinforcing way towards a sustainable future ocean while protecting essential ocean ecosystems and functions.

This report highlights growing global inequalities and the need to accelerate equitable access to ocean opportunities and sharing of benefits from ocean industries. Response measures to support women, who have been disproportionately affected, notably in the tourism and fisheries sectors, will be particularly important to ensure access to decent work opportunities and the full engagement of women in ocean activities. There is also an ongoing need to improve working conditions for vulnerable 'key workers' at sea to better protect fishers and seafarers, who play an essential role in maintaining global supplies of food, medicines, energy and manufactured goods across supply chains.

To ensure a long-lasting economic recovery from the COVID-19 crisis, response measures must trigger investments and societal changes that reduce vulnerability and improve our collective resilience to future shocks (OECD 2020a). Recovery plans have so far fallen short in this regard. To this end, governments must seize the opportunity of stimulus packages to address unsustainable fisheries practices, including IUU fishing, which undermines employment and livelihoods in one of the largest sectors of the ocean economy, exacerbates global poverty and risks the food security

[70] *See, for example, the ocean sustainability principles followed by Norges Bank Investment Management (2020).*

[71] *See, for example, the ocean sustainability principles followed by Norges Bank Investment Management (2020).*

of over 3 billion people, including some of the world's poorest, who rely on the ocean as their primary source of protein. Technological advances introduced during COVID-19 and innovative financial mechanisms may hold the key to advancing such action.

The importance of the ocean to a sustainable future is too important to neglect at this great moment of resetting and rebuilding. The ocean's relevance for global economic and social recovery and future prosperity must become part of global discourse, and a greater part of measures applied to respond to the economic and social impacts of the COVID-19 crisis. The ocean-based or 'blue' investment opportunities detailed in this report offer a departure from business as usual in that they can deliver a more inclusive recovery, premised on a healthy and regenerative ocean to provide global benefits for the longer term.

Embracing a 'sustainable and equitable blue recovery' in the large stimulus packages being agreed worldwide can build ocean health and sustainability into recovery and support the transition towards a more sustainable, inclusive and resilient global economy.

Acknowledgements The authors would like to thank the following people for their review, feedback and inputs on early drafts of this report:

Mark Hemer (Commonwealth Scientific and Industrial Research Organisation (CSIRO)); Sebastian Troëng (Conservation International); Kristin Rechberger (Dynamic Planet); Arni Mattiesen (Food and Agriculture Organization); Kasper Sogaard (Global Maritime Forum); Suzi Heaton (Government of Australia); Betty Nyonje (Government of Kenya); Andrew Rhodes (Government of Mexico); Maria Ines Gameiro (Government of Portugal); Brandt Wagner (International Labour Organization); Chris Gilles (The Nature Conservancy); Lotta Pirttimaa (Ocean Energy Europe); Arian Steinsmeier (Rare); Angelique Pouponneau (Seychelles Conservation and Climate Adaptation Trust); Adrien Vincent (SYSTEMIQ); Elva Escobar (Universidad Nacional Autónoma de México); Andrew Hudson (United Nations Development Programme); Ignace Beguin (United Nations Global Compact); Justin Mundy (Willis Towers Watson); Karin Kemper (World Bank); Ines Aguiar Branco, Mathilde Bouye, Lauretta Burke, Ed Davey, Helen Ding, Erin Gray, Craig Hanson, Erika Harms, Amy Hemingway, Leo Horn- Phathanothai, Norma Hutchinson, Joel Jaeger, Aman Srivastava, Kristian Teleki, Ayushi Trivedi and Arief Wijaya (World Resources Institute); and Louise Heaps (World Wildlife Fund).

While we deeply appreciate the expertise brought by each of these reviewers, this report reflects the views of the authors alone.

The authors would also like to acknowledge the Expert Group Co-chairs, Jane Lubchenco, Peter Haugan and Mari Pangestu for their valuable guidance and support for this report.

Thank you also to Romain Warnault, Alex Martin and Jen Lockard for providing administrative, editing and design support.

About the Authors

Eliza Northrop is the Policy Lead for the Secretariat for the High Level Panel for a Sustainable Ocean Economy and Senior Associate for the World Resources Institute's Sustainable Ocean Initiative. Contact: Eliza.Northrop@wri.org.

Manaswita Konar is the Lead Ocean Economist for the World Resources Institute's Sustainable Ocean Initiative. Contact: Manaswita.Konar@wri.org.

Nicola Frost is the Deputy Head of Secretariat for the High Level Panel for a Sustainable Ocean Economy. Contact: Nicola.Frost@wri.org.

Elizabeth Hollaway is the Research Assistant for the World Resources Institute's Sustainable Ocean Initiative. Contact: Elizabeth.Hollaway@wri.org.

Annex 1

Table 19.4 Research and development to spur innovation and new technology

Interventions	Sector relevance	Economic benefits
Invest in research and development (R&D), including pilot projects, to accelerate the development of sustainable and low-carbon alternative feed options for fed mariculture (e.g. finfish)	Fisheries	19.3 million people globally engaged in aquaculture (FAO 2018a) World food fish consumption in 2030 is projected to be 20% (or 30 million metric tonnes [mmt] live weight equivalent) higher than in 2016 (FAO 2018a) The major growth in production is expected to originate from aquaculture, which is projected to reach 109 mmt in 2030, with growth of 37% over 2016 (FAO 2018a)

Table 19.4 (continued)

Social benefits	Environmental benefits	Potential for the creation of perverse incentives	SDGS
Improved health of local communities. A portion of 150 g of fish provides about 50–60% of an adult's daily protein requirement. Fish proteins are essential in the diet of some densely populated countries where the total protein intake is low, and they are particularly important in diets in small island developing states and least developed countries (FAO 2018a) Alternative feed innovations could ensure an additional 364 mmt of food annually—over six times current capture and mariculture production[a]. This is only possible if mariculture is not dependent on feed from fish products (Costello et al. 2019) Reduction in the diversion of forage fish from communities that rely on it for direct nutrition (Tacon and Metian 2008; Konar et al. 2019b) and protect the cultural value to Indigenous Peoples (Jones et al. 2017; Konar et al. 2019b) Innovations in feed technology could greatly enhance the potential for fed mariculture (Costello et al. 2019; Froehlich et al. 2018) Increasing ocean-based food (including aquaculture) will generate benefits nine times higher than costs (Konar and Ding 2020) Increased job creation through development of algae feed industry (Roberts and Upham 2012)	The global supply of fishmeal may be near biological limits (Costello et al. 2012) Improves resilience under climate change (Gaines et al. 2019)	Increase in pollution from aquaculture operations Introduction of invasive species Job loss from traditional feed sources	1 2 3 8 12 13 14

Interventions	Sector relevance	Economic benefits
Invest in filling data gaps on national coastal and marine ecosystems through employment schemes for surveys, modelling and mapping	Tourism, Fisheries, Marine Conservation	Short-term job creation Long-term economic efficiencies in terms of data availability Potential access to carbon markets and associated on-going streams of revenue for management of ecosystems and local communities
Invest in R&D and innovation grants to stimulate the development of new industries for generating alter- native marine fuels, such as hydrogen and ammonia (invest in land-based infrastructure for fuel gener- ation and supply chains as opposed to ship-related investments)	Transport, Energy	Economic growth opportunity for export of low-cost hydrogen (utilising electrolysers powered by renewable resources)[b] (IEA 2019a, b) and green ammonia as a maritime fuel (Ash and Scarbrough 2019) Economic diversification potential—energy storage, low-carbon heat, transport fuels and a key input in the production of fertiliser (ammonia) (Yara International 2019). Additional uses create synergies and reduce the investment risk, especially in the early phase of the transition (IEA 2020a) Job creation potential in many states and regions (Bezdek 2019). Widespread penetration could create nearly one million new jobs (highly skilled, well-paid technical and professional workers) in the United States by 2030 (ASEA and MIS 2009)
Establish blue economy skills training and capacity development programs in key ocean industries for affected communities and industries (e.g. ocean-based renewable energy, zero-emission vessels, geographic information systems, ecotourism, restoration)	Tourism, Fisheries, Energy, Transport, Marine Conservation	Economic benefits of local developments accrue locally (Gaines et al. 2019) Local investments in renewable energy and energy- efficient technologies can improve local livelihoods and enhance local economic benefits (Gaines et al. 2019)

Table 19.4 (continued)

Social benefits	Environmental benefits	Potential for the creation of perverse incentives	SDGS
Increased participation in 'citizen science' can encourage public action and improve conservation efforts (McKinley et al. 2017) Sustained ocean observations benefit many users and societal goals across society actors (Weller et al. 2019) Community ownership and understanding of natural resources	Improved understanding and mapping of ecosystem extent and species diversity Basis for inclusion of ecosystems in national greenhouse gas (GHG) inventories to enable mitigation for blue carbon ecosystems (mangroves, seagrass and salt marshes), and important for monitoring adaptation benefits from other marine habitats like coral reefs Increased management capabilities		8 13 14
Diversified economic opportunities for local communities	Reduced GHG emissions Improved air quality (based on reduced reliance on fossil fuels as a result of green fuels) Improved water quality, including deep-sea routes		7 8 9 12 13 14
Diversified economic opportunities for local communities Local capacity building in ecotourism (foundation for ensuring revenue is reinvested in the local community) Increased cultural awareness by sharing traditional knowledge Increased community buy-in	Reduced emissions Improved monitoring and protection of marine protected areas and coastal and marine ecosystems Using ecotourism for conservation through programs like sea turtle watch or citizen science		7 8 9 12 13 14

Interventions	Sector relevance	Economic benefits
Invest in research and development, including pilot projects, and incentivise emerging ocean-based renewables to accelerate their development	Energy, Transport, Mariculture	The global market of wave and tidal sectors is estimated to reach €53 billion per year by 2050 (Carbon Trust 2011)

Social benefits	Environmental benefits	Potential for the creation of perverse incentives	SDGS
Ocean-based renewable energy has the potential to generate 400,000 jobs in Europe by deploying 100 GW by 2050 (ETIP Ocean 2020). The global deployment is estimated to be 337 GW (2011), which indicates that ocean energy will generate about 1.2 million jobs globally by 2050	Ocean-based renewable energy can reduce GHG emissions by between 0.05 and 0.87 GtCO2e/year by 2050 (Hoegh-Guldberg et al. 2019). It can also create marine reserves and artificial reefs (Copping et al. 2016)		7 8 9 11 12 13 14

[a] Note that this figure is based on a tripling of global production of seafood for consumption, which would necessitate dramatic shifts in consumer taste and associated demand

[b] Renewable hydrogen costs may fall to as low as $1.40 a kilogram by 2030 from the current range of $2.50 to $6.80, with further reductions to 80 cents by 2050, equivalent to a natural gas price of $6 per million British thermal units (Mathis and Thornhill 2019)

Table 19.5 Regulatory reform to provide an enabling environment for a sustainable ocean economy

Interventions	Sector relevance	Economic benefits	Social benefits	Environmental benefits	Potential for the creation of perverse incentives	SDGS
Establish comprehensive integrated ocean management and marine spatial planning processes to balance marine users and spaces, reduce competition for coastal resources and mitigate permitting and siting issues for sustainable ocean industries	Fisheries, Tourism, Energy, Shipping, Marine Conservation, Mariculture	Potential economic growth and new economic opportunities (European Commission 2020a) Sector growth facilitated through improved framework (Jay 2017) Cost reduction through streamlining regulatory and compliance processes (European Commission 2020a)				
Initiate regulatory reform to promote best practice in climate adaptive fisheries management, including through incentives for industry adoption in the form of taxes and subsidies	Fisheries	More catch and profits through climate-adaptive management than through business-as-usual management (Free et al. 2019) Economic diversification through providing a portfolio of options to fishers and a buffer against climate-driven losses in any one target stock (Free et al. 2019) Economic losses of about US $83 billion in 2012, compared with the optimal global maximum economic yield equilibrium (World Bank 2017)				
Shift harmful subsidies to more sustainable and equitable uses, including supporting small-scale and artisanal fishing industry, ecotourism opportunities for local communities and management and monitoring of MPAs	Fisheries, Tourism, Marine Conservation	6.3% of global GDP ($4.7 trillion) was provided as fossil fuel subsidies in 2015, including uninternalised externalities (Coady et al. 2019) About $35 billion in subsidies are allocated to global marine fisheries alone each year, of which $22 billion are allotted to harmful subsidies (R.U. Sumaila et al. 2019) New economic opportunities for local communities through ecotourism Job protection (or creation) for local communities in MPA management and monitoring The World Bank has estimated that reducing global fisheries overexploitation, of which subsidies are key factor, could generate an additional $53 billion to $83 billion in revenue annually (World Bank 2017)				
			Reduced conflict through improved stakeholder relations and engagement (European Commission 2020a) Inclusivity and recognition of Indigenous rights such as the Beaufort Sea Partnership in Canada, which works with the local Indigenous groups	Streamlined management resulting in more effective governance to mitigate environmental risks posed by ocean-based activities and industries Increased stock through improved management Improved conservation of coastal and marine habitats	Lobbying for greater influence and industry capture	1 2 8 12 13 14 17

Table 19.5 (continued)

Social benefits	Environmental benefits	Potential for the creation of perverse incentives	SDGS
Local and community-based management can increase adaptive capacity by incorporating local knowledge and can improve sustainability by fostering a sense of stewardship (Gutiérrez et al. 2011) These strategies also allow fishers to generate revenues through other compatible activities, such as tourism, recreation and aquaculture (Moreno and Revenga 2014)	Ecological resilience through maintaining healthy stock sizes, age structures and genetic diversity (Free et al. 2019) Reduced impacts of climate change on fish stocks (Free et al. 2019) Thanks in part to adaptive harvest strategies fish stocks not fished beyond their biological limit and overfished stocks allowed to rebuild (Melnychuk et al. 2014)	Overfishing or stock decline if not linked to science	2 8 12 13 14
Subsidies that are disproportionately provided to the large industrial fishing sub-sector serve to undermine the Sustainable Development Goals by aggravating hunger, poverty and gender inequality in coastal communities worldwide (Sumaila 2020) Redirected subsidies could be used to improve gender equality by empowering female fishers (Österblom et al. 2020) Redirected subsidies could support Indigenous Peoples and local communities, many of which practice artisanal fishing, as well as the conservation and sustainable use of marine biological diversity	Improved biodiversity outcomes if redirected subsidies are used to fund jobs in monitoring of protected areas Improved fish stocks if redirected subsidies are used to fund incentives to improve traceability of fisheries, inclusion of women and jobs on coastal restoration works (Sumaila 2020)	Mismanagement of funds	1 2 5 7 8 10 12 14

Interventions	Sector relevance	Economic benefits
Introduce levies and taxes to reinvest tourism revenue in local restoration and conservation efforts	Tourism, Fisheries, Marine Conservation	Additional revenue stream Iceland's Tourist Site Protection Fund promotes the development, maintenance and protection of tourism attractions and is funded by Iceland's accommodations tax, enacted in 2011 (OECD 2018) Reduction of value-added tax on tourism-related goods and services in Ireland was followed by an increase in employment through growth in numbers of tourists (OECD 2014)
Integrate ocean accounts into national accounting frameworks, or develop satellite ocean accounts, to measure and monitor the impact of recovery measures on long-term sustainability of the ocean economy	Fisheries, Tourism, Transport, Energy, Marine Conservation, Infrastructure	Digital solutions are important to facilitate, among other things, enhanced reporting of crisis-related spending, ex post audits and procurement transparency (IMF 2020c) By tracking each budget transaction across government agencies, accounts can produce timely, reliable, accurate and meaningful information to support financial decision-making, improve fiscal discipline, strengthen expenditure control and enhance fiscal transparency (Uña et al. 2019)

Social benefits	Environmental benefits	Potential for the creation of perverse incentives	SDGS
Reinvestment in jobs for local communities (should be done in coordination with local communities, including Indigenous Peoples, local communities and women affected by conservation efforts, to ensure buy-in)	Proceeds from taxes and levies secure funding for the protection of environmental areas In Australia, the Great Barrier Reef Marine Park Environmental Management Charge proceeds are applied directly to the management of the marine park, including through education, research, compliance patrols, site planning, public moorings, reef protection markers, information signs and maps (OECD 2014)	Mismanagement of funds Tourism can harm local ecosystems	8 11 13 14

Table 19.5 (continued)

Social benefits	Environmental benefits	Potential for the creation of perverse incentives	SDGS
Data and improved metrics to track equitable distribution of ocean wealth	Data to account for natural wealth Integration of ecosystem services into decision-making		8 9 12 14 16 17

Table 19.6 Public/private partnerships for a blue transition

Interventions	Sector relevance	Economic benefits
Mobilise private sector investment in hybrid 'green/blue/grey' approaches (e.g. utilising living coastal infrastructure in traditional construction) for coastal infrastructure projects and ports through financial incentives such as tax exemptions and guarantees	Tourism, Fisheries, Marine Conservation	Natural coastal barriers, such as mangroves, wetlands and sandbars, lower costs for grey infrastructure, such as seawalls, sea dikes and groynes. New York City saved 22%, or $1.5 billion, by combining green and grey infrastructure instead of pursuing a grey-only strategy to secure water supply for the city (Bloomberg and Holloway 2018) In Vietnam, an investment of $9 million to restore 9000 hectares of mangroves along the shores of 166 communes as well as 100 km of dike lines cut the cost of dam- ages by $80,000–$295,000 and saved an additional $15 million in avoided damages to private property and other public infrastructure (IFRC 2011) Increased ecotourism opportunities in living infrastructure (e.g. mangroves and wetlands)
Invest in port authorities to transition to 'blue ports' and port reception facilities[a]	Transport, Tourism, Energy, Infra-structure	Low-emission and fuel-efficient terminal equipment will save money through reduced energy consumption Increased efficiency through improved equipment will reduce operation costs Increased investment from offshore wind tenants who may be dealing with outdated port ownership structures and inexperienced owners Synergies with zero-emission vessels and energy production Identify technical and operational innovations to reduce the high transportation costs that exist for many developing countries and other remote locations (UNGC 2020b) Incorporate climate change adaptation considerations into 'blue ports', as ports are at increasing risk of coastal flooding. Infrastructure inventories, higher resolution data, as well as technologies that help improve the understanding of coastal processes under climate change are needed for effective risk-assessment and adaptation planning for critical transport infrastructure, particularly in small island developing states (UNCTAD 2020c)

Social benefits	Environmental benefits	Potential for the creation of perverse incentives	SDGS
Catastrophic risk reduction for loss of life in storm surges through reducing wave energy and the height of a storm surge (Beck and Lange 2016) Main operators of green infrastructure are often local communities, responsible for implementing land stewardship practices and for maintaining the project over the long term (unlike grey infrastructure that is operated and owned by a company or government entity) (Browder et al. 2019)	Climate-mitigation potential (depending on ecosystem) Coastal resilience through reduced storm surges and protection of coastal communities and infrastructure from sea level rise Improved biodiversity, water quality, watershed protection (Browder et al. 2019)		8 9 11 13 14 15

Table 19.6 (continued)

Social benefits	Environmental benefits	Potential for the creation of perverse incentives	SDGS
Improved air quality Improved health and livelihood of people working or living around ports and the 'liveability' of the area surrounding the port Opportunities for gender equity in access to resources, services, markets, incomes and employment (FAO 2018b)	Responsible fisheries management Reduction of shoreside idling (Sharma 2006) by providing shoreside power will reduce noise pollution (NoMEPorts 2008), improve air quality and reduce fuel consumption Reduced waste pollution through improved solid waste handling and recycling programs at port (Svaetichin and Inkinen 2017)	Added ecosystem disturbance through updates	3 8 9 11 13 14 15 17

Interventions	Sector relevance	Economic benefits
Incentivise investment in cold storage capacity through access to affordable credit, government-backed loans, duty-free imports of equipment and tax exemptions[b]	Fisheries	Live, fresh or chilled is the preferred and highest-priced form of fish and represents the largest share of fish for direct human consumption (FAO 2018a) Resilience to future shocks. Increased demand for frozen fish since outbreak of COVID-19 (Saumweber et al. 2020) Increased yields for fishers Increased income for fishers as a result of high-quality fish Marine exports grew by 7.68% in the fiscal year following an investment package by the Government of India, which included ongoing subsidies to build large cold storages for surplus seafood[c] (Narayanswami and Balan 2013)
Scale parametric insurance policies for blue natural capital in SIDS, LDCs and developing countries	Tourism, Fisheries, Marine Conservation	100 m of mangrove barrier can reduce wave heights by two-thirds Building oyster reefs adjacent to shore in the United States can reduce the cost of every metre of coastal protection by over $750, compared to other engineering options (Spalding et al. 2016) In France, the Caisse Centrale de Réassurance has estimated that insured property damages will rise by 50% if no preventive measures for climate change–related effects are implemented (CCR 2018) Marine ecosystems represent natural capital and non-market flows and services. Healthy coral barriers stop the damaging effects of hurricanes and cyclones hitting the coasts The value of marine ecosystems, based on the total bundle of ecosystem services provided by an 'average' hectare of open ocean, is estimated at $490/year, while the value of services provided by an 'average' hectare of coral reefs is almost $350,000/year (OECD 2016)
Stimulate sustainable and environmentally sensitive mariculture (e.g. integrated multi-trophic aquaculture [IMTA]) through financial incentives such as tax exemptions and affordable credit, as well as through government-backed loans	Fisheries, Mariculture	Economic diversification Increased profitability per cultivation unit and higher income (Troell et al. 2009) Resilience to shock and market changes through product diversification. Increased yields. At sites in Canada's Bay of Fundy, growth rates of kelp and mussels cultured in proximity to fish farms were found to be 46% and 50% higher, respectively, than at control sites (Chopin et al. 2004)

Table 19.6 (continued)

Social benefits	Environmental benefits	Potential for the creation of perverse incentives	SDGS
Loss or waste between landing and consumption due to a lack of refrigeration still accounts for an estimated 27% of total catch, representing a missed opportunity in terms of additional protein available for local communities and consumers (FAO 2018a; NoMEPorts 2008) Shifting to freezing could have a positive impact on women's employment, as they constitute a high proportion of workers in the post-harvest/food processing sector (UNCTAD 2020b)	Analysis has shown a net benefit in GHG emissions reduction from expanding cold storage to developing countries. In all modelling scenarios, decreased emissions from food loss and waste from cold chain expansion outpaced newly created emissions from the expansion and use of cold storage by a factor of 10, approximately[d]	Fishers may be incentivised to fish further offshore or more intensely because they can now store food longer	2 5 12 13 14
Climate risk reduction measures to ensure insurance coverage for previously non-insurable situations like sea level rise and other slow-onset events	Coastal resilience through reduced storm surges and protection from sea level rise Improved biodiversity, water quality, watershed protection (Browder et al. 2019)		11 13 14 15
Source of employment for local communities. Increased protein yields Opportunities for regional collaboration. The Yellow Sea Large Marine Ecosystem Project, established under the guidance of the Global Environment Facility and the UN Development Programme, and in a partnership be- tween China and South Korea, is working to implement IMTA in the region	Preservation of local habitats Recycling of waste nutrients and bio-mitigation typically produced through traditional mariculture by lower trophic level crops (Troell et al. 2009)		2 8 12 13 14

[a] 'Blue ports' are considered to be sustainable, support the transition to decarbonised marine transport and shipping fleets through fuel supply chains, promote transparency and traceability for fisheries and utilise nature-based solutions

[b] Any investment in cold storage by the private sector must be coupled with public investment in the supporting supply chain infrastructure. Governments should also eliminate disincentives to cold storage (such as taxes on foreign refrigeration systems) (FAO 2020b)

[c] Other measures included the government's exempting air-conditioning equipment and refrigeration panels used in cold chain from excise duties and allowing duty- free import of refrigerated units used in reefer trucks (Narayanswami and Balan 2013)

[d] In all modelling scenarios, the decrease in the food loss and waste carbon footprint from cold chain expansion clearly outweighs the newly created emissions, by a factor of 10, approximately (GFCCC 2015)

Annex 2

Table 19.7 Additional reference materials on a sustainable ocean economy

Author	Report	Summary
Sustainable ocean economy reports		
UNGC, 2020	*Ocean Stewardship 2030*	This report offers a roadmap for how ocean-related industries and policymakers can jointly secure a healthy and productive ocean by 2030. The report describes five critical areas of success. For each area, the report suggests two ambitions and puts forward several recommendations addressing critical dimensions of public and private actions to accelerate ocean-related solutions
European Commission, 2020	*The EU Blue Economy Report*	This report highlights the need to preserve marine ecosystems to optimise potential benefits of ecosystem services and marine and maritime economic sectors
European Parliamentary Research Service, 2020	*The Blue Economy: Overview and EU Policy Framework*	This report looks into the EU policy framework and the different EU initiatives and actions taken in these areas, both by providing an overview of the cross-cutting 'key enablers' of the blue economy and by providing an analysis by blue economy sector (excluding the sectors of coastal protection and maritime defence)
Konrad Adenauer Stiftung/FICCI, 2019	*Blue Economy: Global Best Practices Takeaways for India and Partner Nations*	This report systematically examines and explains the performance, projected growth in terms of size and value, challenges and precise opportunities for capacity expansion and quality enhancement, including technology and process upgrades, in the relevant sectors of India's blue economy. The report also elaborates the global best practices relevant to India as well as innovative financing tools. The report makes several practical recommendations for an effective way forward, both for the government and businesses
OECD, 2019	*Rethinking Innovation for a Sustainable Ocean Economy*	This report on the ocean economy emphasises the growing importance of science and technologies in improving the sustainable economic development of our seas and ocean
World Bank, 2019	*Indonesia Economic Quarterly: Oceans of Opportunity*	This report discusses the importance of the maritime economy to Indonesia's economic development and presents the challenges and opportunities the country faces in leveraging the maritime economy for greater prosperity
Africa Institute of South Africa, 2018	*The Blue Economy Handbook of the Indian Ocean Region*	This handbook offers insight into the various aspects and impacts of the blue economy in the Indian Ocean region. From shifting paradigms, to an accounting framework, gender dynamics, the law of the sea and renewable energy, it aims to increase awareness of the blue economy in this region and to provide evidence to help policymakers in the region make informed decisions
World Bank Group, UN DESA, 2017	*The Potential of the Blue Economy: Increasing Long-Term Benefits of the Sustainable Use of Marine Resources for Small Island Developing States and Coastal Least-Developed Countries*	Drafted by a working group of UN entities, the World Bank and other stakeholders, this report offers a common understanding of the blue economy. It seeks to highlight the importance of such an approach, particularly for small island developing states and coastal least developed countries; to identify some of the key challenges posed by adoption of the blue economy; and to suggest some broad next steps that are called for in order to ensure its implementation
WWF, 2017	*Reviving the Western Indian Ocean Economy: Actions for a Sustainable Future*	This report aims to help Western Indian Ocean countries achieve the Sustainable Development Goal plan of action for 2016–30 in the ocean sector and thus realise the vision, expressed under the regional strategic action programme, of 'people prospering from a healthy Western Indian Ocean'
Commonwealth Secretariat, 2016	*The Blue Economy and Small States* (Commonwealth Blue Economy Series, no. 1)	The Commonwealth Blue Economy Series presents a synthesis of information and practical advice to Commonwealth governments relating to the potential deployment of a range of policy options for different sectors and opportunities for the road ahead. In so doing, this series aims to support the development of the blue economy in Commonwealth countries by providing a high-level assessment of the opportunities available for economic diversification and sustainable growth
Global Ocean Commission, 2016	*The Future of Our Ocean: Next Steps and Priorities*	To accelerate progress towards reversing ocean degradation and drive the global system for ocean governance, the Global Ocean Commission calls upon UN member states and all relevant stakeholders to agree a stand-alone Sustainable Development Goal (SDG) for the global ocean, thus putting the global ocean front and centre on the post-2015 UN development agenda

Table 19.7 (continued)

Author	Report	Summary
OECD, 2016	*The Ocean Economy in 2030*	This report explores the growth prospects for the ocean economy, its capacity for future employment creation and innovation, and its role in addressing global challenges. Special attention is devoted to the emerging ocean-based industries in light of their high growth and innovation potential, and their possible contribution to addressing challenges such as energy security, environment, climate change and food security
World Bank, 2016	*Toward a Blue Economy: A Promise for Sustainable Growth in the Caribbean*	This report serves as a guide to help Caribbean policymakers plan a successful transition to a blue economy and to socially equitable 'blue growth'. This report attempts to quantify the current value of the ocean economy in the region and to summarise projections about where we may find new pockets of sustainable growth
UNEP, 2015	*Blue Economy: Sharing Success Stories to Inspire Change*	This report shares stories that illustrate how economic indicators and development strategies can better reflect the true value of such widespread benefits and potentially even build on them
WWF, 2015	*Reviving the Ocean Economy: The Case for Action*	This report analyses the ocean's role as an economic powerhouse and outlines the threats that are pushing it toward collapse. This report presents an eight-point action plan that would restore ocean resources to their full potential
WWF, 2015	*Living Blue Planet*	This report provides a science-based analysis of the health of our planet and the impact of human activity upon it
California Environmental Associates, 2015	*Ocean Prosperity Roadmap: Fisheries and Beyond*	This report collects research designed to inform decision-makers, including governments and investors, about effective ocean and coastal resource management strategies to maximise economic, conservation and societal benefits
Global Ocean Commission, 2014	*From Decline to Recovery: A Rescue Package for the Global Ocean*	This report outlines a set of eight practical proposals to address the five drivers of decline, reverse high seas degradation and improve the system of governance, monitoring and compliance
UNCTAD, 2014	*The Oceans Economy: Opportunities and Challenges for Small Island Developing States*	This report is a joint effort by a team of experts from the UN Conference on Trade and Development and the Commonwealth Secretariat to better understand the implications of the nascent and evolving concept of the ocean economy. It underlines the importance of sustainable oceanic activities for the development of small island developing states (SIDS) and other coastal states. The report identifies both opportunities and challenges for SIDS in existing and emerging trade-related sectors such as sustainable fisheries and aquaculture, ocean-based renewable energy, marine bio-prospecting, maritime transport and marine and coastal tourism
Blue Ribbon Panel, 2013	*Indispensable Ocean: Aligning Ocean Health and Human Well-Being*	This report by the Blue Ribbon Panel (composed of 21 global leaders in government, industry, conservation and academia) identifies five high-level principles to guide the selection and prioritisation of initiatives aimed at aligning ocean health and human well-being
UNEP, 2012	*Green Economy in a Blue World: Synthesis Report*	This report analyses how key sectors that are interlinked with the marine and coastal environment can make the transition towards a green economy. It covers the impacts and opportunities linked with shipping and fisheries to tourism, marine-based renewable energies and agriculture
Sector-specific		
UNCTAD, 2019	'Advancing Sustainable Development Goal 14: Sustainable Fish and Sea-food Value Chains, Trade and Climate'	This background note reviews current trends and projections of fish and seafood trade, and recent work undertaken to support implementation of the trade-related activities of SDG 14, with a focus on the work of UNCTAD, FAO and UN Environment
World Bank, 2017	*The Sunken Billions Revisited: Progress and Challenges in Global Marine Fisheries*	This report builds on *The Sunken Billions: The Economic Justification for Fisheries Reform*, a 2009 study published by the World Bank and the Food and Agriculture Organization of the United Nations, but with a deeper regional analysis
Commonwealth Secretariat, 2016	*Capture Fisheries* (Commonwealth Blue Economy Series, no. 3)	This report presents recommendations that could be implemented by small island developing states (SIDS) to protect and sustainably develop their capture fisheries within a blue economy model. The report describes some of the challenges faced in managing capture fisheries, the potential for a blue economy approach to making improvements, some suggestions for strategies and activities that could be undertaken by SIDS to further these aims and a number of case studies illustrating positive actions that have been taken by SIDS and their outcomes

Table 19.7 (continued)

Author	Report	Summary
FAO, 2014	*Global Blue Growth Initiative and Small Island Developing States (SIDS)*	This report identifies fish and fisheries as the mainstay of food security and the wealth of most small island developing states (SIDS). Many SIDS are heavily dependent on their oceanic and coastal fisheries resources for economic growth and development, as well as food security and livelihoods, and are vulnerable to any change in the state of these resources
Aquaculture		
UNGC, 2020	*Seaweed Manifesto*	This report defines a vision for an upscaled, responsible and restorative seaweed industry, playing a globally significant role in food security, climate change mitigation and support of the marine ecosystem, as well as contributing to job creation and poverty alleviation. The Seaweed Manifesto explores the challenges and barriers to responsible development of the industry
TNC, 2019	*Towards a Blue Revolution: Catalyzing Private Investment in Sustainable Aquaculture Production Systems*	This report seeks to articulate the full scale and potential of the aquaculture sector to catalyse investment in projects and companies that can deliver targeted financial returns and improved environmental performance over business-as-usual production
FOA, 2018	'Achieving Blue Growth'	This paper presents the Blue Growth Initiative and the three pillars of sustainable development—social, economic and environmental—that can enable fisheries and aquaculture to contribute to the 2030 Agenda's Sustainable Development Goals. The Blue Growth Initiative is a strategic approach to improving the use of aquatic resources and achieving better social, economic and environmental outcomes
Commonwealth Secretariat, 2016	*Aquaculture* (Commonwealth Blue Economy Series, no. 2)	This volume explores the potential for the development of a blue economy mariculture industry, as well as specific enabling conditions for economic opportunity
FOA, 2015	*Fisheries and Aquaculture in the Context of Blue Economy*	This report looks at the current situation of fisheries and aquaculture in the context of the blue economy or blue growth and its relevance for African coastal countries
World Bank, 2013	*Fish to 2030: Prospects for Fisheries and Aquaculture*	This report presents global prospects for fisheries and aquaculture and analyses future trends out to 2030
Tourism		
IDDRI, 2019	*Sustainable Blue Tourism*	This report explores the ecological impacts of coastal and marine tourism in the Mediterranean, the Caribbean, the Northeast Atlantic, the South Pacific Ocean and the Western Indian Ocean, the major global marine regions, in order to disseminate lessons from the field and develop common policy recommendations for policymakers, tourism stakeholders and other relevant institutional and civil society actors
UNWTO, 2016	*Sustainable Cruise Tourism Development Strategies: Tackling the Challenges in Itinerary Design in South-East Asia*	This report issues a call to action at a critical juncture in Southeast Asian development. It seeks to further awareness of sustainable development in cruise tourism, catalyse collaboration across the region and stimulate the strategic implementation of best practices and innovations
EU Commission, 2016	*Study on Specific Challenges for a Sustainable Development of Coastal and Maritime Tourism in Europe*	This report first presents the findings on specific challenges and innovative response strategies for sustainable development of coastal and maritime tourism, including challenges related to island connectivity (Part A) and innovative practices for marina development (Part B). It then presents findings related to innovative strategies for a more competitive nautical tourism sector, including marina development
UNWTO, 2013	*Sustainable Tourism Governance and Management in Coastal Areas of Africa*	This report presents the results of the research carried out within the framework of the Collaborative Actions for Sustainable Tourism (COAST) project. It builds on Making Tourism More Sustainable: A Guide for Policy Makers, published by the UN World Tourism Organization and UN Environment, assessing how to apply sustainability principles and policy instruments for coastal tourism development in Africa
Shipping		
IRENA, 2019	*Navigating the Way to a Renewable Future: Solutions to Decarbonise Shipping*	This report explores the impact of maritime shipping on CO2 emissions, the structure of the shipping sector and key areas that need to be addressed to reduce the sector's carbon footprint
UK Department of Transportation, 2019	*Reducing the Maritime Sector's Contribution to Climate Change and Air Pollution*	This report provides a framework for assessing current and future economic opportunities in the design, development and commercialisation of technologies and low-emission fuels to reduce UK shipping emissions

Table 19.7 (continued)

Author	Report	Summary
EU Commission, Directorate-General for Mobility and Transport, 2017	*Study on Differentiated Port Infrastructure Charges to Promote Environmentally Friendly Maritime Transport Activities and Sustainable Transportation*	This study assesses existing schemes for differentiating port infrastructure charges according to environmental or sustainability criteria
Sustainable Shipping Initiative, 2016	*Progress to 2015: A Future for Sustainable Shipping*	This progress report details the efforts and key achievements of SSI members to drive debate on and inspire change within the shipping sector
WWF, 2011	*Global Sustainable Shipping Initiatives: Audit and Overview 2011*	This report updates research conducted in 2004 and highlights the fundamental changes to sustainable shipping initiatives since then. It identifies drivers of these changes and shifts in opinion regarding the best methods of delivering global, sustainable shipping
Coastal ecosystems		
OECD, 2019	*Responding to Rising Seas*	This report reviews how countries in the Organisation for Economic Co-operation and Development can use their national adaptation planning processes to meet the challenge of rising sea levels. Specifically, the report examines how countries approach shared costs and responsibilities for coastal risk management and how this encourages or hinders risk-reduction behaviour by households, businesses and different levels of government
World Bank Group, 2016	'Managing Coasts with Natural Solutions: Guidelines for Measuring and Valuing the Coastal Protection Services of Mangroves and Coral Reef'	This guidance note offers recommendations for how to measure and value the protective services of mangroves and coral reefs to support planning for development, disaster risk and coastal zone management
Center for American Progress and Oxfam America, 2014	*The Economic Case for Restoring Coastal Ecosystems*	This report explores the economic contributions provided by healthy, restored coastal ecosystems such as wetlands, seagrass beds and oyster reefs. An analysis of three federally funded projects reveals that well-designed coastal restoration can be highly cost-effective, returning significantly more than the cost of the restoration project
Blue finance reports		
UNGC, 2020	'Blue Bonds: Reference Paper for Investments Accelerating Sustainable Ocean Business'	This paper outlines the opportunities for the environmental, social and governance bond market to secure capital for ocean-related projects and companies that have made, or are planning to make, significant contributions to the Sustain- able Development Goals
Friends of Ocean Action, 2020	*The Ocean Finance Handbook*	This handbook provides an up-to-date overview of the investment landscape in the blue economy. It seeks to formulate a common understanding of sustainable blue economy financing for all stakeholders
Credit Suisse, 2020	*Investors and the Blue Economy*	This study assesses investor perspectives on the ocean, bringing together views on and awareness of the sustainable blue economy among asset owners and managers worldwide
IIED, 2019	'Navigating Ocean Investments'	This briefing considers a business model that could bridge the marine conservation funding gap
Wildlife Conservation Society and Conservation Finance Alliance, 2018	*Finance Tools for Coral Reef Conservation: A Guide*	This working guide to financial tools available for coral reef conservation highlights 13 of the most compelling finance mechanisms

Ocean Solutions That Benefit People, Nature and the Economy

20

Martin R. Stuchtey, Adrien Vincent, Andreas Merkl, Maximilian Bucher, Peter M. Haugan, Jane Lubchenco, and Mari Elka Pangestu

1 How to Use This Report

This report can be read like a book, 'cover to cover'—the reader will follow a narrative arc which balances hope and concern, present and future states, concrete examples and more abstract ideas.

However, it is more probable that this report will be used like a readily accessible compendium of the latest scientific insights, frameworks and ideas that allow readers to find specific facts, messages or concepts and dive deeper on selected sections of the report.

This report aims at answering three core questions:

- **WHY**: Why do we need a sustainable ocean economy and why now? (Sect. 4)
- **WHAT**: What would a sustainable ocean economy look like? What would be the main economic components and the interlinkages between them? What would be the benefits to expect for the economy, the people and the planet? (Sect. 5)
- **HOW**: How should such a complex socioeconomic transition be apprehended? How should a 10-year transformation agenda be structured? How should we get started? (Sect. 6)

Readers looking for arguments about the need for a sustainable ocean economy and reasons for hope about the possibility of one should read the Prologue and Sect. 4.

Readers who want to understand what a sustainable ocean could look like in 2050, and the expected associated benefits, should read Sect. 5.

Ocean practitioners already familiar with the concept of a sustainable ocean economy are invited to go straight to Sect. 6 to discover a fresh and practical approach to guide the transition to a sustainable ocean economy. In particular, Sect. 6.3 presents an 'ocean action agenda' that could be used as a handbook to help decision-makers structure their sustainable ocean economy program, be it at a state or a company level.

This handbook identifies a number of key actions for each area of focus, covering both cross-cutting enablers and ocean-based sectors. Finally, Sect. 6.4 suggests some very concrete ideas that could be implemented immediately to start or accelerate the implementation of the more holistic, 10-year, ocean action agenda.

2 Executive Summary: The New Ocean Narrative

Billions of people have personal connections to the ocean. For many people living in coastal communities, the ocean is not only a source of food and livelihoods, it is an intrinsic part of their culture and heritage. For the millions of people who earn their living from the ocean, it is a source of income and a way of life. For the 40% of the world's population that live within 150 km of the coast and the hundreds of millions of others who visit it, the ocean is central to their lives.[1] The ocean plays an essential and usually unrecognised role in the daily lives of all of the planet's inhabitants. Indeed, breathing itself would be impossible without the ocean, which produces half of the earth's oxygen.[2]

The ocean is also an enormous economic asset. Around 90% of the world's goods are traded across the ocean.[3] Hundreds of millions of people work in fishing and mariculture, shipping and ports, tourism, offshore energy, pharmaceuticals and cosmetics—all of which rely on resources a healthy ocean can offer the ocean.[4] By some estimates, the ocean economy directly contributes more than $1.5 trillion a year to the global economy.[5]

Putting a resource this critical at risk is reckless. But the world has not handled the ocean with care. Poor management has damaged many of the ocean's assets and reduced the ocean's natural ability to restore itself. Ocean health is on a downward spiral, preventing humanity from reaping the riches a healthy ocean could produce and jeopardising the future. The ocean is becoming warmer, more acidic, stormier, higher, more oxygen-depleted, less predictable and less resilient—and neither the problems it is facing nor the wealth it yields are distributed equitably.

Climate change is disproportionately affecting vulnerable and marginalised people, many of whom depend on the ocean for nutrition, identity and income. As they battle a warming ocean and rising sea level, they increasingly face depleted and shifting fish stocks without the ability to change gear or travel further to fish or seek other sources of livelihood.

For years, the overarching view was that the ocean is so vast that it is simply too big to fail. The folly of this approach is now evident. The new dominant narrative is that the problems are so complex that the ocean is simply too big to fix. This view is also incorrect. The ocean's problems are real, but action is already taking place to solve them.

A new way of thinking has immense potential to open the door to a sustainable ocean economy. This approach abandons the false choice between economic development and environmental protection. In contrast to a 'conservation philosophy' of minimising destruction or an 'extractive approach' of maximising the resources that can be extracted from the ocean, the new approach seeks to achieve the integration of the 'three Ps' of effective protection, sustainable production and equitable prosperity. This approach does not mean just leaving the ocean alone; it means proactively managing human activities to use the ocean wisely rather than using it up, in order to help build a much richer future in which people have more wealth and better health, nature thrives and resources are distributed more equitably.

Realising the new vision requires an integrated, rather than a sectoral, approach that is based on five building blocks:

- Using science and data to drive decision-making
- Engaging in goal-oriented ocean planning
- De-risking finance and using innovation to mobilise investment
- Stopping land-based pollution
- Changing ocean accounting so that it reflects the true value of the ocean

Putting these building blocks in place would enable change across the entire ocean economy, not just in specific sectors or locations. Over time, sustainable ocean management could help the ocean produce as much as 6 times more food and generate 40 times more renewable energy than it currently does,[6] contribute one-fifth of the reductions in greenhouse gas emissions needed to keep the world within the 1.5 °C temperature rise limit set by the Paris Agreement goals by 2050,[7] help lift millions of people out of poverty, improve equity and gender balance, increase economic and environmental resilience, build the industries of the future and provide low-carbon fuel and feed for activities on land.

Investments in a sustainable ocean economy are not just good for the ocean. They represent an excellent business proposition. Investing $2.8 trillion today in just four ocean-based solutions—offshore wind production, sustainable ocean-based food production, decarbonisation of international shipping, and conservation and restoration of mangroves—would yield a net benefit of $15.5 trillion by 2050, a benefit-cost ratio of more than 5:1.[8]

The ocean is so vast, and its role in the global economy and the lives of the world's people so fundamental, that it can be difficult to know where to start in creating a sustainable ocean economy. Fortunately, pragmatic solutions are already being implemented, albeit not at the scale needed. These

efforts could jump-start progress on a much larger scale, putting the world on a trajectory that would vastly increase prosperity in the coming decade and the longer term. These approaches embrace a philosophy in which stakeholders—including direct users of the ocean (fishers, shippers, energy producers and beach lovers, among others) as well as policymakers, governments, businesses and others—accept the new paradigm and work together to achieve the same goal of a healthy, productive ocean.

Some of the most promising efforts include empowering communities and modifying incentives to align economic and conservation outcomes. In the Philippines, for example, a network has been created that grants fishing communities clear, exclusive rights to fish in certain areas. In communities that organised to manage 'their' fishing areas and protected zones, boats and fishers are registered, the catch is recorded, regulations are respected and fishers participate in management. By embracing sustainability, participating communities increased their food and financial security and gained access to new markets and sources of capital—improving their own well-being while protecting the ocean. Complementary global trends are also emerging. Open data networks are making it easier to track and detect illegal fishing vessels. Governments are starting to tackle plastic pollution, and financiers are starting to recognise the value of investing in the ocean.

Practical solutions that can be implemented at a modest scale as well as high-level actions could create a sustainable ocean economy, underpinned by the three Ps of effective protection, sustainable production and equitable prosperity. Implementing them requires political will at all levels, including the very top.

The ocean is not too big to fail, and it is not too big to fix. But it is too big to ignore. The more we learn about the ocean, the more we see that it is central to improving the health, wealth and well-being of people. It holds the answers to the most pressing challenges facing humanity, including climate change and food security. It is time to shift away from thinking of the ocean as a victim toward seeing it as an essential part of the solution to global challenges. New partnerships need to be forged that will take action now to achieve a sustainable ocean and a sustainable future. The choice is not between ocean protection and production. Together they can help build a healthy and prosperous future.

2.1 The Health, Wealth and Well-Being of the World and Its People Depend on the Ocean

Maintaining a healthy ocean is vital to improving global health and increasing global prosperity for everyone; expanding opportunities for all people, including women and marginalised groups; and making the world a better place to live for all, even people living far from the ocean. A sustainable ocean economy is obviously important for the traditional ocean sectors, such as fisheries and shipping. But its value goes well beyond the lives of people whose income comes directly from the sea. Because of the interconnectedness of the global economy, what happens in the ocean affects not only fishers in Fiji but also farmers in Zimbabwe, whose imported tools may have travelled to Africa in a container ship and whose air quality and climate are affected by what happens in the ocean.

The ocean provides a wide variety of vital benefits, many of which are often overlooked:

- **It helps make the planet liveable and is critical to managing the effects of climate change.** The ocean produces half of the planet's oxygen, absorbs 93% of the world's anthropogenic heat and moderates the earth's temperature by reducing the heat differential between the poles and the Equator.[9] Without the ocean's regulation of the earth's climate, much more carbon dioxide would be trapped in the atmosphere, exacerbating global climate change.[10]
- **The global economy and the livelihoods of hundreds of millions of people depend on the ocean.** The modern global economy could not exist without the ocean. Around 90% of all internationally traded goods travel by ship.[11] The ocean economy directly contributes an estimated $1.5 trillion to the global economy.[12] The ocean food sector alone provides up to 237 million jobs, including in fishing, mariculture and processing.[13] Millions of people also work in other ocean sectors, including shipping, ports, energy and tourism—and many more are indirectly connected to the ocean economy.
- **The ocean provides billions of people with nutritious food, with a much smaller environmental footprint than land-based food production.** More than three billion people rely on food from the sea as a source of pro-

tein and key nutrients, including omega-3 fatty acids and iodine.[14]

- **Coastal habitats, such as mangroves, provide protection for hundreds of millions of people, nurture biodiversity, detoxify pollutants flowing off the land, and provide nursery areas for fisheries, increasing the supply of food and providing livelihoods.** They are also a source of revenue. Coral reefs alone contribute $11.5 billion a year to global tourism, benefitting more than 100 countries and providing food and livelihoods to local people.[15]
- **The ocean provides a sense of wonder, solace and connection to the natural world and is deeply woven into the cultural and spiritual lives of billions of coastal dwellers**. It also gives pleasure to the hundreds of millions of people a year who visit it.[16]
- **The ocean may store unknown treasures**. In addition to its known benefits, it may be the home of undiscovered resources—including medical ones—and new knowledge.

2.2 Its Potential Is Enormous, But the Ocean Is in Trouble

Human stressors affect virtually the entire ocean, making it more difficult for the ocean to sustain human life on earth. Climate change, overfishing, habitat destruction, biodiversity loss, excessive nutrient loads, pollution and other problems are damaging the ocean's health.

- **Climate change and greenhouse gas emissions are having multiple effects on the ocean**. The ocean is becoming warmer and more acidic, putting pressure on plants and animals from the base of the ocean food web to the top. Ocean warming affects circulation, stratification, oxygen content and sea level. By 2100, as many as 630 million people could be at risk of coastal flooding caused by climate change.[17] Sea level rise also affects agriculture, by submerging land, salinising soil and groundwater, and eroding coasts. It will also erode and submerge tourism infrastructure and beaches. In the Caribbean, for example, sea level rise of 1 m is projected to endanger up to 60% of resorts, damage or cause the loss of 21 airports and severely flood 35 ports.[18] Rebuilding the region's resorts alone is projected to cost the Caribbean $10–$23 billion in 2050.[19]
- **Habitats are being destroyed, biodiversity is declining and the distribution of species is changing—all of which reduce the benefits that ocean ecosystems provide**. Coastal habitats are disappearing at an alarming rate. Global mangrove cover declined by 25–35% between 1980 and 2000, largely as a result of land development and conversion to unsustainable mariculture ponds and rice paddies.[20] The loss of coastal habitats and coral reefs is eroding natural coastal protection, exposing 100–300 million people living within coastal 100-year flood zones to increased risk of floods and hurricanes.[21]

[21] Díaz et al. 2019. "Summary for Policymakers of the Global Assessment Report on Biodiversity and Ecosystem Services of the Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services."

Coral reefs—virtually all of which will be lost at 2 °C warming—are declining rapidly as a result of compounding pressures from rising ocean temperatures, overfishing and nutrient pollution.[22] The biodiversity of the open ocean declined by up to 50% over the past 50 years,[23] and the relative abundance of different species has shifted in favour of species that are more tolerant of low-oxygen conditions, such as microbes, jellyfish and some squid.[24]

- **Plastic, other land-based pollutants and discharge from ships contaminate the ocean**. Because of the common belief that 'the solution to pollution is dilution', the ocean has long been used as a repository for sewage, nutrient run-offs, heavy metals, nuclear waste, persistent toxicants, pharmaceuticals, personal care products and other noxious items. More than 80% of all marine pollution originates on land.[25] Millions of metric tonnes of plastic are dumped into the ocean every year, entangling, sickening and contaminating at least 700 species of marine life.[26] Untreated ballast water from ships is discharged into foreign ports, creating one of the principal vectors of potentially invasive alien species.[27]
- **Overfishing is depleting fish stocks and harming wildlife**. The 'tragedy of the ocean commons' open access that characterises fishing in many parts of the ocean means that too many boats pursue too few fish, at the expense of overall system health and productivity. Exacerbated by subsidies that increase the capacity of the fishing fleet and by illegal, unreported and unregulated (IUU) fishing, fishing has become the number one driver of extinction risk for marine vertebrates (excluding birds).[28] If overfishing continues, annual yield is projected to fall by over 16% by 2050, threatening global food security.[29]

A single stressor, such as overfishing or pollution, can do considerable damage. Worse still, individual stressors locally compound one another, with enormous consequences for ecosystems. Without action, these problems could cost the global economy more than $400 billion a year by 2050. By 2100, the annual cost could reach $2 trillion.[30]

Neglect and abuse of the ocean and the effects of global climate change will make life worse for everyone. But historically underrepresented and underserved communities—including women—will bear a disproportionately large share of the burden. These groups are most vulnerable to food insecurity, loss of livelihoods and sea level rise. They are also the most likely to suffer from the many crimes and human rights violations that take place on the ocean, including human trafficking and smuggling, slave labour and peonage (debt slavery) systems.

2.3 A New Relationship with the Ocean Is Needed: One That Creates a Healthy Ocean and a Sustainable Ocean Economy

In contrast to a conservation philosophy of minimising destruction and an extractive approach that focuses on exploiting the ocean to create wealth, a sustainable ocean economy brings diverse stakeholders together to achieve common goals—the three Ps of effective protection, sustainable production and equitable prosperity. In this new paradigm, groups work together by adopting integrated and balanced management of the ocean in which each of the three Ps contributes to the others. Sustainable production based on regenerative practices (such as climate-ready, ecosystem-based fisheries management or seaweed farming) along with fully protected areas, for example, can help

restore ocean health. The result is a triple win for nature, people and the economy and a world where prosperity is greater and more equitably distributed than it is today (Fig. 20.1).

2.3.1 Protect Effectively

Protecting the ocean doesn't mean just leaving it alone—it means managing human activity wisely, in order to preserve biodiversity and critical habitats, allow the ocean to sustain-

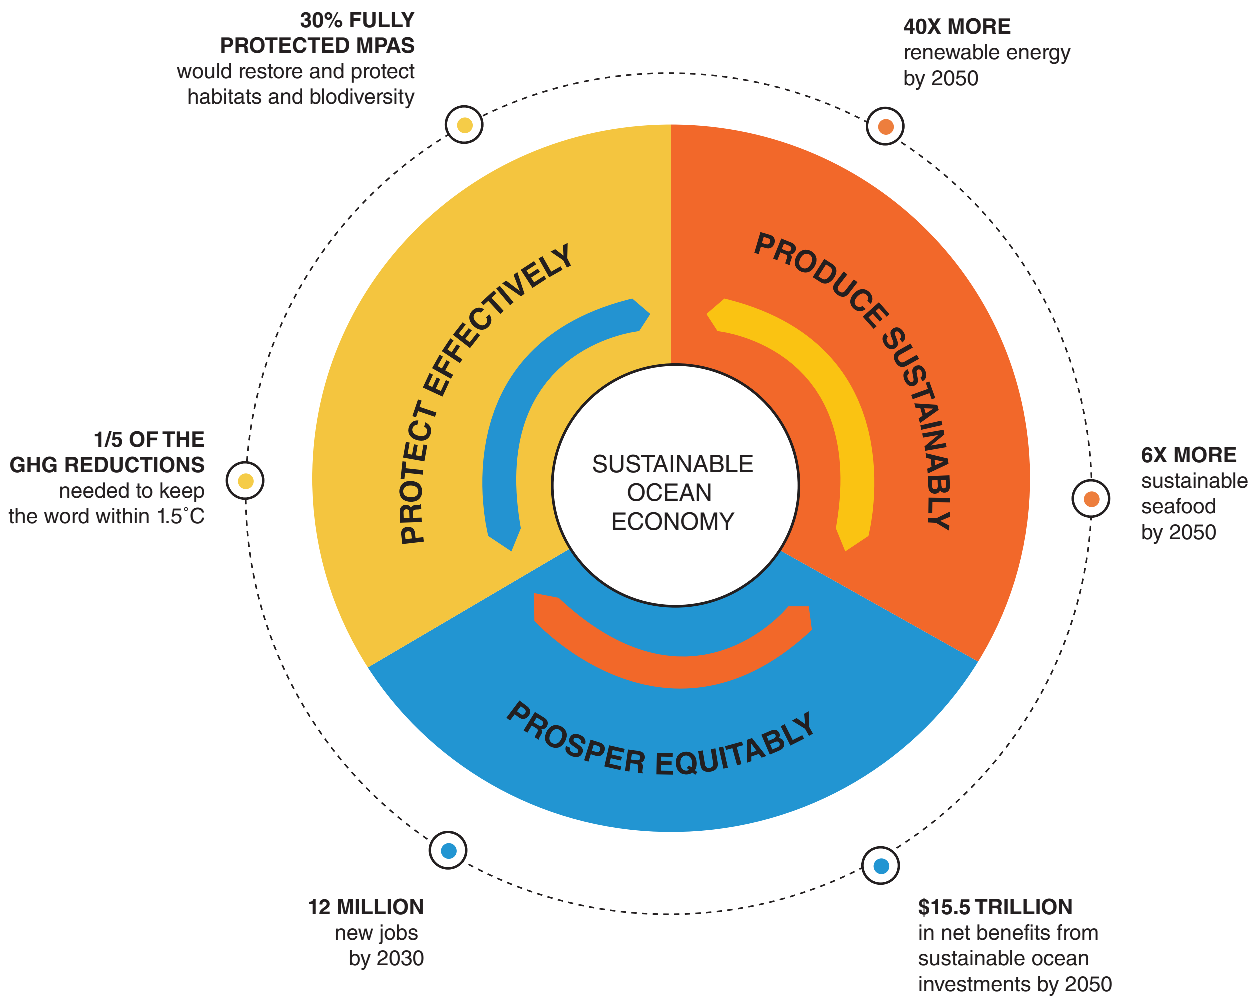

Fig. 20.1 A sustainable ocean economy can create a triple win for people, nature and the economy. *Note: MPAs: Marine protected areas. GHG: Greenhouse gas emissions*. ably yield greater benefits and preserve the ocean's cultural and spiritual value. In some areas, significantly scaling back or prohibiting human activities will be necessary to allow ecosystems to recover and regenerate. In most areas, sustainable practices will be needed that both allow the ocean to produce and maintain ocean health.

Far from holding back production, restoring and maintaining the ocean's health represents the best way to generate ocean-based wealth and make the most of the ocean's unique resources. This new way of thinking is also marked by a shift from incremental improvement to ecosystem-based integrated management and from a narrow focus on gross domestic product (GDP) alone to one that takes account of both the monetary and nonmonetary benefits and assets of the ocean.

A Sustainable Ocean Economy Would Help Protect the Ocean by Reducing the Carbon Dioxide Emissions That Are Threatening It

Ocean-based activities could provide one-fifth of the carbon mitigation needed to meet the Paris Agreement goals by 2050, reducing global greenhouse gas emissions by up to 4 billion tonnes of carbon dioxide equivalent in 2030 and up to 11 billion tonnes in 2050, according to research commissioned by the Ocean Panel.[31] Emission reductions of this magnitude are equivalent to the annual emissions from 2.5 billion cars or all of the world's coal-fired power plants.

Protecting Coastal Habitats and the Ocean's Biodiversity Would Help the Ocean Continue to Provide the Ecosystem Services Humanity Depends on

A restored and protected ocean would help mitigate the impact of storm and sea level rise, saving lives and livelihoods, and would reduce economic costs of damage and recovery. Healthy coral reefs, for example, reduce wave energy by up to 97%, potentially protecting up to 100 million coastal inhabitants from storm risks.[32] By reducing wave heights, mangroves reduce flooding of coastal areas and contribute to biodiversity. Marine protected areas (MPAs) that are fully protected from extractive and destructive activities can rebuild and safeguard biodiversity, mitigate climate change (by preventing emissions from the disturbance of sediment carbon by bottom trawling) and boost the productivity of fisheries in areas surrounding MPAs through the spillover of fish.[33]

Protecting the Ocean from Pollution Could Catalyse Deeper Reform of Contaminating, Wasteful Material Management Practices on Land

The problem of ocean pollution starts on land. Plastic—along with numerous other pollutants, including pharmaceuticals and excess nutrients—enters the ocean because systems for their proper disposal on land are inadequate. The most effective way of stopping pollutants from entering the ocean is to tackle the root causes of pollution on land. Shifting to a 'circular economy'—a system in which resources are designed to be used continually and at their highest possible value added and recovered or regenerated as efficiently as possible at the end of their service—would yield enormous benefits for the ocean economy. Agricultural regulations aimed at reducing ocean dead zones could result in farmers adopting precision agriculture practices to reduce runoff, which would also improve the health of the soil and the quality of water in rivers and streams.

2.3.2 Produce Sustainably

When the ocean is managed effectively, it can produce more and its production can be more sustainable. A shift to a sustainable ocean economy would increase food and energy production without putting extra pressure on marine ecosystems.

The Volume of Food Production from the Ocean Could Soar, Helping Increase Food Security for Almost Ten Billion People in 2050

The ocean's ability to sustainably produce food is vastly under-realised. Managed better and sustainably, the ocean could produce up to six times more food than it does today—and it could do so with a low environmental footprint.[34]

Most fishing today is not economically or ecologically optimised. Too many boats pursue too few fish in ways that are short-sighted and destructive. Too much seafood value is lost to poor handling. Too many non-target species are accidentally caught. If this approach continues, the yield in 2050 is expected to be around 16% lower than it is today.[35] In contrast, if all stocks currently exploited were fished at the maximum sustainable economic yield, production could increase

[35] Costello et al. 2019. "The Future of Food from the Sea."

by 20% over current production levels and by 40% over the catch forecast under a business-as-usual scenario.[36]

The mariculture story is even more promising. The potential to expand finfish mariculture is significant if farms avoid adversely affecting surrounding ecosystems and use fish feed that is not made from wild caught fish. Unfed mariculture also holds great promise. Bivalves (such as oysters and mussels) and seaweed can substantially increase the production of nutritious food and feed, with little negative impact on the marine environment. In some cases, this kind of mariculture could actually enhance wild fisheries by creating artificial habitats and nursery grounds for fish.

About 35% of fish and seafood is currently wasted in the value chain. Reducing this wastage could boost consumption without increasing production.[37]

The Ocean Can Provide a Virtually Limitless Supply of Clean, Renewable Energy

Offshore wind turbines could generate 23 times more power than the present total global electricity consumption.[38] Other potential sources of ocean-based renewable energy—producing energy from waves and tides, salinity and temperature gradients, and floating solar photovoltaic panels, for example—are still in their infancy but hold promise.

Investments in the Ocean Are Highly Cost-Effective

Investment of $2.8 trillion today in four sustainable ocean-based solutions—conservation and restoration of mangroves, decarbonisation of international shipping, sustainable ocean-based food production and offshore wind production—would yield net benefits of $15.5 trillion by 2050.[39] All four interventions have high benefit-cost ratios (Fig. 20.2).

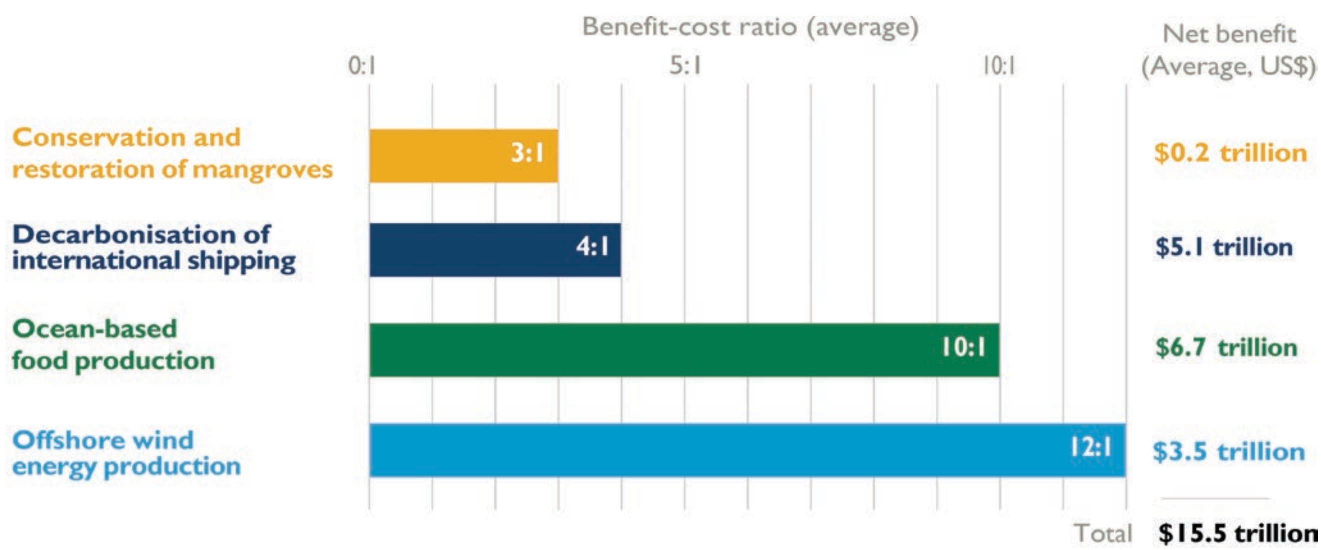

Fig. 20.2 Sustainable ocean-based interventions have very high benefit–cost ratios and could yield trillions of dollars of benefits. *Note: Average benefit-cost (B-C) ratios have been rounded to the nearest integer and the net benefits value to the first decimal place. The B-C ratio for mangroves is the combined ratio for both conservation- and restoration-based interventions. The average net benefits represent the average net present value for investments and are calculated over a 30-year horizon (2020–2050).* (*Source: Konar, M., and H. Ding. 2020. 2.3.3 Prosper Equitably

Left unmanaged, a growing ocean economy could exacerbate economic inequality, as strong, elite incumbents capture the benefits of the ocean while vulnerable and marginalised groups become increasingly exposed to economic, social and cultural impacts, including displacement.

Inequality is a structural feature of the current ocean economy. Women, for example, represent just 2% of the world's formal maritime workers.[40] Poor, vulnerable and marginal communities are bearing—and will continue to bear—the worst effects of global climate change. A sustainable ocean economy would not only create greater wealth, it would also create a world in which resources are distributed more evenly and where all ocean users have an opportunity to have a voice in critical decisions.

A Sustainable Ocean Economy Would Create New and Better Jobs

By some estimates, it could create 12 million net jobs.[41] Some sectors, particularly fisheries, will need to shed jobs. Support schemes will be needed to manage the transition to lower capacity and more sustainable management of fish stocks.

Other sectors will grow significantly. Thousands of new jobs will be created in engineering, information technology, applied science and related areas. The number of jobs in mariculture and offshore wind is projected to soar, and the increase in seaborne cargo volume and the expansion of ports are expected to create millions of jobs. Decarbonising shipping will be critical to ensure that this expansion does not come at the cost of the ocean's health.

The New Agenda Would Empower Local Fishers

The yields of millions of artisanal fishers are far lower than they used to be, partly because of the open-access model of much of the ocean, which has resulted in overfishing. A better-managed approach would benefit many of them.

Empowering fishers by granting them access rights in exchange for sustainably managing their resource is one of the levers of the sustainable ocean economy. Doing so has already proven effective. In the territorial use rights fisheries (TURFs) that Chile created, for example, catches by artisanal fisheries have surpassed industrial catches, and the biomass and size of the target species has risen.[42] Similar approaches have met with great success in many fisheries, recovering depleted fisheries and enabling them to thrive.[43]

International Collaboration and Transparent Supply Chains Could Significantly Reduce Maritime Crime

IUU fishing is estimated to account for 20% of the world's catch (up to 50% in some areas).[44] Illegal fishing is also often an indicator of other types of crime at sea, including labour and human rights violations, money laundering and tax fraud.

Acting Sustainably Would Help Preserve the Cultural Importance of the Ocean

The ocean is more than just a source of economic wealth. It also has spiritual, cultural and recreational value to billions of people.[45] For many Indigenous peoples, it is a key aspect of their culture. Well-designed marine protected areas and other effective area-based conservation measures can help preserve pristine ocean areas and culturally important ocean areas (such as sacred sites, historic wrecks and sea graves).

2.3.4 The Ocean Should Be a Key Part of the Massive Global Economic Recovery from the COVID-19 Contraction

COVID-19 has temporarily halted economic activity in the ocean economy, causing significant income and revenue losses to tourism, fisheries and mariculture, and shipping; adversely affecting the ocean's health; and exacerbating gender and income inequalities. The disruptions have led to cascading and interrelated impacts. The decline in tourism, for example, forced some communities to turn back to unsustainable fishing as a food source, putting pressure on coastal fisheries and reefs.

A key objective of the massive recovery from the COVID contraction will be to restore economic activity without simply restoring old patterns of environmental degradation, instead creating a more sustainable and more resilient future. The ocean economy can play a critical role in this process. Investment in five areas—coastal and marine ecosystem restoration and protection, sewage and waste infrastructure, sustainable unfed mariculture, zero-emission marine transport and sustainable ocean-based renewable energy—could create jobs and spur economic growth in the immediate term.[46]

Investments made over the coming months and years will have long-term effects on the nature of the world's economies and their resilience to shocks. Efforts must be made now to avoid locking in high-emitting, high-polluting and inequitable pathways and locking out regenerative and sustainable futures. The opportunity to reset and rebuild a stronger, more equitable, more resilient and sustainable ocean economy should not be missed.

2.4 The Challenges Are Great, But a Pragmatic Action Agenda Offers Solutions to Meet Them

A world in which effective protection, sustainable production and equitable prosperity go hand in hand is possible. But it will not happen if business as usual continues. Without action, ocean planning will continue to be largely ad hoc, fish stocks will continue to decline and land-based polluters will continue to use the ocean as a liquid dump.

Political and business decisions made now and over the next 30 years could change this trajectory. With action, more systematic, ecosystem-based, inclusive spatial planning would become the norm. Access rights for specific ocean resources would be clarified, eliminating conflicts over resources and ensuring that the wealth of the ocean is equitably distributed. Wild fish stocks would recover, and significant increases in sustainable mariculture would provide nutritious food for billions of people, ensuring food security. Polluters would be subject to legal and political actions that would limit their ability to pollute the ocean.

2.4.1 Maintaining a Healthy Ocean Will Require Action on Many Fronts and Across Multiple Sectors

Delivering effective protection, sustainable production and equitable prosperity is an inspiring and feasible vision that is backed by science. The transition to a sustainable ocean economy will require a realignment of incentives, in-depth reforms of how the ocean is used and managed, and the empowerment of ocean users who are vested in enhancing ocean health.

Governments and businesses can take hundreds of sector-specific actions to improve ocean sectors, from supporting ocean-based renewable energy to create jobs in the wake of the COVID-19 contraction to supporting ecotourism and banning pollutants. These efforts are important, but without getting the fundamentals right, it will not be possible to transform the entire ocean system towards the desired sustainable model. Five building blocks can set the foundation for a sustainable ocean economy (Fig. 20.3). These building blocks put the conditions in place for wider change across various ocean sectors. With these foundations in place, sector-specific reforms, innovations and research can be implemented and accelerated.

Using Data to Drive Decision-Making

Technologies for sensing, simulating, forecasting, tracking, managing and sharing data on open-access platforms have the potential to transform the ocean economy. New technologies can be used to register ocean-related rights and contracts, facilitating rights-based management.[47] Product tracking throughout the supply chain can help brands embrace sustainable practices and small producers connect to global supply chains. Applications can help manage fishing areas and quotas, adjust shipping traffic and avoid endangered species bycatch. In the near future, every ship's journey—and the nature of its business at sea—will be public information. Lawbreakers such as illegal fishers, polluters, smugglers and labour law violators will literally be on the public radar and subject to arrest.

Some of these technologies are already being used on a limited scale. The POSEIDON model, for example, simulates the feedback loop between fishery policies, fishing fleets and ocean ecosystems, allowing policy alternatives to be compared.[48]

But barriers stand in the way of fully harnessing the power of science and data. Collecting data is very expensive, with most sensors custom-built for narrow and specific scientific

Fig. 20.3 Five building blocks are key to creating a sustainable ocean economy. (*Source: Authors*)

missions.[49] Technological innovation in the ocean has therefore been driven largely by governments and large-scale commercial interests.

Data are fragmented into national, corporate and academic domains. Access to data is limited, and data can be difficult to use. Tools designed for marine managers, for example, are often so technical that only programmers are able to use them. Poorer countries and ocean users have little or no access to data that could help them adopt sustainable practices.

Key Actions

Overcoming these and other barriers requires the creation of global data networks that provide broad and automated access to ocean data. Governments can lead the way by mandating these standards and helping create data networks that aggregate decentralised data into a common, searchable database. They can require that data sharing be a non-negotiable condition of access to public resources—whether the resources are fish stocks and mineral deposits or funds for coastal management or for research. To achieve or improve accountability, governments can prioritise technology-forcing regulations governing the real-time monitoring of fishing, seafood imports, shipping emissions, mining, coastal development and pollution.

Engaging in Goal-Oriented Ocean Planning

The sector-by-sector assortment of regulations for some ocean activities, coupled with an open-access model for others has contributed significantly to today's decline in ocean health and cannot continue. The shortcomings of the system are evident. Open-access fisheries almost always fail.[50] Uncoordinated ocean development creates operational inefficiencies, conflicts over use and environmental degradation that undermines future productivity. Unrestricted industrial, nutrient and carbon-related pollution is changing the

[49]OECD. 2019. *Rethinking Innovation for a Sustainable Ocean Economy*. Paris: Organisation for Economic Co-operation and Development. doi: https://doi.org/10.1787/9789264311053-en.

ocean's chemistry and affecting its biology and economic potential.

Given the interconnectedness of the ocean's sectors, it does not make sense to manage them separately. Ecosystem-based management, science-based marine spatial planning and integrated ocean management are tools that can be used to facilitate more systematic and equitable management of the ocean's resources and services. Some locales are already using ecosystem-based management tools that are science-based and grounded in broad stakeholder engagement and focus on achieving a healthy and resilient ocean ecosystem—with excellent results. Xiamen, China, for example, has seen a 40% improvement in socioeconomic benefits from its marine sectors since it adopted integrated ocean management in 1994.[51]

A variety of barriers has held back the widespread uptake of goal-oriented planning. Standards and practices for planning, accountability, transparency and legal rights or protections in the ocean remain a century or more behind their land-based equivalents—partly because businesses fear that integrated planning is a way for conservationists to pursue an antibusiness agenda. Top-down planning processes have failed to engage all users, resulting in inefficient processes and a lack of buy-in and implementation.

To be successful, ocean plans must find a balance between the requirements of different ocean users, between the needs of the ocean and the needs of the coast and its people. Growing evidence from countries in which integrated ocean planning has been used shows how the agendas of ecosystem health, food and energy security, local prosperity and coastal protection can reinforce one another. Scientific and local knowledge are key to understanding co-benefits and navigating the trade-offs.

Ocean planning needs to provide inclusive, equitable access by and recognition of local communities. Local fishers must have access to traditional fishing grounds, cultural sites must be protected and viewsheds must be preserved. Representatives of all types of ocean users must be involved in planning. Resource owners, lessees and access holders must be given secure titling and reliable and effective legal recourse against polluters, trespassers and other violators.

Key Actions

To ensure that goal-orientated planning becomes a reality, countries should establish, fund and implement ocean plans for 100% of the areas under their jurisdiction, using a process that is science-based, inclusive, participatory and adapted to the local context. Doing so is crucial to balancing protection and production and ensuring equitable access and rights for local users.

De-risking Finance and Using Innovation to Mobilise Investment

Current investment in sustainable ocean industries, biodiversity and conservation is grossly inadequate. It needs to quadruple to restore and sustainably maintain ocean health.[52]

Investment is limited for a variety of reasons. The fact that externalities such as the effects of ocean sector activities on global climate change, pollution and human rights are not reflected in the prices producers receive means that ecologically unsustainable businesses can thrive. Harmful subsidies—typically supporting the expansion of large-scale industrial fishing fleets and fossil-fuel extraction—distort the ocean economy.

In some cases, investing in sustainability is a long-term proposition. Rebuilding fish stocks and fishing sustainably can make business sense in the long run, for example, but can be costly in the short to medium run. As a result, opportunities are missed. Governments could help solve the problem by providing resources to mitigate transition challenges—by, for example, repurposing subsidies and implementing fishery reforms that prevent overfishing and help ensure a strong return on investment.

Key Actions

Countries that establish sustainable ocean development as a national priority can hope to attract investment from sovereign wealth funds and development finance institutions. Through their own and other public or philanthropic funding sources, private investment capital can be de-risked, catalysing private investment in novel industries and business models like sustainable fisheries (reforms), or MPAs financed by tourism fees. This bending of public and private capital can be especially catalytic in increasing investments in developing nations. Governments can also help stimulate the pipeline of sustainable ventures and projects by providing grants or other forms of support to early-stage innovation, as Norway has done to support next-generation

[51] Peng, B., H. Hong, X. Xue and D. Jin. 2006. "On the Measurement of Socioeconomic Benefits of Integrated Coastal Management (ICM): Application to Xiamen, China." *Ocean & Coastal Management* 49 (3): 93–109. doi: https://doi.org/10.1016/j.ocecoaman.2006.02.002.

"Investments to Reverse Biodiversity Loss Are Economically Beneficial." *Current Opinion in Environmental Sustainability* 29 (December): 82–88. doi: https://doi.org/10.1016/j.cosust.2018.01.007.

offshore aquaculture and the European Union has done to support offshore wind generation. In the offshore energy sector, governments could support renewable energy by providing low-cost infrastructure, setting feed-in tariffs and providing subsidies for sustainable activities. They could also reduce risk—by ensuring regulatory certainty, providing insurance and providing offtake/demand guarantees, particularly for capital-intensive offshore investments such as wind energy and large-scale mariculture.

Stopping Land-Based Pollution

Virtually every pollutant present on land is also present in the ocean, with compounding and significant deleterious impacts on ecosystem health. Plastics, nutrients (primarily nitrogen and phosphorus), pesticides and parasiticides, antibiotics and other pharmaceuticals, industrial chemicals, oil and gas, heavy metals, toxins, medical waste, e-waste and other types of debris are diverted to the ocean with very few financial consequences for the polluter.

These materials end up in the ocean because waste management and sewerage infrastructure in many countries, especially Asia and Africa, are inadequate. Waste collection is largely unprofitable because few consumer products are recyclable.

Addressing the ocean pollution challenge has been complicated by the difficulties of attribution (many pollutants come from more than one source) and the overwhelming asymmetry of the situation: When heavily protected land-based private interests clash with the interest of a weakly defended common pool resource like the ocean, the ocean loses.

A growing number of governments and industries are taking action. Measures such as banning plastic bags are welcome, but their effect will be insufficient. Current commitments on plastics, for example, are likely to reduce annual plastic leakage into the ocean by only 7% by 2040.[53]

Key Actions

To stop the leakage of plastics into the ocean, a diverse and more ambitious set of solutions is needed that includes reducing unnecessary plastics, recycling materials and safely disposing of waste. Recycled materials must become cheaper than virgin plastic. Companies must be held accountable for how much plastic they use and whether they use recycled content, recyclable product designs and plastic substitutes. Massive investment must be made in waste collection and recycling technology and infrastructure, particularly in developing countries, where such infrastructure is weak. Tackling the underlying cause could also help reduce other pollutants. Adopting precision agriculture on land could help reduce nutrient runoff into the ocean, for example.

Changing Ocean Accounting So That It Reflects the True Value of the Ocean

Traditional measures of the economy, such as GDP, ignore externalities, such as the effect of production on pollution or global climate change. They also fail to place a value on natural resources and ignore the way benefits are distributed.

Measuring only the GDP generated by ocean-based sectors does not capture the true value of the ocean—and can reward unsustainable practices. The ocean's broader value must be fully accounted for and used in decision-making, based on a holistic set of metrics that includes measurements of infrastructure assets, such as ports; natural assets, such as fish populations and coral reefs; and indicators of benefits to people, such as measures of income and well-being.

Key Actions

To measure the value of the ocean more accurately, national statistical offices, in partnership with other agencies, need to develop complete sets of national ocean accounts. Interactive dashboards should be created to allow users to explore the data by aggregating and disaggregating sectors and groups of people.

Having these five building blocks in place will enable change in key ocean economy sectors such as sustainable food from the ocean, renewable energy from the ocean and sustainable tourism. These sectors will also need targeted and sector-specific actions in terms of policies, technology and finance innovation, and scientific research, but having these building blocks in place will set governments and other stakeholders on the right path and lay the groundwork for the achievement of a prosperous and sustainable ocean economy.

2.4.2 This New Way of Thinking About and Managing the Ocean Is Gaining Traction

The ocean is moving up the policy agenda. Coastal countries, especially small island states, are advocating for socially equitable and environmentally sustainable growth. Civil society is increasingly recognising the decline in the ocean and favouring government action to protect the ocean.

The action agenda is ambitious but entirely feasible. Progress in building the foundations for change is already evident:

- The data revolution has begun. Sensors and satellites are increasingly being deployed to monitor the ocean. Data on invasive species in bilge water and nutrients in river deltas, for example, provide actionable information in near real time—the holy grail of adaptive management. Sound fishery management digital tools, including vessel tracking, fishery simulation, and registry and enforcement systems, are widely available.
- Several regions have replaced siloed management practices with more integrated marine spatial planning. For example, the Baltic Sea states have coordinated across borders and sectors to implement a science-based planning strategy and have been rewarded with the return of predators and birds as well as restored fish stocks.[54]
- Sustainable ocean investments are on the rise. In a recent survey, 72% of investors classified the sustainable ocean economy as investable.[55] Thousands of sustainable ocean ventures are emerging across all continents.
- Together, the United States, Europe and Asia adopted 95 policies and pieces of legislation limiting plastic packaging between 2010 and 2019.
- A growing number of countries are adopting more holistic accounting techniques. China, for example, is using gross ecosystem product (GEP) to steer its transition towards inclusive, green growth.[56]

Similar trends can be observed at the ocean sector level. Backed by industry, support is growing for green shipping, the development of new technologies and practices that reduce the impact of mariculture on ecosystems, and community-led programs restoring fish stocks, to name just a few emerging changes. Inspiring success stories, such as the reform of fisheries in the United States, demonstrate that sound ocean management can simultaneously restore fish stocks and benefit fishers and coastal communities.[57] To achieve a sustainable ocean economy, change needs to happen faster and at a bigger scale than is currently happening. Actions at the local and national level can help accelerate change.

2.4.3 Targeted Actions Can Help Accelerate Progress

The huge scale of the challenge and the high stakes involved mean that acting quickly and effectively is crucial. Delivering immediate gains can help demonstrate the long-term benefits of pursuing a sustainable ocean economy, spurring stakeholders to take action. Creating sustainable ocean economic zones and forming national task forces are concrete actions than can move the agenda forward right away.

Sustainable Ocean Economic Zones Can Illustrate the Benefits of a Sustainable Ocean Economy at a Small Scale

Special economic zones (SEZs) are areas within a country that the government sets aside to attract direct investment in particular economic activities. These zones typically offer low rents, taxes, utilities and infrastructure costs; relief from bureaucratic procedures; and loan guarantees to market-rate investors. They range in size from small neighbourhood zones to entire cities.

Taking inspiration from the success of the SEZ concept in a country's exclusive economic zone (the ocean zone over which a coastal state has special rights with respect to marine resources) could be a powerful catalyst for accelerating a sustainable ocean economy. Sustainable ocean economic zones (SOEZs) could provide a test bed for systemic experimentation and innovation, where incentives could be tested, results monitored and adapted to, and risks managed. In the process of designing and implementing these zones, the classic hurdles to ocean management—free access, lack of planning, conflicts over use and externalities—can be addressed in the context of real business, rather than as abstract policy.

SOEZs are a way for countries to support and evaluate the sustainable ocean economy model at a scale they are comfortable with. Biological conditions, existing industries and stakeholders, and local needs determine which activities take place in an SOEZ (Fig. 20.4). One locale might use a SOEZ to attract and test high-technology models combining energy

[57]Natural Resources Defense Council, Conservation Law Foundation, Earthjustice, Ocean Conservancy, Oceana and Pew Charitable Trusts. 2018. "How the Magnuson-Stevens Act Is Helping Rebuild U.S. Fisheries." https://www.nrdc.org/sites/default/files/magnuson-stevens-act-rebuild-us-fisheries-fs.pdf.

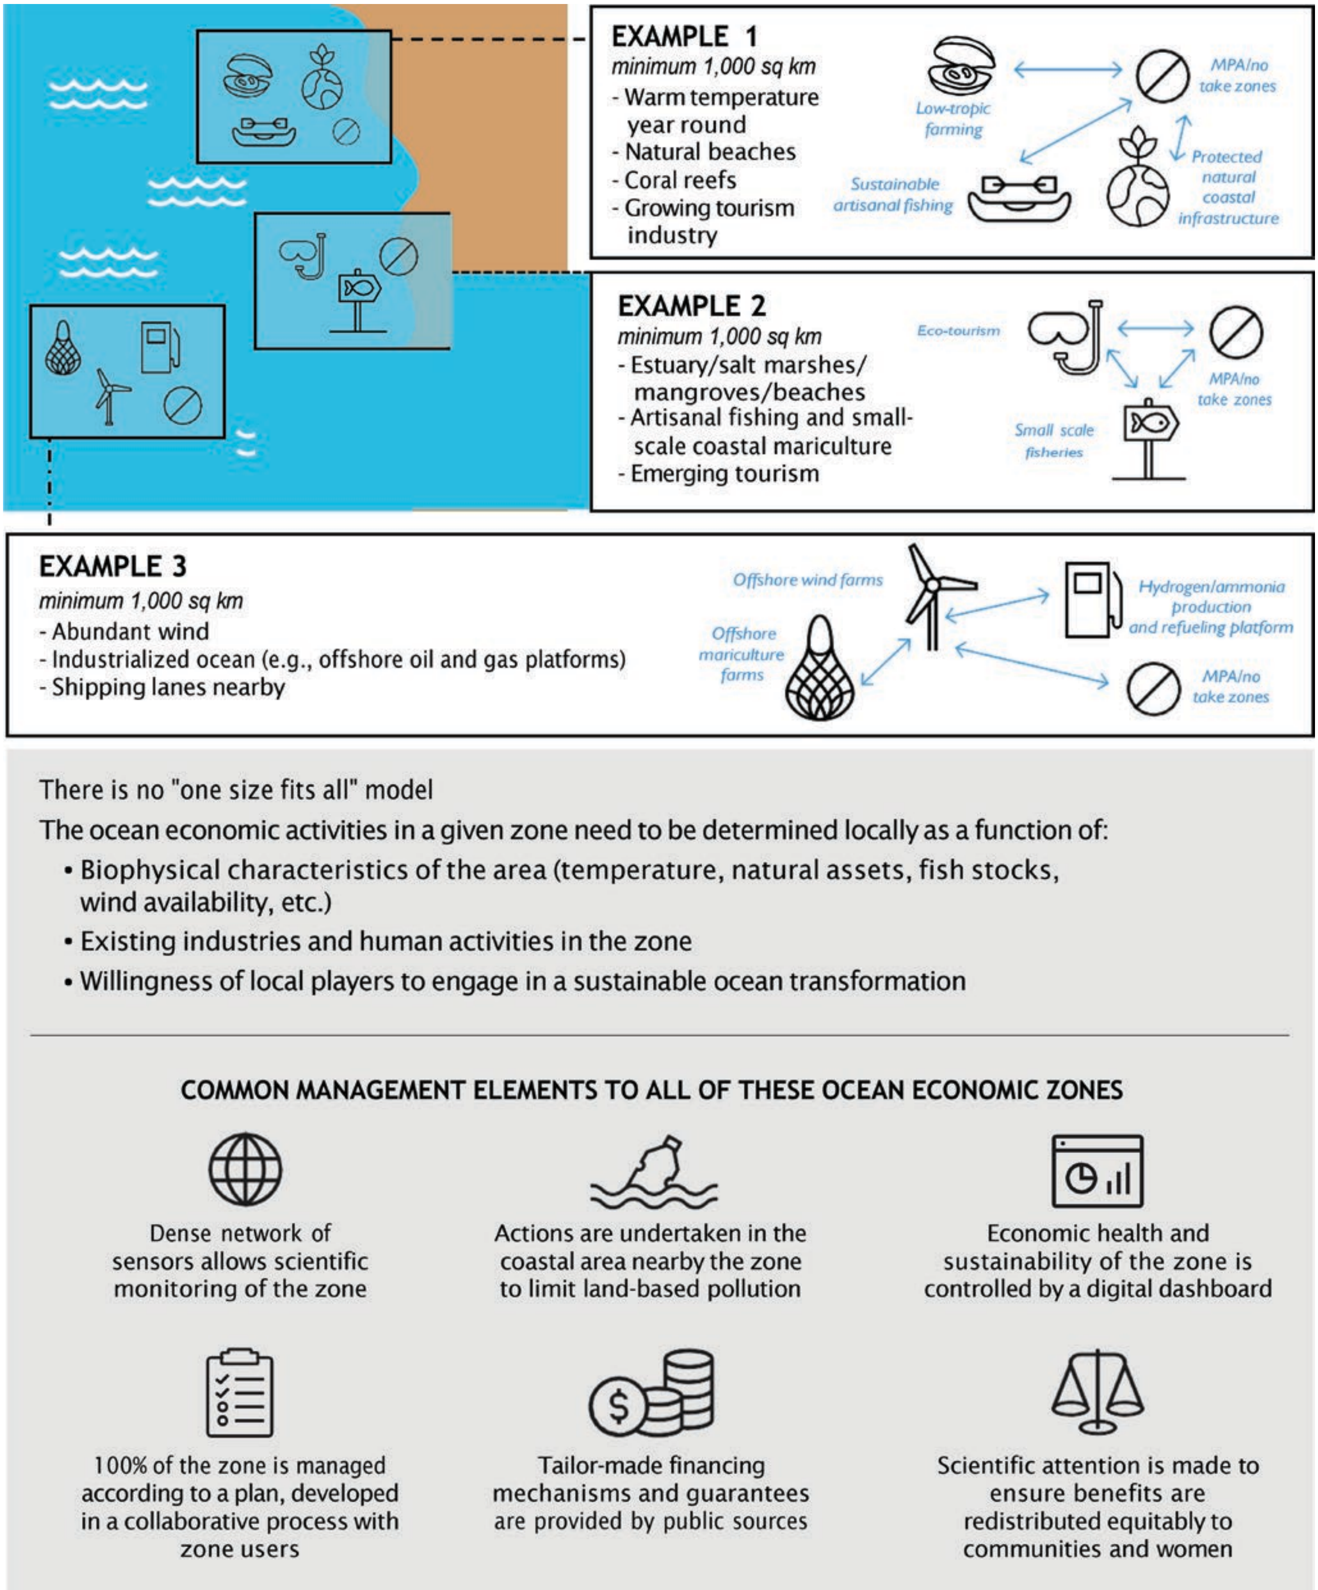

Fig. 20.4 Sustainable ocean economic zones can be test beds for experimentation and innovation. (*Source: Authors*)

generation, shipping and large-scale mariculture. Another might combine carbon-financed restoration, coastal protection, tourism and fishery enhancement.

Whatever activities take place within the zone, all SOEZs share several common elements. The entire zone is managed according to a plan, a dense networks of sensors allows scientific monitoring of the zone and efforts are made to ensure that benefits are redistributed equitably to communities and women.

National Ocean Task Forces Can Accelerate the Shift Towards a Sustainable Ocean Economy

Establishment of a sustainable ocean task force at the (ocean) ministerial or head of state level with a mandate to adapt the sustainable ocean agenda to the national context could accelerate change. Such a task force could perform several important functions:

- Conduct a comprehensive marine resource mapping of 100% of the country's exclusive economic zone.
- Support and facilitate an inclusive, participatory process to develop a plan that ensures a streamlined and efficient regulatory process, avoids conflicts over spatial use and protects and sustains key oceanic systems.
- Bring together relevant ministries and the head of state on the steps required to accelerate the transition towards a sustainable ocean economy, including financial guarantees and risk-reduction measures, policy and regulations, and international coordination.
- In coordination with relevant organisations, academic institutions and civil society groups, lead special initiatives, such as the design of networks of marine protected areas and SOEZs and efforts to control land-based pollutants.

National task forces can be a way to highlight the relevance of the ocean economy to national priorities like food security, international trade and tourism.

2.5 The Ocean Is Not Too Big to Fail, and It Is Not Too Big to Fix, But It Is Too Big and Too Central to the Planet's Future to Ignore

Effective ocean protection, sustainable ocean production and equitable human prosperity are inseparable and compatible. When integrated into a sustainable ocean economy, they can change the current downward trajectory of ocean health, producing positive outcomes for people and nature. Setting the foundations within which the three Ps can be achieved and transforming key ocean sectors will not be easy, but it can be done. Doing so would vastly increase the resilience of the global economy and improve the lives of some of the world's poorest and most vulnerable people. Indeed, creating a sustainable ocean economy would help the world meet all of the Sustainable Development Goals (SDGs), not just SDG 14 (on life below water) (Fig. 20.5).

Current practices, laws and cultural norms help support the open-access model that characterises much of the ocean. All of them can change. History shows that even very complex systems can shift onto new trajectories, sometimes very quickly. The energy transition in Germany, the banning of smoking in bars and restaurants in much of the world, and the adoption of the Montreal Protocol on Substances that deplete the ozone layer are all examples of changes that required major shifts in attitudes and laws that occurred within the space of a few years.

This kind of change can and must take place among stakeholders in the ocean economy. Spearheaded by a new cohort of ocean interests deeply vested in ocean health—sustainable fishers and mariculturists, coastal communities, renewable energy generators, ecotourism operators, scientists, environmentalists, social and civil society organisations—pollution and over-exploitation can be counteracted.

The journey towards a sustainable future has already begun, with pioneers leading the way. New sustainable technologies are attracting investors, and businesses and govern-

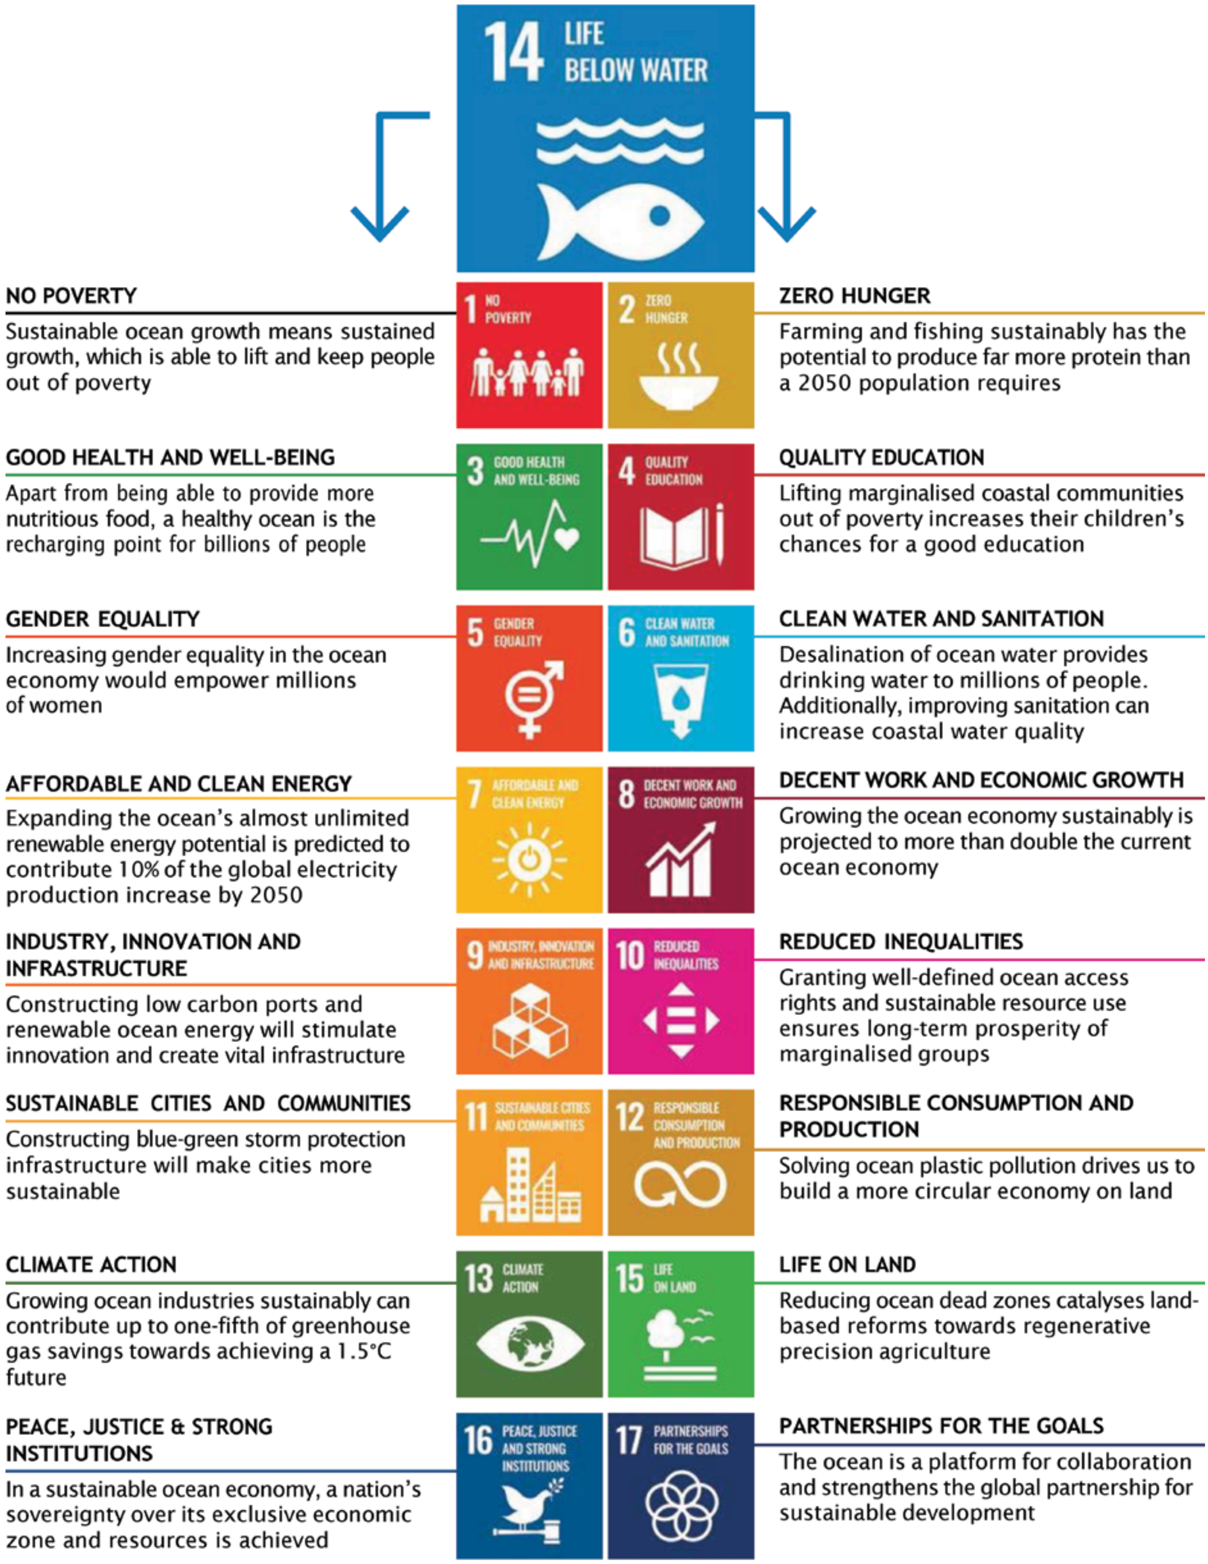

Fig. 20.5 A healthy ocean is critical to meeting the sustainable development goals. *Note: Regarding SDG 6 (clean water and sanitation), the link to the ocean can be made through desalination plants. Regarding SDG 17 (partnerships for the goals), the ocean provides excellent platforms for collaboration. Peaceful ocean science collaboration, for example, has been important for diplomatic relations (e.g. U.S.-Soviet Gulf Stream experiments in the 1960s)*. (*Source: Authors*)

ments are waking up to the opportunities of a sustainable ocean economy in building a new future after COVID-19. They are also increasingly recognising the risks and cost of inaction. Inspiring efforts from around the world provide a glimpse of what can be achieved globally if stakeholders act now.

3 Prologue: Five Sustainable Ocean Economy Stories

What does a sustainable ocean economy look like? Before exploring the rationale, benefits and practicalities of the concept, let's travel to five inspiring places (Fig. 20.6). The first destination is Gazi-Kwale County, Kenya, where a community-based organisation sells blue carbon credits from rebuilding its mangrove forest. The second stop is the Philippines, where a comprehensive approach used with 400 fishing communities helps meet the triple objective of food security, ocean protection and community prosperity. Then on to Europe, where the Medes Islands Marine Reserve in Catalonia, Spain, regenerates ocean biomass, supporting thriving ecotourism and, through spillover effects, sustainable fisheries. Across the Atlantic, on the U.S. East Coast, GreenWave works with fishers and coastal communities to launch regenerative ocean farms which combine seaweed and shellfish production. The final stop is the North Sea, where the Zero Emission Energy Distribution at Sea (ZEEDS) initiative aims to create a revolutionary zero-carbon fuelling system for ships, enabled by offshore wind production. This is a voyage of discoveries, and at some stops the results are not yet proved or fully backed by scientific assessments. But they are ideas, ones that illustrate a range of possibilities happening right now; they demonstrate inspiring innovations with the promise of a sustainable ocean economy. Figure 20.6 (and the report cover) maps this voyage on a representation of Earth inspired by the work of South African oceanographer Athelstan Spilhaus. This projection emphasises that there is one interconnected ocean.

3.1 Stop 1: Mikoko Pamoja, Kenya

Mikoko Pamoja, meaning 'mangroves together' in Kiswahili, perfectly describes the community-based blue carbon credit

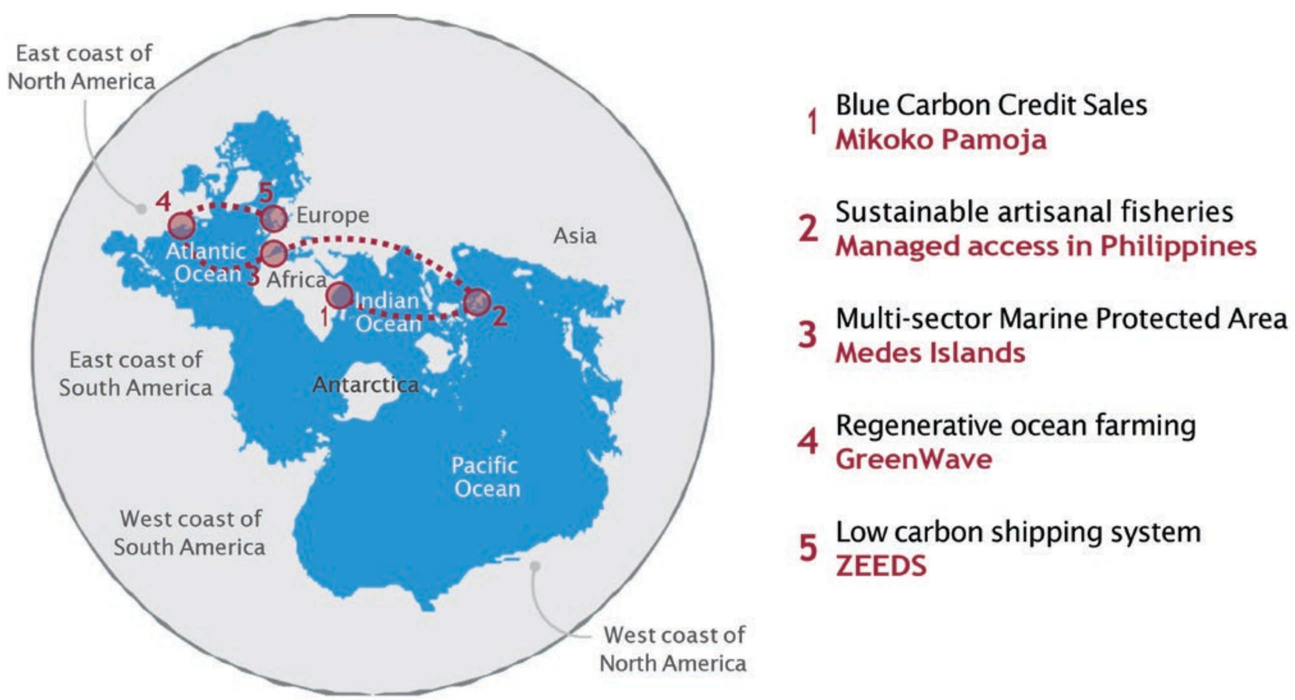

Fig. 20.6 Five sustainable ocean economy stories. Design inspired by Athelstan Spilhaus, Atlas of the World, Geophysical Boundaries, Map XIIIA: "World Ocean Map in a square", conformal, poles in South America and China, 1979. (*Source: Authors*)

Fig. 20.7 Mikoko Pamoja at work. *Note: (top left) Gazi Bay in Kwale County, (bottom left) GRID-Arendal & the Mikoko Pamoja committee members, (top right) Community water project founded by Mikoko Pamoja, (bottom right): close up of a mangrove*. project in Kwale County on Kenya's South Coast. The first effort of its kind, Mikoko Pamoja is improving the livelihood of the local community, regenerating the local mangrove forest and helping fight climate change (Fig. 20.7).

The reduction of local mangroves threatened the livelihood of fishers and destabilised coastlines. Mikoko Pamoja was set up to reverse this trend and find alternatives to mangroves that could provide the community with fuel and building materials while also generating income.

In 2013, a community-based organisation was formed, which was granted co-management rights for the 117-hectare coastal area from the Kenyan government.[58] A few hectares of *Casurina* woodlots were planted to provide an alternative source of fuel- and building wood for the community.[59] On 114 hectares, mangroves were replanted and a carbon credit trading scheme, now accredited by Plan Vivo (an international body regulating carbon credits), was set up.[60]

The trading scheme is now up and running—Plan Vivo sells 2500 credits per year, with 1 credit being equivalent to 1 metric tonne of carbon dioxide (CO_2) per year. These 2500 tonnes are derived from a mix of avoided deforestation and the planting of new mangroves.

On average, the carbon sales generate about $12,500 per year. Thirty-five percent of the revenue is used for the project costs, while 65% is reinvested in the community. [61] In the past it has funded initiatives such as the establishment of a

water system for the whole village, a local soccer tournament and textbooks for the local primary school.[62]

In addition to the credit sales, the community benefits from the restored mangroves through increases in fish catches, beekeeping and ecotourism from the 'Gazi Bay Boardwalk', all of which contribute to more sustainable livelihoods.[63]

Despite facing challenges such as fluctuations in carbon credit prices, the project has largely been a success and has received strong support from the Kenyan government. There has been strong scientific support with partners through the Kenya Marine and Fisheries Research Institute as well as support from the Kenya Forest Services on aspects of forest governance.[64] Mikoko Pamoja won the 'Equator Initiative Prize' and is now the model for future projects, including for 'Vanga', which covers an area about four times that of Mikoko Pamoja.[65] Mangroves are considered to be a natural climate solution because of their ability to help reduce carbon emissions, and currently there are efforts to include mangroves as part of Kenya's nationally determined contributions (NDCs). This work has also enhanced the visibility of the ocean space in Kenya and contributed to the value of safeguarding coastal ecosystems.

3.2 Stop 2: Community-Based Managed Access Network in the Philippines

Fishery reform in the developing world is not just about the fish. It is also about people, coastal communities and fishing as a livelihood, a job and a way of life.[66] Small-scale fisheries are a main source of food, provide millions of jobs and underpin cultures, particularly for the coastal poor.

Rare, an international non-governmental organisation (NGO) that applies behavioural insights to the cause of artisanal fishery recovery in developing countries, the Environmental Defense Fund, and the Sustainable Fisheries Group (SFG) at the University of California, Santa Barbara, launched the Fish Forever program in multiple countries to build a social movement for the better management of coastal fisheries. Rare and SFG took the lead in the Philippines.

Better management starts with managed access areas that give fishing communities clear, exclusive rights to fish in certain areas, which are often aligned with traditional community use rights. The communities' exclusive access is tied to their commitment to use fully protected marine protected areas (MPAs) that are designed to replenish and sustain fish populations and protect habitats and biodiversity.

In communities that have organised themselves to manage 'their' fishing areas and protected zones, management typically becomes more sophisticated. For example, boats and fishers are registered, catch is recorded, regulations are respected and fishers participate in management (Fig. 20.8). In the absence of outsiders skimming off the rewards of good stewardship, a virtuous circle tends to evolve, where results drive good behaviour and vice versa. Households in these communities have been shown to become more resilient in terms of food and financial security, and communities can work together to develop access to previously elusive capital and markets.

This social movement naturally kick-starts a political movement. National governments and international bodies begin to recognise the central role of coastal fisheries to the health, cultural coherence, resilience and wealth of coastal communities, and they start to promote the sector with better policies and improved access to financial resources.

The Philippines have demonstrated these dynamics at work. The 'Fish Forever' program is active in more than 400 communities in the country, clustered in 47 sites. Early results from 20 sites showed that fish biomass inside and outside the reserve was either maintained or increased across all sites. At sites where Rare had been working for 7 years, the increases were as high as 390% inside the fully protected MPAs and 111% outside MPAs. There were also statistically significant increases in 80% of social metrics, including improved attitudes towards fully protected MPAs, participation in management and the sense of social equity. To build financial resilience in fishing communities, fisher households also organised themselves into 'savings clubs'. These enabled more than 1500 members to save close to US $2 million in 2½ years.

The success at the local level is now reflected in a national policy agenda that supports artisanal fisheries. One example is the inclusion of managed access areas in the Philippine Development Plan, the country's central economic and development planning document. Most recently, working with Rare, 300 mayors also passed major resolutions to support artisanal fishers and the issues they face regarding climate change, preferential rights and sustainable financing.[67]

[67] All results received from personal communication with Rare Conservation.

Fig. 20.8 Artisanal fishers planning their community fishery in the Philippines. (*Source: Rare*)

3.3 Stop 3: Medes Islands Marine Reserve, Spain

Two hours northeast of Barcelona, seven idyllic islets can be seen from the Costa Brava. According to the official tourism website, the Medes Islands ecosystem is 'the best natural reserve in the western Mediterranean'. Scuba divers come from all over Europe to see the abundant fish—including large Mediterranean dusky groupers and other predatory fishes—relict red coral populations, octopus and hundreds of other marine species around these islands. How is this possible in a sea known to be overfished, polluted and overrun by invasive species?

It all started over 35 years ago, with the creation of a 51-hectare no-take marine reserve which banned fishing but allowed diving, navigation and moorings only on buoys (Fig. 20.9). Years later, an additional 460 partially protected hectares were added. They permit limited fishing, only by a few local artisanal fishing vessels. (Only seven local vessels have this exclusive access).[68]

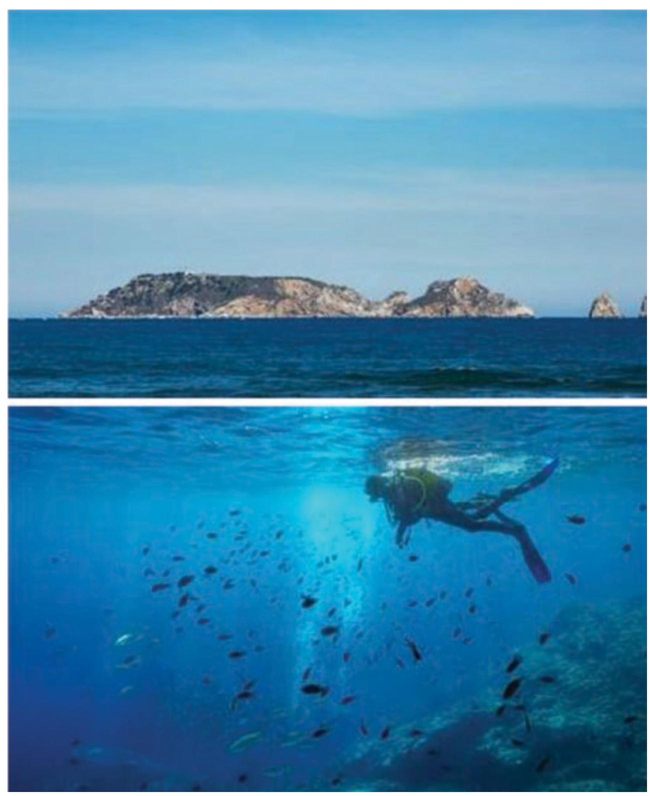

Fig. 20.9 The Medes Islands Reserve, Spain. (*Sources: top: Damsea/Shutterstock; bottom: funkyfrogstock/Shutterstock*)

[68]Merino, G., F. Maynou and J. Boncoeur. 2009. "Bioeconomic Model for a Three-Zone Marine Protected Area: A Case Study of Medes Islands (Northwest Mediterranean)." *ICES Journal of Marine Science* 66 (1): 147–54. doi: https://doi.org/10.1093/icesjms/fsn200.

This protection proved successful on all fronts,[69] even in this relatively small area.

- Fish biomass has fully recovered, and six main species have almost reached the maximum carrying capacity of the ecosystem.
- The restored biodiversity and biomass have transformed the Medes Islands into a paradise for divers and snorkelers, supporting thriving ecotourism in the area. Two hundred full-time jobs are supported and €12 million in revenue is generated, compared with €0.5 million before the creation of the reserve.
- The net present value of the reserve is up to 12 times greater than it would have been without this effective protection and management.

3.4 Stop 4: GreenWave, United States

In his book *Eat Like a Fish*, Bren Smith describes his journey as lifelong fisherman turned regenerative ocean farmer. He is fascinated with species that require no feed inputs and can regenerate their surrounding ecosystem: shellfish and seaweeds. After extensive research, he began to design and build an integrated, multitrophic mariculture farm, or as Bren would call it, a regenerative ocean farm[70] (Fig. 20.10).

On a visit to Bren's farm, at first you will see nothing but a few buoys. Underwater, it's a different story: kelp and mussels grow on horizontal lines of ropes connecting anchored scaffolding, scallops hang in lantern nets, while oysters and clams litter seafloor cages.

According to Bren's NGO, GreenWave, regenerative ocean farms can produce up to 150,000 shellfish and 10 tonnes of seaweed per acre. One farm can turn a profit of up to US $90,000–$120,000 per year—all without needing or buying feed, land, freshwater or fertiliser. Considering his initial investment of $20,000, this is a profitable business for Bren and other farmers, providing year-round income as kelp is harvested in spring, clams in spring to summer, scallops and mussels in autumn and oysters year-round. The 'crop' diversification also provides security for farmers should one of the crops fail.

Fig. 20.10 GreenWave ocean farming model. *Note: Sketch depicting the GreenWave 3D ocean farming model (top), Bren Smith harvesting kelp (bottom)*. (*Source: Top: Inspired by Water Brothers; Bottom: Ronald T. Gautreau Jr. for GreenWave*)

Getting started wasn't easy. Native shellfish (mussels, clams, oysters, scallops) seed was easily obtained from established growers nearby, but sourcing microscopic kelp seed that could eventually grow into 1- to 2-m-long seaweed blades proved more complicated. While seaweed farming is a 1000-year-old industry in Asia, it is nascent in the United States. With the help of kelp scientists and local community partners, Bren and GreenWave built a kelp hatchery that could supply him and other local farmers with seed. Launched to replicate and scale Bren's farming model, GreenWave educates the next generation of ocean farmers about farming in an era defined by climate change. Through its Farmer-in-Training program, GreenWave supports aspiring regenerative ocean farmers as they navigate the complex U.S. regulatory system and teaches them the fundamentals of setting up their ocean farm. The farms are geared towards simplicity and low cost, making it possible for anyone to become a regenerative ocean farmer for '$20k, 20 acres and a boat'[71]—far less than the cost of establishing a farm on land.

[69] Sala, E., C. Costello, J. de Bourbon Parme, M. Fiorese, G. Heal, K. Kelleher, R. Moffitt et al. 2016. "Fish Banks: An Economic Model to Scale Marine Conservation." *Marine Policy* 73 (November): 154–61. doi: https://doi.org/10.1016/j.marpol.2016.07.032.

[70] Bren, S. 2019. *Eat Like a Fish: My Adventures as a Fisherman Turned Restorative Ocean Farmer*. Sydney: Murdoch.

[71] GreenWave. n.d. "Our Model." https://www.greenwave.org/our-model. Accessed 13 May 2020.

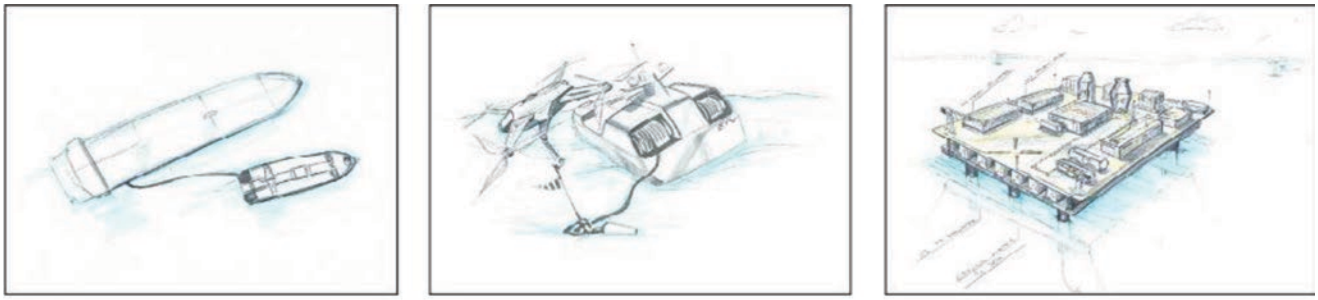

Fig. 20.11 Sketches of zero emission energy distribution at sea. From left to right: Sketch showing ship-to-ship bunkering at sea with zero carbon fuel. Sketch showing drone carrying pilot wire from energy-provider vessel. Sketch of topside of a ZEEDS platform producing and storing green ammonia. (*Source: ZEEDS project*)

GreenWave's goal is to plant 1 million acres of restorative species in the next 10 years. They hope to catalyse the growth of ocean farms across the world, providing a profitable and ecologically regenerative food production system for millions of people. These farms would be organised in GreenWave 'Reefs', with 50 small ocean farms clustered around a land-based hatchery and processing hub, surrounded by a ring of institutional buyers and entrepreneurs.[72]

3.5 Stop 5: ZEEDS Project, North Sea

Shipping is the most carbon efficient way (in tonnes per kilometre [km] travelled)[73] to move goods across the globe and accounts for 90% of cargo transport. Shipping today contributes about 2.2% of global CO_2 emissions, but these emissions could grow between 50% and 250% by 2050, mainly due to the growth in world maritime trade.[74] For instance, container shipping volumes are expected to increase by 243% between 2015 and 2050.[75] However, in April 2018, the International Maritime Organization (IMO) set a target of at least a 50% reduction in total annual greenhouse gas (GHG) emissions by 2050, compared with 2008 levels.[76]

How can a traditional industry like shipping, whose assets have a lifetime of more than 30 years, achieve the IMO's target or even more ambitious decarbonisation pathways?

Let's travel to a hypothetical future in 2030. In the eastern Atlantic, a container vessel is heading towards Rotterdam. This ship is carbon-neutral, having been retrofitted to be powered by green ammonia, a combustible produced through a series of chemical reactions enabled by renewable energy. The ship is low on fuel and slows to six knots as it is met by a small autonomous refuelling ship with a fuel hose suspended in the air by a drone. After 1 h, while still progressing, the now refuelled vessel accelerates on its way to Rotterdam. The fuel-provider vessel heads back to dock at a floating ammonium production platform, which is surrounded by a network of offshore wind turbines (Fig. 20.11).

This is the vision of Zero Emission Energy Distribution at Sea (ZEEDS), a new partnership created in 2018 that gathers leading Scandinavian players in energy, offshore engineering, shipping and technology (Equinor, Wärtsilä, Aker Solutions, Kvaerner, DFDS and Grieg Star). The ZEEDS concept envisions an ecosystem of strategically located offshore clean fuel production and distribution hubs, co-located near busy shipping lanes. Wind will provide the power to create sustainable ammonia for ship-to-ship refuelling.

The good news is that this solution might be more realistic than it looks. Adapted ship engines and production technology at sea are being tested at a pilot scale, and green ammonia is looking very promising as a replacement for heavy fuel oil on long voyages.

4 The Urgency of Today

4.1 Introduction

The five stories in the Prologue are diverse but compelling illustrations of local actions to move towards a sustainable ocean economy. They share a common vision which recognises that the ocean will only be able to regenerate if and when the agendas of protection, production (e.g. food, energy, carbon) and human prosperity are managed holistically.

Yet these examples are exceptions to the general global downward trajectory of ocean ecosystems or their associated economic potential. Action can be inspired by their examples, but the reality is that urgent action is needed to transition towards a more sustainable ocean economy at scale.

This section develops three main arguments to emphasise the urgency of action:

A healthy ocean is crucial for all of humanity and for the global economy The agenda of a sustainable ocean economy applies to the entire world, not just to traditional 'blue sectors' like fisheries or shipping. The diverse services provided by healthy ocean ecosystems make Earth liveable. Feeding ten billion people in 2050 while remaining within a safe planetary 'operating space'[77] will be hard—and the ocean may well hold a big piece of the solution. The ocean could also play a significant role in fighting climate change, meeting up to one-fifth of the carbon mitigation challenge.[78] Finally, global concern about ocean plastic pollution could catalyse a much deeper reform of the profusion of wasteful material management practices on land (Sect. 4.2).

The ocean is under increasing threat The ocean is becoming warmer, more acidic, depleted, stormier, higher, more oxygen-depleted and less predictable. Profound changes (state shifts) affecting many aspects of human life are no longer unthinkable. Neither the ocean economy as a whole, nor coastal communities, nor the social agenda of the Sustainable Development Goals (SDGs) can thrive in such a degraded environment (Sect. 4.3).

Solutions are emerging but urgently need to be scaled up Despite the undeniable challenges, hints of a sustainable ocean mindset are on the rise. The pace of innovation in the ocean economy is accelerating sharply, and investors are starting to find their way to the sustainable ocean economy. A data revolution is underway—enabled by an ocean technology revolution—redefining access to knowledge. Successful, sustainable ocean-related policies are increasingly gaining traction. The voices of citizens and communities advocating for more equitable and sustainable use of planetary resources are getting louder. There is an unprecedented international momentum for a sustainable ocean economy, as seen at meetings of the G7, G20, Ocean Panel, UN Ocean Conference, Our Ocean, World Ocean Summits, UN Decade of Ocean Science and so on (Sect. 4.4).

4.2 A Blue Awakening: Recognising That the Ocean Is Vital to Humankind and the Global Economy

In an international 2020 survey, 94–96% of respondents saw 'the condition of the ocean as important to their country's economy'.[79] At the same time, there is no single broadly accepted definition of the ocean economy. The most commonly used one is the following: 'The ocean economy can be defined as the economic activities that take place in the ocean, receive outputs from the ocean, and provide goods and services to the ocean'.[80]

There is considerable variation in the way this definition is interpreted—the United States includes as few as six industry sectors in the ocean economy, Japan as many as 33. The ocean economy's implied valuation also ranges widely. The Organisation for Economic Co-operation and Development (OECD), defining the ocean economy as 'the sum of the economic activities of ocean-based industries, together with the assets, goods and services provided by marine ecosystems',[81] initially assessed ten ocean-based industries of the global ocean economy, conservatively estimating they represented in 2010 a total of US $1.5 trillion in gross value added [GVA];[82] WWF calls it 'the seventh largest economy in the world', valuing ocean assets at $24 trillion;[83]

and many others assert it to be practically incalculable. The ocean economy includes heavily ocean health-dependent sectors such as tourism (26% ocean GVA), fisheries and mariculture (2–6% ocean GVA), as well sectors principally managed by more exogeneous interests, such as offshore oil and gas (33% ocean GVA), ports (13% ocean GVA) and maritime equipment (11% ocean GVA). In terms of employment, the ten ocean-based industries assessed by the OECD contributed some 31 million direct full-time jobs in 2010, with industrial capture fisheries accounting for the lion's share of the OECD's assessed ocean economy jobs (36% and plateauing), followed by tourism (23% and strongly increasing).[84] If informal or artisanal jobs are included, the ocean's global employment contribution is much higher—estimates for total (formal and artisanal) fisheries employment alone run as high as 237 million full-time equivalent jobs.[85]

These definitions and numbers are insightful but incomplete. To be a useful descriptor of the relationship between humans and the ocean, a broader, more systemic perspective on the ocean economy is needed, in line with the World Bank's definition of a sustainable ocean economy: 'the sustainable use of ocean resources for economic growth, improved livelihoods and jobs while preserving the health of ocean ecosystems'.[86]

In the literature and in national or international initiatives it is common to find references to a 'blue economy', but again the definition and scope varies: sometimes 'blue' refers to the ocean, with the blue economy closer to the definition in this section's first paragraph; at other times 'blue' refers to sustainable (as 'green' would do for sustainable land-based activities), and the blue economy is understood as in the World Bank definition. To avoid confusion, this report will avoid the term 'blue economy' in favour of 'sustainable ocean economy', mostly guided by the World Bank definition. Yet this report also invites readers to embrace a wider paradigm that acknowledges the following:

- The importance of ocean contributions for all of humanity and nature
- The ocean's central contribution to the global agenda of food security
- The untapped opportunity the ocean provides to fighting climate change
- The catalytic role the ocean can play in accelerating a global transition towards more circular and regenerative practices in land-based economies

4.2.1 The Ocean's Contributions to Humanity Exceed the Realm of Its Industrial Production

The ocean absorbs more than 90% of the heat resulting from anthropogenic greenhouse gas emissions. It rebalances the heat differential between poles and equators. It produces 50–80% of Earth's oxygen.[87] Its biological adaptations remain largely unknown and, if previous experience is any indication, contain untold medical, knowledge and commercial resources. For billions of coastal dwellers, the ocean is woven deeply into their cultural and spiritual lives. For all humans, it provides a sense of wonder, solace and connection to the natural world. Millions play in it every day. It provides a deep sense of place.[88]

The 2005 Millennium Ecosystem Assessment report defined ecosystem services as 'benefits people obtain from ecosystems'.[89] This concept was updated and broadened to 'nature's contribution to people' in the latest report by the Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services (IPBES).[90] The IPBES structures nature's contribution to people into three main categories (definitions below are directly inspired by IPBES's):[91]

- **Nature's material contributions to people:** 'substances, objects or other material elements from nature that sustain people's physical existence and the infrastructure needed for the operation of a society or enterprise'. In the context of the ocean economy, these material contributions sup-

port subsistence (e.g. fish), energy (ocean fossil fuels, wind), health (e.g. pharmaceuticals derived from marine species) and construction (e.g. sand), among others. In this report it is assumed that most of these contributions are economically accounted for by conventional indicators like GVA (see Fig. 20.12).

- **Nature's regulating contributions to people:** 'functional and structural aspects of organisms and ecosystems that modify the environmental conditions experienced by people, and/or sustain and/or regulate the generation of material and non-material contributions'. For the ocean and coastal ecosystems, climate regulation is a perfect example of such contributions, but the latter also include, for example, habitat creation and maintenance; regulation of hazard and extreme events; regulation of air quality; and dispersal of seeds, propagules and larvae (see Fig. 20.12).
- **Nature's non-material contributions to people.** 'Nature's contribution to people's subjective or psychological quality of life, individually and collectively'. These contributions include learning and inspiration from the ocean, physical and psychological experiences, and supporting identities (see Fig. 20.12).
- The IPBES also defines a '**maintenance of options**' category for the yet-to-be-discovered or understood use of natural ecosystems and organisms (see Fig. 20.12).

Even in economic and monetisable terms, not every dollar counts the same. For example, coastal fisheries account for less than 1% of the ocean economy as conventionally defined. However, this is most likely a significant underestimation of the sector's true economic importance. To more accurately represent the importance of the marine economy, one would also need to include employment for over 37 million arti-

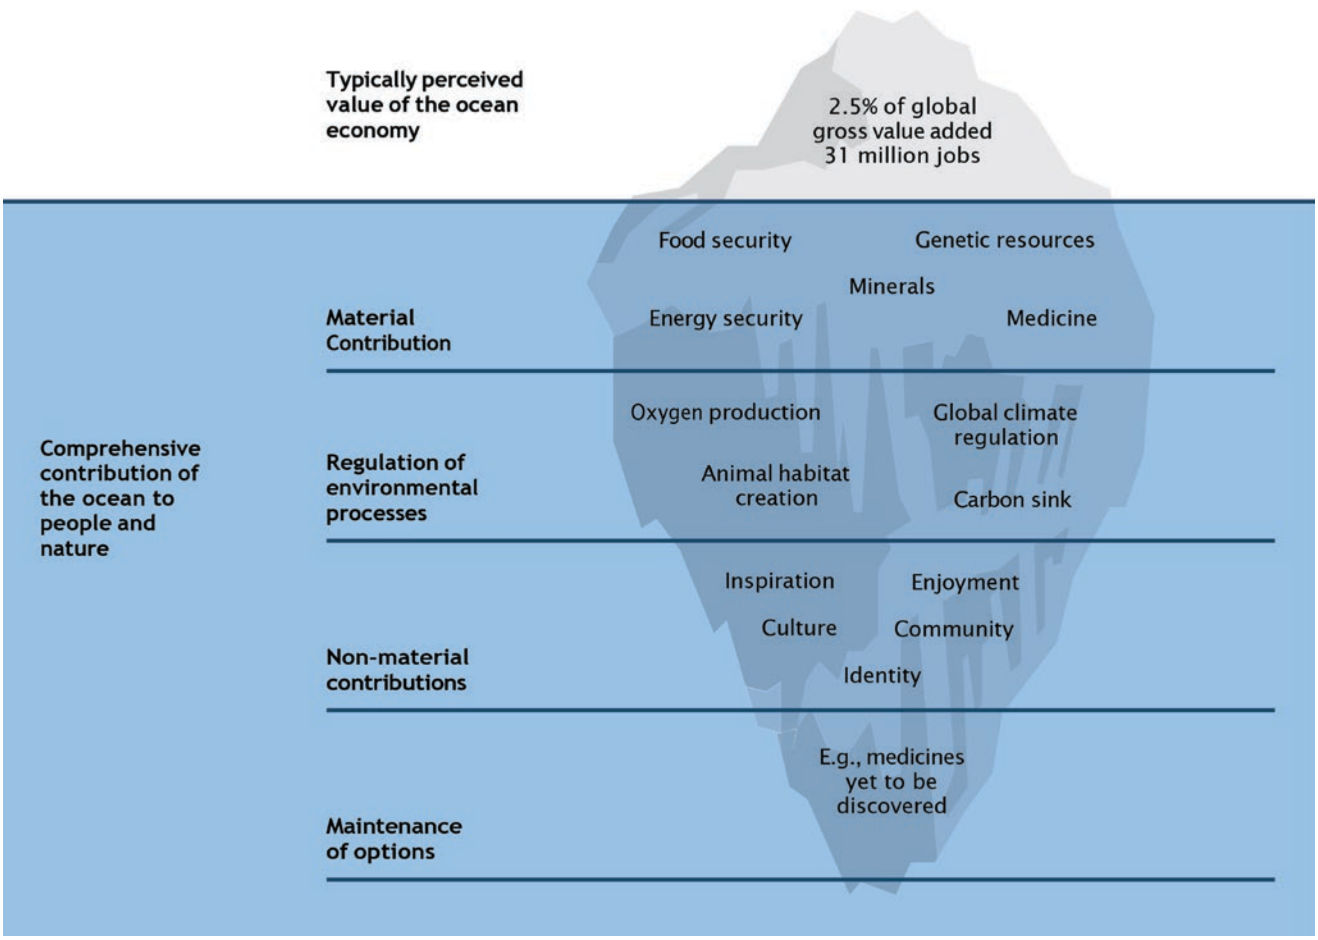

Fig. 20.12 The ocean's importance to humankind. (*Source: Authors, inspired by Díaz, S., J. Settele, E.S. Brondízio, H.T. Ngo, M. Guèze, J. Agard, A. Arneth et al. 2019. sanal fishers,[92] and the ocean's provision of essential food for millions living in poverty along the coasts of the developing world, as well as for the one billion people relying on the ocean for most of their animal protein.[93]

Most global economic activity either depends on the ocean, is based on the ocean or affects the ocean in some essential way. According to the Intergovernmental Panel on Climate Change (IPCC), 'All people on Earth depend directly or indirectly on the ocean and cryosphere'.[94] Some illustrative facts confirm this importance of the ocean for humanity: 50–80% of the oxygen comes from the ocean,[95] 44% of the world's population lives within 150 km of the coast[96] and 90% of all international trade involves marine shipping.[97]

4.2.2 The Ocean Has a Central Role to Play in Global Food Security, But the Way the Ocean Is Currently Used Is Not on Track to Deliver It

Earth's population, 2.5 billion in 1950, has grown to 7.8 billion in 2020 and is projected to peak in 2064 at about 9.73 billion.[98] It has been estimated that 470 million metric tonnes (mmt) of total animal protein will be required annually to feed the 2050 population.[99] The relative sources of land-based, ocean-based and lab-grown supply are not yet clear and will be highly dependent on the evolution of future technologies as well as human preferences. However, ocean-based food will almost certainly have a central role to play in global food security—it is healthy, its carbon footprint is low compared to land-based animal proteins,[100] and it doesn't require extensive use of water or the conversion of land for agricultural use. See Fig. 20.13 for the types of ocean food discussed in this report.

If the EAT-Lancet diet[101]—used here as a solid proxy for a globally sustainable and healthy model of nutrition—were globally adopted, 2050 fish and seafood production would need to increase by 60–118% over 2010 production levels (with the range depending on food waste reduction).[102] This corresponds to a production increase from 109 mmt today to between 160 and 218 mmt by 2050 (in whole weight). These forecasts are currently being refined to assess more precisely the role of ocean food in feeding a 2050 planet.[103]

This is in stark contrast to current, business-as-usual (BAU) projections of seafood supply (Fig. 20.14), which project a decline of capture fisheries from 80 mmt today to 67 mmt by 2050 due to the pressure of overfishing on some stocks and underfishing on others.[104] Finfish mariculture (marine aquaculture) is not projected to fill the gap, as it is seen as constrained by the availability of fish oil (FO) and fish meal (FM)—in other words, 'fishing fish to feed fish'. At reasonably probable future inclusion rates for FO and FM, annual finfish production is forecast to reach a maximum of only 14.4 mmt: around twice the current production—far short of what would be needed to fill the gap.[105] Bivalve mariculture (e.g. of mussels and oysters) does not require outside feed and therefore has a greater growth potential than wild-capture fisheries and farmed finfish, even in a business-as-usual scenario. A steady increase in bivalve production (aligned with the past 10 years' annual growth rate) therefore makes the biggest contribution to a

projected overall doubling of mariculture production, from 29 to 66 mmt in 2050.

Summing these three potential contributions under a BAU scenario leaves a shortfall of up to 85 mmt (Fig. 20.14).

The BAU scenario, of course, is not etched in stone. If properly and sustainably managed, capture fisheries could contribute about 98 mmt by 2050—over 40% more than the BAU projection.[106]

In addition to this wild-caught potential volume, finfish mariculture can contribute higher yields once (partially) decoupled from FM/FO.[107] Mariculture must and can be done right. Unfed species (bivalves, seaweeds) are generally more benign to the environment, but barriers remain to higher production and consumption (e.g. the gap between perceived risk and actual risk).[108] Finfish mariculture will require further technology development, and strict environmental regulations on antibiotic and effluent pollution, before it can produce very large volumes, presumably offshore, with lower local impacts and without reliance on fish-based feeds. Recent developments are encouraging; progress in both governance (e.g. the 'traffic light system' in Norway, which conditions production on environmental assessments) and technology (e.g. disease control, alternative feeds, etc.; see Sect. 4.4) is underway. Additionally, equity issues associated with mariculture must be attended to, ensuring the full inclusion of women, equal treatment of all ethnic and racial groups, adoption of safe labour standards and fair treatment of smallholder farmers.[109]

Unfed mariculture, including seaweed production, is also currently greatly underdeveloped compared to its advantages and biological potential (see Sect. 5).

4.2.3 Ocean-Based Solutions Are Underappreciated and Essential to Fight Climate Change

The significant carbon mitigation challenge inherent in a 1.5 °C future is well understood and documented.[110] Usually

Numbers projected here are simplified by assuming that the ratio between freshwater and marine fish remains unchanged in 2050 versus the baseline year*)

seen as victims of climate change, the ocean and its coastal regions also offer a wide array of potential options to reduce GHG emissions. A comprehensive review was undertaken as part of a report commissioned by the High Level Panel for a Sustainable Ocean Economy (Ocean Panel). The Special Report 'The Ocean as a Solution to Climate Change'[111] estimates that ocean-based climate solutions could reduce global GHG emissions by up to 4 billion tonnes of carbon dioxide equivalent (CO_2e) annually by 2030 and by up to 11 billion tonnes annually by 2050. This could contribute as much as one-fifth (21%) of the emission reduction required in 2050 to limit warming to 1.5 °C and 25% for a 2 °C target (Fig. 20.15). Emission reductions of this magnitude are equivalent to the annual emissions from all coal-fired power plants worldwide or taking 2.5 billion cars off the road every year. These numbers correspond to an upper range based on strong political signals and investments.

The ocean-based options explored in this report include scaling ocean-based renewable energy generation (as a replacement for fossil fuel generation), reducing GHG emissions from marine transport (domestic and international), switching from emission-intensive land-based protein to low-carbon protein from the ocean, using seaweed as an alternative low-carbon fuel and feed for terrestrial activities, increasing the sequestration and storage potential of coastal and marine-based carbon stocks, and storing carbon in the seabed. These options did not feature prominently in the first round of nationally determined contributions (NDCs) communicated by countries or the long-term low GHG emission development strategies communicated to date under the Paris Agreement, but they offer island and coastal nations significant opportunities to consider in addition to land-based emission reduction measures.[112]

Currently, these solutions are delivering significantly less than their full mitigation potential. For example, the ocean's renewable energy contribution totals less than 0.3% of total global energy production.[113] Alarmingly, not only is the carbon sequestration and storage potential of coastal and marine ecosystems not fully being captured through efforts to pro-

tect and manage these ecosystems but the degradation and loss of these ecosystems—mangroves at 0.21%/year,[114] saltmarshes at 1–2%/year[115] and sea grass at 2–5%/year—is releasing significant emissions back into the atmosphere.[116]

4.2.4 The Ocean Can Catalyse a Global Transition Towards More Circular and Regenerative Practices in Land-Based Economies

The 'ocean economy' is usually associated with purely ocean-based industries—shipping, fishing and so on. Nonetheless, almost all land-based industries rely on the services provided by the ocean. Perhaps the most difficult, and intriguing, part of the ocean economy puzzle concerns the chain reactions caused in global markets by changes in ocean-related production of fish, renewable energy or minerals. Everything is connected—a reduction of anchovy harvests in Peru affects the price of Scottish farmed fish, Chinese pigs and omega-3 capsules (all dependant on fish meal and fish oil, products extracted by drying and grinding up fish like anchovies).[117]

The ocean economy can thus not be viewed in a siloed 'blue' fashion. Moreover, this connectedness applies not only to what people remove from the ocean but also to what they put into the ocean. Over 80% of all global marine pollution originates on land[118]—all too often, the ocean 'serves' as the ultimate planetary sink. It absorbs 30% of anthropogenic (land-based) CO_2, [119] 90% of excess heat caused by anthropogenic GHG emissions[120] and an estimated 9–14 mmt of plastic pollution per year.[121] Following the old fallacy of 'the solution to pollution is dilution', the ocean has been expected to absorb invisible pollution like nutrient runoff, heavy metals (e.g. mercury, cadmium), nuclear waste, pharmaceuticals, persistent toxicants (DDT, TBT, pesticides, furans, dioxins, phenols), sewage and personal care products.

Keeping the ocean functioning within the bounds of the 'safe operating space' for humanity can also catalyse profound and profitable changes in land-based systems: moving away from the 'blue silo' allows for the explicit connection between SDG 14 (conserve and sustainably use the oceans, seas and marine resources for sustainable development)[122] and the acceleration of SDG 15 (life on land), as well as other SDGs often thought of as land-based, including SDG 12 (sustainable consumption and production), SDG 9 (sustainable infrastructure) and SDG 7 (affordable and sustainable energy).

The fate of the ocean is directly linked to a broader shift towards a circular economy[123] approach to consumer goods and industrial production—a system where resources are used continually, at their highest possible value added, and recovered or regenerated as efficiently as possible at the end of their service. It is also linked to a land-based transition towards renewable energies, and to improved land use practices in agriculture and in coastal development. But looking at it the other way around, the ocean could be a unique opportunity to advance the broader global agenda of sustainability while 'leaving no-one behind'.

As a compelling example, the ocean is now the principal driver of fundamental work on the plastic value chain. The unprecedented crisis of ocean plastic pollution is bringing scientists, businesses, governments and civil society together to look for solutions.[124] For instance, in October 2018 in Bali, 250 organisations, including many of the packaging producers, brands, retailers and recyclers, as well as governments and NGOs (altogether representing 20% of all plastic packaging produced globally) committed to eradicate plastic waste and pollution at the source. Following the plastic example, the wasteful agriculture system could be challenged by the sustainable ocean agenda, obliging it to accelerate the transition towards precision farming, less toxic fertilisers and pesticides, and the collection and treatment of human and livestock waste and wastewater.

4.3 Failing the Environment and the People: The Need for Urgent Action

Physical, geological, chemical, biological and ecological processes interact in the ocean in complex ways. Those processes and interactions have now been fundamentally altered by human activities, with concomitant changes to the services provided to people by natural ecosystems. For example, loss of biological diversity, major perturba-

tions of biochemical cycles, and climate change each alter the functioning of ecosystems, and that in turn impairs or limits the benefits that ocean ecosystems provide to people.

As the rate of change in most socioeconomic areas has accelerated past any historical precedent in the first half of the twentieth century, so have most earth system indicators—a phenomenon described as 'the Great Acceleration' (Fig. 20.16).

There is also increasing strain on the ocean system: the 'blue acceleration'—humanity's expansion into the ocean for food, materials and space—has been unparalleled in history.[125] The direct consequences of these trends are exhaustively documented today (see details below).

The direct footprint of human activity is visible almost everywhere. Sixty-six percent of the marine environment is experiencing significant cumulative impact by human actions.[126] Only 13% of the ocean area can still be classified as wilderness,[127] and less than 3% of the ocean is unaffected by multiple human stressors.[128] For example, between 1970 and 2000, sea grass meadows declined by roughly 30%, mangroves by 35% and saltmarshes by 60%, whilst between 11% and 46% of marine invertebrates are threatened.[129] Below, the main stressors on the ocean caused by human activity are briefly described along with their directly observable consequences.

Overfishing The direct over-exploitation of fish stocks and the unintended impacts of fishing gear on non-target species may be the most tangible manifestation of direct pressure from human activity. [130] This has been exacerbated by harmful fisheries subsidies (i.e. those directed at capacity expansion) as well as the effects of illegal, unreported and unregulated (IUU) fishing. Industrial and artisanal fishing fleets have been identified as the main driver of extinction for all classes of marine vertebrates except birds.[131] Estimates of overfished stocks range from 33% ('overfished' category in the Food and Agriculture Organization of the United Nations [FAO] database)[132] to 47% ('over-exploited or collapsed' category in the Sea around Us Project's classification).[133] Higher trophic level species and predators such as sharks, tuna and billfish are especially depleted.[134] For example, a 2020 global shark survey found no sharks in almost 20% of the 371 surveyed reefs across 58 nations, with levels of shark depletion being closely correlated to poor governance, the density of human population and distance to the nearest market.[135]

Open ocean diversity has declined by 10–50% over the past 50 years, a trend that has coincided with increased fishing pressure.[136]

Climate change The raw numbers are sobering: ocean waters have absorbed 93% of the excess heat caused by greenhouse gas (GHG) emissions[137] and sea surface temperatures have increased by 0.7 °C since 1900.[138] New analysis confirms that 2019 was the warmest year on record for ocean temperature, and saw the largest single-year increase of the decade (Fig. 20.17).[139] The 12 years with lowest Arctic sea ice extent all happened in the past dozen years,[140] and 2017 marked the lowest Antarctic sea ice extent on record.[141]

Climate change generates stronger winds.[142] This intensification of surface winds has accelerated the global mean ocean circulation over the past two decades, especially in tropical regions.[143] These changes in ocean currents can affect not only weather patterns on land (e.g. the Gulfstream's

influence on the European climate[144]) but also fisheries through, for instance, modification of larval dispersal[145] or changes in the intensity of coastal upwelling[146] (the movement of cold, nutrient-rich water to the ocean surface). These upwelling changes can enhance fishery productivity, as with anchovies along the coast of Peru; but if the upwelling is too intense, it can have the opposite effect, triggering 'dead zones' with insufficient oxygen to support fish and other marine life. Changes to ocean circulation are regionally variable. For example, the Atlantic Meridional Overturning Circulation (AMOC), which redistributes heat between tropics and higher latitude in the Atlantic, is one exception to the general pattern of speedier currents at the global scale. AMOC is 'very likely to weaken over the twenty-first century', according to the IPCC.[147] Considerable uncertainty remains, however: the IPCC cites a range of between 1% and 54% for AMOC weakening, depending on the warming scenario chosen.[148]

Humanity's GHG emissions have also acidified the ocean by 26% since the Industrial Revolution,[149] and climate change is impacting dissolved oxygen content in ocean systems across the globe (see more details about dead zones later in this section). The combined effects are putting additional stress on many coastal and oceanic species, including the shell-forming animals (corals, phytoplankton, zooplankton, bivalves and more) which represent the foundation of the marine food webs.

Habitat destruction Key coastal habitats such as mangroves are being lost at an alarming rate: global mangrove cover has declined by around 25–35% (up to about 57,000 km^2 from 1980 to 2000),[150] largely due to land reclamation and conversion to aquaculture ponds and rice paddies.[151] This loss has resulted in reductions in fisheries and coastal food production,[152] and increasing threats to species with a fragile conservation status. These coastal habitats help protect communities against life-threatening storm surge during tsunamis, typhoons, cyclones and hurricanes. Mangroves, sea grasses and saltmarshes are labelled 'blue carbon' ecosystems because they actively sequester and store organic carbon from the environment,[153] meaning their loss increases emissions.[154] The seafloor habitats have also been significantly affected by destructive fishing gear and methods. Bottom trawling has destroyed cold water coral and sponge ecosystems, which will take centuries to recover;[155] dynamite and cyanide fishing has contributed to the decline of coral reefs.[156]

Plastic pollution At least 700 species of marine life have been demonstrated to interact with plastic,[157] with the main impacts occurring through entanglement, ingestion and chemical contamination from macroplastics. The annual flow of plastic into the ocean is predicted to nearly triple by 2040 to 29 million metric tonnes per year if no serious action is taken.[158] This number corresponds to an equivalent 50 kg of plastic for every metre of coastline worldwide.[159] There is also clear evidence that microplastics are ingested by a wide range of species, including marine mammals, birds, fish and small invertebrates at the base of the food chain.[160]

Other land-based pollutants Ocean ecosystems and marine life are damaged by many land-based pollutants, such as pesticides, antibiotics, parasiticides, pharmaceuticals, heavy metals, persistent organic pollutants and excessive amounts of nutrients such as nitrogen and phosphorus. For instance, in Southeast Asia, an estimated 600,000 tonnes of nitrogen end up in the ocean every year, discharged from major regional rivers.[161] Direct impacts vary considerably, depending on the pollutant, its amount and the presence of other stressors.[162] Impacts can include excess productivity that triggers dead zones (low- or no-oxygen; see details later in this section), reduced photosynthetic efficiency, chronic stress on marine organisms, cancer in animals, likely inhibition of reproduction and birth defects.[163]

Invasive species Discharge of untreated ballast water from ships is considered one of the major threats to biodiversity that, if not addressed, could have severe public health, environmental and economic impacts.[164] One cubic metre of ballast water can contain up to 50,000 zooplankton specimens[165] and/or 10 million phytoplankton cells.[166] With 10 billion tonnes of it transferred throughout the world each year,[167] ballast water is one of the principal vectors of potentially invasive alien species.[168]

Compounding stressors In many occurrences these individual stressors locally compound one another with exponential consequences on ecosystems. For instance, coral reefs around the globe are exposed not just to overheating but also to overfishing and pollution. The decline of average hard coral cover on Caribbean reefs from 50% in the 1970s to 10% in the early 2000s, for example, was caused by the introduction of a pathogen killing an important herbivore (sea urchin), on top of decades of overfishing of herbivores and grazers (parrotfish and multiple other species of fishes) as well as predators essential to the integrity of the system, sediment from deforestation on land, warmer water from climate change, and physical destruction and pollution from overdevelopment in coastal areas (see Fig. 20.18).[169] In Asian and Australian waters, the primary drivers are switched. For example, in 2016 the Great Barrier Reef experienced an unprecedented die-off of staghorn and tabular corals on a third of its reefs,[170] caused by a record heatwave, with pollution playing a secondary

role. Overall, the outlook for coral reefs is deeply concerning: annual severe bleaching (ASB) is forecast to affect 75% of all global reefs before 2070, even if the Paris Agreement carbon reduction pledges are followed.[171] With coastal overfishing endemic in most developing countries, the resilience of reefs to ASB events will be greatly diminished. With global warming of 1.5 °C, coral reefs would decline by 70–90%, and virtually all (>99%) would be lost at 2 °C warming.[172]

It should be noted, however, that large, remote coral reefs that are fully protected from extractive and abatable destructive activities (in fully protected marine protected areas) have proved to be more resilient to warmer water and other environmental stressors. Coupled with the finding that some strains of corals are becoming more tolerant of warmer waters,[173] this suggests that it may not be too late to save coral reefs if strong action is taken to reduce carbon emissions[174] and create large, fully protected areas in the ocean.

4.3.1 Indirect Effects Can Already Be Observed

When these pressures increase beyond a certain tipping point, the interconnected ocean system may no longer be able to provide the benefits people want and need. The combination of their effects can be unexpectedly severe and larger than the sum of their parts. If these stressors start compounding on a larger scale, potentially serious and fundamental indirect, 'second order' consequences occur, such as loss of biological diversity and abundance. Though analytically demanding in terms of attribution and measurement, such consequences are highly significant for the ocean's future. Even more concerning is that indirect effects may fundamentally shift key parts of the ocean system from one state to another that is often functionally different (Fig. 20.19). At this level, even sophisticated models and 'data revolution' tools can only suggest *what* might happen but not precisely *when* and *where*. Given what is at stake, these effects need to be considered in decisions, even if uncertainty is high.

Stratification Ocean stratification occurs naturally when waters with different properties (temperature, salinity, density) form layers, which act as a barrier to mixing.[175] Usually, wind, currents and storms help mix the cold (deep) and warm (upper) layers.[176] Climate change disturbs this dynamic: rising surface temperatures exacerbate the layering and decrease the rate of mixing. This, in turn, decreases the amount of nutrients travelling up to surface waters, which further affects biological productivity, heat redistribution, carbon uptake and oxygen production. The data show that upper ocean stratification will be greater everywhere during the second half of the twenty-first century, indicating a more pronounced decoupling between the surface and the deeper ocean.[177] The areas most affected include the Arctic, the tropics, the North Atlantic and the northeast Pacific.[178]

Deoxygenation In the open ocean, deoxygenation is primarily caused by global warming: oxygen solubility decreases with increasing temperature, and less oxygen reaches the deep ocean layers because of stratification. In the past 50 years, the ocean's oxygen content has decreased by 2%,[179] and ocean models predict a further decline of up to 7% by 2100.[180] Oxygen-minimum zones in the open ocean have expanded by several million square kilometres.[181]

In estuaries and other coastal systems strongly influenced by their watershed, oxygen declines can be linked to agriculture, sewage and the combustion of fossil fuels, which generate increased loadings of nutrients (particularly nitrogen and phosphorus) and organic matter.[182] An influx of nutrients causes an increase in microscopic algae, which ultimately die and decay, and the resulting decomposition process consumes oxygen, leading to oxygen depletion in the surrounding water. The Baltic Sea is a prime example of low-oxygen conditions caused by high nutrient loads from land runoff.[183] Oxygen decline in coastal systems is exacerbated by climate change (as in the open ocean) and by increasing nutrient delivery originating from increased precipitation.[184]

Overall, around 700 sites worldwide are now affected by low-oxygen conditions—up from only 45 in the 1960s.[185] Deoxygenation can have far-reaching biological consequences. Larger fish species with high metabolic rates, including yellowfin tuna and swordfish, are especially vulnerable to deoxygenation, and there is evidence that the balance of marine life is starting to shift in favour of species that are more tolerant of low-oxygen conditions, such as microbes, jellyfish and some squid.[186] Low-oxygen conditions can also make animals more susceptible to pathogens and parasites, increasing morbidity and mortality from diseases.

Reduced biomass and biodiversity, and redistribution of species Physical changes and overfishing have profound second-order consequences for the biological ocean. The IPBES estimates that 'more than 40% of amphibian species, almost a third of reef-forming corals, sharks and shark relatives, and over a third of marine mammals are currently threatened with extinction'.[187] Overfishing disproportionately removes predators, which are replaced by shorter-lived and smaller species, and the food chain becomes much simpler, less dynamic and less resilient.[188] Predatory fish biomass today is about one-third of 1920 levels.[189] Warming and deoxygenation are predicted to cause a large-scale redistribution of global fish and invertebrate biomass by 2055, with a 30–70% increase in high-latitude regions and a drop of up to 40% in the tropics.[190] Loss of biodiversity leads to measurable decreases in ecosystem functionality, including the number of viable fisheries (non-collapsed), the provision of nursery habitats, as well as the filtering and detoxification services essential for water quality and the reduction of harmful algal blooms, fish kills and beach closures.[191]

Sea level rise Sea level rise results from a combination of thermal expansion caused by the warming of the ocean (since water expands as it warms) and increased melting of glaciers and ice sheets.[192] A range of positive feedback mechanisms makes predictions exceedingly complex. For example, the melting of glaciers accelerates their rate of flow into a warming sea. It has been assessed that the global average sea level

has risen by about 16–21 cm since 1900,[193] at an accelerating rate over the past two decades.[194] The future extent and level of potential damage from sea level rise is therefore the subject of intense research and debate. The IPCC frames the range of outcomes between the empirical record of similar events in the distant past, and much more cautious simulations from process-based computer models: 'Paleo sea level records from warm periods during the last 3 million years indicate that global mean sea level has exceeded 5 m above present (very high confidence) when global mean temperature was up to 2 °C warmer than pre-industrial (medium confidence)'.[195] Perhaps more relevant to climate policies than the slow rise over centuries to millennia is the risk of rapid melting of Antarctic or Greenland ice that could lead to sea level rise of several metres over a span of decades. The risk of such catastrophic events is notoriously difficult to evaluate based on observational records.

Phenomena such as deoxygenation and reduction of biomass and biodiversity are highly synergistic—one propels the other. It is not analytically feasible to predict precisely *when* and *where* these complex chains of events will occur. However, new 'big simulation' tools allow us to describe *what* might happen in any given ocean region.[196] Typically, these simulations show that while a single source of stress (e.g. overfishing, pollution) can do considerable damage, multiple and compounding sources can do worse by orders of magnitude.[197] Put simply, ocean risk is a function of how bad the stressors are, the degree to which they reinforce each other and the natural variability of the ocean they are affecting.

The 2019 IPCC report *The Ocean and Cryosphere in a Changing Climate* estimates that climate-induced declines in ocean health will cost the global economy US $428 billion/year by 2050 and $1.98 trillion/year by 2100 (Fig. 20.20).[198] These numbers encompass costs associated with declines in ocean health and services due to climate-change, overfishing, excessive nutrient loads and plastic pollution.

Of course, the synergy story has an upside as well. If each new layer of stress increases overall risk disproportionately, then the opposite is also true: for each layer taken away, the system becomes more resilient. This makes it possible to buy valuable time when dealing with long-term issues such as warming or acidifying waters.

4.3.2 The Decline of Ocean Health Is Threatening Most Ocean Sectors

Insufficient action to reform the ocean economy and protect and restore ocean health can negatively impact ocean sectors that depend on a healthy, productive and resilient ocean or are directly exposed to its physical manifestations (e.g. sea level rise, waves, extreme events).

Wild-catch fisheries Climate change will impact wild-catch fisheries in terms of both stock productivity (i.e. its potential sustainable yield) and distribution (i.e. its physical range). The IPBES states that 'climate change alone is projected to decrease ocean net primary production by 3–10%, and fish biomass by 3–25%' by 2100, depending on climate scenarios.[199] These global numbers mask even more significant variation in changes across stocks and regions. Poleward regions such as the North Atlantic and North Pacific are predicted to see a 30–70% increase in catch potential, while equatorial regions face a 40% decrease.[200]

Where stocks decrease or move away from traditional fishing grounds, fishers must spend more resources to locate and catch them.[201] Conversely, any shifts to shallower water may make stocks easier for local fishers to catch but more vulnerable to overfishing. Overall, smaller-scale fisheries which rely on vessels with limited range and low technological capabilities are likely to be most vulnerable to shifts in

range or migratory patterns.[202] The equity implications of longer travel and/or declining yields are pronounced, especially since artisanal fisheries provide the protein of last resource in many developing countries' coastal areas.

Regulatory constraints may also hinder fishers' ability to adapt, particularly if species move across management boundaries.[203] Depending on the chosen climate scenario, between 28% and 72% of current global fishery yields will shift across country boundaries by 2100.[204] In addition to economic impacts, the redistribution of catch potential is likely to increase the risk of conflicts among fisheries, authorities and communities. In the absence of a coordinated response, the compounding effects of overfishing and stock (range) shift could severely threaten future global fishery yields and profits.[205]

With these conditions expected to change and levels of uncertainty to grow, more adaptive management of fisheries will be critical to a better future (e.g. through rights-based fishery or secure-access systems).[206]

Mariculture The overall potential of mariculture is likely to remain high under climate change. With careful planning, improvements in feed technology and the implementation of best practices for preventing or reducing negative impacts on ecosystems and communities, mariculture could offset long-term losses in food and income from capture fisheries in most countries that will experience losses in that sector. However, a study found that a severe climate scenario would create both gains and losses in the studied 180 cultured finfish and bivalve species.[207] Lower trophic species such as bivalves were affected disproportionately due to the compounding effects of shifts in temperature, chlorophyll and ocean acidification.

The Indo-Pacific region—China, India, Bangladesh and Indonesia—is particularly impacted; finfish mariculture

could decline by as much as 30% in some areas, and the risks to bivalve farmers are even higher.[208] Many coastal residents in these regions depend heavily on seafood for employment and food security.

Anthropogenic pollution is already having an effect on mariculture operations. Apart from farmed species requiring pristine water conditions for optimal growth, the accumulation of anthropogenic pollutants, especially microplastic in farmed (and wild) species, is a significant concern.[209] This is especially true of non-fed mariculture species like bivalves,[210] who feed by filtering suspended material—including the accidental microplastics—out of the water column.

Tourism Sea level rise will erode and submerge tourism infrastructure and beaches, with many resorts sitting at less than 1 m above the high-water mark.[211] In the Caribbean, a sea level rise of 1 m is projected to endanger 49–60% of tourist resorts, damage or cause the loss of 21 airports and cause severe flooding of 35 ports.[212] In 2050, according to one estimate, rebuilding tourist resorts alone will cost the region US $10 billion to $23.3 billion.[213] In Venice, higher water levels are threatening building integrity, eroding the lagoon and subjecting the city to more than twice as many floods since 1960.

The tourism industry also will be hit by the loss of coral reefs. Coral reefs contribute $11.5 billion annually to global tourism revenues, benefitting more than 100 countries.[214] Coral reefs would be virtually all lost at 2 °C warming,[215] with serious impacts for tourism in Australia and small island developing states (SIDS) in the Caribbean and elsewhere.[216]

Tourism is both a source and a victim of pollution.[217] Beach closures due to sewage pollution affect countries worldwide. Other direct forms of pollution impacting tourism include plastic waste on beaches, making them undesirable for tourists to visit. Indirect impacts of anthropogenic pollution on tourism also exist: the combined effect of elevated sea surface temperatures, excess fertiliser and increased nutrient runoff due to deforestation are potential causes of the explosive growth of sargassum seaweed[218] that is washing up on tourism beaches in the Caribbean, the Gulf of Mexico and West Africa, driving down hotel bookings in certain areas.[219]

On top of these worrying trends, the COVID-19 pandemic is having severe impacts on coastal tourism, for example. SIDS are expected to experience a 7.3% fall in gross domestic product (GDP) given their tourism dependency, and this drop could be up to 16% in highly tourism-dependent SIDS like Seychelles or the Maldives.[220]

Ports and supply chains Severe disruptions due to extreme weather events can be expected. A 2013 study[221] finds that the supply chain consequences of compounding sea level rise, higher storm surges, increased cyclone intensity and

destructiveness,[222] wave regimes[223] and river floods of ports,[224] coastal refineries and chemical plants could cause operational delays at a scale of billions of U.S. dollars per day,[225] with incalculable effects on business cycles, supply chains and the overall operating risk of companies.

4.3.3 The Risk to Coastal Communities Is Increasing

Major and irreversible shifts in ocean functionality threaten coastal communities and habitats in many ways—the current ocean economy system is far from delivering prosperity for all. Further, the effects of these shifts will be disproportionately felt by vulnerable, historically underrepresented and underserved communities in both developed and developing countries.

Flood damage New research has demonstrated that extreme coastal inundation events are increasing, and in some regions increased chronic flooding has been observed.[226] Many small islands already face large, sometimes existential, flood damage, and damage from sea level rise could equal several percentage points of GDP in 2100.[227] Risk associated with floods and hurricanes are accentuated for the 100–300 million people living within coastal 100-year flood zones, as the loss of coastal habitats and coral reefs reduces natural coastal protection.[228] In Europe, annual damage from coastal floods is expected to rise from €1.25 billion today to €93–960 billion by the end of the century.[229] Without drastic changes towards climate-smart coastal development, major disruptions can be expected in addition to damages to coastal communities.

Risks to agriculture Sea level rise will affect agriculture through land submergence, the salinisation of soil and fresh groundwater, and land loss due to permanent coastal erosion.[230] Countries heavily dependent on coastal agriculture, such as Bangladesh, are likely to experience reduced production and livelihood diversity, as well as greater food insecurity (Fig. 20.21).[231]

Permanently displaced coastal populations Rising sea level will be experienced not only as a long-term, gradual event but also as a series of extreme events caused by the compounding effects of spring tides, stronger and slower-moving hurricane surges, spring floods and land loss. Based on a scenario without effective climate change mitigation policies,[232] a 1 m rise in sea level would entail dramatic increases in the frequency of 100-year extreme weather events in cities such as Shanghai, New York and Kolkata (Fig. 20.21). Some cities will have the means to adapt with major feats of engineering, but other areas will become unliveable, generating waves of displaced people in the context of disasters and climate change. Indeed, 88 million to 1.4 billion people are estimated to be at risk of displacement.[233] In the United States, 3 ft (~0.91 m) of sea level rise

by 2100 threatens four million people.[234] The situation is particularly dire for SIDS, for whom raising seas can become an existential threat.[235]

4.3.4 Ocean Activities Are Currently Not Delivering on the Social Sustainable Development Goals

If not properly regulated and managed, a growing ocean economy can lead to even greater economic inequality than already exists.[236] Benefits will continue to be captured by an elite and strong incumbents, whilst vulnerable and marginalised groups become even more exposed to economic, social and cultural impacts and displacements.[237] In this scenario, the ocean economy could have a net negative effect on progress towards UN Sustainable Development Goals (SDGs) such as no poverty, zero hunger, good health and well-being, and reducing inequalities (see Sect. 5.4 for a detailed assessment of the link between SDG 14 (life below water) and the other SDGs).

Increasing inequalities Global inequity is increasingly acknowledged as a substantial challenge to the ocean economy. Inequities are contrary to and will undermine progress towards the Sustainable Development Goals as they have contributed to a deteriorating ocean environment, with negative effects on human well-being primarily borne by the most vulnerable. Climate change risks aggravate existing inequity. The vulnerable and marginalised will be disproportionately affected by the effects of climate change. The lack of alternatives and high dependence on fish stocks for nutrition and income disproportionally expose the coastal poor to the effects of climate change.[238] Growing demand for fish feed can also exacerbate inequalities by diverting small pelagic fish like pilchards from domestic consumption for food, where such fish are a key component of the diet for many communities.[239] In addition, poor communities have

fewer resources to respond to shifting fish stocks by changing gear types or travelling further to fish, as well as fewer resources to shift livelihoods altogether. Gender inequality is pervasive in many ocean industries overall, and climate change could be especially devastating for the most marginalised coastal women.[240] The international community's global ambition to 'leave no one behind' can only be realised through inclusive governance and the fair distribution of ocean benefits. An increased focus on equity will be instrumental for the legitimacy, effectiveness and sustainability of the ocean economy.

Food insecurity and malnutrition Projected changes in fish distribution and abundance will put income, livelihoods, nutritional health and food security at risk in communities that rely on marine resources, such as those in the Arctic, West Africa and small island developing states.[241] Globally, climate change puts up to three billion people at risk of food and economic insecurity.[242] Food security and human health are also threatened by harmful algal blooms, with communities in areas without sustained monitoring programs and dedicated early warning systems most vulnerable to these risks.[243] Cultural diet changes in certain parts of the world, particularly Pacific island nations, are shifting diets away from healthy, local reef seafood towards imported, often highly processed, high sugar and fat foods. The results are rising malnutrition and increasing prevalence of non-communicable diseases.[244]

Job safety and security The isolation of ships at sea and the liability protection of vessel owners afforded by current flag state regulations serve to conceal human rights abuses, whilst labour protections are poorly enforced in many countries. Informal or unregulated economies and fishing activities, such as shellfish gathering or fish processing, face significant exposure to unregulated exploitation and disproportionally employ women[245] and marginalised groups.[246] Unreported catches and illegal activities can mask labour trafficking, peonage systems, unsustainable resource use and health and sanitary issues whilst simultaneously avoiding taxation and detracting from wider economic benefits.[247]

BAU ocean industries development is likely to cause and exacerbate inequities across the spectrum of ocean sectors, and people with vulnerable marine livelihoods (who are more likely to be women, ethnic and racial minorities, migrants, youth and Indigenous People) are likely to be disproportionately affected. A new paradigm urgently needs to be embraced.[248]

Human rights Organised crime and human rights violations are a known plague within the ocean economy, especially the fisheries sector. Apart from the human impact, these crimes continue to have negative impacts on the environment as well as the global economy. The crimes can include, among others, tax crimes, money laundering, labour offences, drug trafficking and migrant smuggling. Many of these crimes can be associated with or facilitated by illegal, unreported and unregulated (IUU) fishing,[249] which is estimated to account for 20% of the world's catch (up to 50% in

some areas).[250] These offences have been notoriously challenging to address due to jurisdictional disputes and inadequate or absent legal frameworks and enforcement. Attention has been drawn to this issue on an international level, with increasing understanding of the complexities of organised crime in the fishing sector. In 2008, the UN General Assembly requested that states assist in gathering more information on the connection between illegal fishing and organised crime.[251]

4.4 Embracing Hope: The Building Momentum for a Sustainable Ocean Economy

When reading through the litany of threats to the ocean, two uncomfortable questions arise: Is the ocean so complex and damaged that it is *too big to fix*?[252] Is the only way out to immediately curtail most ocean activities? The answer to both is a decisive 'no'. A profoundly different mindset is emerging, in an unprecedented number of global initiatives through the G20 and G7, the Ocean Panel, the UN Ocean Conference, Our Ocean, the World Ocean Summits, the UN Decade of Ocean Science, World Trade Organization meetings on ending harmful fishing subsidies, COP26 on climate, COP15 on biodiversity, the RISE UP Blue Call to Action (led jointly by NGOs and civil society)[253] and so on. Coastal nations, especially small island states (alternatively referred to as 'large ocean states')[254] are advocating for socially equitable and environmentally sustainable growth.[255] Civil society is realising the ocean's decline and vigorously endorsing governmental action to protect it: a 2020 survey found, for instance, that 92% of Japanese respondents supported the establishment of MPAs, 92% of U.S. respondents believed that 'ocean governmental regulations are necessary' and 92% of Indonesian respondents 'supported environmental conservation regulations to protect the ocean'.[256]

In response to the growing pressures described in Sect. 4.3, innovations and trends are emerging that demonstrate through trial and error that alternatives are possible.[257] These 'niche innovations' can be geographical and/or sectoral spaces, where innovators coalesce in response to perceived pressures affecting the ocean. These niche innovations can be protected from market dynamics (through subsidies, soft money) or political interference (through regulation or location in the non-profit sector). This section identifies (non-exhaustively) seeds of change already sprouting and in need of careful nurture: celebrated in their beginnings, prioritised in policy and finance, and promoted publicly.

This section first looks at selected sectorial innovations and trends (in particular in fisheries, mariculture, energy, shipping and tourism) before identifying additional cross-sectorial ones (in data, ocean planning, finance, anti-pollution efforts and accounting).

4.4.1 Hopeful and Promising Sectorial Trends and Innovations

Sustainable fisheries Three main trends will accelerate sustainable reforms:

- **The turning institutional tide.** Most national fishery ministries are now committed to the goal of maximum sustainable yields. Most, however, still struggle to attain that goal. In recent years, regional fisheries management organisations (RFMOs), long constrained by consensus decision rules, have finally been able to restore some tuna stocks, notably Atlantic bluefin tuna and southern bluefin tuna.[258] The plight of artisanal fishers is being more fully considered in fishery management plans, but this is tempered by the lack of catch and effort data from artisanal fisheries, which are often equal in size to industrial fisheries. Fish-dependent nations in Asia (e.g. Indonesia, Fiji, the Philippines, the Marshall Islands) and Africa (e.g. Mauritius, Seychelles)

are committed to restoring the efficiency and equitability of their fisheries and/or have made substantial protected area commitments.

- **A data revolution.** Sound fishery management digital tools are now widely available, including vessel tracking, fishery simulation, registry and enforcement systems (e.g. satellite imagery, eDNA and drones). Philanthropically funded initiatives to study the ocean have mushroomed (e.g. REVOcean, OceanX). Market demand in the developed world for sustainably sourced fish has never been higher and can now be reliably serviced with chain-of-custody certification. Shortcomings in data availability are being addressed through new collection technologies (onboard cameras, scanners) and new data analysis and treatment methods. Lowering the costs of such technology and new models around sharing will be necessary to also benefit the broader base of small-scale fishers.
- **Asset turnover.** Many of the developing country fishing fleets are ageing as profits have been too low to fund depreciation. The fleets of Ghana, the Philippines and Senegal, for example, all have an average age of more than 30 years.[259] In the absence of capacity-related subsidies, many of these boats cannot be profitably replaced—if market discipline is maintained (no capacity subsidies or assistance, from either the country itself or foreign nations through loans and/or selling of fishing rights). In such cases, fishing capacity is allowed to drop, and the profits of remaining boats can slowly recover towards the maximum sustainable yield point; creating feedback effects that financially reward sustainable fishers.

Box 20.1 presents two inspiring case studies of fishery recovery (at national and international levels), demonstrating that sound measures properly implemented can lead both to restoration of fish stocks and economic and social gains.

Box 20.1 Successful Fishery Recovery Can Happen: Two Hopeful Case Studies

The United States Sustainable Fisheries Act of 1996 (SFA), and amendment to the 1976 Magnuson-Stevens Fishery Conservation and Management Act or Magnuson Stevens Act (MSA), governs fisheries management in the U.S. exclusive economic zone (EEZ) (up to 200 miles offshore). It is widely credited with saving U.S. fisheries. The original MSA established the legal basis for many essential fishery management mechanisms, such as the permitting of vessels and operators, and the ability to restrict gear, access and periods of fishing. However, for the first 20 years, and despite language aspiring to 'sustainable fishing', it did not explicitly prevent overfishing. The SFA changed this decisively. Its most important features were mandates to (1) not only end overfishing but also recover overfished species to sound, fully documented population levels (usually about one-third of the estimated pre-fishing population) within 10 years (with certain exceptions), (2) require that fishing quotas (catch limits) be set for each fishery, based only on scientific evidence about what is biologically sustainable, and include accountability measures to adjust future quotas in the case that overfishing accidentally occurs, and (3) allow the use of rights-based fishery management approaches if appropriate for that particular fishery. The inclusion of specific timelines and accountability measures made all the difference.

These amendments were highly successful. Forty-three fish stocks have been rebuilt since 2000, and over two-thirds of overfished stocks have been rebuilt or begun rebuilding since 1996. Revenue from 1996 to 2010 is up 54% in real terms.[a] The key features—reliance only on scientific evidence, use of rights-based approaches, strict catch limits and accountability measures, and the 10-year rebuilding plans—have been widely copied by fishery managers worldwide.

The law enjoys considerable support from the commercial fishing community and has generally held up well to inevitable pressure to extend deadlines for rebuilding stocks, relax catch limits and monitoring requirements, and limit the influence of science. Support for the law reflects the fact that stocks are rebuilding and fishers have input into the process, but especially because fishers' long-term incentives are aligned with their short-term incentives. The approach also combines national standards with regional tailoring. Regional fishery management councils propose management plans for each fishery that take into account local knowledge and factors but must also satisfy strict national standards.

The Parties to the Nauru Agreement (PNA) include the Federated States of Micronesia, the Republic of Kiribati, the Republic of the Marshall Islands, the Republic of Nauru, the Republic of Palau, the Independent State of Papua New Guinea and the Solomon Islands. Because these nations' mostly contiguous EEZs hold considerable fishery resources (especially tuna), they have developed a uniform management structure that prioritises resource sustainability and transparency.[b]

[259] FAO. n.d. "The Status of the Fishing Fleet." http://www.fao.org/3/y5600e/y5600e05.htm. Accessed 6 May 2020.

The agreement most prominently features three major arrangements:[c]

1. A regionwide register and monitoring of fishing vessels, with trackers on each boat.
2. No transshipment at sea, mandatory daily catch and effort reporting, regular logbook maintenance, 100% onboard observer coverage and an electronic data transmission device that provides position and catch information.
3. No fishing in the high-seas pockets between PNA nation EEZs, no fishing on floating aggregation devices between July and September, and mandatory retention of any bigeye, yellowfin or skipjack tuna caught.

The resulting comprehensive data collection makes it possible to set up and enforce the Vessel Day Scheme—a type of fishing quota that allocates 'allowed days of fishing' to individual vessels. Based on a scientific stock assessment, an overall 'days of fishing' effort is determined (44,033 in 2019 and 2020)[d] and appropriated to the PNA countries.[e] The countries can then sell their allocated fishing days to fishing vessels, resulting in sizable revenues for the PNA countries—nearly US $400 million in 2015.[f] The fishing days are tradeable between countries, which helps optimize fishing across the entire PNA territory—an important feature in managing highly migratory tuna stocks. It also ensures that the fishery's benefits are shared by all PNA countries, regardless of where the tuna happen to be in any given year.[g]

The agreement has increased revenue for the PNA countries while maintaining sustainable, science-driven harvesting practices. It has stabilised the stocks, provided the PNA (and other) nations with the lasting value derived from a well-managed fishery and has become a model for other ocean states. In 2012, this led the PNA skipjack tuna fishery to become certified by the Marine Stewardship Council, making it the world's largest independently certified tuna fishery.[h]

Mariculture Trends in marine aquaculture also point towards future sustainable expansion:

- **National priority.** China and Norway lead the development of large, next-generation offshore finfish farms (Box 20.2) which attempt to address issues of containment, disease control and nutrient efficiency. Archipelago nations, such as Indonesia and the Philippines, are exploring locally relevant approaches such as combined seaweed and low-trophic mariculture farms. National commitments to spatially explicit planning, streamlined permitting, rigorous operating standards and state-supported R&D are likely to further accelerate mariculture.
- **Improvement in fish meal/oil alternatives' availability and price.** The conversion of former biofuel or ethanol fermentation facilities to algae production (in places like Brazil or the U.S. Midwest) would scale up production so significantly that price points for omega-3 fatty acids as FM/FO alternatives and proteins could tumble (Box 20.2). Given the problems in the current biofuel markets, this

could happen soon, and with considerable government support to prevent the stranding of these major industrial assets. Insect-based fish feeds also are attracting increasing attention, creating a source of revenue out of food waste (insects such as black soldier fly larvae can be grown out of food waste and be used to feed farmed fish).[260]

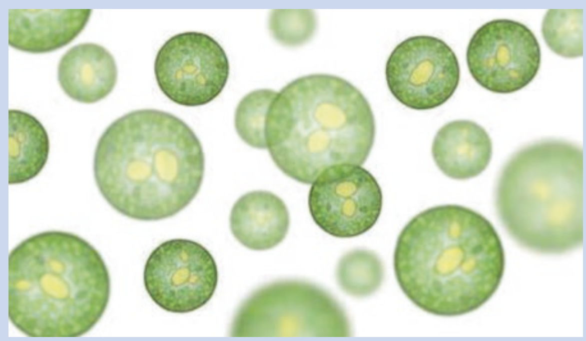
- **Progress made on limiting environmental impact of finfish mariculture.** Apart from feed, the main challenges of mariculture are (1) fouling of the water column and sea floor, (2) parasites (sea lice) that migrate to native (wild) species, (3) leakage of antibiotics used to (over) treat diseases and (4) the escape of non-native (and/or genetically modified) species. New technologies offer some promise. Remote video-controlled feeding systems can reduce food waste; parasites can be controlled drug-free through the addition of cleaner fish,[261] lasers, electric fences and sudden changes in temperature; [262] disease resistance can be boosted with selective breeding;[263] control systems such as the Norwegian 'traffic light' system can control the growth of farmed salmon;[264] and rigid-structure caging systems can reduce escapes. Finally, the combination of bivalves and seaweed into multi-trophic farms is a promising approach to limit some impacts of finfish farming.[265]

Box 20.2 Examples of Mariculture Tech-Driven Innovations

Credit: SalMar

SalMar's Ocean Farm 1 is one of the largest offshore marine mariculture pens. Built in China and deployed in Norway, the 110-m-wide-structure is predicted to be able to hold over 1 million salmon.

Apart from its enormous size (250,000 cm^3), it is able to withstand 12-m waves and is equipped with over 20,000 sensors monitoring the well-being of the fish.



Credit: Perception7/Shutterstock.

Grown by feeding sugar derived from sugarcane to algae in a fermentation tank through a special fermentation process, the algae turn the sugar into omega-3 oil, which can be (and is being used as) a replacement for fish oil in fish feed.

A frontrunner in this space is Corbion's DHS Algal prime, managing to save 40 metric tonnes of forage fish per tonne of DHS Algal prime. Algal prime is already produced at a commercial scale, and with prices falling its algae omega-3 oil is at price parity with fish-derived omega-3.

DSM has partnered with Evonik to develop a similar algae-based solution, called Veramaris. They claim 1 tonne of Veramaris algal oil is the equivalent of 60 tonnes of avoided wild-caught fish.

Accelerating ocean-based renewables Offshore wind is an increasingly mature and competitive technology, but other ocean-based renewable energy sources are also actively being explored: energy extracted from waves and tides, from salinity and temperature gradients (e.g. by ocean thermal energy conversion or by heat pumps for heating and cooling), and floating solar photovoltaic systems are beginning to emerge in marine environments.[266] Three major factors are encouraging the growth of ocean renewables:

- **Increasingly competitive electricity cost.** The levelised cost of electricity (LCOE) for offshore wind was $124–$146 per megawatt-hour (MWh) in the United States in 2017 and somewhat less in Europe.[267] Recently, auctions in the European market have seen contracts drop to about $50/MWh,[268] which is highly competitive with other sources of electricity. Low cost of capital drives down LCOE for offshore wind, and economies of scale are significant, with costs declining at 18% per doubling of capacity.[269] Non-wind sources are largely uncompetitive today, with LCOE often above $250/MWh. Wave energy and ocean thermal energy conversion are capital intensive and unlikely to scale below $150/MWh and $70–$190/MWh,[270] respectively, making them most useful for very specific applications such as for small island nations currently reliant on imported fossil fuels.
- **Rising global investments in offshore wind.** The ebb and flow of projects responding to policy has resulted in volatile global investment volumes (ranging from $30 billion to less than $15 billion in the past 5 years), but the overall trend is bullish. With decreasing offshore auction prices, the increasing water depth of projects, increasing turbine capacity and declining LCOE, global investments are nearly certain to increase—especially as Europe's commanding lead is challenged by Asia, Australia and even the Middle East in the years to come[271] (see Box 20.3).
- **Declining environmental impact.** There is growing consensus that offshore wind farms can be built without significantly damaging the environment, if proper planning and mitigation measures are put in place to address bird strikes, construction and operation noise, and sea floor damage.[272] The carbon mitigation benefits of ocean-based renewable energy production are significant and accrue back to ocean health and functionality.

Box 20.3 Offshore Wind in Vietnam

The southern coast of Vietnam has demonstrated technically feasible wind potential, with average wind speeds of 7–11 m/s. Faced with gradually depleting hydro and fossil fuel energy sources and burgeoning demand, the country plans to install 6.2 gigawatts (GW) by 2030. As a major first step, a site survey licence has recently been issued for the 3.4 GW Thang Long wind project offshore from Ke Ga Cape—the world's largest wind project, located in a 2800 km^2 area 20–50 km offshore from Binh Thuan Province. This is the first step towards a US $11.9 billion, six-phase build-out designed to take optimal advantage of progressing Mitsubishi and Vestas turbine technology between now and 2026. The first 600 MW phase is expected to comprise 64 turbines at a best-in-class capacity of 9.5 MW and to be operational in 2023.

The project is emblematic of the special financial and operational conditions in developing countries. On the downside, developers generally are on their own with development costs, and projects win or lose on strict market terms. On the upside, the natural conditions are often perfect, and the onshore infrastructure/offtake facilities and supply chains are often new and up-to-date.

Shipping, often considered as a traditional, slow-moving sector, is experiencing a real revolution

- **Shipping decarbonisation momentum.** The International Maritime Organization's Energy Efficiency Design Index requires ships built after 2022 to be at least 50% more efficient over 2008 levels,[273] and total shipping GHG emissions to be reduced by at least 50% in 2050.[274] The industry is now actively working and collaborating on this agenda. For instance, Mærsk, a leading shipping company, is estimated to have invested several billion U.S. dollars between 2014 and 2019 in researching carbon-free shipping technologies.[275] The efforts are also focusing on addressing the difficult problem of collaboration: the 'Getting to Zero Coalition' convenes more than 100 companies and shipping-related stakeholders (e.g. ports) to develop 'commercially viable zero emission vessels, powered by zero emission fuels by 2030'.[276] The 'Green Maritime Methanol consortium' is exploring use of methanol as a shipping fuel.[277] Another cross-industry collaboration—Project ZEEDS—aims to create the 'zero fuel station of the future'—green ammonia fuel stations at sea that are powered by surrounding offshore wind farms (see the Prologue of this report). Zero-carbon fuels are still at a very early stage for long-haul trips, but recent advances in battery technology have allowed short-haul ships—mostly passenger and car ferries in developed countries—to become electrified (see Box 20.4).[278] Finally, on the energy efficiency front, optimised hull, propulsion and (existing) engine designs could deliver energy efficiency improvements of 30–55% compared to current fleets.[279]
- **Ballast water treatment improvements.** In 1991, the 'International Guidelines for preventing the introduction of unwanted aquatic organisms and pathogens from ships' ballast water and sediment discharges', developed by the Marine Environment Protection Committee (MEPC),[280] set the stage for ballast water control. These standards have been followed by the 2017 Ballast Water Management Convention (BWM),[281] which requires ships to treat their ballast water by 2024.[282] The BWM has been supported by the GoBallast program, a global partnership of—among others—the Global Environment Facility (GEF), the IMO and the UN Development Programme (UNDP) aimed at reducing global ballast water pollution.
- **Improved port management.** The World Port Sustainability Program is designed to 'enhance and coordinate future sustainability efforts of ports worldwide and foster international cooperation with partners in the supply chain'.[283] On a national level, many ports are leading the way towards becoming more sustainable. The Port of Rotterdam's €5 million 'Incentive scheme for climate-friendly shipping' aims to make the port a leader in carbon neutrality.[284] A joint project by the Port Authority of Bari (Italy) and DBALab uses 'artificial intelligence for environmental monitoring and prediction' of the port's activities. The program's display environmental and port activity data allow operators to minimize the port's environmental footprint.[285]

Box 20.4 Decarbonising Short-Haul Shipping: Electric Ferry
The Danish towns of Fynshav and Søby are connected by an electric ferry 60 m long and 13 m wide. The relatively short trip length of commuting ferries facilitates the use of batteries and electric engines. Since the first electric ferry was put in service in Norway in 2015, the number of electric ferries operating in the country has been rapidly increasing and will reach between 60 and 70 in 2021. Also, cities in the United States, Canada and Denmark have concrete plans (or even orders) to electrify their car and passenger ferries.

Successful coastal/marine conservation initiatives

- **Restoration**. 'Soft' coastal approaches using tidal marshes, mangroves, dunes, coral reefs and shellfish reefs are increasingly part of coastal defence. Sixteen thousand acres of tidal marshes in San Francisco Bay are under restoration, and the Mississippi marshlands are under restoration to protect New Orleans and southeast Louisiana from storm surges. The Netherlands and Belgium combine 'hard' solutions (e.g. seawalls, dykes, sluice gates) with 'soft' restoration, with the latter showing highly efficient results.[286] In the Belgian Scheldt estuary, up to 4000 hectares of historically reclaimed wetlands are being converted back into floodplains; when finished in 2030 at a cost of €600 million, this will alleviate a 2100 yearly risk of flood damage estimated at €1 billion.[287] In Southeast Asia, mangrove forest plantations are being considered as protection against storm surges,[288] but restoration projects are small compared to the area already lost. In cities as diverse as Amsterdam, Abidjan and Lagos, beach and dune barriers are being built as crucial defences against coastal flooding.[289]
- **Protection.** Marine protected areas provide levels of protection ranging from strict 'no-take' to more permissive 'sustainable extraction' (see MPA guide in Fig. 20.27). If properly sized, sited and delineated, they can generate multiple benefits. The strongly protected 'no-take' zones,

for instance, have been shown to restore fish stocks by a factor of up to six times within the area;[290] to support ecosystem complexity, health- and associated ecosystem services;[291] to help with climate resilience;[292] to reduce carbon released from seabed floor;[293] to increase ecosystem resilience;[294] and to provide pristine ocean areas important to many cultures around the world.

- As of today, the Convention on Biological Diversity (CBD) estimates, 14.4% of national waters and 5.7% of the global ocean are protected.[295] However, only 2.4% of the ocean can be considered to be in fully protected MPAs.[296] Too often, MPAs are categorised as environmental measures at odds with economic interests (starting with fisheries).
- When full protection cannot be achieved, 'extractive MPAs'—defined as ocean areas subject to some restriction on use and/or extraction—can represent a viable form of protection for many countries with coastlines (>75% of countries in 2013).[297] Properly designed, they can be effective in protecting key coastal habitats, and they may represent an underused means to block particularly destructive coastal land uses and resource-extraction practices.

4.4.2 Structural Changes Across Ocean Economy Sectors

This section reviews recent progress in ocean data, ocean planning, finance, anti-pollution efforts and accounting of the ocean economy.

The ocean data revolution The technology is here now. It is now technically possible to sample the ocean on its true spatial and temporal scales with a remote-sensing network covering the physical, biological, ecological[298] and chemical properties of the global ocean surface (although full coverage remains far off). From the proliferation of sensors and platforms (Argo floats,[299] REMUS,[300] Wave Glider[301]) and satellites (from SeaSat onwards) to cabled observatories[302] and acoustic modems, remote sensing and transmission of data from a variety of platforms is becoming an 'always on, always connected'[303] operating system. The connection of intelligent devices into an 'Internet of Things' is moving from land to sea, analysing data ranging from invasive species in bilge water to nutrients in river deltas, allowing for an ever-more complete picture in near real time—the holy grail of adaptive management. The open-access platforms necessary to store, share and process the innovation are technically available (and in broad use in many cloud-based data systems), but their application in the ocean realm is still lagging behind (see Sect. 6.3 for in-depth discussion).

Data processing is keeping pace with the sensing revolution. Processing capacity has increased 1 trillion times in the past 50 years, making it possible to build massive dynamic

model simulations ranging from cosmological galaxy formation[304] to weather, climate prediction and hurricane prediction. The implications for ocean governance, management and economic development are profound.

Growing traction on ocean planning The safety issues associated with multiple uses in a turbulent ocean environment (e.g. stationary wind farms or mariculture facilities vs. cargo, fishing and navy shipping lanes) are complex and a major cause of regulatory delays today. The regulatory difficulties of securing long-term, reliable permits and access rights are hurting the mariculture industry. Carbon- and offset-financed restoration projects are hard to structure without long-term title protections. Open access for all interested parties is the primary driver of overfishing in the developing world. On land, nobody would expect investors to deal with the legal and regulatory uncertainties of such an open-access system.

At the same time, the technical hurdles to delineating, monitoring, and enforcing access rights in a remote ocean are no longer applicable—the remote-sensing revolution offers multiple alternatives to expensive patrol-based enforcement schemes. For example, Caribbean protected area managers and technologists have jointly developed low-cost acoustic sensors that identify violating vessels.[305] Another example is Global Fishing Watch,[306] which visualises, tracks and shares data on global fishing activities in near real time.

As a result, several regions (northeast United States; Netherlands/North Sea; Baltic Sea; Norway; Xiamen, China; and the Australian Great Barrier Reef) have broken down siloed management practices in favour of more integrated spatial planning. Xiamen, for example, has pioneered a spatially explicit approach to coastal management since 1994, with a 40% improvement in socioeconomic benefits from its marine sectors.[307] Hundreds of territorial user rights for fisheries (TURFs) areas are being set up across the globe to protect community fisheries in multiple developing countries (e.g. Chile, Indonesia, the Philippines), with emerging evidence of recovering stocks, and increasing catches and profits.[308] The Baltic Sea states have coordinated across borders and sectors to implement a science-based planning strategy and have been rewarded with the return of predators and birds as well as restored fish stocks in the past 20–30 years.[309]

The ocean as the new investment opportunity The tide is turning on ocean investment. In a recent Credit Suisse survey,[310] 72% of investors ($n = 200$) classified the sustainable ocean economy as 'investable'. Several sustainable ocean economy private investment funds have been established recently: Sky Ocean Ventures, Althelia Sustainable Ocean Fund, Katapult Ocean, Ocean 14, BlueInvest Fund, Blue Oceans Partners and Fynd Ocean Ventures just to name a few. For more mature technologies such as wind energy, investments have also become sizeable offshore: 2018 investments in new offshore wind farms in Europe totalled €10.3 billion, 24% of total new power investments in that year.[311]

International funding for sustainable innovation includes a 2019 proposal for an IMO-administered US $5 billion fund to 'accelerate the R&D effort required to decarbonise the shipping sector and to catalyse the deployment of commercially viable zero-carbon ships by the early 2030s'.[312] Also in 2019, the Asian Development Bank launched the Action Plan for Healthy Oceans and Sustainable Blue Economies for the Asia and Pacific region, with committed funding of $5 billion from 2019 to 2024 to finance and provide technical

assistance for ocean health and marine economy projects in the region.[313]

Unprecedented momentum in the fight against land-based pollution Ocean pollution reforms are on different tracks. For plastics, the ocean is a major driver of global movement from linear to circular material management systems on land. For nutrients, pesticide runoff and industrial pollution, ocean interests have not yet reached the same level of influence, explaining a reform agenda lagging behind.

The transformation of the current linear plastic value chain to a more circular one represents enormous potential economic value, with estimated potential materials savings worth hundreds of billions of dollars per year,[314] together with significant co-benefits for the climate (9.3 gigatonnes [Gt] of CO_2e in 2050—equivalent to eliminating transportation emissions), and employment upsides.[315] A recent comprehensive modelling exercise concluded that solutions available today to industry and governments—if massively deployed—could reduce annual land-based plastic leakage into the ocean by around 80% by 2040, compared to a business-as-usual scenario, and also help advance other societal, economic, and environmental objectives.[316]

The crisis is now forcing the hand of plastic resin manufacturers, converters, and consumer brands. New consumer brand commitments to 'plastic neutrality' and recycling-friendly design are proliferating. The plastic industry as a whole is increasingly recognising its extended responsibilities for the entire product lifecycle and exploring cooperative schemes to improve waste management and collection. Over 95 plastic packaging policies and laws were signed in the United States, Europe and Asia from 2010 to 2019; and the New Plastics Economy Global Commitment had over 400 signatories, including from investors, innovators and NGOs. Cumulatively these commitments still fall far short of solving the crisis—but they represent only the beginning of what could become a comprehensive redesign of the plastic economy.[317]

New, more holistic ways to account for the ocean economy are now available Today's economic policy is concerned with outcomes and sustainability, not simply managing monetary inflation—'twenty-first century progress cannot be measured with twentieth century statistics'.[318] The System of Environmental Economic Accounting is being updated to include ecosystem accounting; there is discussion of revising the internationally agreed System of National Accounts to focus on sustainability.[319]

The most fundamental remaining accounting challenge is the monetisation of ocean and other natural assets—an essential input. The international standards for national accounts—the 2008 System of National Accounts (SNA)—provides little guidance for doing so. But methods for the valuation of non-produced or natural assets do exist,[320] including a 'Capital Asset Pricing for Nature' software package.[321] The Inclusive Wealth Index (2012) of the UN Environment Programme (UNEP), adopted by 140 countries, is piloting the measurement of natural capital,[322] and many partnerships aim to develop technical capacity, such as the WAVES (World Bank), BIOFIN (UNDP), MAES (EU) and UNEP-TEEB-CBD partnerships. Washington, DC: World Resources Institute.* https://www.oceanpanel.org/blue-papers/national-accounting-ocean-and-ocean-economy)

(NOAA), the Institute of Chartered Accountants in England and Wales and others brought together 60 leading ocean-related organisations in 2017 to ignite the creation of the Natural Capital Protocol for the Ocean[323] to supplement the recognised Natural Capital Protocol.[324]

Other natural capital valuation methods are already changing policy and investment decisions[325] (most advanced are perhaps those in China and the United Kingdom, but also other countries are taking up this information and transforming policy and investment, e.g. Belize[326]). These initiatives didn't start in countries' statistical offices but instead were initiated in sector-related ministries (e.g. fisheries, tourism, environment) and in finance ministries.

The digital revolution provides a major boost for ocean national accounting.[327] Online, digital dashboarding makes it possible to drill down quickly to specific indicators of interest in policy analysis and evaluation. The future has begun: an ocean proto-account for Norway can be displayed as an interactive dashboard (Fig. 20.22), and the United States hosts an interactive ocean proto-account.[328]

A user of the Norway dashboard can define the ocean economy through any combination of six sectors and explore how these interact along various indicators of production,

value created, capital used and the like. Although data holes remain (most fundamentally, Norway does not yet include monetisation of its natural capital stocks), the dashboard radically expands the breadth of questions that can be asked and answered.[329]

This section makes clear that a healthy ocean and a subsequent sustainable ocean economy are crucial allies to address some of the most pressing challenges humanity will face in the twenty-first century, including food security, climate change and social inequalities. Today the ocean's health is under increasing pressure from anthropogenic stressors. If not addressed these could compound with each other with dramatic consequences. A growing number of initiatives, technologies and business solutions are emerging and show that the possible alternative path of a sustainable ocean economy is realistic and feasible. The next section offers a vision where these positive developments are generalised and a sustainable ocean economy can emerge that benefits the people, the economy and the planet.

5 The Possibility of Tomorrow

5.1 Introduction

For centuries, the ocean has been viewed as '**too big to fail**'.[330] However, as shown in Sect. 4, this belief cannot be considered true anymore: overfishing, habitat destruction, climate change and pollution represent a de facto uncontrolled experiment. The size of the challenge could easily lead one to think that the ocean is now '**too big to fix**'.[331]

This report offers a more hopeful narrative. Section 5 posits that the agendas of ocean and terrestrial resource productivity are no longer separable; neither are the agendas of ocean protection and ocean productivity. As pressure rises on business and political leaders, and as new, sustainable types of ocean ventures demonstrate compelling economics, the tide can turn and the ocean as a source of sustainable prosperity can become '**too important to ignore**'.[332]

[329]Many of the data needed to feed these dashboards and to parameterise these connections already exist, but they are highly dispersed. A first step towards understanding the dynamics at play is to highlight the current high-level status of ocean account data with a live version of the dashboard at https://environment.yale.edu/data-science/norwegian-ocean-economy-dashboard/.

Section 5 of this report invites the reader to take a journey towards an alternative tomorrow, where a set of sound early decisions launches the productive disruptions, pioneers and dynamics that lead to a sustainable ocean economy over the coming decades. This section paints a 'vision' of what a sustainable ocean economy could look like and the benefits it could generate. This vision is anchored in science and is feasible if the right decisions are made and several systemic barriers are removed (analysed in depth in Sect. 6, Sect. 6.2).

This section starts by introducing seven fundamental design principles, suggested as a guiding 'Southern Cross' or 'North Star' (Sect. 5.2) to scale up the promising trends presented in Sect. 4. It then lays out a vision where five fundamental transformations enable the development of truly sustainable ocean sectors (Sect. 5.3). Finally, it presents evidence that such a vision can deliver a 'triple benefit' of effective protection, sustainable production and equitable prosperity (Sect. 5.4).

5.2 Defining a Compass Direction: Principles for a Sustainable Ocean Economy

Seven fundamental design principles are introduced below to help decision-making and prioritisation towards a sustainable ocean economy. Every measure, transformation and example in this section is based on these seven fundamental design principles (Fig. 20.23).

Guarantee equity The ocean, as 'the common heritage of humankind', needs to benefit all of humanity. Avoiding coastal food and energy insecurity, labour exploitation and gender discrimination should be given the highest priority and form the bedrock of decision-making related to the ocean economy. This includes respecting relevant international agreements like the SDGs, the UN Declaration on the Rights of Indigenous Peoples and the UN Declaration of Human Rights.[333]

Align with the Paris 1.5 °C target The 2019 UN emission gap report states that the world is currently on course for 3.2 °C global warming over pre-industrial levels[334]—presenting a stark contrast to the 1.5 °C limit now commonly recognised as critical for ocean health. Establishing a regenerative ocean economy, focused on restored and protected 'blue sinks' (e.g. mangroves, sea grass, saltmarshes) and

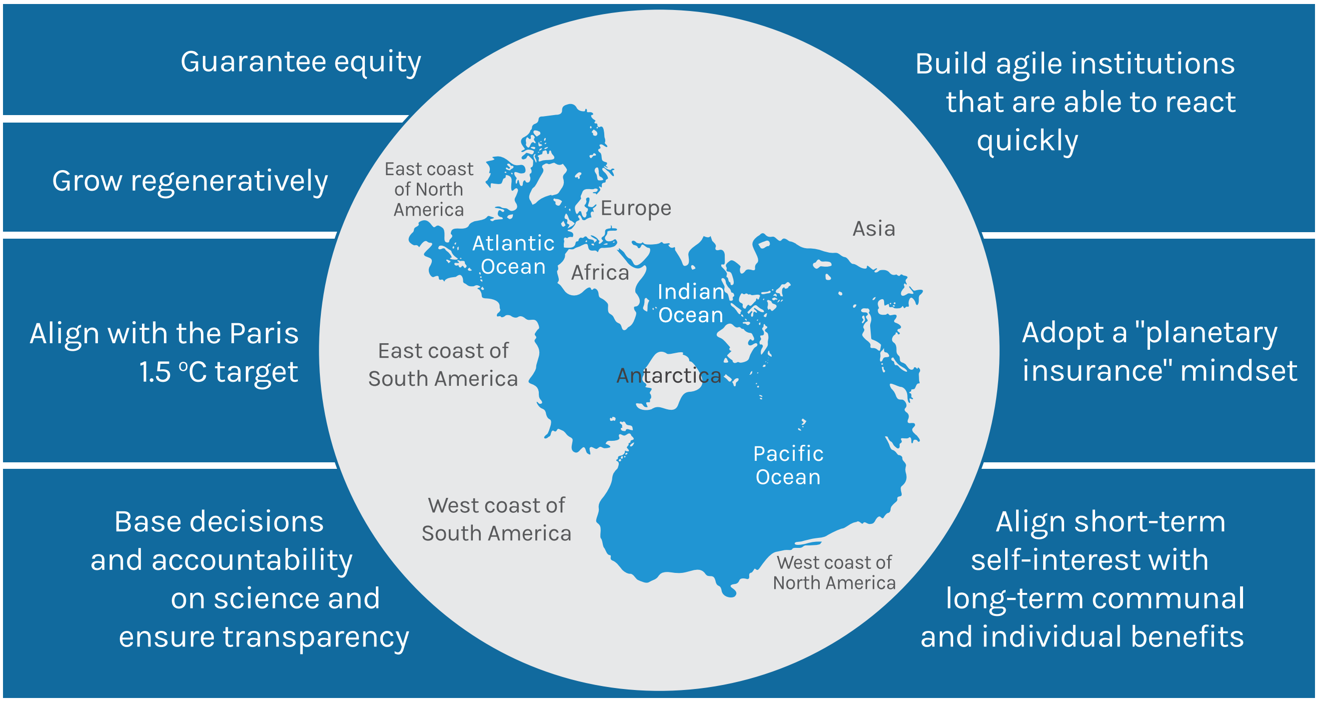

Fig. 20.23 Principles for a sustainable ocean economy. (*Source: Authors*)

zero- or low-carbon production of food, energy and transportation, is essential to that goal.

Base decisions and accountability on science and ensure transparency The age of the unfathomable, inexhaustible ocean is over. Future management must rely on a clear-eyed view of the impacts of climate change, the ocean's resource dynamics, its natural cycles of decline and regeneration and the resilience and vulnerability built into its infinitely complex biological systems. This requires the full and creative use of the data revolution for ocean purposes, the full appreciation and use of scientifically accurate local and Indigenous knowledge, and the commitment of management institutions to follow the advice of scientists.

Grow regeneratively The ocean economy, at every relevant scale, needs to cumulatively regenerate the ocean's vitality, diversity, and resilience. A sustainable ocean economy needs to ensure that marine economic activities are at least carbon-neutral and support the ocean's biodiversity. Not every project can be carbon-negative or rebuild biodiversity—but projects must be linked such that they bend the arc towards greater ocean health.

Build agile institutions that are able to react quickly In an increasingly fast and unpredictable world where 'governance failure is routine'[335] and crises like COVID-19 could become more frequent, institutions need to optimize themselves based on the principle of agility and ability to react quickly, while making decisions in an inclusive 'top-down, bottom-up manner'. This move towards shorter reaction times would allow governments, community networks and supra-national interests to adapt quickly to rapidly changing climatic and sociological conditions.

Align short-term self-interest with long-term communal and individual benefits Current misplaced incentives (economic incentives and behavioural norms) that drive destructive outcomes need to be reconfigured towards a new set of incentives aligned with the other six principles and the vision of a sustainable ocean economy.

Adopt a 'planetary insurance' mindset The ocean is becoming more unpredictable—the degradation of its health and ecosystem services is accelerating and is non-linear. Setting aside large areas of fully intact and comprehensive ecosystems and habitats is an essential insurance mecha-

Department of Sociology at Lancaster University, 21. https://www.lancaster.ac.uk/fass/resources/sociology-online-papers/papers/jessop-governance-of-complexity.pdf.

nism. The science is clear: large, properly designed protected areas increase the ocean's resilience to a variety of stressors, including warming and acidification. Similarly, the level of uncertainty at play does not allow for uncontrolled experiments and should encourage the following of a stricter, precautionary approach, whether in the exploration of new commercial species or the exploitation of known stocks and new resources like seabed minerals and metals.

Taking these general principles to their logical conclusion, a potential future emerges that diverges from the dystopian future evoked in Sect. 4.

5.3 A New Picture Is Emerging: The 2050 Sustainable Ocean Economy

It is impossible to predict precisely any version of the 2050 ocean economy—but it is possible to describe an optimistic scenario that combines the main linked components of a sustainable ocean economy (Fig. 20.24).

In this sustainable 2050 scenario, a new network emerges of interest groups including fishers, ocean farmers, scientists, civil society, local communities, as well as key energy, shipping and tourism players. This network is economically empowered and culturally deeply vested in ocean health and the sustainable ocean economy principles stated above. The groups of which it is composed create significant societal and economic values by linking offshore wind farms, mariculture, zero-carbon shipping, fuel production and tourism with unprecedented production efficiencies (see Fig. 20.24). Carefully situated non-fed and multi-trophic, zero-feed mariculture produces food for millions of coastal inhabitants. Large fully protected marine areas and MPA networks preserve intact ecosystems. Other effective area-based conservation measures and lightly protected MPAs accommodate some sectoral uses of ocean spaces that are compatible with some conservation goals. Large-scale restoration projects (e.g. mangroves, sea grass) are now financed by carbon mitigation fees and offset mitigation arrangements. Wild-caught fisheries implement climate-smart, ecosystem-based fisheries management. Collectively, this new cohort of ocean interest groups, of which youth and women are integral parts, works powerfully within the political economy to advocate for an equitably used ocean, free of pollution and over-exploitation, and with large fully protected areas to ensure ocean health and guard against unexpected changes.

Ocean-user interest groups have championed the importance of healthy ocean ecosystems, kick-starting an increased global understanding of the immense potential of a sustainably managed ocean economy. The spatial complexities of implementing linked and complementary ocean uses have encouraged more systematic ocean planning. Access rights for specific ocean resources have been clarified. Legal and political actions have been taken against land-based polluters. New finance and transaction recording (ledger) technol-

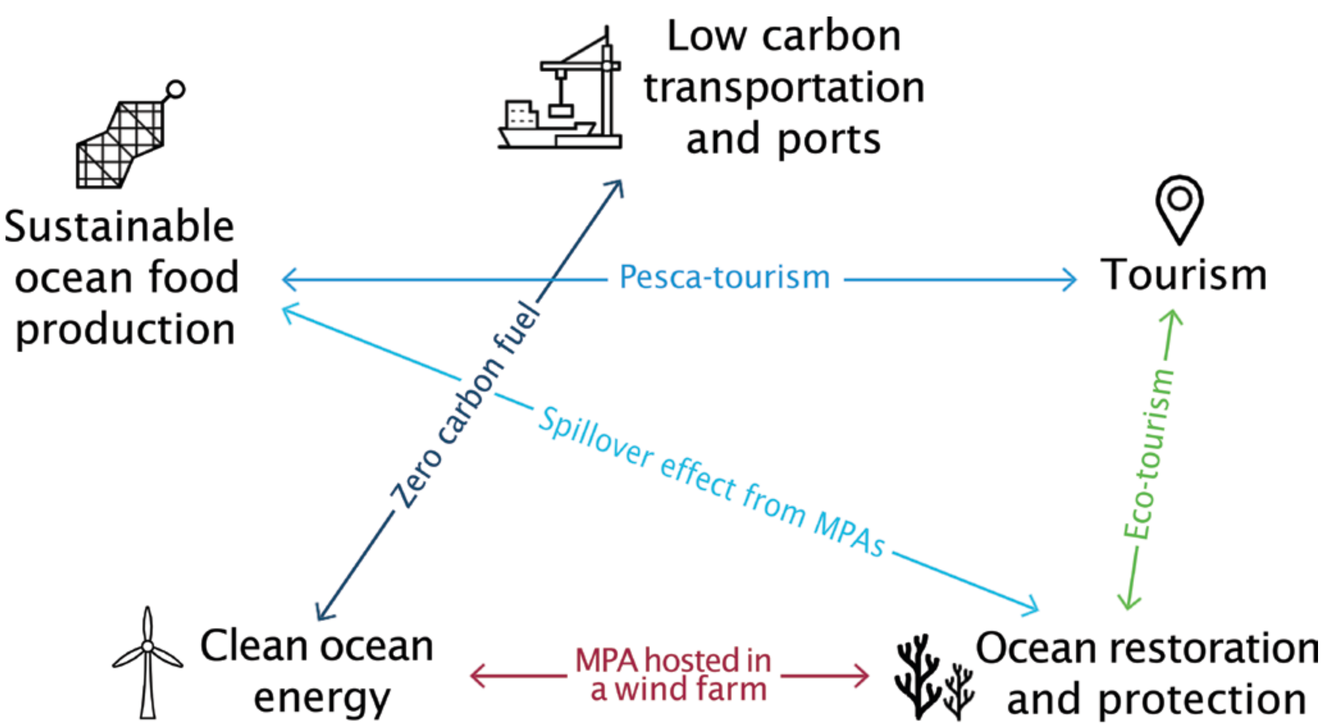

Fig. 20.24 The new contours of a sustainable ocean economy. (*Source: Authors*)

ogies have opened global markets for small artisanal producers while ensuring traceability and fair redistribution of the value created. Knowledge commons are allowing transparent sharing of data, assessments and lessons of what is working and what is not, leading to far more agile responses by communities, businesses and nations.

The political realm has responded to the new economic realities. Operating standards and permitting procedures have been clarified and standardised. Net margins of new and innovative ocean businesses are now supported through appropriate risk-reduction measures. Regulatory pressure on land-based polluters has increased. Access laws have been reformed to better balance the goals and needs of multiple stakeholder groups, including commercial and subsistence users. Labour laws have been strengthened, setting international standards to eradicate human rights abuses, and these laws are enforced.

Coastal communities, especially in the tropical realm, have reasserted their traditional use rights and are empowered to regulate access to local fisheries and ocean resources. Secure in their rights of access, they have the luxury of planning for the long term, and they have switched to sustainable stewardship practices. Women-owned cooperatives running near-shore mariculture operations, processing facilities and logistics have become the norm.

In this scenario, this 2050 state did not appear by magic. It was made possible by deliberate political decisions made in the early 2020s and dynamic changes continuing over 30 years to overcome a series of well-established barriers and habits. In this scenario, from 2020 onwards several countries shifted their focus to sustainable ocean management, clearly defined what they wanted to achieve and decided to manage sustainably 100% of their areas under national jurisdiction.

To learn and demonstrate feasibility at scale, these countries set up 'sustainable ocean economic zones' (SOEZs). These zones promoted 'projects of choice' (in line with the seven principles introduced in Sect. 5.2) with attractive logistical, financial and regulatory benefits. Projects integrated multiple and symbiotic sectors (e.g. energy, food, tourism); provided for well-designed marine protection and restoration areas; and prioritised ocean health, food security and labour protection. A network of scientists, technologists, investors, sustainable businesses, regulators, local communities and government officials collaborated to design these zones, and they defined uses, standards, finance instruments, and conservation and regeneration requirements.

International negotiations on harmful subsidies, illegal fishing, high seas management, Arctic protection and seabed mining came to a productive conclusion. New visions of a stable, zero-waste and regenerative ocean economy moved into the industrial mainstream.

These decisions, directly informed by properly funded science, triggered a chain of transformative events:

- **Ecosystem-based, inclusive spatial planning became the norm**. Careful science-based planning was required to make these spatially and operationally complex projects a reality (see discussion of marine spatial planning in Sect. 6). Siting decisions had to be formalised, access rights legalities had to be codified and potential use conflicts had to be eliminated through careful apportionment. Conservation offsets (fully protected MPAs, coastal restoration projects, buffer zones) had to be clearly defined and gazetted. Over time, ocean planning became an institutionally well-engrained habit, informed by excellent knowledge of the complex ocean ecosystems and the ability to monitor and adapt management to changing environments, driven by economic utility and managed inclusively with all stakeholders.
- **Polluters paid.** The initial projects, and those following in their footsteps, created a strong community of shared economic interests. As pollution from industrial and agricultural sources began to directly affect sustainable ocean economy success, ocean users and land-based communities came together to find solutions to stop leakage of pollution into the ocean. In many countries, courts and agencies found in favour of the ocean interests and reforms on land leaned towards more circular and regenerative practices. At the same time, increased ocean food production forced new food safety standards, covering pollutants such as plastics and mercury.
- **Automation and the data revolution hit the ocean.** As ocean economies became more sophisticated, advanced remote-sensing technologies became indispensable for delineation and enforcement. Distributed ledger and registration technologies (e.g. blockchain[336]) were used to track the differentiated traits of ocean economy products and (ecosystem) services all the way across the value chain to the consumer, responding to stringent sustainability demands from consumers. The demand pressure from major new maricultural development sped up the development of new sources of feed supply. At the same time, information-sharing went both ways—local outcomes, yields, business results, assessments and the like became readily available to investors and policymakers.
- **Investors woke up.** As the economic viability of a sustainable approach to the ocean economy emerged more clearly, investment volumes naturally increased. Over time, financial markets became more sensitive to the risks resulting from competitive distortions (e.g. subsidies of fishery capacity or fossil fuel electricity) and declining ocean productivity (e.g. pollution and/or habitat degradation). At the

[336]Blockchain is a distributed ledger technology in which requests for transactions need to be validated by the entire network rather than by a single point. After validation, the transaction becomes an immutable block within the transaction's history, which exists for as long as the network exists.

same time, financial technologies allowed small-scale ocean players to access global markets and strengthen their voice.

- **National accounting changed.** Nations started to make informed decisions based on a full range of metrics covering production, natural capital and human well-being—potentially through official 'national ocean accounts'. The changing nature of the ocean economy was increasingly and positively reflected in such national accounts and eventually began to shape public investments and policies in the ocean realm.

With these trends arcing towards greater balance and efficiency of ocean use over time, the sustainable ocean economy began to thrive, driven mainly by the linked contributions of five economic sectors (see Fig. 20.24 and Box 20.5). The paragraphs below describe the dynamics that led to this 2050 vision.

Box 20.5 Concepts of Ocean Multi-Use and Sector Coupling

Marine spatial planning is a proven and crucial tool to manage conflicts between ocean users and advance towards more sustainable uses of the ocean.[a] However, the development of sustainable ocean industries remains limited if they are considered as individual and separate activities, ignoring potential synergies:[b] spatial efficiency, circular models (e.g. waste from one as input to another), shared costs and so on. Consequently, there has been a growing interest in the development of a sustainable 'ocean multi-use' concept that fosters synergies among ocean sectors (sector-coupling).

This concept, at the heart of the 2050 sustainable vision described in this section, has been defined by a recent paper as follows:[c] 'Ocean multi-use is the joint use of resources in close geographic proximity by either a single user or multiple users. It is an umbrella term that covers a multitude of use combinations in the marine realm and represents a radical change from the concept of exclusive resource rights to the inclusive sharing of resources and space by one or more users'.

The EU Commission has been pioneering this concept by funding research and a series of large-scale collaborative projects over the past 10 years, including TROPOS, MERMAID, H_2Ocean, Multi-use in European Seas (MUSES) and Marine Investment for a Blue Economy (MARIBE). These concepts are today mostly at the (advanced) blueprint stage, but new 3-year funding has just been confirmed to test pilots until 2023 (project UNITED).[d]

5.3.1 Sustainable Ocean Food Production

Multi-/low-trophic mariculture Mariculture quickly became popular and successful. With a major concentration on low-trophic-level species (seaweed, bivalves, molluscs), it increased the level of local biomass, created new habitats, created new jobs and local income, and provided an alternative to land-based, carbon-intensive meat production, as well as a source of key nutrients like omega-3 fatty acids and iodine. Higher-trophic-level finfish mariculture shed its dependence on fish-derived feeds and adopted strict operating standards addressing disease control, local pollution and escapes. In some cases, low- and higher-trophic production combined into 'integrated (or co-located) multi-trophic farms' with fed (salmon, seabass, grouper, etc.) and unfed species (e.g. bivalves, seaweed) growing together in a symbiotic and low-waste ecosystem. Where relevant, mariculture operations co-located with offshore wind farms, which provided a low-cost and reliable source of electricity for the farm and clean fuel for ship traffic. Strict labour standards were adopted for mariculture operations, while profits and operating risks became evenly spread along the mariculture supply chain. Expansion of mariculture was achieved in a harmonious way that respects Indigenous rights to healthy ocean resources.

Wild-caught fisheries Fishing fleets (commercial and artisanal) became profitable and stable because fishers' economic and conservation incentives were aligned, wild fish stocks were restored (especially predators), protected against poachers and allocated fairly to fleets and communities to be fished at optimal capacity. Sustainably fished stocks proved more resilient to climate shocks and provided increasingly predictable returns to appropriately sized fleets. International collaboration and strong local enforcement massively reduced IUU fishing, corruption and forced labour on fishing boats. With access rights to fish stocks more firmly defined and enforced, fishing fleets increasingly adopted sustainable yield standards as the most long-term profitable model of fishing. Fuelled by increasing demand and leadership from seafood incumbents, traceability 'from ocean to plate' in the fish supply chain became the norm and supported generalisation of best practices. Perhaps most important, as communities gained more control over local ocean access, benefits became more equitably shared through sustainably financed mechanisms and the food security needs of coastal inhabitants became paramount.

5.3.2 Clean Ocean Energy

The offshore wind sector continued its exponential growth and replaced fossil fuels as the main source of power from the ocean. Intermittency issues were addressed by a new grid and storage infrastructure. Offshore wind farms increasingly provided energy to other offshore uses (e.g. mariculture, shipping) and anchored and delineated large-scale MPAs. In many cases, they emerged as the natural 'centre' of many ocean economic zones.

5.3.3 Low-Carbon Transportation and Ports

Shipping continued to move around 90% of globally traded goods but accelerated decisively towards zero emissions. A combination of efficiency measures, together with the introduction of new fuels (such as green ammonia or hydrogen), led to a net-zero global shipping fleet. Offshore wind farms provided the energy to generate ammonia or hydrogen, transferred to ships either locally through floating platforms or through ports. Uncontrolled ballast discharges became a thing of the past, and transport efficiencies were boosted through increased automation and revolutionised cargo-tracking systems. Ports became carbon-neutral, eliminated air pollution, implemented labour laws and synchronised their activities with the marine ecosystem they were situated in (adapting shipping lanes to avoid whale strikes, smart dredging, etc.).

5.3.4 Ocean Restoration and Protection

Ocean restoration and protection were largely driven and financed by the pragmatic agendas of carbon mitigation and sequestration, fishery productivity, coastal protection and ocean tourism. Carbon mitigation funds underwrote sea grass and mangrove restoration as highly efficient carbon sequestration projects. Cities and coastal industries underwrote wetland and marsh restoration as the most effective measure exposure to storms and tides. Networks of fully protected and enforced MPAs became commonplace in integrated fishery management and protection of carbon storage plans, often co-located with offshore wind and food production facilities. Ecotourism facilities routinely took advantage of the rich underwater environment of fully protected MPAs.

5.3.5 Tourism

Sustainable tourism showed off the beauty of a healthy ocean and created a broad set of ocean defenders, all the while celebrating rather than destroying habitats and diversity. The industry continued to grow, providing enjoyment and livelihoods for millions of people. This growth was based on sustainable tourism growth plans, which countries developed and implemented in the early 2020s. These plans, written in conformity with the sustainable tourism principles of the UN World Tourism Organization, allowed the industry to grow with minimal environmental (no virgin coastal land conversion, carbon-neutral cruise ships, no effluent discard, limitation of visitors to delicate ecosystems) and social impact (no over-tourism). Payment for ecosystem services got mainstreamed through tourism taxes. Through the adoption of these ecosystem fees, coastal tourism accrued benefits to local communities and financed the restoration and maintenance of the coastal and marine ecosystems it relies on.

5.3.6 Other Sectors

For different reasons, several ocean-related economic sectors are not included or detailed in this report's 2050 scenario of a sustainable ocean economy: industries like maritime engineering and equipment are assumed to follow the development of the above-mentioned sectors. Other sectors not included or detailed in this report's sustainable ocean economy scenario include the following:

Marine biotech The scale of genomic diversity in the ocean is difficult to comprehend and poorly understood. Over 33,000 marine natural products—naturally occurring molecules produced by marine organisms—have been discovered,[337] many with remarkable levels of biological activity, and probably only representing a very small subset of the total ocean genomic diversity. The revolution in gene sequencing and bioinformatics has allowed for considerable innovation in ocean protection and production. Sequencing costs have declined 1000-fold over the past decade, and 100,000-fold since the beginning of the millennium,[338] allowing millions of DNA fragments to be sequenced simultaneously and inexpensively, creating an intensely data-rich field. However, the sector is still in its infancy. Since its future is hard to predict, the marine biotech sector has been excluded from the future vision scenario.

Deep-seabed mining As an emerging industry in the ocean, deep-seabed mining is often considered as an example of the 'new blue economy'. It fits the blue economy definition of the EU Commission (i.e. all economic activities related to the ocean), but it remains to be seen if it will meet the World Bank definition (i.e. sustainable use of ocean resources for economic growth, improved livelihoods and jobs while preserving the health of ocean ecosystems). Indeed, recent science clearly states that greater knowledge of the environmental impacts, as well as the ability to mitigate these to acceptable levels, is required before we can be confident that engaging in industrial-scale deep-seabed mining would bring a global net benefit.[339]

The proponents of deep-sea mining typically claim that the extraordinary richness of the underwater ores would result in far lower environmental impacts than mining on land, making deep-seabed mining the best option to supply a growing global demand for cobalt, copper, nickel, silver, lithium and rare earth elements, driven by the green transition of the economy (e.g. solar photovoltaics, wind turbines, electric cars).[340] Mining deep-sea polymetallic nodules is indeed calculated to release less CO_2 per kilogram than mining on land.[341] Mining interests such as Deep Green and Global Sea Mineral Resources (GSR) consider deep-sea minerals to be essential to combating climate change.[342] If profitable, deep-sea mining could also provide an economic development opportunity for many countries.

However, these claims need to be balanced against the risks. Current scientific understanding of deep-sea ecosystems—the range of species, their movements, ecological connectivity and susceptibility to mining stress—is still in its infancy. Deep-sea communities are known to recover from disturbance very slowly, if at all.[343] The impact of deep-seabed mining on marine life—with its associated toxicity, dredging, noise and intense disturbance of the seafloor—is likely immense given the great longevity (thousands of years) and slow growth of many deep sea animals.[344] The profitability of national mining operations, without governmental support or comparably low taxes, remains questionable. If the operations are profitable, it will also raise questions about the equitable sharing of profits derived from

a resource taken out of humanity's common heritage.[345] Finally, deep-sea mining may conflict with other marine uses, with complex legal and political ramifications in the international waters of the open ocean.[346]

Until the need for, and potential consequences of, deep-sea mining are better understood, the concept is conceptually difficult to align with the definition of a sustainable ocean economy and raises various environmental, legal and governance challenges, as well as possible conflicts with the UN Sustainable Development Goals.[347] It is thus not discussed further in this report.

Oil and gas 'The whale in the room': how should the oil and gas sector be included in a report on a sustainable ocean economy? On the one hand, it is the largest sector of the current ocean economy by far, accounting for 34% of its GVA, according to the OECD.[348] Massive capital investments are locked into extraction facilities, many with decades to go in their useful lives. Equally massive investments are planned soon: in the next 20 years, projected offshore crude oil output will grow from 30% to 50% of total global production, and almost half of remaining technically recoverable oil reserves are offshore.[349] Within the offshore realm, the share of deep water (125—1500 m) and ultra-deep water (>1500 m) production is projected to increase to 50% by 2020. More than half of major oil and gas discoveries since 2000 have been in the deep ocean.[350]

At the same time, exploitation of the technically feasible offshore oil deposits would exceed the remaining CO_2 budget commensurate with the 1.5 °C or even 2 °C future, which is crucial for ocean stability and viability.[351] In addition, the new frontiers (the deep ocean and the Arctic) are technically challenging, ecologically risky and often occur in remote areas, far from ports and infrastructure. The Deepwater Horizon disaster is a vivid example of the potential scale of oil spills, and the U.S. Bureau of Ocean Energy Management estimates a 75% chance of one or more large spills over the lifetime of development and production in Alaska's Chukchi Sea.

Continued or increased offshore oil and gas exploration is conceptually difficult to align with the definition of a sustainable ocean economy, and it is thus not discussed in this report.

The decommissioning of existing offshore platforms may offer interesting possibilities. Decommissioning expenses are estimated to increase from $2.4 in 2015 to $13 billion/year in 2040. The cost of removal is often tax-supported and could be reduced with potential re-use applications.[352] For example, North Sea countries are gradually decommissioning about 600 oil and gas installations[353] at the same time as they are installing massive new offshore wind capacity. Decommissioned oil and gas platforms could conceivably be used to convert and store offshore wind energy (e.g. in the form of hydrogen or ammonia fuels) in ways that eliminate costly hook-ups with onshore grids.[354] Other conversions, such as 'rigs to reefs' conversions or repurposing as tourist centres, are already used today.[355]

The development of offshore wind capacity is extensively discussed in this report. There are very interesting opportunities for using renewable offshore energy as the focal point for other sustainable ocean ventures, ranging from mariculture

to shipping fuel generation, tourism and protected areas. The widespread and essential development of ocean renewable energy will require wide-ranging reforms of ocean planning and access control systems, all of which are also discussed in this report.

5.4 The Big Reconciliation: Protect Effectively, Produce Sustainably and Prosper Equitably

This section demonstrates that a sustainable 2050 ocean economy could simultaneously deliver in three ways: (1) it could effectively **protect**, reducing greenhouse gas emissions while safeguarding biodiversity and associated ecosystem services; (2) it could sustainably **produce**, helping sustainably power and feed a planet of ten billion people; and (3) it could enable humanity to equitably **prosper**, creating better, more equitable jobs and redistribution of benefits, and supporting economic growth, household income and well-being, while prioritising access, equitable decision-making and benefits that support equity and reduce unequal impacts and harm on the most vulnerable (Fig. 20.25).

5.4.1 Protect Effectively

A sustainable ocean economy can help keep the climate within the Paris Agreement boundaries and protect and

regenerate the ocean's biodiversity and associated ecosystem services.

Climate Absorbing a third of the planet's CO_2 emissions and about 93% of the world's human-induced additional heat,[356] the ocean is already shouldering a significant part of regulating Earth's climate. In the process, it is becoming warmer, more acidic and higher. Nonetheless, the ocean economy's potential role in active climate mitigation is far from realised today. In a sustainable ocean economy, ocean-based renewable energy could play a much more important role than today: shipping would be zero-emission, fisheries and mariculture would be much more energy efficient, coastal ocean assets would be restored and protected, and CO_2 could be stored in the seabed. 'The Ocean as a Solution to Climate Change' (2019) analysed the CO_2 abatement potential from these five areas and concluded that the ocean could contribute up to 21% (or 11.8 $GtCO_2e$) of the emission reduction required to achieve a 1.5 °C trajectory by 2050[357] (Fig. 20.26). In such a vision, the ocean would move away from being solely a climate change victim (warming, acidification, etc.) towards actively participating in the climate change mitigation solution.

A sustainable ocean economy would also help catalyse deep reforms of the land-based plastics value chain. Indeed, a holistic, circular approach to ocean plastics could reduce annual ocean plastic leakage by 80%, compared to a BAU scenario where this flow is expected to triple by 2040.[358] Given CO_2 emissions associated with plastics production, use and end of life, this holistic approach has the potential to reduce CO_2e emissions associated with the plastics value chain by 25% compared to BAU 2040.[359] The plastics value chain would otherwise emit an estimated 4.5 $GtCO_2e$ by 2050—roughly 7% of global emissions in a BAU scenario—with the attendant warming and acidification effects on the ocean.[360]

Reduced other sources of pollution from land By drastically limiting leakage into the ocean, the plastics value chain holistic and circular approach would limit the growing pressure on ocean fauna and flora. The same logic could apply with other land-based pollution. Even if the correlation is harder to demonstrate, the sustainable ocean economy agenda could help catalyse broader reforms of the land-based food system, most notably in agriculture. One can expect that agricultural regulations aimed at reducing ocean dead zones could result in farmers adopting precision agriculture practices to avoid runoff. The adoption of precision agriculture, in turn, would have a positive impact on soil health and water quality in rivers and streams.

Ocean and coastal ecosystems, biodiversity and biomass In a 2050 sustainable ocean economy, the economic value of restoration of ocean and coastal natural capital would be recognised and turned into action, with carbon finance and coastal protection funds playing a major role in large-scale restoration projects. Restored and protected natural blue assets would then be able to deliver ecosystem services for coastal populations, especially in ensuring human safety by helping to mitigate the impacts of storms and sea level rise. For instance, healthy coral reefs reduce wave energy by up to 97%, protecting up to 100 million coastal inhabitants from storm risks.[361] In addition, a study has found that a '100-m-wide belt of mangroves can reduce wave heights between 13% and 66%, and up to 100% where mangroves reach 500 m or more in width'.[362] This study also found that saltmarshes can attenuate up to 50% of smaller waves, even with a barrier of just 10 m.[363]

'Planetary insurance' in the form of MPAs would have been generalised and integrated within the 100% managed EEZs and a legal mechanism to create large, fully protected MPAs on the high seas. By restoring biodiversity, these MPAs increase the resilience of the ecosystems, since they provide a protected home for communities that are capable of 'differential response'.[364] These MPAs would be primarily highly or fully protected and actively managed to obtain the greatest conservation outcomes.[365] In visual terms, if plotted on the chart of Fig. 20.27, the majority of MPAs in a sustain-

able ocean scenario would be in the top right-hand corner. Indeed, species richness has been found to be 21% higher and biomass up to six times greater within fully protected marine areas (from here on simply called MPAs) compared to the adjacent unprotected areas.[366]

In a sustainable ocean economy scenario, the MPA placement would not be chosen randomly but designed according to science-based criteria, local knowledge and in consultation with diverse stakeholders. For instance, scientific analyses can produce scenarios to locate areas that maximise three benefits of MPAs: (1) rebuilding and safeguarding biodiversity, (2) mitigating climate change (by avoiding emissions from the disturbance of sediment carbon by bottom trawling and eventually deep-sea mining) and (3) boosting fisheries productivity (by increasing fisheries catches around MPAs through the spillover of fish). The food benefits would only be captured if the MPA strategy has been coupled with the sustainable management of the surrounding fisheries and an inclusive process that actively involves local communities and marginalised groups in the design and establishment of the MPAs.

5.4.2 Produce Sustainably

In the sustainable ocean economy scenario adopted in this section, effective ocean protection would enable sustainable ocean production. Most notably, the ocean can produce a near unlimited amount of renewable energy and significantly more seafood than today. In this section, an ambitious but realistic production potential is described.

Ocean-based renewable energy There appear to be no relevant physical limits to ocean-based production of renewable energy. Estimates for total technically feasible global offshore wind power generation potential range from 157,000 terawatt hours per year (TWh/yr.) to 631,000 TWh/yr.[367]—6–23 times more than the total global electricity consumption in 2018 (26,700 TWh/yr.).[368] Europe's offshore wind potential alone (71,845 TWh/yr.) is estimated to be over three times the current global electricity demand.[369] Other forms of ocean-based energy also have a very significant technically feasible potential, such as tidal energy (around 6200 TWh/yr.),[370] wave energy (between 1750 and 5550 TWh/yr.),[371] ocean thermal energy conversion (technical potential uncertain)[372] and salinity gradient energy (1650 TWh/yr.).[373] However, their cost is far from competitive today. By most realistic estimates, offshore wind will remain the most competitive offshore energy source, although the pace of development will remain far below theoretically feasible levels over the coming decades.

The International Energy Agency estimates that 570 GW of offshore wind could be installed by 2040.[374] An OECD scenario projects 900 GW by 2050[375] and the International Renewable Energy Agency (IRENA) REmap Scenario projects 1000 GW of installed offshore wind by 2050.[376] This suggests that even the upper range of the scenarios used in the Ocean Climate Special Report[377] may turn out to be conservative.

Sustainable seafood The ocean could in theory sustainably produce six times more food than today under an optimistic scenario,[378] thereby playing a significantly greater role in ensuring the food security of a planet with ten billion people in 2050. It has the potential to do so with a low environmental footprint (e.g. with sustainable fed mariculture and sustainable fisheries) or even in a regenerative way (e.g. with non-fed mariculture). Delivering this potential, however, depends on climate-adaptive, in-depth reforms of wild-catch fisheries, evolution of consumer preferences and significant scaling of (sustainable) mariculture:

- **Wild-catch fisheries.** Currently, most fishing is not economically or ecologically optimised. Far too many stocks are pursued by too many boats; far too much seafood value is lost due to poor handling; and far too many non-target species are accidentally caught. If this approach continues, 2050 yield is expected to decrease to about 67 mmt/year.[379]

[379] Costello et al. 2019. "The Future of Food from the Sea."

However, if all stocks currently exploited were to be fished at maximum sustainable economic yield,[380] production could increase to 96 mmt/year in 2050: an additional 16 mmt/year of seafood compared to today.[381] This represents a 20% production gain over today's production levels, and a 40% increase over estimated BAU catch. It is important to note that these optimistic gains depend on the deployment of effective, climate-adaptive fishery reforms, strengthened international institutions and cooperation, in combination with scale-up of marine protected areas (see Sect. 6 for more details).

- **Mariculture.** The production of sustainable fed (finfish) and unfed (bivalve, seaweeds) mariculture is currently at a very small fraction of its biological potential (the theoretical production limit is estimated at 15,000 mmt/year—far more than 470 mmt of meat will be required annually in 2050 to feed the projected global population of more than 9.7 billion).[382]
  – Fed mariculture requires external feed (today including fish oil and fish meal) and is currently severely constrained by the price and availability of feed. Under optimistic projections assuming a 95% reduction of fish meal and fish oil content in mariculture feed, current production could be multiplied tenfold.[383] However, the siting and operations of monocultural, high-trophic finfish farms, especially in pristine areas, is often highly controversial. A re-imagined approach to finfish farming, focused on local food security concerns, multi- and low-trophic species, new disease control and containment technologies, and avoidance of pristine areas, will be essential to capture the biological potential in a sustainable way.
  – Non-fed mariculture is ecologically largely benign and offers great potential. Bivalve mariculture (e.g. mussels, oysters), for example, could theoretically be increased more than 30-fold beyond current production to its biological potential of 460 mmt/year (bivalves only).[384] Seaweed, with a suitable cultivation area of 48 million km^2, has the potential to play a substantially larger role in supplying humanity with food and land animals and fish with feed. Seaweed also constitutes a very promising low-carbon source for raw materials that can be used in biostimulants (fertilisers), cosmetics, bioplastics, biofuels and other applications. In a sustainable ocean economy, the current economic, technological and regulatory barriers hindering the expansion of non-fed mariculture must be overcome (see Sects. 6.2 and 6.3).[385]

With these elements in mind, it is safe to say that reforming wild-caught fisheries and growing sustainable mariculture (especially unfed species) could multiply current ocean food production by up to six times by 2050 (Fig. 20.28).[386]

5.4.3 Prosper Equitably

This discussion describes prosperity in terms of jobs, economic wealth creation, inclusivity and equity if a sustainable ocean economy vision is realised. Only a small and simple sampling is possible—an exhaustive account of the relative upside of a restored, vibrant and productive ocean would fill libraries.

The future of ocean jobs, in many ways, echoes the general employment trends on land. In the energy sector, job growth is shifting to renewables, with many high-level engineering and support jobs created, especially in the developed world. Rising levels of productivity and automation would shift jobs in shipping, commercial fishing and large-scale mariculture from the front line to expert support (engineering, information technology, data, applied science, infrastructure). Small-scale fisheries would increasingly come under local control, recovering their productivity but imposing limits on fishing effort, enabled by smart policies that ensure secure access.

This report describes potential long-term evolutions of ocean jobs, building on various sources and projections from the pre-COVID period. The COVID-19 pandemic has seriously affected many ocean industries, making these projections and future jobs trajectories highly uncertain. For instance, up to 100 million jobs are today considered at risk in the tourism sector alone.[387] In addition, the crisis affecting ocean-based sectors is disproportionately hitting women and more vulnerable groups (low-skilled workers, small-scale fishers and businesses, Indigenous community members, younger workers, etc.).[388] Recovery and economic stimulus

[380] MSY and MEY: Maximum sustainable yield (MSY) is the long-term maximum amount of catch for a given fishery, purely based on the stock's biology. Maximum economic yield (MEY) adds the dimension of fishing costs to optimize for the most profitable, sustainable amount of catch, which is generally slightly lower than MSY catch. Information retrieved from World Ocean Review. "The Profits of Fishing." Maribus, after Quaas. n.d. plans supporting a sustainable ocean economy are expected to help maintain employment in ocean sectors and/or help transition towards the jobs required to develop the sustainable ocean sectors presented in this section.

- **Offshore energy.** Offshore energy is growing fast from a small base. Even in a conservative scenario, many jobs could be created: the OECD's BAU scenario (assuming no significant new government incentives) estimates the creation of 440,000 new jobs by 2030 in the offshore wind sector.[389] More assertive energy and industrial strategies could increase this number sharply. In the longer term, renewables are expected to outperform fossil fuel jobs in both relative and absolute numbers. In 2017, the U.S. Bureau of Labour Statistics listed turbine technician as the second-fastest-growing occupation in the United States. With periodic downturns in the offshore oil and gas industries, many oil and gas workers are turning to the wind industry for high-paying jobs. In U.S. coastal regions, 160,000 gross jobs could be supported by the offshore wind industry in construction, installation, operations and maintenance.[390]
- **Shipping and ports.** According to the OECD, seaborne cargo volume, driven almost entirely by GDP, will almost double from 11 billion tonnes in 2015 to 20 billion tonnes in 2030, which can be expected to significantly increase employment.[391] A more granular view reveals the major trends. A major expansion in ports, driven at least in part by China's massive Maritime Silk Road initiative, can be expected to increase trade. Larger and more automated vessels may slow job growth in shipping and shipbuilding, however (tonnage of ships larger than 7600 20-foot equivalent units (TEUs) can be expected to increase 6–6.5 times between 2010 and 2030, much faster than for ships under 7600 TEUs, projected to grow 1.4–2 times).[392]
- **Fishing and mariculture.** Global fishing, at the commercial and artisanal or small scale, operates at significant overcapacity today; there are too many fishers and too many boats. Because of this overcapacity, fish stocks, productivity and yields are depressed, and coastal livelihoods can be threatened. Net job growth is thus not the relevant metric to be applied to fishing—but job security

is, alongside food security and productivity. Nevertheless, the reduction of fishing capacity, and the associated stranded assets, may create tensions which must be thoughtfully addressed (through structural adjustments, reskilling, etc.; see discussion in Sect. 6.2). For industrial capture fisheries, jobs can be expected to decline, as fleets slowly reduce capacity and increase efficiency. Artisanal jobs are much harder to define and track—estimates range from 12[393] to 37 million, with an additional 100 million artisanal jobs being dependent on fishing (e.g. fish processors).[394] Many artisans fish opportunistically for food, rather than as a full-time pursuit. In a sustainable ocean economy, their time on the water will decrease, and yields will increase.

- The OECD projects strong mariculture employment growth to 3.2 million jobs in 2030, up from 2.1 million in 2010 under a BAU scenario. However, much higher job growth is possible if new technology can eliminate current constraints on feed availability and the production of non-fed mariculture is boosted. Buoyed by the growing maricultural capacity and recovering industrial capture yields, jobs from the seafood processing sectors can be expected to grow as well.[395]
- **Tourism**. Payment for ecosystem services through tourism fees could be adopted to finance the restoration and maintenance of the natural ecosystems (future) coastal tourism jobs rely on. Pre-COVID, the tourism sector was expected to continue its strong growth, directly accounting for over 8.5 million jobs in 2030 (up from 7 million in 2010).[396] Post-COVID, the trajectory for the tourism sector is still uncertain.

The economic future The size of the prize of the transition to a sustainable ocean economy is significant and appears to be limited far more by political and economic constraints than the ocean's productive potential. As for the jobs section, the numbers presented below reflect long-term evolutions and economic gains, building on various sources and projections from the pre-COVID period. Significant economic losses have been experienced by ocean sectors during the COVID-19 pandemic, and there is a high uncertainty as to the pace of recovery and transition towards a sustainable ocean economy for these sectors. For instance, cancellation of shipping is estimated to have caused revenue loss of US $1.9 billion for the carriers in a matter of months.[397]

On the conservative side, the OECD predicted in 2016 that economic growth and employment under a sustainable scenario would outpace both an 'unsustainable' and a 'BAU' scenario (see Fig. 20.29).

The OECD projections were based on 2010 data points as a baseline. A more recent study commissioned by the Ocean Panel provides a far more optimistic picture, with a net benefit estimated at $15 trillion by 2050 if $2.8 trillion were invested today in four sustainable ocean-based solutions: sustainable ocean food, renewable ocean energy, decarbonisation of international shipping, and conservation and restoration of mangroves.[398] The benefit-cost ratio differs for each of these opportunities, but overall it remains very attractive—see Fig. 20.30 below. These numbers are accounted through a holistic view that encompasses benefits of three kinds: economic (e.g. increased profits from higher fisheries productivity), environmental (e.g. avoided damages from coastal flooding) and health (e.g. reduced mortality from improved air quality).

Such an analysis has a number of limitations, as it does not represent the distribution of the benefits (and costs), it puts a monetary value on nonmarket goods with debatable assumptions, and it is obliged to omit certain benefits that are still very hard to monetise (e.g. prevention of the loss of natural habitats from increased ocean acidification). However, it serves as a very useful pointer, emphasising that ocean-based solutions should be considered as high-return investments and essential engines of a post-COVID economic, social and environmental recovery strategy.

Looking at the more detailed assessment of these four ocean-based solutions, this benefit-cost analysis offers conclusions in the following areas:[399]

- Mangrove conservation and restoration**:** Every $1 invested in mangrove conservation and restoration generates an average benefit of $3. Conservation has a far higher return on investment (88-to-1) than restoration (2-to-1), which can mainly be explained by the higher cost of mangrove restoration and the low survival rates following restoration. The total value of net benefits for mangrove restoration over 30 years ($97–$150 billion) is, however, higher than for conservation ($48–$96 billion), as the surface is assumed to be 10 times larger for restoration.

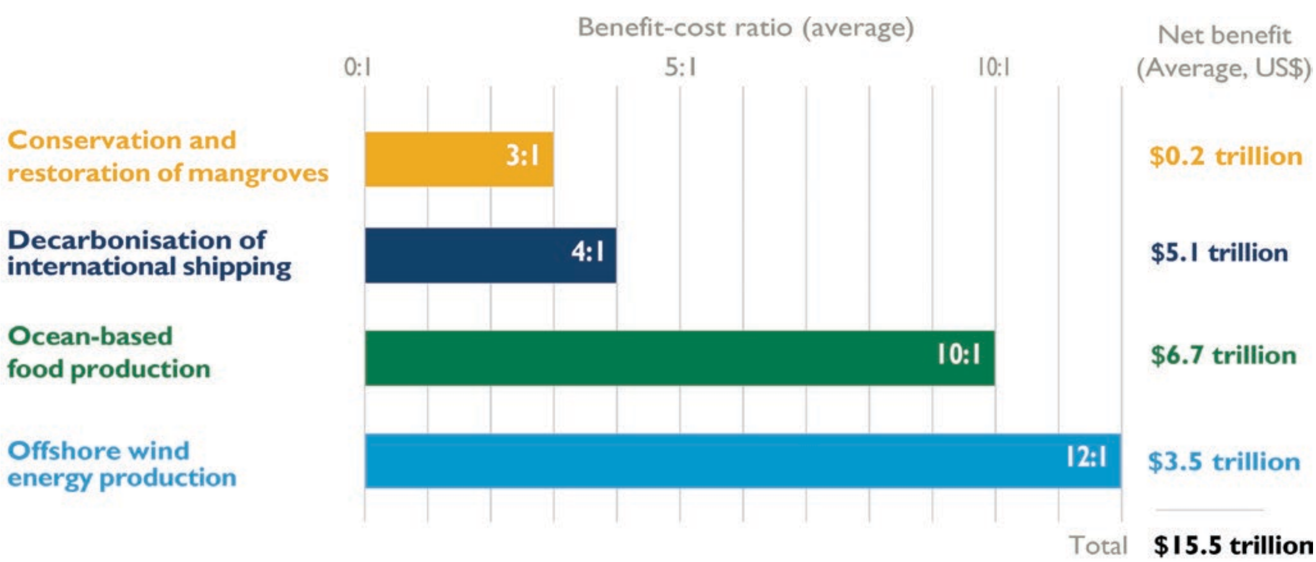

Fig. 20.30 Benefit-cost ratios and net benefits by 2050 for four sustainable ocean-based interventions. *Note: Average benefit-cost (B-C) ratios have been rounded to the nearest integer and the net benefits value to the first decimal place. The B-C ratio for mangroves is the combined ratio for both conservation- and restoration-based interventions. The average net benefits represent the average net present value for investments and is calculated over a 30-year horizon (2020–2050).* (*Source: Konar, M., and H. Ding. 2020. "A Sustainable Ocean Economy for 2050: Approximating Its Benefits and Costs." Washington, DC: World Resources Institute.* https://www.oceanpanel.org/Economicanalysis)

- Offshore wind**:** Every $1 invested in scaling up global offshore wind production generates a benefit estimated at $2–$17, depending on the cost of offshore energy production and transmission and the types of generation that would be displaced. The return on investment will increase as technology and efficiency improvements bring down costs for offshore wind energy generation.
- Green shipping**:** Every $1 invested in decarbonising international shipping and reducing emissions to net zero by 2050 is estimated to generate a return of $2–$5. The analysis assumed that the significant capital expenditure to switch to zero-carbon emissions will happen after 2030, and limiting the analysis to 2050 captures only a portion of returns from these investments, which will continue beyond 2050.
- Sustainable ocean-based food production: Every $1 invested in increasing production of sustainably sourced ocean-based protein is estimated to yield $10 in benefits. The increase in demand for ocean-based protein to provide a healthy diet for 9.7 billion people by 2050, which

would replace a percentage of emission-intensive land-based protein sources, can be achieved by reforming wild-capture fisheries and by increasing the sustainable production of ocean-based aquaculture. Both measures will deliver benefits such as better health outcomes to consumers, higher revenues to fishers, lower GHG emissions mitigating the risks of climate damage, reduced land-based conflicts and lower water usage.

In addition to these four ocean-based solutions, additional evidence in the literature suggests that a sustainable ocean economy can generate significant economic returns. The creation of MPAs, especially when coupled with ecotourism, substantially increases revenue for local economies. Integration of ecotourism with MPAs needs to be approached with care to avoid natural habitat degradation through over-tourism. If precautions are taken, however, the creation of MPAs can have a significant economic benefit (Fig. 20.31).

The sustainable ocean economy agenda can also help catalyse land-based economic gains, especially regarding the currently wasteful plastics value chain. A systems approach to ocean plastics could result in annual savings for governments of $70 billion/year in 2040 while also reducing plastic leakage into the ocean by 80% compared to a business-as-usual trajectory.[400] Pioneering businesses in the circular economy also avoid financial and reputational liabilities.

Finally, the ocean agenda can also help catalyse broader reforms in agriculture. Agricultural regulations aimed at reducing ocean dead zones could result in farmers adopting precision agriculture practices to avoid runoff. This could eventually contribute to a broader food system reform towards sustainability, which has been estimated to repre-

[400]Lau et al. 2020. "Evaluating Scenarios toward Zero Plastic Pollution"; Pew Charitable Trusts and SYSTEMIQ. 2020. *Breaking the Plastic Wave*.

sent new business opportunities worth up to $4.5 trillion a year by 2030.[401]

The equitable future A healthy ocean is linked to prosperity and well-being.[402] The Blue Paper 'Towards Ocean Equity' argues that without an active consideration of equity, sustained and increased inequity will be the default outcome.[403] In the vision presented in this section, the sustainable ocean economy not only leads to prosperity of countries and economic sectors but also ensures adequate mechanisms for sharing the benefits of prosperity and alleviating climate change-induced inequalities. A fundamental principle of the SDGs is to 'leave no-one behind'.[404] Equality and equity considerations are implemented in the sustainable ocean economy for more than just moral reasons; they ensure the future legitimacy of the sustainable ocean economy agenda. Inequity remains a structural and persistent feature of the current ocean economy. Addressing these equity risks will counter accelerating social tensions, as well as strengthen the credibility and legitimacy of the sustainable ocean economy agenda. A recent report by the OECD, *Sustainable Ocean Economy for All*, includes a more detailed equity discussion, with a special focus on developing countries.[405]

Achieving 'procedural equity'—defined as the recognition of rights and needs of all groups and the level of inclusion and participation in decision-making related to ocean development[406]—will need to be a key achievement of the sustainable ocean economy. Indigenous knowledge which is compatible with scientific conclusions will be central to a sustainable ocean economy, and will need to be made widely accessible in knowledge commons. In terms of gender equality, women today comprise only 2% of the world's formal maritime workforce (1% for sailors).[407] By achieving gender equality, with respect to workforce participation, pay, leadership representation and advancement within a career, the sustainable ocean economy will fully unlock the productive and innovative potential of half of the world's population.

Ensuring the equitable sharing of marine genetic resources will be fundamental to ensuring a level playing field for furthering humanity's common heritage. To ensure this, the sharing of benefits from areas beyond EEZs must be based on the exchange of information, transfer of technology, capacity building and sharing of benefits arising from commercialisation.[408]

Yields of many artisanal fishers have declined precipitously in recent decades, and food insecurity runs high in many coastal communities in the developing world.[409] Climate change is expected to worsen current inequalities by disproportionally affecting communities in least developed countries.[410] Building a more equal and just ocean economy will be critical for economic prosperity.[411] Empowering local fishers by granting access rights will be one of the key levers of the sustainable ocean economy. Granting access rights has already been shown to be effective: a case study from Chile demonstrates that after the introduction of territorial use rights for fisheries, artisanal fisheries gained in importance, with landings even surpassing industrial catch while recovering the biomass and size of the target species.[412]

Rebuilding fish stocks and expanding non-fed aquaculture would significantly contribute to the alleviation of malnutrition (undernutrition and nutrient deficiency). Young children (<5 years) bear the burden: an estimated 150.8 million children are currently stunted (low height for age), another 50.5 million have weight too low for their age and 38.3 million are overweight.[413] Seafood contains critical trace minerals, omega-3 fatty acids, iodine and other micro-

Bristol, UK: Development Initiatives. https://globalnutritionreport.org/reports/global-nutrition-report-2018/.

nutrients and vitamins crucial for healthy development.[414] These key nutrients could also help to reduce the 11 million annual deaths related to poor diet[415] if consumers shifted their eating habits to include healthier and more nutritious options, such as seafood.[416] Indeed, the IPBES states that 'shifting diets towards a diversity of foods, including fish, fruit, nuts and vegetables, significantly reduces the risk of certain preventable non-communicable diseases (e.g. cardiovascular diseases, cancers, diabetes), which are currently responsible for 20% of premature mortality globally'.[417]

The development of transparent supply chains and international collaboration can significantly reduce maritime crime. Transparent supply chains can minimize IUU fishing, leading to increased food provisioning to marginalised communities (often the worst affected). Other fisheries-associated crimes can be reduced by stronger international cooperation: the adoption and implementation of the International Declaration on Transnational Organized Fisheries Crime in the Global Fishing Industry must lead to reductions in forced labour and in the smuggling of people and contraband.

A celebrated ocean 'Happiness is among the most fundamental of all human goals'.[418] Millions of people a year travel to the ocean to enjoy themselves—an estimated 120 million are estimated to annually engage in marine recreational activities like diving, whale watching or recreational fishing.[419] A sustainable ocean economy would be able to maintain the healthy ocean required for ocean recreation.

Apart from providing leisure, the ocean is central to the aesthetic, religious and spiritual ways of many cultures,[420] especially Indigenous ones. A healthy ocean is essential to the maintenance of its immense cultural significance. MPAs and other effective area-based conservation measures can help preserve pristine and culturally important ocean areas (e.g. sacred sites, historic wrecks and associated war graves). In ocean areas where the sustainable extraction of resources by Indigenous groups is a key aspect of their culture, their rights to secure access and control should be guaranteed.

The ocean in service of the SDGs Building a more protected, productive and prosperous ocean economy offers solutions to accelerate other Sustainable Development Goals (see Figs. 20.32 and 20.33).[421] Replenishing and sustainably managing the ocean will be a significant part of achieving SDG 2 (zero hunger). A more sustainable ocean produces more food indefinitely.[422] The ocean's immense wind energy potential[423] advances the energy independence goals of SDG 7. Addressing ocean-based pollution could catalyse land-based reforms towards achieving SDG 15 (life on land) and push the world towards more responsible production and consumption, SDG 12. A study examined the relationship between SDG 14 targets and other SDGs at a more granular level, detailing the link, co-benefits or potential trade-offs[424]—see Figs. 20.32 and 20.33.

6 A Roadmap to a Sustainable Ocean Economy

6.1 Introduction

Section 4 makes an urgent case for action: the ocean is vital for humankind and the entire economy, current ocean management struggles to deliver on the dimensions of protection, production and human prosperity, and more and more successful sustainable stories and pioneers are in desperate need of support and scale-up. Section 5, which shows how ocean protection and ocean productivity can serve each other, outlines an alternative, generalised 'triple win' future. The case for a healthy ocean supporting a healthy economy is well documented. So why is this so hard? Why isn't the sustainable ocean economy at the centre of all the post-COVID recovery discussions and financial stimulus packages? How can this urgently needed shift be accelerated?

The global struggle against climate change is both immediately relevant and in an analogous stage. The science is compelling; consequences are rigorously documented (IPCC); the cost of inaction is quantified, as is the business case for change; pledges are in place (UN Framework Convention on Climate Change/Paris Agreement); a majority of people find this to be the defining crisis of their lives; investors are starting to move away from fossil fuels. And yet, progress is falling short: the UN Environment Programme's *Emissions Gap Report 2019* states that the world is heading for a 3.2 °C global temperature rise over pre-industrial levels,[425] far beyond the 'below 2 °C' target.

The relationship between the ocean and humanity goes both ways—one shapes the other. In this classic 'complex adaptive system',[426] the biological, chemical and physical ocean responds to an array of human forces which, in turn, are shaped by regulation, taxation, financial interests, consumer preferences, historical legacies, and diverse traditions and cultures. Any change in a system of such complexity, almost by definition, has unforeseen and complex consequences. For climate and the ocean, the implicit and explicit rules are based on the lessons of the past, not the future—and they are legally, politically and culturally entrenched and protected.

How, then, can the shift be accelerated from the urgency of Sect. 4 to the more hopeful future of Sect. 5? At a time when governments are actively looking for solutions to recover from the COVID-19 shock, how can the integral role of the sustainable ocean agenda in rebuilding a more sustainable, resilient and just economy be ensured?

This final section focuses on the 'how' and provides a roadmap addressing the following questions:

- What are the barriers to change, and what lessons from the experience of similar industrial and societal transitions could be applied to the ocean economy? (Sect. 6.2)
- What main transitions are required and how can this sustainable ocean economy agenda be structured? (Sect. 6.3)
- What catalytic interventions can help enter an upward spiral? (Sect. 6.4)

6.2 Harnessing Complex Adaptive Systems: Lessons for the Sea

The social, economic and ecological systems in the ocean realm connect into a complex adaptive system, where the 'behaviors of individual actors at the local scale influence interactions and emergent properties at the regional or global scale. Emergent properties, in turn, can feed back to the small scale and influence subsequent behaviors of the individuals'.[427] This complexity can explain why the current model of ocean management exists and is so hard to transform. But the adaptability also leaves room for evolution if the mechanics and incentives are changed, and if feedback loops are switched from vicious to virtuous.

This section first describes the barriers which have made the pace of reform appear timid and slow. Learning from other socioeconomic and industrial transitions, this section then identifies a framework that could be used for a successful transition towards a sustainable, more equitable ocean economy.

6.2.1 Major Barriers to a Sustainable Ocean Economy

The complex adaptive system of the ocean economy is shaped today by strong incumbent interests, cultural norms, institutional constraints, policies and laws. In this status quo, the feedback loops and incentives are driving behaviours that hinder a transition towards a truly sustainable, regenerative ocean economy. These incentives can be of different kinds: economic, reputation-driven or personally motivated social norms.[428] In the current ocean economy, these incentives share a common feature: they ignore or vastly discount environmental and social impacts. To shift these incentives towards alignment between effective protection, sustainable production and equitable prosperity, the first step is to dissect

some of their main root causes, presented here as six systemic barriers (Fig. 20.34).

Institutional inefficiencies A complete description of the ocean-related institutional structures and agreements is beyond the scope of this report, but some inefficiencies can be listed here: complexity of governance, lack of overarching mandate towards a healthy ocean and rigid and static processes poorly informed by science.

Complexity of governance. International ocean management is a web of intertwined, converging and competing demands and interests[429] involving no fewer than 576 bilateral and multilateral agreements,[430] which are administered by a multitude of institutions with widely varying mandates, resources, authorities and capacities (Fig. 20.35).

'Polycentric governance', that is, governance that includes multiple centres of semiautonomous decision-making, can be an efficient model to manage at a global scale a complex adaptive system like the ocean.[431] Polycentric models indeed allow decision-makers to 'experiment with different governance solutions tailored to particular scales and socioecological contexts'.[432] However, if collaboration, transparency and clear mandates are ill-defined, polycentricity can be a double-edged sword and limit efficiency and capacity for change and more sustainable management.

At the global level, the exact reach and authority of even well-established ocean organisations based on global treaties is often unclear. For example, the extent of the International Whaling Commission's legal competence is in dispute, with some nations restricting it to great whales (baleen and sperm whales), while others include all cetaceans. In many cases, individual nations claim exceptions to specific articles of the convention, while still remaining members. As another example, the ongoing negotiations on biodiversity beyond national jurisdiction are exceptionally important but unlikely to call for a new international framework for ocean governance under the UN umbrella. Nevertheless, there are also examples of well-functioning international frameworks. High-level international forums such as the Arctic Council and the Parties to the Nauru Agreement focus more on pragmatic advantages of cooperation (such as shipping safety in the Arctic or cooperation in tuna stock management) than the painstaking process of formal treaty negotiation.

London: Routledge*)

Lack of overarching mandate towards a healthy ocean. Most of the ocean-related institutions have been established to support the development of a given ocean-based sector. This development has usually been assessed against conventional and incomplete metrics like sector revenues (or GDP) or number of jobs. These institutions are rarely driven by an overarching mandate that would transcend the sectorial silos and also aim to achieve healthy ocean ecosystems (see the next barrier, 'Lack of planning and poor integration among sectors').

Rigid, static poorly science-informed processes. In most cases these ocean institutions are not equipped to pilot the management of a complex adaptive system. Because they depend on laws and/or consensual decisions that take time to change and reform, they usually deliver their mandate in a static fashion, and react a posteriori to shocks and unexpected events. As stated above, social, environmental and economic systems are intertwined in a complex adaptive system whose proper governance requires adaptability and agility. Besides, the management of the ocean today is not informed enough by solid science, and personal or national interests can often outweigh recommendations from the scientific community. The upcoming UN Decade of Ocean Science for Sustainable Development is a great opportunity to strengthen this science-policy interface.

International fisheries are a good example of many of these institutional inefficiencies. Myriad bilateral, trilateral and multilateral fisheries management agreements and regional fisheries bodies exist. However, for the high seas, only the 16 regional fisheries management organisations (RFMOs) are mandated through the UN Fish Stocks Agreement to adopt legally binding measures. The RFMOs differ widely in their funding, scientific capacity, relative authority with member states and, ultimately, fishery outcomes.

Since decisions are generally made only based on (near) unanimity among member states, the process can be slow and somewhat weighted towards avoiding losses by individual states, rather than optimising the fisheries or ensuring healthy ocean ecosystems.[433] Co-operation among RFMOs is improving, and even though discrepancies in performance and transparency of RFMOs remain,[434] several of them are more closely following the conclusions of their scientific committees. Even if more than an RFMO, the ecosystem monitoring program of the Commission for the Conservation of Antarctic Marine Living Resources, which applies the precautionary principle and commits to 'best available science' standards in its management of krill and finfish restoration efforts,[435] may be an example of better management practices, although it, too, needs improvements. The steadily improving data transparency on fisheries driven by FAO is also leading to broader reforms.

Lack of planning and integration among sectors Ocean development, so far, has largely occurred ad hoc. When communication among the food, energy and shipping sectors does occur, it is more often about conflict resolution than symbiosis and collaboration.

Formal coordination remains rare, since ocean sectors are often governed by different regulating entities, making cross-sectoral communication and planning difficult. As of today, only 22 countries[436] systematically assess the efficient, safe and symbiotic use of the ocean's resources—its power generation, biological productivity, carbon sequestration and so on. Typically, such a planning process provides guidance on the integration of ocean uses, avoidance of spatial use conflicts, standards of operation, streamlined and efficient regulatory process, and the overall protection and sustainability of the key oceanic systems. It is sometimes supported by new incentives ('carrots' or 'sticks') including public sector demand and offtake guarantees, feed-in tariffs, infrastructural support and public participation in the required investments.

Without such a process, ocean economy sectors are left to compete in an operational and regulatory vacuum. Even fully mature technologies, such as offshore wind farms, often struggle in such a regulatory environment; for example, the offshore wind industry along the U.S. Eastern Seaboard, despite compelling economics and ample demand, has been mired in regulatory setbacks for the better part of a decade. Innovative concepts—such as multi-trophic farming, co-location of fish and seaweed farming, and the use of offshore wind energy to produce shipping fuels (hydrogen and ammonia), power large-scale aquaculture or power desalination plants—are very difficult to realise without integrated planning, explicit national priorities, regulatory support and time-tested emerging technology incentives.

Concerns about stranded jobs and communities A sustainable ocean economy looks very different from today and implies real structural shifts—such as the reduction of fishing fleets and jobs, on the one hand, and the increase of wind energy and mariculture jobs, on the other. Many coastal communities are built around fisheries and fishery-related jobs that constitute their heritage and social glue. Some of these communities may find themselves disadvantaged by this transition: economically speaking, they may not be able to find alternative sources of income overnight, potentially causing significant short-term equity issues; culturally speaking, it will be very hard for these communities to give up on decades or centuries of social norms centred on traditional activities. Their concerns are entirely legitimate and clearly require public support, guarantees and a transparent and inclusive dialogue.

A good example is in fisheries. Global current fishing capacity is estimated to be between 1.5 and 2.5 times more than what is needed to fish under maximum sustainable yield.[437] To rebuild global fisheries, millions of the current 4.3 million fishing boats need to be decommissioned at a global scale, and between 15 and 22 million fishers (assuming linearity, which is probably simplistic) would need to shift to other pursuits.[438] However, fishing jobs do not convert easily, and alternative wages tend to be low.[439] The economic challenge is real but not insurmountable if proper solutions, support and compelling change management are

put in place. For instance, 75% of fishers in Hong Kong would be 'willing to leave the industry if suitable alternatives or compensation were available'.[440] Similar sentiments are likely to arise in other countries.[441] Cultural and spiritual dimensions need to be seriously considered, however, as in some communities fishermen do not want to leave fishing—even if suitable alternatives exist.

High costs of capital The cost and availability of capital is a serious constraint across the spectrum of ocean enterprise. The latest data from the IEA (2019), for example, show that the levelised cost of electricity (LCOE) from offshore wind is reduced by 30% if the weighted average cost of capital is reduced from 8% to 4%.[442] This clearly shows the importance of creating access to stable financing. Capital-intensive ventures such as ocean-based renewable energy and large-scale mariculture encounter technical, infrastructural and regulatory challenges, which grow exponentially with the distance from shore—precisely where most large-scale food and energy production could be sited. Key technologies may not yet fully be tested in the cauldron of open ocean conditions and intensifying storms. Onshore competition, such as from onshore wind, freshwater aquaculture and alternative proteins, is a source of considerable uncertainty. Lastly, there are many potential sources of use conflicts and attendant regulatory risks and delays. The sum of these risks leads to capital premiums, and many institutional investors may stay away altogether. There is no shortage of innovative thinking, concepts, blueprints and business plans in the sustainable ocean economy—but the leap from concept to reality is harder in the ocean than it is on land.

On the less capital-intensive side of the spectrum, financing issues also loom large. In fisheries, for example, real or implied discount rates are high. Artisanal fishers often do not have the luxury of planning for tomorrow's catch. Even in more organised commercial fishing, open-access laws and overcapacity lead to a 'race for fish' that heavily discounts future yields. The current market-hunt nature of wild-catch fisheries is very difficult to fit into an investment structure requiring legally robust, long-term ownership of future cash flows. The same dynamics have made the financing of fishery recovery efforts especially difficult, and terrestrial crop insurance mechanisms have, by and large, not been translated to fish stocks. Except at unsecured, very high rates, small fishers in the developing world have little access to the capital needed to build port-side infrastructure, develop efficient transportation and value-adding processing, buy safer boats and prepare long-term management strategies.

Suboptimal market dynamics The tragedy of the ocean commons can be quite pronounced, with some economic rents procured at the expense of overall system health and productivity. Too often, legal or regulatory recourse is elusive when one nation overfishes at the cost of another, when land-based polluters harm fishers, or when climate change destroys reefs that protect communities. The gains (mostly terrestrial interests) and losses (mostly ocean interests) can be in the billions of U.S. dollars (see examples in Sect. 4). In many cases, these characteristics of the system prevent change towards sustainability—for example, regional fisheries management organisations have been seen to allow member countries to block reforms, even when the economic and scientific rationale is compelling; terrestrial polluters are still mostly legally indemnified from their ocean liabilities; and the international vessel registration system is designed to allow the origins of economic and legal ship ownership to be separate. These can be significant hurdles to overcome on the way to reform.

Existing laws often protect incumbent interests. Open access to ocean resources is enshrined in law, culture and convention—in many developing countries, it is regarded as a constitutional right of artisanal fishers, even if it makes local ownership and stewardship nearly impossible. International law enshrines the right to fish, free passage and open access to open ocean resources. Open access may appear equitable, but it often leads to a race for resources which ultimately favours depletion and inequalities over stewardship. Similarly, parties who are making the investment in sustainably managing a resource do not always reap the benefits of their investment, as in the case of highly migratory fish species that cross multiple EEZs during their lives. If one country invests in species management within its EEZ, other countries benefit from this investment—through the free-rider effect—due to increased catches. The potential free rider's overfishing behaviour of the shared stock could nullify any efforts by the investing country once it reaches that country's EEZ.

Subjectivity and irrational behaviours: (Not) making sense of the largely unknowable Subjectivity and irrational behaviours conspire against systems thinking and the transition towards a sustainable ocean economy. A number of individual behaviours can be explained by cognitive biases, which result from simplifications the human brain does to make decisions out of complex information. For instance, humans tend to react to the possibility of highly worrisome news (such as a scenario describing a potentially

[440] Teh, L., W.W.L. Cheung, A. Cornish, C. Chu and U.R. Sumaila. 2008. "A Survey of Alternative Livelihood Options for Hong Kong's Fishers." *International Journal of Social Economics* 35 (5): 380–95. doi: https://doi.org/10.1108/03068290810861620.

[442] IEA. 2019. *Offshore Wind Outlook 2019*.

catastrophic future) by seeking to confirm the belief that they are safe—and they are much more likely to believe those peers who confirm this belief (called 'confirmation bias'). This bias is easily exploited by those who use the inherent uncertainty of ocean state predictions to invalidate them. Confirmation bias is exceedingly difficult to overcome with new scientific information alone—it needs to be addressed on a cultural level. Similarly, when faced with the need for reforms which require short-term sacrifice for long-term gain (as is the case with many fishery reforms), humans tend to systematically overvalue present over future assets—even when (rational) discount factors are included. From a systems perspective, this can all amount to a hard-to-break feedback loop: bad habits are systematically re-enforced by the very system they shape. This bias is reinforced by short political cycles: many coastal and ocean decisions being made in the present have time horizons of decades to over a century, far longer than the lifespan of the governance arrangements facilitating them.

Any person's decision-making is hard—it needs to weigh long-term over short-term return, the value of different forms of wealth (financial, natural, cultural and personal) now and in the future; risk and peace and security, status, cultural and religious norms and so on. In many countries, cultural, legal and religious norms re-enforce a view of the ocean as both inexhaustible and commonly owned, with the spoils going to those who 'brave the sea' and take risks. Thus, understanding people's values and resulting emotional responses is critical in a system transition. Legal norms pertaining to activities taking place on the ocean tend to be weaker than those on land, and less enforced. Ownership of ocean resources tends to be far less defined, and far less definable, than on land.

On the positive side, these (subjective) personal incentives can also be used for good: altruism, ethical values, reciprocity and other types of intrinsic motivations can become powerful drivers of positive change.[443] Enhancing reputation and brand image can also be a strong incentive for businesses or governments to proactively lead on sustainable practices.[444]

6.2.2 To Move the System, It Is Important to Learn from Other System Transitions

Despite barriers, even very complex adaptive systems can shift onto new trajectories—sometimes very quickly. Economic history is replete with examples. When new information is plentiful and there is strong support for change, the shift can be entirely designed and purposeful—such as the energy transition in Germany, the Global Vaccine Alliance, smoking bans in bars and restaurants in Ireland and France, or the Montreal Protocol on Substances That Deplete the Ozone Layer. Even in the absence of new information or strong support, shifts can happen—sometimes they emerge from a new framing of an older issue (non-traditional marriage in the United States) or they take a less obvious, emergent form (such as the downward trajectory of meat consumption per capita in OECD countries in the past decade[445]). Deriving key success factors from these shifts as well as from the latest literature on system transitions,[446] a framework for a transition towards a sustainable ocean economy can be articulated (Fig. 20.36).

The first building blocks of this transition framework are three fundamental shifts in the established socially constructed order (top layer in Fig. 20.36). These shifts are expected to create new conditions and social norms that incentivise a company, a country or individuals to modify their way of interacting with the ocean in favour of more sustainable and equitable behaviours:

- **Balanced top-down/bottom-up governance.** Major shifts in the way a complex adaptive system behaves rarely occur in an entirely purposeful, 'top-down' fashion. This is certainly true for the shift towards a sustainable ocean economy, where a multitude of (hard to predict) feedback loops can jeopardise the goals of a purely top-down approach.

  Top-down governance, to be sure, is essential. Land use, for example, is governed by a much more structured system of product and operating standards, clear access and property rights, the provision of legal recourse and so on. In many cases, top-down rule setting has launched, rather than shackled, global industries. Today's thriving telecom industry, for example, would not exist without compatibility of transmission formats, a global process for frequency allocation, consolidation limits and so on. A global pharmacological market could not exist without global testing and production protocols. The internet protocol (TCP/IP) is at the heart of much of today's commerce. A modified, ocean-relevant version of such protocols, rights and obligations is essential for the difficult, risky and capital-expensive development of a sustainable ocean economy. Investors are sure to require long-term resource access guarantees, reliable regulatory protocols, standardised transfer points, and clear operating and performance standards. Yet this top-down gover-

Fig. 20.36 Framework for a successful transition towards a sustainable ocean economy. (*Source: Authors*)

nance needs to become more adaptive, faster and more deeply connected to communities. In recent years, the lines between the 'top down' and the 'bottom up' have often become blurred—generally to very good result. The Paris Agreement, for example, blends a voluntary commitment structure with a centralised monitoring, reporting and verification function.

Bottom-up governance and grass-roots movements have been transformed by digital communication. For example, fishing communities in the Philippines are now collaborating in turning their local experiments with territorial use rights into a regional and national movement—by collaborating in the alignment of regional and national fishing policy with local needs, in obtaining financing for their fleets at favourable (joint) rates and offering education to other communities interested in joining the movement. As the movement grows, local collaboratives assume quasi-governance functions and authority—a welcome development.

- **(Digital) knowledge access generalised for all.** It is predicted that by 2020 data generation will increase annually by 4300%.[447] Digitalisation provides rare, necessary open spaces for experimentation and innovation towards more sustainable, equitable management of the economy.[448] Some examples in the literature define *open source* (freely, publicly available information, data or software): 'When open source principles prevail, countless inquiring eyes can scrutinize everything—the infrastructure, the transactions, the dialogues, the individuals—which minimizes the opportunities for quiet subterfuges and backroom deals'.[449] The processes of governance are more likely to be honest and fair, and be seen as such.[450] For instance, in the ocean economy realm, critical data on storm tracks, market pricing, logistics, demand and the like have increasingly become available even to the smallest fishers and according to Bollier 'could help usher in new, more ecologically benign forms of decentralized production and consumption'.[451]
- **Ocean stewardship enabled by new frameworks and partnerships**. Stewardship actions have been defined as 'the suite of approaches, activities, behaviors, and technologies that are applied to protect, restore or sustainably use the environment'.[452] The concept proposed here is to empower the ocean economy players (fishers, communities, businesses, etc.) to better manage shared ocean resources. For instance, the territorial use rights for fisheries (TURFs) system, in Chile, the Philippines and Indonesia has bestowed exclusive control of local fishing

grounds to coastal communities—which have generally responded with much improved resource stewardship.[453] Similar stewardship initiatives can be found in the business world: CEOs from the ten largest global seafood companies (including fishing, aquaculture and aquafeed manufacturing) have joined forces through Seafood Business for Ocean Stewardship (SeaBOS), with the strong belief that through engagement with keystone actors, it is possible to both raise the sustainability bar for global companies that have significant influence within their industries and provide incentives for smaller companies to catch up with their peers.[454]

At the surface, each of these new social norms sounds obvious—in practice, they can be controversial and hard to implement because of the barriers mentioned above. For this reason, these fundamental shifts need to be supported by two core elements:

- **An action agenda** (middle layer in Fig. 20.36). Major shifts can happen ad hoc, but it's better to have an agenda. Industrial strategy agendas, for example, were a mainstay of public policy before 1990, briefly fell out of favour during the early digital revolution and are now making a major comeback with China's massive Belt and Road initiative, Britain's Industrial Strategy, Germany's Energie Wende and similar efforts. Shifting the commodity value chains (palm oil, tropical wood products, wild-caught and cultured fish, etc.) towards sustainability was the result of very deliberate agendas designed by NGOs, major buyers and government agencies. The Arctic Council's vision for risk-managed and sustainable development in the Arctic Ocean is based on a deliberate, shared, multinational agenda.

  In the context of this report, such an action agenda offers a clear, holistic picture of the various components of ocean economy reform, builds on emerging innovations and front-running projects and aims to scale them up. Section 6.3 lays out this agenda in detail—the case for change, the feasibility and the concrete opportunities for action.
- **A robust delivery mechanism** (bottom layer in Fig. 20.36). Delivering the action agenda can appear quite daunting for any decision-maker or national leader. This report identifies three complementary levels of intervention to start or accelerate the journey towards a sustainable ocean economy. They do not pretend to be exhaustive solutions, but they offer some options to be considered by decision-makers (particularly policymakers):
  - Local, catalytic interventions are essential to create support from the base and demonstrate tangible results on the ground—seeing is believing. Section 6.4 elaborates on a concept of small ocean 'special use' areas, which could be used as laboratories and demonstrators of a sustainable ocean economy.
  - National, coordinated 'ocean task forces' should be established. Using the best practices of performance management inspired by decades of practice in the private sector, they should deploy the implementation of the ocean agenda at the country level. Section 6.4 elaborates on the key features of such ocean task forces.
  - International leadership will be needed in various forms: ratifying and enforcing international treaties, conventions and agreements (such as the upcoming legally binding instrument on biodiversity of areas beyond national jurisdiction, or the Port State Measure Agreement to fight IUU fishing), or promoting new international public-private partnerships to advance knowledge and best-practice sharing, and remove roadblocks to the implementation of a sustainable ocean economy (see Sect. 6.4).

6.3 Charting a Direction: The Ocean Action Agenda

Change will not come with the stroke of a pen, or through a normative policy process only. The conditions for a top-down approach—predictability, enforceability, high levels of support, abundant feedback from diverse sources—are simply not in place, and a different, much more networked and adaptive process must be used. But just as clearly, the sustainable ocean challenge cannot be left to itself—a plan, an agenda is needed.

It is not necessary to start from a clean sheet though: the outline is in place in terms of governance and policy, technologies and business models, international collaboration and new consumer demands (see Sect. 4.4).

This section proposes an action agenda to deliver the overarching mandate of effective protection, sustainable production and equitable prosperity; this action agenda is based on five cross-cutting enablers, which collectively will help five main sustainable ocean sectors to thrive.

These ten components cannot be seen or advanced in isolation. Like the system they aim to change, these components are highly interconnected. The enabling conditions can support each other (e.g. better data in support of de-risked finance, smart planning and upgraded ocean accounting),

[453] Costello et al. 2016. "Global Fishery Prospects under Contrasting Management Regimes."

[454] Blasiak, R., R. Wynberg, K. Grorud-Colvert, S. Thambisetty et al. 2020. "The Ocean Genome: Conservation and the Fair, Equitable and Sustainable Use of Marine Genetic Resources." Washington, DC: World Resources Institute. www.oceanpanel.org/blue-papers/ocean-genome-conservation-andfair-equitable-and-sustainable-use-marine-genetic.

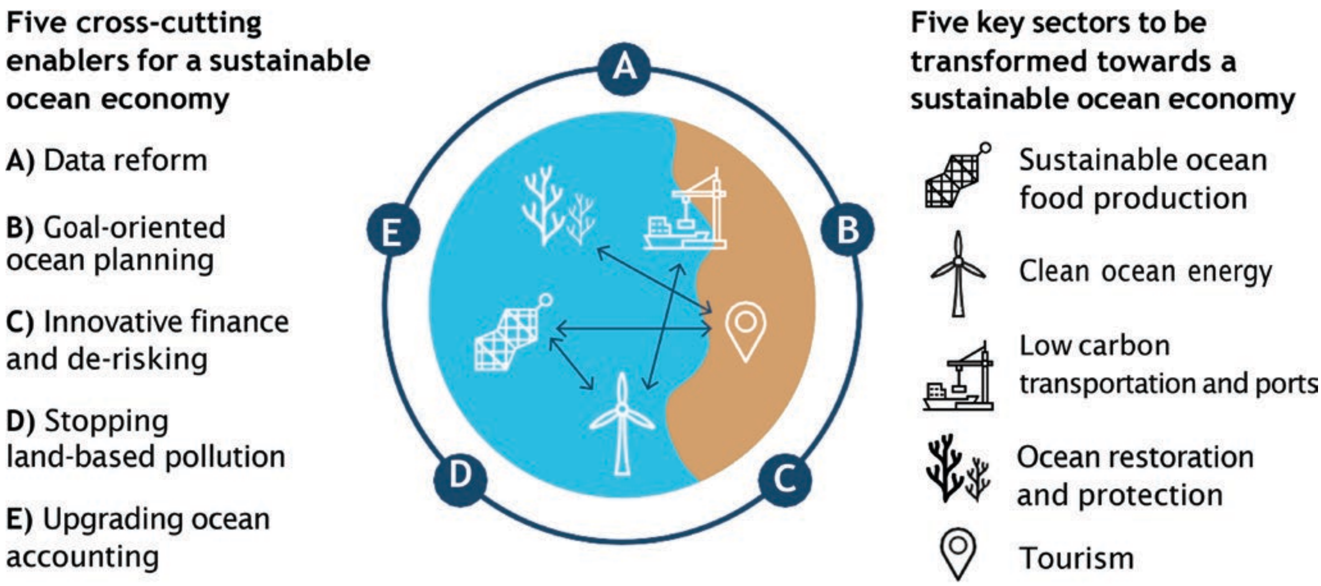

Fig. 20.37 One mandate and ten components of the action agenda for a sustainable ocean economy. (*Source: Authors*)

and the sectors have to develop in harmony with each other to exploit synergies (clean energy from offshore wind farms to fuel green ships; co-location of MPAs and offshore wind farms; co-location of seaweed, bivalves and finfish mariculture farms; MPAs to provide nursery grounds for fisheries, etc.; see arrows in Fig. 20.37).

This agenda stands on the shoulders of good work already done but provides a powerful new boost towards a truly sustainable ocean economy. This action agenda recognises the inherent challenges associated with a transition of such scale and would also have to be adapted to fit local, national or regional contexts. The OECD report *Sustainable Ocean for All* is a valuable source of insights regarding the specific challenges faced by developing countries seeking to embrace a sustainable ocean economy agenda.

6.3.1 Five Cross-Cutting Enablers for a Sustainable Ocean Economy

After extensive review of Blue Papers commissioned by the High Level Panel for a Sustainable Ocean Economy, scientific literature and expert consultations, five cross-cutting topics crystallise as the core enablers to provide the right conditions for a sustainable ocean economy to thrive (left-hand side of Figs. 20.37 and 20.38):

Data reform The revolution in data production (enabled by new technologies), collection and management (sensing, tagging, sharing), processing (simulation, forecasting, optimisation, tracking, process management) and sharing (open data platforms) can have a profoundly positive impact on all aspects of the ocean economy. This will require a comprehensive reform of currently proprietary sensing, storage and application methods.

Goal-oriented ocean planning Explicit guidance towards the overarching mandate (protect effectively, produce sustainably and prosper equitably) is required to ensure the avoidance of spatial use conflicts, uniformly high standards of operation, a streamlined and efficient regulatory process, the integration of symbiotic ocean uses, the overall protection and sustainability of the key oceanic systems, the efficient management of fishing rights and a just transition for workers of the ocean economy.

Innovative finance and de-risking Potential sustainable economy investors (sovereign wealth, institutional) require basic guarantees on infrastructure access and pricing, long-term access rights, regulatory certainty, reliable operating standards and solid legal recourse options. These are not uniformly in place today. Public financing might be required to mitigate inherent costs required to kick-start a sustainable ocean economy.

Stopping land-based pollution The sustainable ocean economy cannot thrive if land-based pollution ending in the ocean is not significantly reduced through ambitious and systems-inspired reforms.

Upgrading ocean accounting A sustainable ocean economy needs to be piloted through a holistic set of metrics which measure flows and stocks, economic and natural capital.

Fig. 20.38 Five building blocks are key to creating a sustainable ocean economy. (*Source: Authors*)

These five enablers can set up new rules and a favourable environment in which a sustainable ocean economy can develop. In particular, five sectors are reviewed in depth in this section, as the future champions of a sustainable ocean economy (right-hand side of Fig. 20.37). For each of them, this report analyses why such a sector needs to be transformed and identifies some concrete opportunities for action that could be taken to capture the full sustainable potential of these sectors.

Sustainable food from the ocean How the provision of healthy, low-carbon and nutritious food can be scaled while regenerating the ocean ecosystems and better redistributing benefits.

Clean ocean energy How societies can be powered by harvesting renewable ocean forces.

Low-carbon transportation and ports How national and international transportation of goods and people can be provided in a climate- and biodiversity-friendly, socially acceptable way.

Ocean restoration and protection How insufficient, isolated activities can be turned into a thriving sector, generating jobs, revenues and numerous ecosystem services.

Tourism How the beauty of coasts and the ocean can be enjoyed while restoring them.

This section explores each of these areas in terms of their importance, their path dependencies and barriers and, most important, opportunities for action.

Data Reform: How Could the Data Revolution—Enabled by New Technologies—Change the Way Informed Decisions in the Ocean Realm Are Made?

Why Is It Important?

The data explosion—in other words, the rapid increase of data and information created and made available—can reshape understanding and management of the ocean. The ocean is notoriously reluctant to reveal its secrets—far too little is understood about the interface between humans and the ocean ecology. New sensing, data management, visualisation, simulation and modelling technologies can change that—but current sharing practices are not yet fit for purpose.

In the near future, every ship's journey, and the nature of its business at sea, will be public information. Lawbreakers such as illegal fishers, polluters, smugglers and labour law violators will literally be on the public radar and subject to arrest. The Sea Around Us[455] project, for example, is providing entirely new levels of transparency on the state of the world's fisheries, while Global Fishing Watch[456] visualises, tracks and shares data on global fishing activities in near real time.

New ledger technologies can register ocean-related rights and contracts, both for public titling and private contracts, which opens up new horizons in rights-based management.[457] Product tracking throughout the chain of custody can help brands embrace sustainable practices[458] and would help small producers connect to global supply chains.

For ocean resource managers, replacing trial-and-error methods with reliable simulations lowers feedback and response times from years to hours, and allows quick insight on how the ocean reacts to specific inputs, rules and incentives. A number of these 'flight simulator' efforts are now in development for applications ranging from fishery management to ship routing and ecosystem conservation. The POSEIDON model,[459] for example, simulates the feedback loop between fishery policies, fishing fleets and ocean ecosystems, allowing for real-time testing of policy alternatives. These applications will allow managers to adjust to changing conditions,[460] such as dynamic management of fishing areas and quotas, ship traffic adjustments or avoidance of endangered species bycatch.[461]

What Is Preventing (Faster) Change?

Four main obstacles currently prevent the full capture of this potential.

- **On the technical side**, ocean sensors require power, which is hard to obtain for anything but the slowest-moving device. Undersea communications, unable to use electromagnetic waves, are notoriously challenging. The analytical methods required to harness the data into nimble, robust and transparent ocean management systems are complex and underdeveloped. Another technical challenge relates to the origin of data, which in some cases will not simply come from high-tech connected sensors but will have to be extracted from paperwork and measurements done by hand.
- **More daunting are the institutional, political and analytical challenges**. The fragmentation of ocean data into national, corporate and academic fiefdoms is a huge problem. Data inequities abound, with poorer nations and resource users largely excluded from the data bounty. And most important, oceanic data collection is still very expensive, with most sensors custom-built for narrow and specific scientific missions.[462] Technological innovation in the ocean has therefore been largely driven by government and large-scale commercial interests. Many needs remain simply unserved.
- **Financing has been difficult.** Much of ocean technology has relied on the trickle-down of commercial (mostly oil and gas) and defence technologies. National R&D expenses dedicated to ocean science vary greatly from country to country (21.4% in Argentina, over 2.5% in the United States, 0.1% in Russia),[463] but they can generally be considered as too low. Data collection in the harsh ocean environment is expensive—even medium-sized research vessels have operating budgets above $20,000 a day, with some globally operating vessels having budgets as high as $40,000 a day.[464] A business-as-usual approach will not come close to paying for the needed ocean technology.
- **Lastly, there is a capacity issue.** Even when relevant data are available, managers often do not get the information they need because of data access restrictions, or because they do not have data scientists to address the

[464] IOC-UNESCO. 2017. *Global Ocean Science Report*.

most policy-relevant questions.[465] Decision-support tools designed explicitly for marine managers are often so technical that only programmers are able to use them.[466] For example, fishery management in data-poor, developing-country environments often requires sophisticated data extrapolation techniques and extensive adaptation of standard analytics to local conditions.

What Are the Opportunities for Action to Overcome These Barriers?

Data management is evolving towards a 'digital ecosystem for the environment'[467]—a systemic, dynamic and collaborative model[468] that aggregates data into entirely new levels of synthesis, visualisation and managerial utility. This model uses huge networks of cheap, standardised and connected sensors (an 'Internet of Things for the ocean'[469]) with no regard to specific, predetermined purpose. These networks deposit data into unstructured data 'lakes' which enable users to build their own knowledge systems. This approach has already transformed machine learning and analytics, democratising the data[470] and allowing for the massive economies of scale needed to understand the ocean in all its complexity.

Universal data tagging standards are essential to allow data to be combined in federated data networks and data lakes that support verified and automated global access.[471] Governments can lead the way directly by taking bold steps to mandate these standards and to help create and contribute to federated data networks.[472] They can also require data-sharing and compliance with tagging standards as a non-negotiable condition of access to public resources—whether the resources are fish stocks and mineral deposits or funds for coastal management or for research.

Capitalising on the Decade of Ocean Science for Sustainable Development, UNESCO's Intergovernmental Oceanographic Commission (IOC) can establish global standards for metadata, query and data tagging that allow existing datasets to be connected and automatically accessed, as well as sensor positioning and interoperability.[473] Governments, industry and research institutions can use these standards to make their data broadly available in a global federated data network. New partnerships with cloud service providers (such as NOAA's partnership with Amazon Web Service) should be formed to create open-access data lakes.

In addition, governments can prioritise technology-forcing regulations that target real-time monitoring of fishing, seafood imports, shipping emissions, mineral development, coastal development and pollution and that create public accountability. In the case of fisheries, mandates for vessel-based electronic monitoring, for example, could speed the translation of existing artificial intelligence expertise to ocean management.

The private sector plays a huge role. Many new companies and privately funded initiatives, such as Planet, the Ocean Data Foundation, the Center for the Fourth Industrial Revolution for the Ocean, OceanX and Schmidt Marine Technology Partners, are generating new ocean data and/or providing them free of cost to researchers. Knowledge services can pay for data networks. Already, ocean and climate data are being used as the basis for complex insurance decisions, targeted weather forecasts for precision agriculture and other lucrative knowledge products. Growing corporate interest in traceability across the value chain spawns new solutions, such as the recently launched blockchain platform OpenSC. Tech innovators partnering with NGOs and big seafood companies can extend that capability to small-scale fisheries.

Finally, governments, researchers and the private sector need to work together.[474] Jointly developed technology standards are essential to create a fertile ecosystem for innovation. FAO's Port State Measures Agreement, for example, creates new requirements for port monitoring and control that are applied globally and that will require technological innovation in data collection and sharing.[475] In addition, the sectors can collaborate to lower data storage costs. For a summary of these points, see Box 20.6.

Box 20.6 Key Triggers to Unleash the Ocean Data Potential

- Capitalise on the UN Decade of Ocean Science for Sustainable Development to create a global data network that provides broad and automated access to ocean data.
- Liberate ocean data. Enabled by federated networks, data holders should establish a new default—that ocean data are broadly available to other users unless there are compelling security, proprietary or other interests.
- Create an 'Internet of Things' for the ocean. Coordinated efforts by industry, researchers and governments can create advanced sensor networks that provide high-resolution, real-time information about the ocean to anyone who needs it.
- Automate ocean management based on near real-time data on ocean conditions and resource use.
- Create incentives for innovation. Existing markets do not incentivise many of the technological innovations needed for ocean stewardship and research. Governments and companies can change that.
- Mobilise capital for technologies for underserved markets. Many markets for ocean technologies do not offer commercial returns. Innovative financial instruments are needed that can leverage the expectations and risk tolerances of different investors.

Goal-Oriented Ocean Planning: Why Does Ocean Planning Matter So Much, Why Is It Not Mainstreamed Yet and How Can It Be Generalised?

Why Is It Important?

The literally 'free for all' model of ocean use cannot continue. Unrestricted, open-access fisheries almost invariably fail;[476] uncoordinated ocean development creates operational inefficiencies and use conflicts (with attendant litigation and regulatory delays); and unrestricted industrial, nutrient and carbon-related pollution is changing the fundamental ocean chemistry and affecting its biology. More systematic, equitable management is needed for the ocean's resources (principally food and energy), services (weather modulation, carbon sequestration, recreation) and certainly its absorption of externalities (heat and pollution). The current standards and practices of oceanic use planning, accountability, transparency and legal rights and protections remain a century or more behind their terrestrial equivalents. A fresh look at these practices is necessary, shaped by three major systemic objectives:

- **Efficiency and safety.** The different sectors of the ocean economy, such as food, energy and tourism, as well as carbon sequestration and coastal protection, are often symbiotic and have much to gain from being planned as an integrated whole. For example, offshore renewable energy production, the production of non-carbon shipping fuels (ammonium, hydrogen) and large-scale maritime operations all are operationally linked. They could generate significant efficiency gains and avoid impeding on fishing grounds and shipping lanes if carefully integrated with onshore grids and energy markets, and potentially co-located with offshore tourism sites and platforms. Seaweed, finfish and bivalves farms could be co-located (or integrated) to benefit to each other, reduce waste and synergise capital expenditure and operating costs (e.g. boats).
- **Reliable and defensible resource and access rights**. Resource owners, lessees and access holders need secure titling and reliable and effective legal recourse against polluters, trespassers and other violators. Coastal communities and small-scale fishers need inclusive and equitable access to resources, and recognition of their rights and tenure (food resources, protective reefs and habitats). Investors need reliable, long-term resource access guarantees.
- **Integration and balance of production and protection**. Production and protection need to be in balance, with a strong emphasis on ocean regeneration. This requires careful integration along the dimensions of mitigation offsets (e.g. MPAs in balance with high-use areas), stringent and consistent operating standards (e.g. mariculture standards for containment, disease control, feed composition) and careful facility siting to ensure efficient production while avoiding ecological damage.

Goal-oriented ocean planning is central to these objectives. Three main concepts are usually mentioned when talking about ocean planning: ecosystem-based management, marine spatial planning and integrated ocean management—see Box 20.7 below.

[476] Costello, C., S.D. Gaines and J. Lynham. 2008. "Can Catch Shares Prevent Fisheries Collapse?" *Science* 321 (5896): 1678–81. doi: https://doi.org/10.1126/science.1159478.

Box 20.7 Ecosystem-Based Management, Marine Spatial Planning or Integrated Ocean Management?

Ecosystem-based management: Management of natural resources that focuses on the health and productivity of a specific ecosystem, a group of ecosystems or selected natural assets as the nucleus of management.

Marine spatial planning: Identifies what spaces of the ocean are appropriate for different uses or activities in order to reduce conflicts and to achieve ecological, economic and social objectives. Usually associated with zoning.

Integrated ocean management: A holistic, integrated, knowledge- and ecosystem-based approach that considers multiple uses and pressures, reconciling competing uses, with the objective of ensuring the sustainability of marine ecosystems.

The three approaches: similarities and differences:

Similar and overlapping in many ways, all three are holistic approaches to human use of the ocean, based on well-defined ocean areas or ecosystems.

The difference is in the main 'angle' taken by each of these three approaches: integrated ocean management is rooted in 'management' thinking (processes, institutions); ecosystem-based management in ecosystem thinking (interactions between humans and ecosystems); marine spatial planning in analysis instruments such as geographic information systems and zoning.

Aberdeen, Scotland: International Institute of Fisheries Economics and Trade*

Yet if ocean planning should always be science-based, there is no 'one-size-fits-all': an efficient planning process has to be guided by science but tailored to the local parameters, needs and players involved. Some countries have, at least partially, developed and implemented ocean planning and have gone through the testing, failing, learning and adaptation stages. Sharing this variety of experiences internationally would be extremely helpful to nations with less experience. Platforms could be expanded for this purpose. The IOC-UNESCO Marine Spatial Programme, for example, is already 'documenting marine spatial planning initiatives around the world, identifying good practices of marine spatial planning, collecting references and literature on marine spatial planning and building capacity through training marine spatial planning professionals'.[477]

The planning concept should also recognise the social considerations inherent in a transition towards new or more sustainable sectors. Indeed, the Just Transition Centre states that 'transparent planning that includes just transition measures will prevent fear, opposition and inter-community and generational conflict'.[478] Inspiration for such national strategies or planning regarding jobs transition can be found in Canada's 'Just Transition Task Force', which was established to support workers who would be affected by the national target of phasing out coal-fired electricity by 2030. This task force is working closely with labour organisations and communities to ensure a just transition plan for Canadian coal power workers and communities.[479]

What Is Preventing (Faster) Change?

Most of the world's ocean remains largely unplanned and poorly managed for a number of reasons:

- **Planning backlash.** Opposition to ocean master planning is often fierce. It can come in certain regions from the offshore oil and gas sector, in others from commercial fisheries (while the shipping industry is often supportive because of its focus on safe and reliably protected shipping lanes). The opposition is typically concerned that ocean spatial planning is not about rational planning and conflict avoidance but instead a Trojan horse for conservationists seeking new legal tools to pursue a perceived anti-business agenda.
- **Opposition to access control.** Today, titled access happens routinely in the form of extractive leases (e.g. oil and gas platforms and deep-sea mining) and foreign fishing fleet access rights to national waters. While some fishing rights have been in place for decades, in recent years, fishery access rights have been conferred on only 200 fisheries and coastal communities (e.g. 'individual trading quotas'

Government of Canada. https://www.canada.ca/en/environment-climate-change/services/climate-change/task-force-just-transition/final-report-complete.html.

and 'territorial use rights').[480] Opposition to ocean access rights can be strong from all points on the political spectrum. Some worry about monopolisation or 'corporatisation' of the ocean by the wealthy and well connected, to the exclusion of traditional user groups. Commercial fishing industries are wary of ever-expanding exclusions of their fleets. Coastal inhabitants and competitors often fiercely contest lease sales for near-shore energy and mariculture operations. Legal provisions guaranteeing free ocean-access provisions are on the books in many countries, and certainly enshrined on the high seas through the UN Convention on the Law of the Sea (UNCLOS).

- **Access to data.** Knowledge of the ecosystem is the foundation of integrated ocean management: the biology (fish stocks, migrating patterns, invasive species, primary productivity, etc.), the chemistry (acidity, temperature, nutrients), the physics (currents, waves), the human activity (fisheries, aquaculture, shipping routes, etc.) and the existing regulations and zoning (especially in basins shared by multiple countries). Norway—which has used integrated ocean management for years—is one of the highest spenders in the world, in absolute terms, on marine science. But many countries do not have sufficient scientific capacity or baseline data to provide the knowledge foundation required. The 2017 *Global Ocean Science Report* demonstrated that many countries lack fundamental scientific capacity to underpin their efforts at ocean governance.[481]
- **Unfit top-down planning processes.** Top-down planning processes tend to be inefficient. For instance, 265 separate knowledge products concerning ocean management have been produced over 5 years of a major coral conservation program in Asia—position papers, books, training manuals, field guidance manuals and the like. A recent survey revealed that 54% of program participants never or rarely used these knowledge products, and only 20% frequently or often used them.[482] On the contrary, in some SIDS, participatory approaches have been very effective at the local level for all phases of the MPA process (MPA planning, implementation, monitoring and evaluation, feedback, adaptation of management plan, etc.).[483]

What Are the Opportunities for Action to Overcome These Barriers?

Many countries have started to create marine spatial plans (MSPs), a fair number of countries have implemented MSPs in parts of their EEZ, but very few have implemented MSPs for the whole of their EEZ.

A national mandate for an EEZ-wide (and eventually international high seas) ocean planning process can explicitly signal the end of damaging 'free for all' use practices. At its core, this process needs to show how the agendas of ecosystem health, food and energy security, local prosperity and coastal protection can fully re-enforce each other—and what form this takes in explicit spatial, regulatory and operational terms. The process needs to find the spatial balance between production and protection zones (see Sect. 6.3, point 9, 'Ocean restoration and protection'), between the requirements of different ocean users and between the needs of the ocean and the needs of the coast and its people. It needs to provide inclusive, equitable access and recognition for local communities, such as access to traditional fishing grounds, protection of cultural sites, preservation of viewsheds and so on.[484]

The development of an ocean plan covering 100% of the ocean areas under national jurisdiction is a time-consuming exercise of broad shareholder participation and shared exploration. This long process is crucial, however, since, apart from economic use considerations, thorough (and often costly) public stakeholder consultations to address gender, equity and distributional issues should be held (see 'Unfit top-down planning processes' above). The development of a protected ocean area plan for the coast of California, for example, required hundreds of community meetings. The interests of shippers, ports, fishers, wind developers, coastal cities, scientists, the navy, local security forces, farmers, water users and so on need to be heard, respected and integrated. This can take 2–3 years. Once a plan is established, its ongoing implementation requires continued funding.

In the shorter term, the benefits of planning can be demonstrated on a smaller scale. This report champions the idea of smaller 'sustainable ocean economic zones' (SOEZs)—ocean areas which serve as testbeds for a new breed of fully sustainable and regenerative ocean projects (such as multi-trophic farms, renewable energy and the like; see Sect. 6.4). These SOEZs can catalyse development of an integrated, sustainable ocean economy plan encompassing the entire EEZ or areas under national jurisdiction. For a summary of these points, see Box 20.8.

[484] Allison et al. 2020. "The Human Relationship with Our Ocean Planet."

Box 20.8 Major Components of Integrated Ocean Planning and Management

- At the country level, establish comprehensive integrated marine spatial plans for 100% of the areas under national jurisdiction. The process (science-based, inclusive, participatory, adapted to local context) is as important as the plan itself.
- Ensure continued funding and capacity for the ongoing implementation of ocean management plans.
- Develop sustainable ocean economic zones as spatially defined 'laboratories' for fully managed areas comprising various sectors, multi-sectoral projects and fully protected areas.
- Develop an international platform to develop and share best practice principles and guidelines for sustainable planning (which could be done by leveraging the ongoing IOC-UNESCO Marine Spatial Programme).

Innovative Finance and De-risking: Why Is Finance Pivotal, and How Can More Money Be Mobilised Towards a Sustainable Ocean Economy?

Why Is It Important?

The ocean economy is currently greatly underinvested (even among impact and blended finance investors, SDG 14—'the ocean SDG'—receives the smallest share of them all[485]). Over the 2013–2018 period, an average of US $1.5 billion of official development assistance (ODA) a year was allocated in support of the sustainable ocean economy, representing less than 1% of global ODA.[486] The finance available for biodiversity and/or conservation is significantly below its need.[487] It has been estimated that currently only about 0.002% of global GDP is invested in the conservation and sustainable use of ocean biodiversity, and that about four times the current level of investment is required to meet conservation needs.[488]

A growing, sustainable ocean economy needs funding from sources ranging from philanthropy to market-rate investment.

- **Financing innovation**. Many of the sustainable ocean technologies of the future require further commercialisation. This includes floating offshore wind, large offshore multi-trophic mariculture, alternative feed for mariculture, carbon-financed restoration and coastal protection and production of non-carbon shipping fuels. The linkage and symbiosis of these sectors will require considerable development and experimentation. Public finance and subsidies are essential components of the 'industrial strategy' required, as demonstrated exhaustively on land. Demonstration projects are needed to develop 'proof of concept' that can convince institutional investors to engage at scale.
- **Financing infrastructure**. The infrastructural support required is not uniformly in place. This includes offtake and grid access points for offshore energy; energy supply for offshore mariculture; port investments required for the management of sustainable fisheries; marine safety and rescue.
- **Financing the transition**. Transition costs may require public support. This can include investments in worker retraining; consumer awareness campaigns; and much more extensive programs to 'buy down' future (unpriced) costs, such as coastal erosion, expanding dead zones, pollution on beaches and so on. In the context of fisheries, the transition implies a deep reduction of capacity and fishing effort to help rebuild stocks before they are fished (sustainably) again. One study has estimated that the total amount governments need to invest to rebuild world fisheries ranges between $130 billion and $292 billion in present value, cost to be spread over several years and among countries.[489]

What Is Preventing (Faster) Change?

Six main barriers are preventing more financial flows from entering the sustainable ocean economy space:

- **The investable pipeline for a sustainable ocean economy is not evident.** Investment-grade projects are currently limited and/or hard to find. A survey commissioned in 2020 by Credit Suisse shows that '[l] ack of investment-grade projects/firms at scale' and '[n]ot enough internal expertise' are the two main barriers identified by investors (n = 249) to greater investment in a sustainable ocean economy.[490] Examples of new parametric insurance

[485] Libes, L., and M. Eldridge. 2019. "Who, What, Where and How: 440 Investors—a Deepening View of Impact Investing." http://investorflow.org/wp-content/uploads/Investorflow-Report-440-Investors-March-2019.pdf.

schemes (e.g. coral reefs insurance) are promising but still mostly confined to the pilot stage. Recent solutions have been developed to mobilise commercial impact finance into marine protected areas through long-term management lease of the MPAs. The scalability of the approach must nonetheless be demonstrated. In the short term, the number of MPAs with tangible business models that include monitoring of abuses and enforcement of sanctions seems limited.

- **Incentives are either not in place or are out of place**. In the absence of national 'ocean industrial strategies', harmful subsidies have been allowed to distort the current ocean economy, typically promoting the expansion of fishery capacity (mostly directed to large-scale industrial fishing fleets[491]) and the extraction of oil and gas. At the same time, constructive subsidies supporting sustainable ocean enterprises—such as demand guarantees, low-cost infrastructure support and access to low-cost capital—have lagged far behind. In addition, the risks associated with unsustainable management of the ocean have been inadequately considered: most externalities (e.g. climate change, pollution, violation of human rights) are today not priced by the market and allow unsustainable businesses to thrive.
- **It is generally risky to invest in the ocean space**. In many cases, key technologies are available but not yet fully tested in the cauldron of open ocean conditions, intensifying storms, increasing acidification and shifting currents. Onshore competition, such as from onshore wind, freshwater aquaculture and alternative proteins, is a source of considerable uncertainty. Lastly, potential sources of use conflict abound, with the attendant regulatory risks and delays. Sovereign wealth funds have so far not lined up behind 'ocean industrial strategies' in the same way they have done on land. Institutional investors still lack some of the knowledge and capacity to invest in new ocean technologies. In the absence of sovereign guarantees and institutional growth capital, development finance institutions and multilateral development banks also have largely stayed away. Blue bonds have grown but are complex to replicate and have narrow applications.
- **Impact of (sustainable) finance in the ocean space is not well measured.** The positive impact of sustainable investments on economic, social and environmental dimensions is not well understood and measured. For instance, a recent analysis has taken stock of existing impact evaluation studies relevant to the conservation and sustainable use of both terrestrial and marine ecosystems. It finds that of the nearly 80 impact evaluation studies identified, only three were relevant to ocean issues (mainly MPAs).[492]
- **Governments don't invest enough in the 'transition'.** Fishing companies and fishers are likely to lose profits and wages (in the short to medium term) if fishing efforts are reduced so fish stocks can rebuild.[493] Several studies have forecast an attractive economic return for rebuilding fish stocks and fishing them sustainably, but governments may need to invest extra resources in the short term to mitigate transition challenges. Policymakers 'often perceive this rebuilding cost to be too expensive in the short-term'.[494] Consequently, policymakers usually avoid taking the actions necessary to start the transition[495] (e.g. repurposing subsidies, supporting fishers in a transition to other livelihoods, providing financial compensation where appropriate, etc.). Recently, NGOs such as the Blue National Capital Financing Facility (part of the International Union for Conservation of Nature) have been advancing this agenda.
- **The ocean and finance communities lack shared language.** One of the challenges for creating investable pipelines in some ocean sectors (nature-based solutions, wild-caught fisheries) is that these communities cannot effectively communicate their needs in ways that financiers can easily understand;[496] there is particular misalignment in the generation of metrics from the conservation sector that can produce data applicable to financial decision-making. The *Ocean Finance Handbook*, recently published by the World Economic Forum, is helping to address this barrier.[497]

What Are the Opportunities for Action to Overcome These Barriers?

In a more investor-friendly world with secured resource access rights, infrastructure and offtake guarantees, well-

established operational standards and regulatory frameworks, and availability of sovereign wealth funds as lead investors, the capital markets are likely to open for ocean investments.

The following strategies can accelerate change:

- **Provide investment conditions required by sovereign and institutional investors.** Experience with emerging industries on land has shown that sovereign wealth funds typically play a central role in providing a debt capital pool for nationally prioritised and strategic emerging industries. In many cases, these funds guarantee matched debt or equity funding from a coalition of development finance institutions. This concentrated and coordinated approach has the dual benefits of (1) systematically de-risking the investment in unfamiliar industries and (2) creating a pool of domain knowledge and capacity ahead of the market. Both benefits are essential in attracting investments from the institutional finance community, which remains relatively unfamiliar with many aspects of the sustainable ocean realm. Investment by sovereign wealth funds and development finance institutions will require appropriate national commitments. In many cases, they will require that sustainable ocean development be nationally prioritised and formalised in an ocean-industrial strategy. In some cases, this strategy can be trialled and launched in special ocean economic zones dedicated to the development of specific conforming ocean industries within strict selection and operating standards.
- **Boost and diversify the investment pipeline**. National technology innovation programs, typically using a mix of research support, grants and below-market-rate investments in prototypes and early-stage application, can significantly accelerate commercialisation (e.g. Norway's support of next-generation offshore aquaculture and the European Union's support of offshore wind generation). With appropriate titling in effect (e.g. conservation and restoration leases) and the reduction of transaction costs,[498] carbon and offset finance could become a major investment vehicle for large-scale restoration and conservation projects. Incubation and acceleration programs, partnerships with schools, universities or corporations can all help accelerate ocean innovation. The investment pipeline also needs to be pushed to include more women, Indigenous people and minorities. For instance, the Impact Investment Exchange (IIX) Sustainability Bonds—developed and implemented by the IIX and IIX Foundation USA—explicitly targets the inclusion of women in economic activities.
- **Improve investment conditions in a sustainable ocean economy.** Public support in the form of margin enhancement (e.g. low-cost infrastructure costs, feed-in tariffs, subsidies) and risk reduction (e.g. regulatory certainty, insurance, offtake and demand guarantees) is also often required, in particular for capital-intensive offshore developments such as wind energy and large-scale mariculture. Significant oversight is necessary, however, to ensure that public support is catalytic (i.e. designed to accelerate commercialisation and innovation) and does not devolve into permanent and ultimately unproductive subsidies. Environmental and sustainability standards can also be advanced by applying stringent criteria in public procurement auctions for products and services, as in the CO_2 emission criteria for public ferries in Norway, which make later electric ferry projects economically attractive.
- **Develop blended finance solutions to de-risk private capital investment**. The concept of blended finance is to use public or philanthropic money to reduce investor risk or improve returns. This is one way to unlock commercial capital for a sustainable ocean economy, especially in higher-risk countries or for new technologies. Using a tranched fund structure to 'blend' capital with different risk appetites and impact mandates is one of the most common forms of blended finance in the ocean space (e.g. Althelia's $100 million Sustainable Ocean Fund, Rare's $30 million Meloy Fund, the California Fisheries Fund or Climate Fund Manager's upcoming 'Climate Investor Two'), but many other structures can also mobilise commercial capital for sustainable ocean assets. More case studies and an explanation of different blended finance structures can be found in the reports published by the Blended Finance Taskforce[499] and the Friends of the Ocean Action.[500]
- **Repurpose harmful subsidies to more equitable and sustainable uses.** Multilateral forums, such as APEC, the G20 and the G7, have called repeatedly for phasing out inefficient fuel subsidies and distortive support measures.[501] This momentum for reform can be channelled into better policies for the ocean economy, for instance in rebuilding fisheries (see 'Governments don't invest enough in the "transition"' point above). The World Trade Organization (WTO) missed its own December 2019 deadline to reach an agreement to 'prohibit certain forms

of fisheries subsidies that contribute to overcapacity and overfishing and eliminate subsidies that contribute to illegal, unreported, and unregulated fishing'. A new deadline has now been set (December 2020) for the WTO ministerial meeting. This is an essential milestone.
- **Map financing flows**. The OECD *Sustainable Ocean for All* report presents the first-ever estimates of ocean-relevant official development assistance, covering the (sustainable) ocean economy as well as land-based activities with impacts on the ocean. This is a great first step towards much more comprehensive monitoring of public, private, domestic and international financial flows into the ocean economy, which is urgently needed. For a summary of these points, see Box 20.9.

Box 20.9 Key Triggers to Unlock Finance for a Sustainable Ocean Economy
- Provide investment conditions required by sovereign and institutional investors.
- Boost and diversify the investment pipeline.
- Improve investment conditions in a sustainable ocean economy.
- Develop blended finance solutions to de-risk private capital investment.
- Repurpose harmful subsidies to more equitable and sustainable uses.
- Map financing flows.

Stopping Land-Based Pollution: How Does the Current Political and Economic Constellation Make It Nearly Impossible to Stop Ocean Pollution? How Could This Be Changed, and Where Do We Start?

Why Is It Important?

Ocean pollution is largely an externality of the terrestrial economy. Plastics, nutrients (primarily nitrogen and phosphate), pesticides and parasiticides, antibiotics and pharmaceuticals, industrial chemicals including persistent organic pollutants, oil and gas, medical waste, e-waste and disaster debris are diverted to the ocean with very little financial consequence for the polluter. But ocean dilution is no longer the solution to pollution—the consequences, as described in Sect. 4, are significant and deeply concerning.

Marine plastic litter has received the most attention recently. Plastic pollution is ubiquitous (9–14 million metric tonnes leaking into the ocean every year[502]) and iconic (animals starving from plastic ingestion, strangulation, littered beaches). The root cause is straightforward: waste management infrastructure in industrialising countries (especially in Asia and Africa) is lagging far behind their rapidly rising consumption of plastic. With few consumer products designed for recyclability (just 2% of plastic packaging is made from former plastic[503]), waste collection is largely unprofitable and plastic 'leakage' into the environment is correspondingly high.

Ocean 'dead zones' are also proliferating, as are toxic algal blooms. Around 700 sites worldwide are now affected by low oxygen conditions—up from only 45 in the 1960s.[504] These result from a combination of climate change (warmer waters absorb less oxygen) and nutrient pollution from fertiliser, sewage, animal and aquaculture waste, which causes excessive growth of algae, leading to oxygen depletion when later decomposed by bacteria.[505]

The impact of industrial, pesticide and oil-spill pollutants on the marine food web is also well documented. Bioaccumulation of mercury in food fish, for example, is so high that health organisations are issuing safe human consumption guidelines for many predator species, including tuna, billfish and sharks.[506] Virtually every pollutant present on land is also present in the ocean at detectable levels, with compounding and significant impacts on ecosystem health. Oil spills such as the Deepwater Horizon accident in the Gulf of Mexico have had devastating long-term impacts on the ocean floor and coastal habitats.[507]

What Is Preventing (Faster) Change?

In general, addressing the ocean pollution challenge has been complicated by the difficulties of attribution (many pollutants are non-point-source) and by the overwhelming asymmetry of the situation: when heavily protected terrestrial private interests clash with the interest of a weakly defended common pool resource like the ocean, the ocean loses.

Accessed 12 May 2020.

Reform of the plastic economy is specifically impeded by three principal factors:

- **Price differential between virgin and recycled products.** The current price of virgin plastic resin is historically low, making recycling of most polymers unprofitable without subsidies. An adjustment of virgin cost, through voluntary industry initiative or imposed through policy, would (1) launch significant entrepreneurial activity in the waste management and collection sector, (2) make collection of plastic waste more profitable and (3) provide a major incentive for consumer brands to include recyclability in their packaging product design.
- **High capital and operating costs of waste management infrastructure.** Introducing modern plastic waste collection infrastructure into the developing world will require capital expenditures of billions of U.S. dollars per year[508] (with operating costs several multiples higher). The public sector in these countries is going to rely on the 'extended producer responsibility' schemes used by developed countries for sources of finance. However, translating these schemes into the infrastructure, governance and legal frameworks of developing or industrialising countries is challenging. In addition, the costs associated with the development of new technologies (e.g. chemical recycling) and the transition towards plastic substitutes are considerable, and it is not clear how those costs can be equitably allocated among industry players.
- **Lack of transparency.** The flow of recyclable and non-recyclable plastics through the value chain, from the resin producer through the brands to the waste manager, is currently largely undocumented. It is thus difficult for a producer or brand to differentiate its 'plastic performance', and to be rewarded by the market as a leader and good faith actor in the fight against ocean plastic. On the opposite side of the coin, it is nearly impossible for civil society to hold responsible companies which are side-stepping the ocean plastic problem.

Pesticide, nutrient and industrial pollution control is largely a political challenge. Agricultural and industrial production has long benefitted from the ocean's dilution of excess nutrients, pesticides and industrial toxins, and the resulting rents tend to be well protected legally, politically and culturally. In the United States, for example, it is very difficult to pursue legal action against non-point-source polluters. Environmental enforcement budgets are constantly under attack.

[508] Lau et al. 2020. "Evaluating Scenarios toward Zero Plastic Pollution"; Pew Charitable Trusts and SYSTEMIQ. 2020. *Breaking the Plastic Wave*.

What Are the Opportunities for Action to Overcome These Barriers?

A growing number of governments and industries are announcing new measures and commitments (e.g. plastic bag bans). However, a recent study quantified that such efforts will barely make a difference: by 2040, current government and industry commitments are likely to reduce annual plastic leakage into the ocean by only 7% relative to a BAU scenario.[509]

There is no silver bullet solution to ocean plastics pollution. A more diverse portfolio of more ambitious solutions should be deployed, including reduction of unnecessary plastics, substitution with other materials, recycling (mechanical and chemical) and safe disposal (see Fig. 20.39).

Many technical solutions are available today to governments and industry, but they could be accelerated by three major reforms:

- **Recalibrate the economic advantage of virgin plastic** to stimulate the demand and competitiveness of recycled materials. This can be done in multiple ways; for instance, through the global adoption of extended producer responsibility (EPR) schemes or the increased taxation of virgin production.
- **Invest massively in waste collection and recycling technology and infrastructure**. The highest priority in the short term is collection infrastructure in the developing world—collection rates need to stay ahead of recycling capacity to ensure reliable feedstock flows.
- **Bring transparency and accountability to the flow of plastic polymers through the value chain.** The performance of companies selling plastic products needs to be fully transparent over time (in terms of shifting to more recycled content, recyclable product design and plastic substitutes).

These measures are within reach. The management of plastic waste in the developing world will not remain as an unpriced externality much longer—virgin plastic taxation schemes are under discussion in many countries. Plastic producers and brands may choose to pre-empt taxation with alternative, industry-led EPR initiatives and funding mechanisms. Recent announcements by industry, including the plastic industry's $1.25 billion Alliance to End Plastic Waste and Nestle's $2.1 billion commitment to tackle plastic waste, are not likely to be the only major commitments forthcoming soon.

In the fight against nutrient pollution, dead zones and toxic algal blooms, the sustainable ocean economy is in a

[509] Lau et al. 2020. "Evaluating Scenarios toward Zero Plastic Pollution"; Pew Charitable Trusts and SYSTEMIQ. 2020. *Breaking the Plastic Wave*.

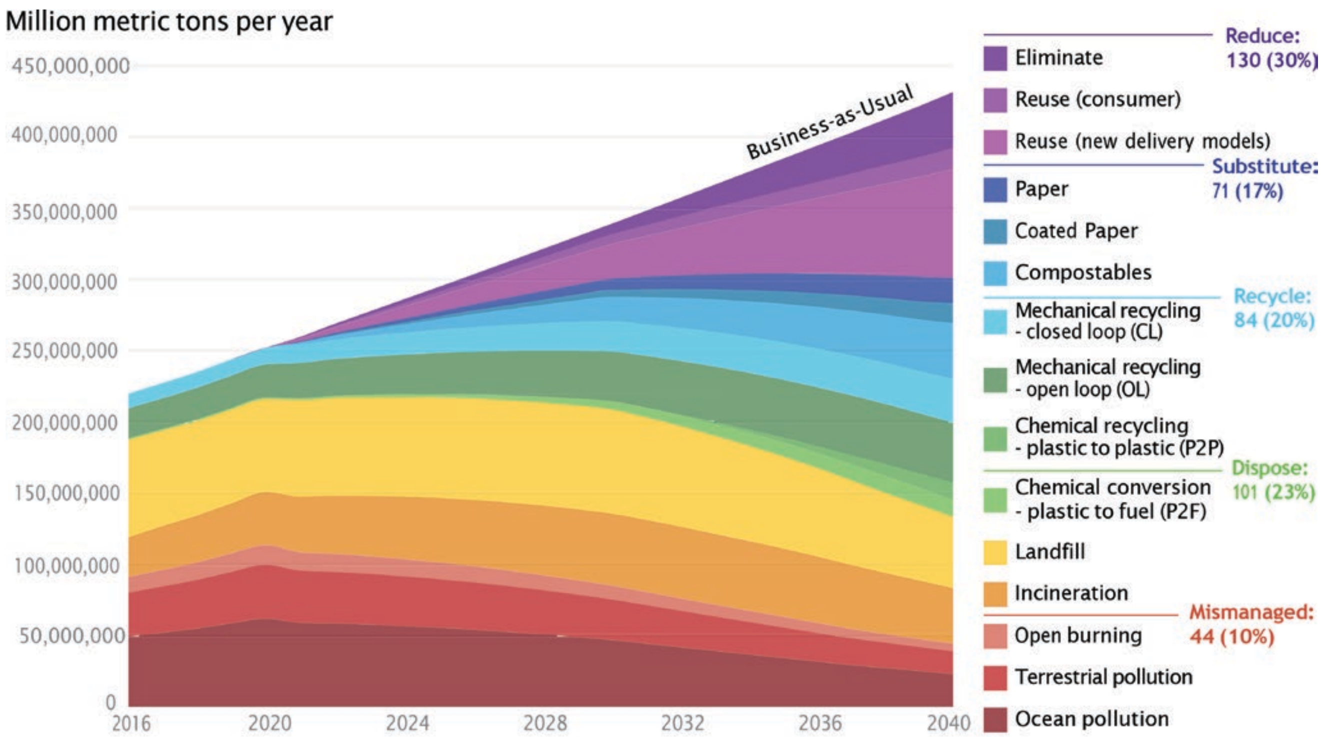

Fig. 20.39 Plastic leakage into the ocean can be reduced significantly only if all solutions are implemented concurrently, ambitiously and starting immediately. *Note: The 'wedges' figure shows the share of treatment options for the plastic that enters the system over time under the System Change scenario. Any plastic that enters the system has a single fate, or a single 'wedge'. The numbers include macroplastic and microplastic*. (*Source: Lau, W.W.Y., Y. Shiran, R.M. Bailey, E. Cook, M.R. Stuchtey, J. Koskella, C.A. Velis et al. 2020. "Evaluating Scenarios toward Zero Plastic Pollution." Science, July. doi:* https://doi.org/10.1126/science.aba9475)

direct confrontation with land-based agricultural interests. The technologies for precise applications, runoff controls and soil regeneration are well established[510] and could drastically reduce the need for input on crops, but they are not mainstreamed yet on a global scale. As the sustainable ocean economy develops further, its economic interests will be more fully represented in the political and legal realm—and it is doubtful that the periodic death of entire coastal ecosystems will remain uncontested for very long.

- It would, of course, be far preferable to avoid this inevitable confrontation by proactively requiring precision fertilisation, low-input farming and regenerative agriculture, especially along major rivers. However, the current political economy will likely require ocean interests to assert their interests in a formal way for this to occur. For a summary of these points, see Box 20.10.

Box 20.10 Key Triggers to Reduce Land-Based Pollution in a Sustainable Ocean Economy

- Recalibrate the economic advantage of virgin plastic.
- Invest massively in waste collection and recycling technology and infrastructure.
- Bring transparency and accountability to the flow of plastic polymers through the value chain.
- Require the adoption of precision agriculture to avoid nutrient runoff.

Upgrading Ocean Accounting: How Do Current Metrics and Public Accounting Conventions (Gross Value Added, Gross Domestic Product) Drive the Wrong Priorities, What Can Be Changed, and How Can We Start the Change Today?

Why Is It Important?

Ocean macroeconomics has long focused on 'outputs', typically expressed in terms of GDP metrics. Microeconomic metrics—market size, growth rates, returns—have been sim-

[510] FOLU. 2019. *Growing Better*.

ilarly output-focused. But these metrics are flawed—they measure the flow of capital but ignore the 'stocks', the value of the manufactured and natural capital involved in the production process. They also don't measure the importance of human capital (knowledge, aptitude, education and skills). For decades, world-class economists (Dasgupta, Jorgenson, Kuznets, Nordhaus and Tobin, Solow, Stiglitz, Weitzman, etc.[511]) have warned about the perils of a focus on GDP only, arguing that it ignores the true cost of production and does not put human well-being at the centre of the economic debate: 'Growth is a means to an end, rather than an end in itself'.[512]

The broader value of the ocean must be fully accounted for and used in decision-making.

The System of National Accounts (SNA) could document progress along the dimensions of productivity, job creation, food security, regional stability and long-term ecosystem health. A complete set or 'sequence' of national ocean accounts could provide highly insightful information for the sustainable management of the ocean economy. Three key high-level indicators can already provide a much more holistic picture than the use of GDP only to inform policy and ocean-related decisions: ocean product, net change in the ocean balance sheet and ocean income:

- **Ocean product** is the traditional measure of the ocean's output, generally monetised in terms of ocean 'gross domestic product' (GDP) or 'net domestic product' (NDP).
- **Net change in the ocean balance sheet** provides a sustainability indicator. It accounts for the reserves of natural and produced capital in the ocean, as driven by economic activities. Changes in the balance sheet indicate physical and monetary changes to show how wealth and opportunity change through time (adjusted for anticipated price changes).
- **Ocean income** measures benefits to nationals from the ocean, the 'ends' or 'outcomes' of policy. It is generally expressed in terms of net or gross national income (NNI or GNI). Income can include non-monetary types of income, though these are often expressed in monetary equivalents.

What will an ocean account monitoring these three indicators change? Good information is not sufficient to ensure good decisions, but it helps. The development of national accounts has had an impact on inflation and the business cycle, which has generally made the economy more stable and enhanced human well-being.[513]

In parallel, it is useful to promote more flexible approaches to natural capital valuation and use in decision-making that can be tested and deployed with less inertia and complexity than with the SNA, with the eventual goal of reconciling these two approaches. Some examples of such alternative methodologies include using payment for ecosystem services schemes that have been used in the United Kingdom[514] and Costa Rica,[515] for instance, or the gross ecosystem product (GEP), which is increasingly used by the Chinese government as part of a transformation to inclusive, green growth.[516]

What Is Preventing (Faster) Change?

Developing national accounts to guide economic development is less daunting than it may seem. Most of the data already exist in national accounts, in government agencies or in scientific databases. The knowledge to build the connec-

tions exists, although it is dispersed throughout the government, academic, business and NGO sectors. Many countries already produce 'marine GDP' reports that may be a good starting point.

Several barriers remain:

- **Old habits.** Even in 2020, economic and policy decisions are still mostly based on nineteenth-century economic paradigms, with rigid definition of economic sectors and metrics, a failure to differentiate sources of income in terms of externalities and no monetisation of natural capital.
- **Siloed data.** Much of the information needed for ocean accounts exists but is siloed in multiple government agencies, as well as in the academic, business and NGO sectors. In a few cases the data are not yet available, for instance, biophysical data needed to quantify natural stocks. Also, the tagging of databases is not standardised, making it difficult to know precisely what's available.
- **Methodology.** Despite the rising momentum behind this new generation of accounting, there is still a need for standardisation and reforms of existing accounting systems and valuation methods, within and across countries.
- **Lack of track record in informing decision-making.** Policy- and decision-makers are lacking demonstrations showing how these indicators actually can inform decisions (and are informing them).

What Are the Opportunities for Action to Overcome These Barriers?

Four main areas of action could accelerate the development and use of these holistic ocean accounts:

- **Create national ocean accounts.** National statistical offices, in partnership with marine agencies, need to develop a complete sequence of national ocean accounts: product, income, balance sheets and supply and use tables. This should be achievable by 2025. In particular, they need to ensure the compatibility of ocean accounting efforts with international statistical standards and approaches, mainly the System of National Accounts, the System of Environmental Economic Accounting (SEEA), the ten Fundamental Principles of Official Statistics endorsed by the UN General Assembly in January 2014[517] and other broadly accepted initiatives.[518] Next to these accounts, more flexible approaches to natural capital valuation and use in decision-making can be encouraged (e.g. GEP in China and other examples mentioned above), and alignment should be ensured between these approaches and the ones using national accounts.
- **Develop and use interactive dashboards for ocean account reporting**. Such dashboards allow users to explore the data, aggregate and disaggregate sectors and groups of people, alter the account boundaries and access ethically acceptable disaggregation by digital means. These dashboards would stimulate decision-making based on more holistic information more than GDP only, and they would track national progress over time.
- **Encourage international collaboration and standardisation.** National governments should ensure that their national accountants, economic analysts and marine scientists participate in workshops organised by the UN Statistical Division and associated organisations for developing ocean accounts. This will help to maintain standards and increase credibility. These international organisations need to evolve to provide a degree of third-party verification of accounts coupled with capacity-building assistance.
- **Invest in data architecture and engineering, and build know-how in national statistical offices.** Governments need to invest in data architecture and engineering at levels surpassing global multinational companies. These investments are necessary to connect fine-scale data about the marine environment with detailed economic data in supply-and-use structures and other data structures for national accounting and forecasting the ocean economy. These investments should build on existing Earth observation programs when possible. Investment must also include investments in people. The costs of implementing the ocean accounts—including embedding them in relevant laws, policies and action plans—will likely be far outweighed by the benefits current and future generations gain from sustainable ocean economies. For a summary of these points, see Box 20.11.

Box 20.11 Key Triggers to Develop and Mainstream Ocean Accounts

- Create national ocean accounts covering product, income, balance sheets and supply and use tables.
- Develop and use interactive dashboards for ocean account reporting.
- Encourage international collaboration and standardisation.
- Invest in data architecture and engineering, and build know-how in national statistical offices.

6.3.2 Five Key Sectors to Be Transformed Towards a Sustainable Ocean Economy

Sustainable Food from the Ocean: How Can Sustainable Ocean Fishing and Farming Feed a Planet with Ten Billion People?

Why Is It Important?

Ocean fish provides about 3.2 billion people with almost 20% of their average intake of animal protein.[519] This number is even higher in developing regions such as Indonesia, Sri Lanka and many small island developing states, which derive 50% or more of their animal protein from aquatic foods.[520] Ocean food is also a unique source of long-chain omega-3 fatty acids, minerals, calcium, iodine and vitamins.[521] To simplify, food from the ocean can be split into two main sectors: wild-caught fisheries and mariculture—the latter can then be divided into unfed (e.g. seaweed and filter-feeders) and fed mariculture (e.g. finfish and crustaceans). Today the lion's share of ocean food production comes from wild-caught fisheries (in tonnes of edible food equivalent; see Fig. 20.40).

The ocean can contribute to sustainable food security for ten billion people. Ocean animals are more efficient than terrestrial systems in producing protein;[522] their impact on climate change and land use is in general much lower than terrestrial animal proteins (Fig. 20.41) and their production is not limited by suitable area available.

By applying realistic demand scenarios to the sustainable seafood supply potential presented in Sect. 5 (six times more seafood than today), a recent paper determined the plausible future equilibrium quantity of food from the sea that could be produced and consumed. This still represents a significant expansion, calculated to represent a 36–74% production increase compared to today's levels.[523]

Yet the current ocean production system is not on track to deliver this production increase in a sustainable way.

FAO estimates that 33% of global fish stocks are overfished, and nearly 60% exploited at maximum capacity.[524] The wild-caught production has been stagnating in the past three decades at about 80 mmt/year of landed weight. Illegal, unreported and unregulated (IUU) fishing remains a major problem, accounting for 11–26 mmt of catch and creating financial losses of between $10.0 billion and $23.5 billion/year.[525] Fisheries on the high seas (e.g. tuna, jacks) are subject to multilateral management institutions which have, in the past, frequently not adopted scientific recommendations.[526] In a BAU scenario, 2050 yields could decrease by almost 16% to about 67 mmt/year because of the cumulated pressures of overfishing, climate change and pollution.[527] Commercial fishing activities also affect fauna like birds, marine mammals and turtles. For example, the World Ocean Assessment states that 'each year, incidental bycatch in longline fisheries is estimated to kill at least 160,000 albatrosses and petrels, mainly in the southern hemisphere. For marine reptiles, a threat assessment scored fishery bycatch as the highest threat across marine turtle subpopulations'.[528]

Mariculture has been growing at a stable pace in recent years, around 5.8% annually,[529] but finfish mariculture is too often associated with unsustainable practices (e.g. fish escapes, local fouling, overuse of antibiotics, disease transfer) and is critically constrained by the need to 'fish wild fish to farm fish'. As a result, many consumers still consider wild-caught fish to be of higher quality than farmed fish.

Finally, the significant amount of food waste in the seafood value chain represents a missed opportunity to boost consumption without increasing production. Indeed, FAO estimates that 35% of fish and seafood is wasted, including 8% of all fish caught being thrown back into the water (in most cases, these fish are dead, dying or badly damaged).[530] This waste is equivalent to almost 3 billion Atlantic salmon.[531]

The current and BAU production numbers fall far short of the ocean's productive potential. If all stocks were sustainably managed and fishing effort were maximised for profit, yields from wild-caught fisheries could increase to 98 mmt/year in 2050. This is an about 20% increase from current levels and represents an increase in profit of $53 billion in 2050 (in comparison to BAU).[532] These gains are dependent on widespread policy reforms, such as rights-based approaches that incentivise conservation and hold fishing fleets accountable to science-based limits.[533]

The mariculture story is even more promising. Finfish mariculture expansion potential is almost unlimited if the feed can be decoupled from fish meal/fish oil (FM/FO);[534] the biological potential for finfish mariculture production is estimated to be around 15,000 mmt. Unfed mariculture also holds great promise: a study found that the ocean has the potential to produce nearly 768 mmt of bivalves (shell-on weight), and about 60% of this production would be profitable at roughly the current price for blue mussels ($1700/mmt).[535] Unfed mariculture (e.g. bivalves and seaweed) can also substantially increase nutritious food and feed with a lower impact on the marine environment, and may in some cases enhance wild fisheries by creating artificial habitats.

Seaweed production is growing strongly (11% annually) from a small base (30 mmt/year). Seaweed and macroalgae have the potential to help solve food security issues, act as a form of carbon sequestration, reduce ruminant methane emissions and so on[536] (see Box 20.12). There are few geo-

physical (48 million km² are suitable for cultivation)[537] or technical constraints to doing so.[538] This industry is clearly still in its infancy, with much consumer product development and testing yet to be done.

Box 20.12 Seaweed: The Versatile Ocean Super Crop

Seaweed cultivation is the fastest growing mariculture sector (7%/year),[a] already producing over 30 million metric tonnes (valued at US $4.8 billion).[b] As a 1000-year-old industry in Asia, it is unsurprising that the largest share of the world's seaweed is produced on the coasts of this continent—China and Indonesia alone produce over 85% of global volume.[c] About ten species are intensively cultivated.[d] Europe and North America are catching up to the benefits of producing this super crop. Through the Pegasus project, for instance, the European Union developed guidelines for the sustainable aquaculture of seaweeds. The project showcased the many benefits of seaweeds. Not only do they not require land or freshwater, but seaweed farms also provide habitat for many marine species, mitigate storm damage, sequester carbon, provide bioremediation services (e.g. degrade or assimilate contaminants as excess nitrogen and phosphorus) and can protect calcifiers from projected ocean acidification.[e] Their uses are similarly broad and promising. Seaweeds are already extensively used in the pharmaceutical and nutraceutical industries, consumed directly as human food (e.g. directly in soups and salads or processed into noodles and seasoning) and food additives, transformed into fertiliser or refined into biofuels. They are being increasingly explored as animal feed (even shown to reduce methane in ruminants by a factor of up to 80% in one case, even if more research is needed[f]), or can be a base ingredient for bioplastics.[g]

With new seaweed applications being found yearly, and a potential cultivation area of 48 million km² (about three times the current area used for growing crops—16 million km²),[h] seaweeds could become an ever more present sustainable ocean crop in the decades to come—if their farming development is supported by adequate marine spatial planning[i], and if innovations help seaweed-based products to enter new markets.

What Are the Opportunities for Action to Accelerate Change?

There is no alternative to regulation—and enforcement—in fisheries. Unregulated, 'free access' fisheries almost invariably overfish.[539] Unregulated fleets tend to grow to the point of little or no profit for the individual boat—a point that is ecologically and economically irrational and destructive and which can be driven to absurdity by national subsidies. Ports allowing illegal or untraced seafood to be unloaded without verification are maintaining these destructive practices. The governments of most industrialised nations have addressed this problem with various types of catch restrictions and port controls. With rare exception, stocks have shown a heartening capacity to recover once the pressure is eased.

Reform is impossible without rules to protect the stocks and allow for an efficient, fair and equitable allocation of catch.[540] First and foremost, the commercial right to fish needs to be predicated on a plan to fully restore the target stock within 10 years (or as soon as possible for fish stocks with longer recovery time).[541] This has been the key feature of the Magnuson-Stevens Fishery Conservation and Management Act, which successfully restored fish stocks and fisheries in the United States (see case study in Sect. 4.2), and the European Common Fisheries Policy. Second, within the framework of these restoration targets, catches must be restricted to a level that results in the rebuilding of fish stocks, followed by sustainable levels of fishing.[542] Third, the allowable catch must be allocated fairly—to provide food security to artisanal fishing communities and to tie the fortunes of commercial fishers to the health of 'their' stocks.[543] Fourth, the Port State Measures Agreement must be enforced in all ports to close illegal fishing. Finally, the implementation of fully protected MPAs has been demonstrated to generate significant spillover effects that can benefit surrounding fisheries.[544] Such MPAs could be an integral part of a fishery recovery plan for some fisheries. Finally, several technical innovations can help reduce bycatch and lost fishing nets, as well as prevent food loss during fishing and processing. In addition to regulatory changes, the financial community can deploy innovative funding mechanisms to support the transition towards sustainable fisheries (e.g. Meloy Fund, California Fisheries Fund).

The acceleration of sustainable mariculture will require the coordinated intervention of governments and investors, as well as an adjustment of consumer preferences. The Food and Land Use Coalition strongly recommends that governments 'support new feed technologies with clear targets (standardized performance specifications for feed applications), strong incentives (feed efficiency standards), and guaranteed demand (feed standards for government seafood purchases)'.[545] Without compromising strong and independent oversight, governments also need to update regulations so they conform to new best practice technology standards, with low- and multi-trophic operations involving seaweeds and bivalves made a priority. Additionally, governments need to lower the barrier to entry for marine aquaculturists; for example, by providing environmentally stringent, yet easily navigable aquaculture governance frameworks and/or assistance to (excess capacity) fishers who transition to become marine aquaculturists. Finally, governments need to work with farm operators to support the development of model farms which are innovative in terms of feed technology, as well as the integration of different trophic levels (multi-trophic farming), scale, containment, siting and so on.

There is now strong consensus that new feed technology and vaccine delivery systems, as well as improved breeding and genetic selection, have enhanced the investment grade of top-performing mariculture operations.[546] The hope is that continued improvements will lead to a mature and stable industry. Venture and early-stage funding has also entered this space from different sources, including corporate food and feed investors, Silicon Valley firms attracted to the artificial-intelligence and technology aspects of aquaculture, and specialised funds (e.g. Aqua-Spark, a $180 million Dutch aquaculture investment firm). Given the potentially increasing role of aquaculture in the global diet, a strong push will be needed from public funding and official development assistance, ideally led by a consortium of countries with expertise and interest in scaling up. However, appropriate species and local conditions, including market opportunities, differ significantly and will require tailored approaches. Hatcheries and farmers will need to address and preserve genetic diversity while breeding selectively for desirable traits. At the same time, precautions will need to be taken to keep genetically modified species from escaping mariculture operations and altering, or in the worst case replacing, local populations.[547]

In both fisheries and mariculture equity issues persist: from forced labour on fishing boats, to lack of recognition

[547] Rogers et al. 2020. "Critical Habitats and Biodiversity."

and full integration of women in all parts of the fishery and mariculture industry, to unfavourable risk distributions for smallholder mariculture farmers. Solving these equity issues will require the combined force of strong labour legislation, effective enforcement and ensured traceability throughout the supply chain to keep seafood from bad actors out of seafood markets.

Consumers still regard aquaculture finfish as a food category of its own rather than as a potential replacement for poultry, pork and beef—there is little evidence of switching between the two as prices rise and fall.[548] Very little work has been done on predicting how the substitution economics between seafood, plant-based alternative protein and meat will evolve as a function of shifting tastes, prices and processing technologies. The safest bet currently is that additional production of farmed finfish is more likely to meet the protein demand of the new generations than to replace the meat habit of the older ones.[549] Additionally, consumer awareness and resulting demand for sustainably fished or farmed and humanely processed seafood needs to be raised by promoting sustainability labels like those of the Marine Stewardship Council and Aquaculture Stewardship Council.

Research into novel seafood sources, like lab-cultivated seafood, should be supported. Even though lab-cultivated seafood is not grown in the ocean, it still has its genetic roots there. This requires the understanding of cell lines from highly sought-after seafood species. This research should be enabled by easily navigable legislation.

Last but not least, scientific understanding of the implications of harvesting low-trophic species like krill, zooplankton and mesopelagic fish should be increased. The mesopelagic zone, also called the twilight zone, is the layer of water between 200 and 1000 m below the ocean surface, just beyond the reach of sunlight.[550] Many animal species live in this zone: zooplankton, crustaceans, squids, gelatinous animals and a multitude of few-inch-long fish usually referred to as mesopelagic fish (the most famous being the bristlemouth fish). The biomass in the twilight zone is not well known, but according to some estimates it could be bigger than the rest of the ocean biomass combined. Many mesopelagic organisms also travel from and to the surface daily, playing an important role in the broader ocean food chain and carbon flux exchanges between the atmosphere and the deep sea. In recent decades, there has been increasing interest in investigating the commercial fisheries catch potential of this immense biomass, for instance, to be used as fish meal or fish oil for aquaculture. However, until reliable stock assessments, and the impact of their harvest on the ocean's food web and the carbon cycle, are understood, a precautionary approach should be followed. The Woods Hole Oceanographic Institution, for instance, is funding a $35 million research project to answer the following questions:[551]

- What species live in the twilight zone, and in what quantities?
- How long do twilight-zone organisms live? How quickly do they grow? At what age do they reproduce?
- To what extent do large ocean predators such as whales and tuna depend on twilight-zone organisms as a source of food?
- How much carbon do twilight-zone animals transfer to the deep ocean through their daily migration? How much carbon sinks out of the twilight zone into deeper waters as marine snow and in other forms?

In Europe, the Ecologically and Economically Sustainable Mesopelagic Fisheries (MEESO) project involves 20 European research centres and universities pursuing similar research on mesopelagic fish.[552] For a summary of these points, see Box 20.13.

Box 20.13 Key Triggers to Revolutionise Food from the Ocean

- Increase official development assistance for fisheries management capacity.
- Artisanal fisheries: Ensure inclusive and equitable access rights to local, well-managed fish stocks.
- Align economic interests and stock health of industrial and small-scale commercial fisheries through capacity and granting of access rights; impose science-based mortality controls in line with sustainability principles for each commercial stock.
- Create climate-smart fisheries and mariculture management structures that plan for, and can adapt to, changing oceanographic conditions under climate change.
- Integrate technologies available for highly adaptive fishery management, new fleet control and tracking technologies, and seamless chain of custody tracking and registration of rights, ownership, titles, obli-

gations and so on through new ledger and registration technologies.

- Repurpose subsidisation of fishing capacity for fleet control infrastructure, port improvements (e.g. enforcement of the Agreement on Port State Measures, icing facilities) or financing of the cost of fish stock recovery.
- Ban damaging fishing, such as destructive bottom-trawling and blast fishing, and incentivise fishing gear and techniques that minimise bycatch of non-target species.
- Develop the required modalities and business models to support fishers in their transition (to be developed by insurers and investors, including through sovereign or outward direct investment, development finance institutions and multilateral development banks).
- Streamline mariculture permitting through easily navigable permitting processes that include environmentally rigorous permitting requirements.
- Boost development of fish feed alternatives (e.g. algae-based, insects, etc.).
- Increase scientific research on the ecosystem implications of harvesting krill, zooplankton and mesopelagic fish and follow a precautionary approach until these implications are understood.
- Promote more (sustainably) farmed finfish, seaweeds and bivalves in diets.
- Implement and build capacity to enforce strong labour standards for the fishing and mariculture industry.
- Require transparency of seafood supply chains ensuring full ocean-to-plate traceability.

Clean Ocean Energy: How Can the Ocean Deliver Much More Zero-Carbon Energy in a Sustainable Way?

Why Is It Important?

Of all the ocean-based climate mitigation options identified (see Sects. 4 and 5), ocean-based renewable energy technologies hold the greatest potential, up to 10% of the global needed annual GHG emissions reductions by 2050.[553]

The required growth path for ocean-based renewable energy generation is a very aggressive departure from a very low baseline. By the end of 2018 the total worldwide installed capacity of wind energy amounted to 564 GW, of which only 23 GW were offshore.[554] The great majority of installed offshore capacity is in Northern Europe, although there is significant technically feasible generation potential in Brazil (748 GW), South Africa (589 GW) and Vietnam (214 GW), as well as Indonesia, India, the Philippines and Sri Lanka.[555] All other ocean-based renewable energy technologies remain at the experimental or demonstration stage today (e.g. wave or tidal power, floating solar).

The target is massive. By several estimates, offshore wind capacity installed will need to be multiplied by a factor of 40–45 by 2050 to contribute to a 1.5 °C compatible trajectory (see Sect. 5). The path from baseline to target is extremely steep—it requires the installation of around 30 GW/year for 30 years, which exceeds the current growth rate by almost an order of magnitude and involves the installation of thousands of turbines per year. Current capacity projections confirm the critical gap: Asian countries are planning for 100 GW of offshore wind by 2030[556] (including South Korea 18 GW, India 30 GW, Japan 10 GW and Taiwan 5.5 GW).[557] This, combined with the commitments of Europe (70 GW)[558] and the rest of the world, adds up to a 2030 global capacity of about 220 GW[559]—not close to the ambition needed for 2050. But the technical resource is massive, and as the costs of electricity from offshore wind continue to come down below other sources, continued rapid growth is conceivable.

What Are the Opportunities for Action to Accelerate Change?

The construction of wind farms is a matter of national consensus and political priority, as reflected in regulatory support, public budgets, local support and financial market stability. Technical challenges and economics matter—offshore wind does not make sense for every country or every coastline. Without support from national governments (e.g. country targets for wind power, explicit inclusion of offshore wind in marine spatial plans, infrastructure for grid connectivity and storage), the offshore wind industry will be hard-pressed to build capacity at the scale required to compete with land-based energy sources.

There are other accelerating factors, of course. Institutional investors are not sufficiently knowledgeable about the offshore energy asset class and its risk and return profiles, but they are quickly catching up. Incumbents (utilities, fossil fuel energy generators) may be reluctant to share portside or grid infrastructure. However, with a favourable regulatory and incentive structure in place, these challenges can be overcome. For a summary of these points, see Box 20.14.

Box 20.14 Key Triggers to Boost Clean Ocean Energy from the Ocean

- **Precisely assess local and national opportunities.** Fund the scientific assessment of offshore power resources and site characterisation, including unique weather, oceanographic, ocean ecosystem and seafloor conditions, and design lease tracts accordingly to optimise for development and construction costs, operating conditions, and safety.
- **Formulate national targets.** Announce clear and time-bound national targets increasing the share of offshore wind energy in the national energy mix; set firm operating standards.
- **Develop marine spatial planning** (see Sect. 6.3.1, point 2, 'Goal-oriented ocean planning'). Convert these national targets into explicit plans for ocean-based energy development in national marine spatial plans and proactively sort use conflict issues with other ocean users such as fishers, shippers and so on.
- **Offer incentives.** Establish the modalities and schedules for incentive packages, including energy production and investment tax credits, feed-in tariffs and renewable portfolio standards.
- **Streamline administrative processes.** Provide a consistent, efficient and clear permitting process, based on development and operating standards, with predictable timelines.
- **Improve infrastructure.** Reduce the burden of specialised infrastructure cost through appropriate public and joint investments, such as in ocean energy delivery and grid integration, port facilities and properly leveraged existing infrastructure.

Low-Carbon Transportation and Ports: How Can a Traditional Industry Embrace Sustainability?

Why Is It Important?

Ocean transport is currently moving around 90% of the world's traded goods,[560] or about 11 billion metric tonnes (2018).[561] There were 94,171 commercial vessels in 2018 globally, mostly bulk carriers, tankers and container ships. Fuelled by increasing global trade, shipping is expected to continue growing above GDP rates in the coming years (the UN Conference on Trade and Development [UNCTAD] is forecasting a 3.8% annual growth rate for shipping between 2018 and 2023).[562]

Ocean transport currently produces about 2.2% of global greenhouse gas emissions,[563] and such emissions are expected to double until 2050,[564] in sharp contrast to what is needed to keep global temperature rise well below 2 °C and consistent with a 1.5 °C increase (IPCC 2013) and align with the goals of the Paris Agreement (UNFCCC 2015). Decarbonising shipping could also reduce other pollutants usually associated with ocean transport: about 17% of the human-induced sulphur dioxide[565] and 8% of nitrogen oxide[566] emissions globally. Phasing out such pollution could cut premature deaths by 4100 by 2030 and 10,000 (annually) by 2050.[567]

Ocean-based transportation has the potential for a roughly 100% reduction in operational net GHG emissions by chang-

Vienna: International Institute for Applied Systems Analysis. https://www.cittadiniperlaria.org/wp-content/uploads/2019/04/Shipping_emissions_reductions_main.pdf.

ing the way it stores and consumes energy onboard: batteries could be used to store electricity, particularly in ships on the shortest voyages. Low- or zero-carbon synthetic or 'e-' fuels could replace fossil fuels: examples include renewable hydrogen, hydrogen-based fuels such as ammonia, and fuels that have been processed with capture and storage of CO_2. Transitioning ocean shipping to more efficient and low- or zero-carbon fuels, and the mitigation potential in 2030 and 2050, is largely determined by the time scales needed to renew or retrofit the existing fleet and develop the infrastructure to use and supply these new energy sources.

An additional challenge associated with shipping is the discharge of untreated ballast water from ships. It is considered one of the major threats to biodiversity that could have 'severe public health-related, environmental and economic impacts'.[568] One cubic metre of ballast water can contain up to 50,000 zooplankton specimens[569] and/or 10 million phytoplankton cells.[570]

Ports, the gateways to the sea, present many challenges themselves. Their operations emit carbon, moving of goods creates significant amounts of air pollution (dust, exhaust), (mishandling of) waste products pollutes local waterways, and the resulting heavy ship traffic creates (underwater) noise. The increase in shipping traffic along ports has been associated with ship strikes.[571]

What Are the Opportunities for Action to Accelerate Change?

Tighten and enforce energy efficiency requirements of ships Countries should ensure the implementation of the IMO's Energy Efficiency Design Index (EEDI) and move beyond it (e.g. redesign the EEDI formula to ensure that vessels are being optimised for minimised fuel consumption in real operation at sea rather than being optimised only to pass the test[572]), while furthering the goal of fully decarbonising shipping by 2050. To reach these standards, countries should develop national roadmaps, and support the IMO in creating an international one, of how to fully decarbonise ocean transport by 2050.

Test and deploy low-carbon fuels Countries and shipping companies should foster offtake agreements between ship operators and harbours to incentivise the construction of zero-carbon fuel infrastructure and ensure its use by shipowners. These low-carbon fuel offtake agreements are essential to overcome the chicken-and-egg problem of building low-carbon fuel infrastructure in harbours versus building the ships requiring such low-carbon fuel infrastructure.

Incentivise decarbonisation of shipping Governments should set clear port access targets based on carbon emission standards and/or tax ship GHG emissions or create emission trading systems for shipping companies.

Eliminate port air pollution through environmental regulations This includes electrifying port operations and making shore power available for ships. It also includes integrating ports into local decarbonised land transport systems to ensure continued low-impact transportation of goods and people.

Harmonise port operations with the local environment This includes ensuring that port expansions do not destroy sensitive habitats. High-traffic shipping lanes usually associated with ports should be planned in accordance with whale migrations to minimise ship strikes. Ports should not be expanded into sensitive habitats or built in locations requiring continuous harmful dredging.

Support retraining programs for port and ship jobs that are expected to be automated Ports are often major employers within their region. Increased automation can replace jobs while raising the average skill level demanded of the retained employees.

Governments should support retraining programs for current port and shipping works to ensure that there is no skills gap, while retaining a maximum of current employees. For a summary of these points, see Box 20.15.

Ocean Restoration and Protection: How Can Protected Areas Be Mainstreamed and Enforced?

Why Is It Important?

A century or more of coastal urbanisation, ocean and coastal resource exploitation, infrastructure expansion, river channelling, land reclamation, mangrove removal and pollution has taken its toll. Globally, an estimated 50% of salt marshes, 35% of mangroves, 30% of coral reefs and 29% of sea grasses have been either lost or degraded.[573] By 2100, as many as 630 million people could be at risk of coastal flooding caused by climate change,[574] with several atoll states in danger of disappearing entirely.[575]

Reversal of these trends is urgent. Intact coastal ecosystems provide critical services to all of humankind. They are critical to fisheries and recreation. They protect cities and coasts from storms and sea level rise. They host unique biodiversity.

An ecologically healthy coast does, of course, have intrinsic economic value, offering protection from storms, surges and swells,[576] the nursery of coastal fisheries,[577] recreational value and so on. However, a narrowly defined economic metric is unlikely to win the day for the coast—short-term cost-benefit calculations can just as well make the case for coastal destruction[578] and they certainly do not account for the damage done when ecological thresholds are irreversibly crossed.[579]

That said, some monetisation of coastal ecosystem values is possible—the storm protection and wave attenuation services of healthy coastal biota, for example, have been well documented. Over 500 million people worldwide live in a coastal zone that is protected by coral reefs.[580] Without their protection, flood damages from 100-year storms would increase by 91% to $272 billion.[581] U.S. coastal wetlands provide $23.2 billion a year in storm protection services—a benefit of over $33,000 per hectare (median $5000 per hectare).[582] Mangroves reduce annual flooding globally by more than 39%/year for 18 million people, and reduce annual property damage by more than 16%, or $82 billion.[583]

Berlin: The Nature Conservancy. https://conservationgateway.org//ConservationPractices/Marine/crr/library/Documents/GlobalMangrovesRiskReductionSummaryReport10.7291/V9930RBC.pdf.

Similarly, the value of coastal ecosystems in terms of nursery and habitat for fishes and other marine species, regulation of water flow and filtration, carbon sequestration, and contaminant storage and detoxification has also been calculated for coastal habitats, ranging from $100 to $10,000 an acre.[584]

The greatest risks of coastal degradation are to populations already at risk on other fronts. Forty-six percent of Bangladeshis live within 10 m of sea level, with declining levels of storm protection from mangrove forests. Developing countries account for nine of the ten nations with the largest share of the population living in low-elevation areas (the Bahamas, Bangladesh, Belize, Djibouti, Egypt, the Gambia, Guyana, the Netherlands, Suriname and Vietnam).[585] In the United States, approximately 39% of residents of coastal counties fall into an elevated coastal hazard risk category (i.e. children, the elderly, households where English is not the primary language and those in poverty).[586] When Hurricane Katrina's storm surge reached New Orleans with almost no interference from its highly degraded surrounding wetlands, nearly 85% of people killed were aged 51 and older, and almost half were older than 75 years of age.[587]

Upstream river management aimed at flood protection, irrigation and hydroelectric power generation have resulted in drastic sediment imbalance and have accelerated coastal erosion by depriving coastal landscapes of sand or silt.[588] Globally, an estimated 25–30% of the total suspended sediment flux is potentially trapped in artificial impoundments of about 45,000 reservoirs.[589] This reduces marine sediment supply to deltas and estuaries.[590] If no mitigation measures are undertaken and sediment retention continues, approximately 28,000 km^2 of the deltaic area in 40 deltas could suffer from increased flooding and coastal erosion by 2050.[591] Uncoordinated upriver flood protection has proved to be counterproductive, as the flood risk is often simply transferred and amplified to downriver communities.[592] The river deltas are paying the ultimate price, as they have no way to escape the erosive effects of faster and more intense river flows.

What Are the Opportunities to Accelerate Change?

Map and account for benefits A comprehensive mapping of the areas of high diversity, productivity, carbon concentration, coastal protection from sea level rise and storms, fishery support (nursery habitat and other critical life stages) and tourism values is the essential foundation of planning and must be the first priority. Such mapping informs sustainable ocean economy planning, national greenhouse gas inventories (if conforming to IPCC 2013 protocol) and nationally determined contributions (NDCs). The carbon flux and sequestration capacity of reefs, mangroves, sea grasses and salt marshes should be systematically accounted for. To the degree that the capacity for such rapid, accurate and comprehensive ocean mapping efforts is not in place in every country, technical assistance may be required (see Sect. 6.3, point 2, 'Goal-oriented ocean planning').

Integrate restoration and protection into sustainable ocean economy plans With a comprehensive ocean resource mapping in hand, protection and restoration or regeneration need to be systematically merged into a sustainable ocean economy development planning process (see Sect. 6.3, point 2, 'Goal-oriented ocean planning'). The baseline ambition needs to be a global fully protected set-aside of 30% of the ocean for coastal protection, fishery recovery, biodiversity restoration, controlled recreation and

so on. With proper planning this can be fully complementary to the economies of fishing (stock restoration), tourism (diving, pristine areas), offshore wind (protected buffers around turbines), shipping (avoided risk of whale strikes, safe distance from turbines), mariculture (vibrant, nutrient-rich, healthy ecosystems) and the protection of coastal assets (storm-surge protection). Conservation and restoration or regeneration should be regarded as a fully legitimate sector of the sustainable ocean economy, with its own economic logic, financing sources (carbon, wetland and nutrient credit and offset markets; carbon finance; infrastructure funding), and fully accountable and measurable contribution to both 'flow' (i.e. gross value added) and 'stock' (i.e. natural capital) metrics.

Include quantified nature-based solutions in nationally determined contributions and other relevant climate policies for mitigation and adaptation Ocean-based mitigation options do not feature as prominently as they could in countries' NDCs or long-term low greenhouse gas emission development strategies under the Paris Agreement.[593] This is an extremely important moment, as emphasised by the IPCC (2018): the chances of 'failing to reach 1.5 °C [will be] significantly increased if near-term ambition is not strengthened beyond the level implied by current NDCs'. Given the consequences of failing to limit global average temperature rise to 1.5 °C, or at least to 'well below' 2.0 °C, capturing the potential offered by blue carbon in NDCs could forcefully accelerate restoration and protection of these ocean and coastal natural assets.

Connect ocean protection and restoration with land-based initiatives and stakeholders Coastal restoration and protection cannot succeed in isolation. Delta restoration requires river management that optimises sediment flows. Near-coast MPAs are highly sensitive to nutrient contamination. Symbiotic MPA, mariculture and energy projects require clean and abundant freshwater flows. For example, Florida's Apalachicola Bay once housed the highest concentration of oyster beds in the United States. As the abundant waters of the Apalachicola River were depleted by growing upriver cities, the beds atrophied, and today only small remnants of the oyster industry remain. Restoration of the bay would require close coordination with upriver water and reservoir managers to optimise freshwater flows. Most comprehensive, EEZ-wide ocean planning efforts thus need to closely coordinate with river authorities. For a summary of these points, see Box 20.16.

- Connect ocean protection and restoration with land-based initiatives and stakeholders.

Tourism: How Can Tourism Be Turned into a Zero- or Positive-Impact Industry?

Why Is It Important?

Tourism is estimated to contribute to about 10% of the world's economic activity and is a key source of foreign earnings for many developing countries.[594] The industry has been growing steadily over the last half century. Between 1965 and 2019, the number of international tourists alone has increased about 13-fold: from 113 million in 1965 to 674 million in 2000 to 1461 million in 2019, a trend that is expected to continue.[595] It is hard to determine how much of the global tourism is purely coastal, but there are good indications that a significant amount of it is. Over 46% of Europeans, the largest group of international travellers, cited 'beach access' as their holiday travel reason.[596] Estimates vary, but between 60 and 350 million people annually travel to the world's coral reef coasts.[597] In many coastal nations, coral reefs support over one-quarter of all tourism value and over 6%, and up to 40% (about 43% in Palau and in the Maldives) of the nation's GDP.[598] Cruise tourism, growing

strongly, is predicted to move 30 million people across the ocean (2019), up from 18 million a decade ago.[599]

The growth of the coastal tourism industry came at a price for coastal ecosystems. The negative impact of tourism on ecosystems is well documented and threatens the long-term socioeconomic value of the industry itself. Much like other natural resource-based industries, tourism can deplete the very resource it most depends on, in this case, a healthy and beautiful ocean environment. Unlike other industries, however, 'sustainable yield' is not clearly defined in tourism, and most of the industry operates outside internationally accepted certifications and transparent performance standards. The resulting damage has been exemplified by the closure of Maya Bay in Thailand, the degradation of near-shore reefs in Indonesia and the massive destruction of coastal wetlands by tourism development. The concentration of tourism further intensifies the impacts: destruction of natural habitats, excessive groundwater extraction leading to saltwater intrusion, introduction of exotic species and sewage pollution, to name just a few.[600]

The sector is also constrained by the deterioration of its target areas by outside forces. As early as the 1960s, human-driven eutrophication of the Black Sea led to a decline in tourism revenues of $500 million.[601] Today, cleaning beaches in the European Union alone costs over €413 million/year.[602] Having already put a very high strain on the environment, using the tourism industry as a force for sustainable growth rather than environmental destruction will be critically important.

The COVID-19 pandemic has had major effects on tourism: because of the lockdowns and travel ban implemented in most countries, tourism is expected to lose $2.1 trillion in GVA in 2020, with 100 million jobs at risk.[603] This sudden and massive hit on the tourism industry raises existential questions: Will this be an opportunity to reinvent tourism as an eco-friendly experience? Is this a hard stop from which the industry will not recover? Will the industry rebuild as it was before?

What Are the Opportunities to Accelerate Change?

Countries and tourism operators should consider a number of possible approaches when thinking about the future of coastal and ocean tourism:

Create national tourism strategies and implement governance systems that ensure the sustainable and equitable development of the tourism industry. These plans should include a clear spatial plan for the sustainable, climate-smart expansion of tourism resorts, and ensure capacity for waste and traffic infrastructure to cope with the increase in tourism. The plans could also include requirements for certified climate-friendly travel as conditions for accepting tourists to points of interest or even to the country.

Implement tourism taxes as payment for ecosystem services the industry relies on The revenue from these taxes should be used to restore degraded nature and maintain coastal and marine ecosystems. Additionally, it can provide a source of funding to build the necessary infrastructure and help the local tourism industry transition to a more sustainable operating model. A back-of-the-envelope analysis reveals the potentially enormous contribution of such a tourist ecosystem service tax: assuming that one-third of international tourism is coastal and an (only) 1% ecosystem tax is levied on international tourism expenditures (roughly $1500 billion[604]), $5 billion in funds would become available for coastal and marine ecosystems—four times the current marine philanthropic funding and official development assistance combined.[605]

Agree on and implement international environmental standards for coastal tourism New, more ambitious environmental standards could become the norm for the tourism industry after COVID-19. Much-needed standards regulating the coastal and cruise tourism industry with respect to its CO_2, air, over-tourism, waste and effluent pollution should thus be created and implemented internationally. Ideally, the tourism industry itself would advocate for and hold countries to adopt these standards as the tourism industry itself benefits from a healthy ocean. For a summary of these points, see Box 20.17.

Box 20.17 Key Triggers to Turn Tourism into a Zero- or Positive-Impact Industry

- Create national strategies for sustainable tourism growth.
- Implement tourism taxes as payment for ecosystem services.
- Agree on and implement international environmental standards for coastal tourism.

6.4 Launching the Voyage: Three Levels for Possible Immediate Action

The voyage needs to start not with a bang but with a thousand rising voices. A set of expert recommendations can provide very helpful guidance for decision-makers, but it will only make a difference if the solution works for its beneficiaries—economically, culturally and socially.

Launching the voyage is about creating self-evident movement, a sense of inevitability, by building on the work already underway—the networks of innovators (in both industrialised and developing countries) who are the living embodiments of the overall change that is needed. It is far more about anchoring the transition to tomorrow in the reality of today than it is about theoretical best practices.

There is no shortage of such innovators—in policy, technology, resource management, inclusion, governance and so on. These business ventures, technology trials, corporate coalitions, investment partnerships, civil society programs and policy innovations are at the heart of a great experiment the world needs in testing, failing and learning.

Standing on the shoulders of these pioneers, this final section of the report suggests three ideas for a quick start towards change. These ideas do not pretend to be silver bullets, or to be exhaustive and to replace existing initiatives led by governments, businesses and civil society. These ideas are suggestions for interventions that are expected to create a snowball effect and accelerate change towards a sustainable ocean economy, in complement to the broader, more comprehensive action agenda presented in Sect. 6.3.

These suggested ideas to launch the voyage are especially critical in the context of the post-COVID recovery. They constitute concrete propositions to rebuild the economy bluer, more sustainable and more resilient, at a time when many hold onto business as usual for their own survival and advocate for postponing ambitious sustainability reforms.

At the local level, this report introduces the concept of sustainable ocean economic zones (SOEZs), which could become laboratories and demonstrators of the broader ocean action agenda, in complement with broader science-based planning for the entire EEZ, and ultimately for the high seas. At the national level, inspired by a successful international track record, the report considers the establishment of national ocean delivery task forces. Finally, at the international level, several no-regret moves and potential collaboration areas are encouraged.

6.4.1 Local Intervention: Catalysing Change Through Sustainable Ocean Economic Zones

On land, special economic zones are a long-established and well-proven component of industrial strategy. Typically, these zones provide a shell within which select ventures can thrive, offering low rents, low taxes, low utility and infrastructure costs, relief from heavy bureaucratic procedures, and low-cost debt from central government funds, providing guarantees to market-rate investors. These zones have been used to attract new businesses to revitalising urban areas, support emerging and high-risk industries, promote cooperative business models, stimulate exports and so on. They scale from small neighbourhood zones to entire cities (e.g. Dubai, Shenzhen and Hong Kong).

If done correctly, with all planning, legislation, approval, construction, investment and operation carefully designed to be fit for the intended purpose, and by respecting labour rights and social sustainability, they can be quite successful. There are 5400 zones in over 147 nations today, directly employing between 90 and 100 million workers.[606]

With very few exceptions, they have not been used to promote a sustainable ocean economy. There have been hurdles: the concept of spatial planning and restricted access in the ocean commons is often controversial, the siting of permanent ocean structures is politically difficult and any alternative to the current 'free for all' has not been mainstreamed yet.

Replicating the success of the (sustainable) economic zone concept in nations' EEZs might prove to be a powerful catalyst in accelerating a local sustainable ocean economy. Sustainable ocean economic zones could provide a testbed for systemic experimentation and innovation, a way for nations to support and evaluate the sustainable ocean economy model at a scale they are comfortable with. For different nations, such zones can look very different in almost every respect (Fig. 20.42). Some industrial nations, for example, can use them to attract and test high-technology models that combine energy generation, shipping and large-scale mariculture. A low-lying coastal nation may use them to combine carbon-financed restoration, coastal protection, tourism and fishery enhancement. Another country may concentrate on

[606] UNCTAD. 2019. *World Investment Report 2019: Special Economic Zones*. UN Conference on Trade and Development World Investment Report (WIR). New York: United Nations. doi: https://doi.org/10.18356/8a8d05f9-en.

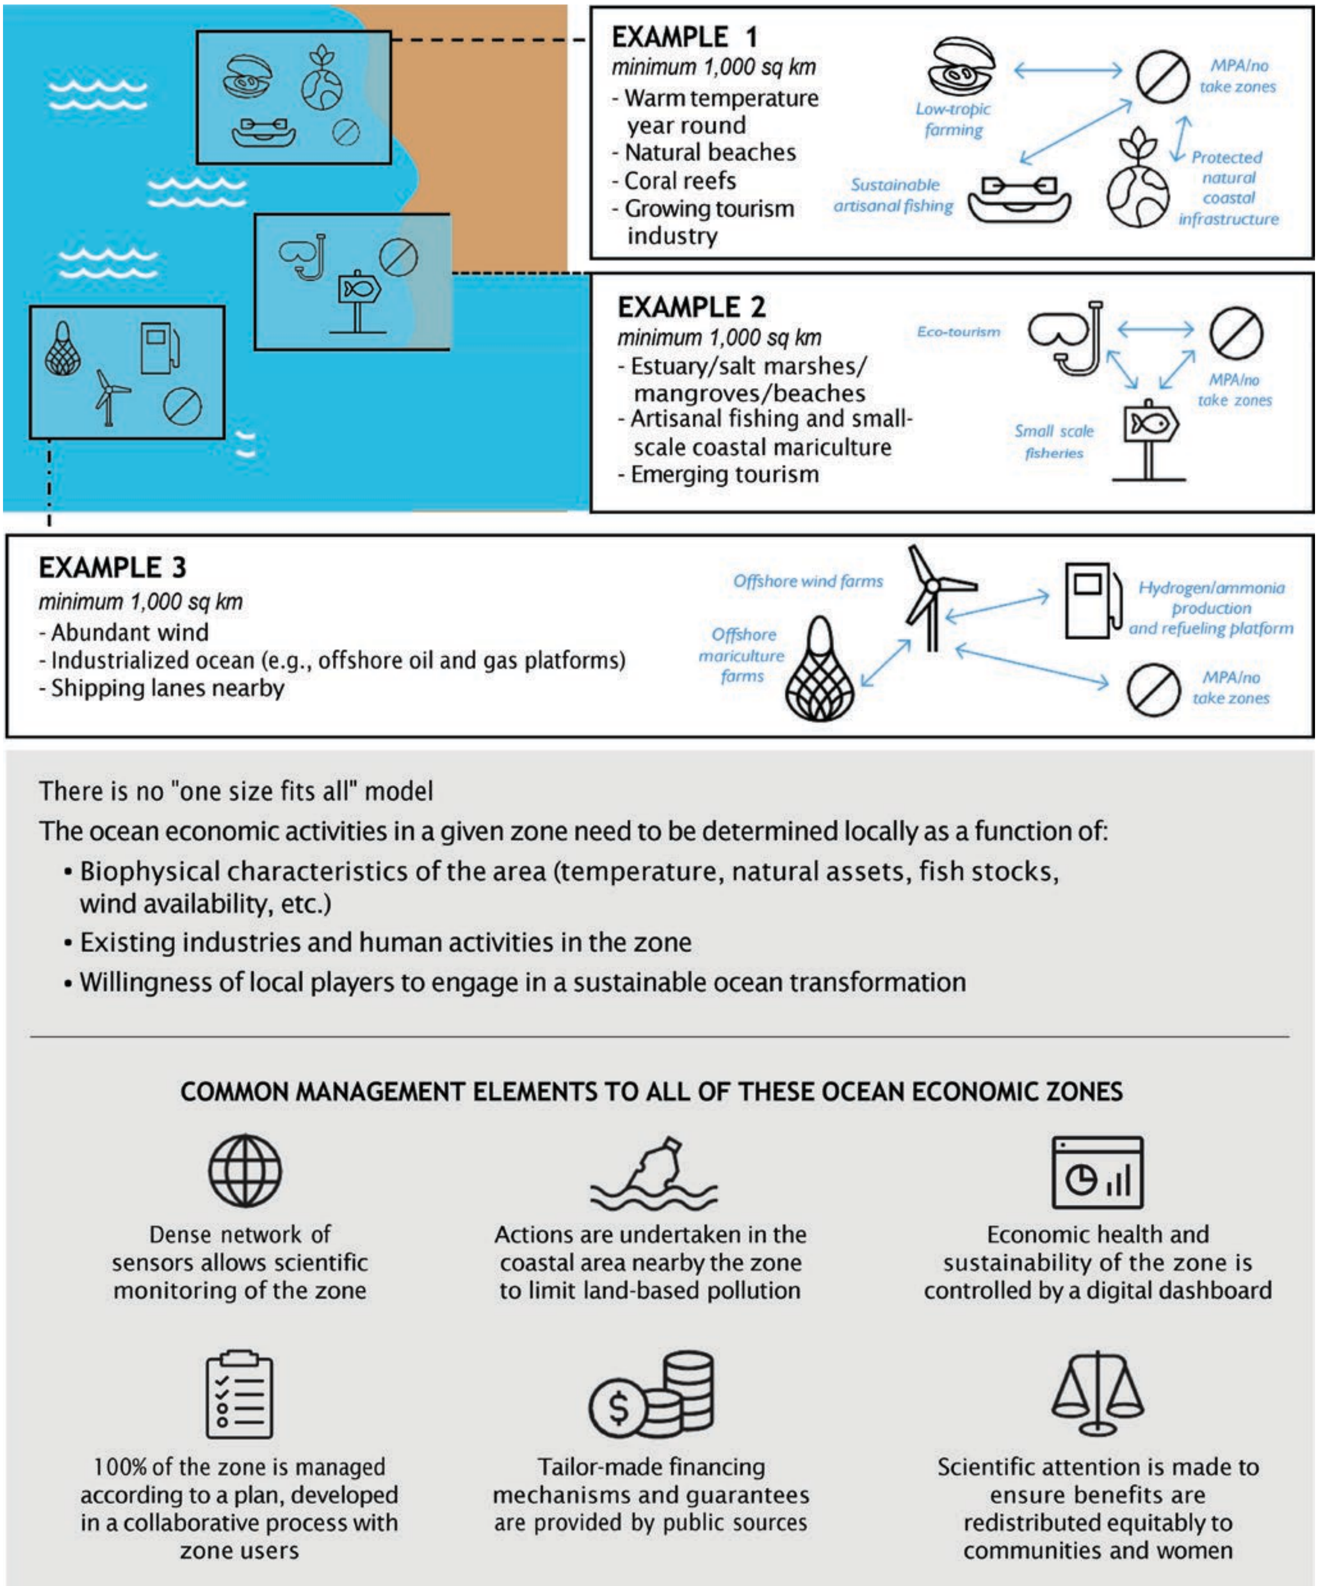

Fig. 20.42 Illustrative examples of sustainable ocean economic zones. (*Source: Authors*)

the symbiotic mariculture of many types of seafood in one place, combined with ecotourism.

A country's path to the design of a sustainable ocean will likely involve a series of steps:

- **Use case and delineation.** Using a working group of existing ocean users, technologists, financiers and public sector heads, an initial ocean industrial strategy could be developed that helps to identify which special zone models a nation wants to test in its EEZ (Fig. 20.42). This would determine the required utility of each zone (its 'use case') in terms of the types of ventures targeted, their siting and infrastructural requirements, their inherent potential symbiosis or conflict with other sectors and so on. For example, a special use zone focused on the symbiotic production of multiple trophic levels of food would have very different siting needs from an area focused on renewable ocean energy production. Each ocean SOEZ would then be delineated more precisely as a function of the specific use case, based on the biophysical characteristics of the area (temperature, natural assets, fish stocks, wind availability, etc.), existing industries and human activities, and the willingness of local players to engage.
- **Legislative certainty.** Once the use case is established, governments would need to approve the zone's placement and guarantee the zone's long-term authority to provide use rights to its tenants. This will be critical since it creates a lasting, easily navigable legislative framework within the SOEZ that gives certainty to investors.
- **Commitments and privileges.** The terms of the SOEZ contract—the commitments and privileges—need to be made very clear. At a minimum, participants should commit to the following:
  - A net-regenerative balance of production and protection—such as more carbon saved and sequestered than released, net habitat restored and so on.
  - Inclusion of multiple linked sectors—such as energy and food, multi-trophic food, restoration, tourism and so on.
  - Compliance with safe operating principles—such as mariculture standards for feed, containment, disease control, fouling and so on.
  - Equitable practices—such as preference for local market distribution, adherence to labour standards and respect of human rights, and support for women and marginalised groups.

A set of 'privileges'—specific support packages provided by the government—needs to be tailored to the purposes and uses of each zone. In general, these will require measures to increase margins (low-cost onshore infrastructure access, price guarantees), reduce risk (offtake guarantees, streamlined permitting, insurance vehicles), reduce capital costs (below-market debt, tax breaks) and bring in market-rate debt.

In practice, the efficient provision of below-market debt may require the pooling of resources. For example, several sovereign wealth funds may pool resources to create an ocean economy debt fund providing subsidised debt to the SOEZs of participating countries. Ideally, this would be used to guarantee a matched fund provided by a coalition of development finance institutions. This concentrated and coordinated approach would have the dual benefits of (1) systematically de-risking the investment in emerging industries and (2) creating a pool of domain knowledge and capacity ahead of the market. Both benefits are essential to attracting investments from the institutional finance community, which, today, remains largely unfamiliar with the ocean economy realm and is structurally risk-averse.

To qualify for access to this fund, SOEZs would have to fulfil basic economic and ecological requirements—an additional measure of quality assurance. For example, they could require that an SOEZ have signed up a minimum critical number of anchor tenants, that coastal infrastructure be available and accessible, and that sponsoring nations provide sufficient cost and demand supports. It is essential that the link between the 'commitments' and the 'privileges' be explicit—these zones cannot become oases for cheap profits and minimum performance.

- **Adaptation and learning**. What matters most is that SOEZs be deliberate—they are meant to provide a contained laboratory and demonstration arena, where incentives can be concentrated and tested, results collated and adapted to, and risks managed. In the process of designing, launching and implementing the zones, the classic hurdles to ocean management—free access, lacking planning, use conflicts and free externalities—should be addressed in the context of real business, rather than abstract policy. Finally, SOEZs would be knowledge-intensive. When things go wrong, experiments fail and conflicts arise, the lessons learned would be reflected in the SOEZs' design and operations. On land, special economic zones have clearly evolved from an emphasis on manufacturing, trade and exports to a focus on knowledge, such as new technology frontiers and research and development (R&D).
- **Scaling the model**. Experience on land has shown that special economic zones today are instruments for the support of emerging technologies and business concepts and are not infinitely replicable. The goal is to accelerate commercialisation to the point where market-rate institutional capital moves in. In the case of SOEZs, there is an additional goal: to demonstrate the business case for a more systemically managed and accessed ocean, and to create a new, self-interested set of communities ready to defend their health on economic grounds.

SOEZs are a possible catalytic experiment for a sustainable ocean economy. They are bespoke, limited in scope and risk, and high in knowledge development. They can catalyse a new epoch but need to be supplemented by the array of more systemic policies and business priorities described in this report's action agenda (Sect. 6.3) and by additional catalytic interventions at national and international levels (see below). In the medium term, lessons learned from the SOEZs established by pioneering countries or regions should be codified in global standards, protocols, evaluation frameworks and the like to allow more countries to launch their own SOEZ without having to test and learn all dimensions of the concept.

6.4.2 National Intervention: Getting Things Done with National Ocean Task Forces

In recent years, the art and science of complex change management has been greatly refined and codified. Long familiar to the private sector, the principles of performance management have been applied to the public realm, with great success in increasing the performance of such complex networks as schools, health care, security and transportation systems, with measurable and transformative impact on metrics such as test scores, crime rates, health outcomes and the like. Typically, these approaches work even in the challenging context of multiple agencies and jurisdictions, conflicting objectives, complex logistics and significant uncertainty—as long as the approach is an extension of senior leadership. In general, these types of approaches involve small, non-hierarchical and highly competent teams, led by very senior and respected managers, with full access to all relevant information and working under a powerful and time-constrained mandates and targets.

Additionally, these task forces should appropriately represent all kinds of diversity and communities in their members, or at least represent them through thorough consultations.

Originally conceived in 2001 by Tony Blair as a 'Prime Minister Delivery Unit', this approach is now widely used. In the past 2 years alone, more than a dozen other governments—including those of Costa Rica, Ghana, Kenya, New South Wales (Australia), Pakistan, Peru, Saudi Arabia and Serbia—have created such units (see Fig. 20.43). Results can be quite encouraging (with necessary caution with respect to how metrics are calculated). In Britain, the number of people waiting more than a year for surgical procedures fell from over 40,000 to below 10,000; in Malaysia, reported street crime fell by 35% between 2009 and 2010; in Pakistan's Punjab province, the vaccinator attendance rate rose from 22% to over 90% between 2014 and 2015; in the U.S. state of Maryland, infant mortality dropped from 8 per 1000 live births in 2008 to 6.5 per 1000 live births in 2014.[607]

In the context of the shift to a sustainable ocean economy, this delivery unit approach can be very powerful if done right.

In the Dutch North Sea EEZ, for example, the need for explicit spatial planning became abundantly clear in 2015. Sand mining, oil drilling, dredging, cabling, shipping, military manoeuvring, land reclamation, fishing, aquaculture, wind energy and recreation had been accommodated in an integrated management plan since 2005—but the plan lacked explicit spatial guidance. A newly announced subsidy for wind farms led to 75 proposed projects and an unmanageable tangle of overlaps and potential use conflicts—with no relevant rules in place. For example, what would be a safe distance between a wind farm and a shipping lane where 400-m tankers would pass by? The ministers mandated a full, spatially explicit plan which combined zoning for MPAs in six main sectors of national importance: shipping routes, oil and gas installations, carbon capture and storage, renewable energy, defence and sand mining. Also, explicit rules were made to resolve potential conflicts between these priority functions.[608] The process—clearly mandated at the ministerial level, extensively consultative, highly expert, science-driven, target- and performance-oriented, and time-constrained—was a classic delivery unit approach. The approach could be similarly used to design ocean sustainable economic zones, develop multi-sector ocean development concepts, plan restoration projects or MPA networks and the like, within the 100% managed EEZs.

A first implementation step for the shift to a sustainable ocean economy could thus be the appointment of an SDG 14 (sustainable ocean) task force—appointed at the (ocean) ministerial or head of state level, and with an incontrovertible mandate to translate the sustainable ocean agenda into the appropriate national context by undertaking the following actions:

- Conduct a comprehensive marine resource mapping effort covering the entire national EEZ.
- Support and facilitate a participatory, inclusive process to develop an ocean plan which provides explicit guidance to assure the avoidance of spatial use conflicts, uniformly high standards of operation, a streamlined and efficient regulatory process, the integration of symbiotic ocean uses and the overall protection and sustainability of the key oceanic systems (in a minimum of 30% of the ocean as protected areas).
- Advise the relevant ministries and head of state on the specific steps required to further accelerate a regenerative ocean economy, including the design of special sustainable ocean economy zones, financial guarantees and risk

reduction measures, policy and regulatory implications, and international coordination issues.
- Lead special technological and bureaucratic initiatives—in coordination with relevant existing organisations, academia and civil society—such as the design of MPA networks, the detailed design of special sustainable economic zones and the recommended approach to controlling land-based pollutants.

In keeping with the basic delivery unit principles, this task force will have to be carefully set up and mandated. The following basic requirements would need to be met:

- The mandate would be issued formally and publicly at the ministerial and/or head of state level and clarify all mandate overlap issues with the appropriate federal and state agencies.
- The task force would be granted full access to all government-owned data sets (excepting only those of considerable national security significance).
- A firm timeline of deliverables would be provided.
- The task force would be provided with a core team of highly competent technical experts, full agency technical support and sufficient funding.
- The heads of all relevant agencies would be formal members of the task force governance and personally accountable for its success.
- The task force would have the full authority to conduct outreach and consultation in the name of the mandating minister or head of state.

Some countries will be better resourced and prepared to embark on this approach than others. Steps should be taken to develop a technical support platform which can provide targeted assistance to requesting nations, such as advanced capabilities in geographic information systems and mapping; resource mapping and sensing; protected area network delineation and design; operational standard setting for key industries; sector-specific knowledge (wind energy, mariculture, shipping safety); project finance and so on.

Some other countries might find that this approach is not suited to their culture and usual way of working and will have to consider a different, tailor-made approach.

This task force approach can be very efficient when short-term results and impacts are expected, such as in post-COVID recovery, where immediate solutions are expected to re-boost the economy and create jobs while avoiding the replication of environmentally detrimental practices from before COVID-19. For instance, national 'blue task forces' could be set up to support some immediate 'blue' recovery priorities, as identified in the latest special report commissioned by the Ocean Panel:[609]

- Coastal and marine ecosystem restoration and protection
- Sewage and waste infrastructure
- Sustainable non-fed mariculture
- Zero-emission marine transport
- Sustainable ocean-based renewable energy

These priorities are fully in line with the action agenda presented in Sect. 6.3 and could constitute a good starting point to embrace a more holistic transformation journey towards a sustainable ocean economy at scale.

6.4.3 International Intervention: Raising the Bar

Local and national interventions can generate significant catalytic effects but should not underestimate the importance of international collaboration. Indeed, several international agreements, treaties and conventions have already identified the challenges and solutions required but are still insufficiently ratified and poorly enforced. In addition, a growing number of global initiatives underway related to the sustainable ocean economy would benefit from additional recognition and support.

The following **international treaties, agreements and conventions** can greatly help accelerate a sustainable ocean economy:

- **The Paris Agreement.** 'The' landmark climate agreement aims to reduce global emissions to keep the planet's warming to 'well below' 2 °C and to pursue a 1.5-degree Celsius future warming scenario.[610] Of 197 parties, 189 have ratified the agreement, covering 97% of the world's emissions.[611] Instead of settling on a minimum common denominator, individual country commitments to the climate agreement are made through nationally determined contributions, allowing each country to commit as much as it is able—or willing—to contribute. As of 2020, only a handful of countries are on track to meet their climate

[609] Northrop et al. 2020. "A Sustainable and Equitable Blue Recovery to the COVID-19 Crisis."

[610] UN Framework Convention on Climate Change. n.d. "The Paris Agreement." https://unfccc.int/process-and-meetings/the-paris-agreement/the-paris-agreement. Accessed 12 May 2020.

[611] UN Framework Convention on Climate Change. n.d. "Paris Agreement: Status of Ratification." https://unfccc.int/process/the-paris-agreement/status-of-ratification. Accessed 12 May 2020.

goals.[612] It is critical that all countries ratify commitments made under the agreement to maintain the ocean, while expanding their NDCs to include the wealth of ocean climate-mitigation opportunities.

- **The Agreement on Port State Measures** is the first binding international agreement to specifically target IUU fishing. Its innovative approach is to prevent vessels engaged in IUU fishing from using ports and landing their catches, an approach assumed to be more cost-efficient than tracking and pursuing these vessels at sea. As of 2019, 105 countries are committed to the implementation of the agreement, but many of them are still struggling with the financing and capacity needed to fully enforce it.[613]
- **The Hong Kong Convention** is aimed at 'ensuring that ships, when being recycled after reaching the end of their operational lives, do not pose any unnecessary risks to human health, safety and the environment'.[614] To achieve this goal the convention also covers the design, construction, operation and maintenance of ships and can encourage circular design.[615] Although it was adopted in 2009, the convention cannot enter into force until it is ratified by '15 States, representing 40% of the world's merchant fleet and their ship recycling volume constituting not less than 3% of the gross tonnage of these contracting States' merchant fleet'.[616] Yet, as of 2019, it had been ratified or acceded to by only 12 states: Belgium, Denmark, Estonia, France, India, Japan, the Netherlands, Norway, Panama, the Republic of the Congo, Serbia and Turkey.[617]
- **The Intergovernmental Conference on Marine Biodiversity of Areas beyond National Jurisdiction (BBNJ).** This process, being negotiated under UNCLOS, represents 'an opportunity to provide a new governance model with legal clarity'[618] for the global commons in areas beyond national jurisdiction, including (1) a path to designate, implement and manage area-based management tools, including marine protected areas; (2) a trigger and a process for carrying out environmental impact assessments; (3) ensured fairness and equity of access to and benefit-sharing arising from the use of marine genetic resources; and (4) a means to foster developing capacity and transfer of technology to countries in need.[619] As soon as an agreement on marine biodiversity of areas beyond national jurisdiction is adopted, ocean-minded countries should ratify, implement and operationalise it.
- **The Convention on Biological Diversity**. Entered into force in 1993, the Convention on Biological Diversity (CBD) aims to conserve biological diversity, promote the sustainable use of the components of biological diversity and ensure the fair and equitable sharing of the benefits arising from the use of genetic resources.[620] Under the CBD, Parties are negotiating the post-2020 global biodiversity framework, to be adopted at the 15th meeting of the Conference of the Parties (COP 15) in China in 2021. This framework will contain a new set of global goals and targets for biodiversity, and it is crucial that ambitious targets be agreed on to support a healthy ocean and a sustainable ocean economy.

In addition, the IMO, regional fisheries management organisations, regional seas conventions and others provide tools that can be used much more actively. It would also be possible to establish regional ocean management organisations that manage the ocean cross-sectorally, to seek international support for a Paris-like agreement for the ocean and to set up a task force on ocean-related financial disclosures. Another possible tool is a global ocean accountability board, composed of leaders from a number of sectors, which sits outside the international forums and seeks to (1) avoid catastrophic ocean collapse and (2) hold the world to account for its ocean action.[621] This panel would be modelled on the G20 Financial Stability Board.

In addition, the idea of creating a supranational ocean agency of some kind could be explored. Learning the lessons

from UNESCO's 'Man and the Biosphere' programme,[622] this institution could be mandated to provide a flexible set of frameworks and protocols to empower local actors to collaborate, with the goal of protecting and regenerating ocean commons at regional levels.[623] This ocean agency could be created by UN resolution, or it could be created by a founding group of nations who invite others to participate. Its establishment should ensure legitimacy and safeguards against capture by special interests.[624]

A key to sustainable development and to developing a sustainable ocean economy is a cross-sectoral approach. Given the complexities of international law, access to ocean resources and various constraints, it is likely that polycentric systems of governance will prevail.[625] A thorough expert review of the existing governance mechanisms and how they should be changed to support the development of a sustainable ocean economy is beyond the scope of this report. However, such a review should be performed as a matter of urgency.

Beyond the purely political efforts mentioned above, a growing number of initiatives are gathering a variety of actors willing to accelerate a sustainable ocean economy. Supporting such initiatives is a concrete immediate next step to advance a shared vision, identify solutions to remove roadblocks and initiate public-private partnerships. None of the identified ocean challenges and opportunities can be solved or captured by one entity alone—bringing together the private sector, public entities and civil society along the journey and identifying stakeholders on the ground that are willing to support efforts to address system change is key. Building coalitions around certain ocean themes can help align stakeholders into a unified voice, build on synergies and help identify and develop high-impact, investable opportunities.

7 Conclusion

This report has argued that the agendas of effective ocean protection, sustainable ocean production and equitable human prosperity are inseparable and compatible. It has framed the economic, social and ecological upside of getting the ocean economy right—and the deeply concerning and potentially sweeping consequences of getting it wrong.

Getting it right means a fundamental shift away from the 'free for all' model, which assumes an ocean of unlimited potential to regenerate, dilute and absorb. This model is maintained by current practices, laws and cultural norms, but it is not inviolate. Spearheaded by a new cohort of ocean interests deeply vested in ocean health—including sustainable fishers and mariculturists, coastal communities, renewable energy generators, tourism operators, scientists, environmentalists and social and civil society organisations—pollution and over-exploitation can be powerfully counteracted. It will require thoughtful policy support, including transparent and comprehensive national ocean planning, mandatory standards for open data access, investment of (sovereign wealth, development and private) capital, new legal protections from polluters and a national accounting approach focused on the ocean's natural capital and production in equal measure.

The report argues further that the ocean's essential contribution to sustainable planetary food and energy production can be achieved without abandoning a precautionary, insurance-based approach. The consequences of systemic failure in the ocean are grave, and there is no logic in 'harming the ocean to save the planet'. The approach calls for the inclusion of at least 30% fully protected areas at a global scale, the avoidance of new extractive activities whose impact is not fully understood and the widespread adoption of rigorous operation standards for all ocean uses.

Learning from the successes and stalling points of other industrial and societal transformations, this report has developed a comprehensive 10-point action agenda for a sustainable ocean economy. Further, it proposes three concrete options to commence and accelerate change: sustainable ocean economic zones, centre-of-government delivery units and interventions at an international level.

The journey towards a sustainable future has already begun, with pioneers leading the way. New sustainable technologies are attracting investors, and businesses and governments are waking up to the opportunities of a sustainable ocean economy—as well as to the risks and cost of inaction. It is an enormously inspiring journey. Antoine de Saint-Exupéry describes the awe and wonder that the ocean evokes, and the power of humanity's determination to connect with it: 'If you want to build a ship, don't drum up people to collect wood and don't assign them tasks and work, but rather teach them to long for the endless immensity of the sea'.[626]

[626] Saint-Exupéry, A. 1948. Citadelle. Original text in French: 'Créer le navire ce n'est point tisser les toiles, forger les clous, lire les astres, mais bien donner le goût de la mer qui est un, et à la lumière duquel il n'est plus rien qui soit contradictoire mais communauté dans l'amour.'

The COVID-19 pandemic has severely hit most ocean-based sectors, with significant social and economic impacts. Without deprioritising the need for immediate responses and quick recovery, this shock could also be seen as an opportunity to accelerate the transition towards a sustainable ocean economy. As Arundhati Roy observes, 'Historically, pandemics have forced humans to break with the past and imagine their world anew. This one is no different. It is a portal, a gateway between one world and the next. We can choose to walk through it, dragging the carcasses of our prejudice and hatred, our avarice, our data banks and dead ideas, our dead rivers and smoky skies behind us. Or we can walk through lightly, with little luggage, ready to imagine another world. And ready to fight for it'.[627]

Acknowledgements The authors would like to thank the individuals listed below for their contributions towards the creation and publishing of this report.

Contributing to the report creation: Barbara Karni and Katie Flanagan for leading the development of the summary; as well as Henry Wang and Katherine Woods for their contributions to the overall report.

Offering review, feedback, and inputs to the report: Meg Caldwell, Jason Clay, Anthony Cox, Exequiel Ezcurra, Steve Gaines, Craig Hanson, Janis Jones, Ghislaine Llewellyn, Justin Mundy, Karine Nyborg, Nicolas Pascal, Ina Porres,

21 Transformations for a Sustainable Ocean Economy: A Vision for Protection, Production and Prosperity

High Level Panel for a Sustainable Ocean Economy

1 Our Call to Action

We have a collective opportunity and responsibility to protect and restore the health of our ocean, and build a sustainable ocean economy that can provide food, empower coastal communities, power our cities, transport our people and goods and provide innovative solutions to global challenges.

In accepting this responsibility and seizing this opportunity, we can give a blue boost to the economy today while mitigating and building resilience for future crises.

The framework and five areas of transformation presented here secure ocean health and wealth for generations to come. We urge other governments, industries and stakeholders to join us in this endeavour.

We, the 14 members of the High Level Panel for a Sustainable Ocean Economy (the Ocean Panel), are heads of state and government representing people from across all ocean basins, nearly 40% of the world's coastlines and 30% of exclusive economic zones. We recognise that the ocean is the life source of our planet and is vital for human well-being and a thriving global economy.

The ocean is home to many complex ecosystems facing significant threats. The actions we take now can safeguard the ocean's capacity to regenerate, in order to deliver substantial economic, environmental and social value and offer powerful solutions to global challenges. Rapid action must be taken today to address climate change, acidification, ocean warming, marine pollution, overfishing, and loss of habitat and biodiversity. Failure to act will jeopardise global health, well-being, and economic vitality and exacerbate inequalities.

The COVID-19 pandemic has highlighted the deep interconnections between human and planetary health and the need for nations to work together to respond to global threats. The pandemic has caused a dramatic disruption of the global economy, major impacts to our societies and a huge toll on our communities. It has put increased financial pressure on developing countries and in particular Least Developed Countries and Small Island Developing States.

We have an opportunity and obligation to reset and build a more equitable, resilient, knowledge-based and prosperous future that is in harmony with nature. The ocean and its related economy offer a wealth of opportunities to support this transition.

Building a sustainable ocean economy is one of the most important tasks and greatest opportunities of our time. It is critical to achieving the goals of the 2030 Agenda for Sustainable Development, and it is vital if we are to emerge from current and future crises with stronger economies, healthier people and more resilient communities.

We commit to bold transformations towards a sustainable ocean economy where environmental protection and conservation, and economic production and prosperity, go hand in hand. These transformations must unleash the full force of innovation across sectors in technology, finance and governance, and do so at pace and scale, guided by the following principles:

- **Alignment:** Ocean protection and production must align with the UN Framework Convention on Climate Change and the Paris Agreement, the Convention on Biological Diversity, and the Polluter Pays Principle as set out in the Rio Declaration. Actions must be aligned across ocean-based and land-based activities and ecosystems.
- **Inclusiveness:** Human rights, gender equality, community and Indigenous Peoples' participation, through their free, prior and informed consent, must be respected and protected.
- **Knowledge:** Ocean management must be informed by the best available science and knowledge, including

indigenous and local knowledge, and aided by innovation and technology.
- **Legality:** The UN Convention on the Law of the Sea is the legal basis for all ocean activities, and existing international ocean commitments must be implemented as a foundation for achieving a sustainable ocean economy.
- **Precaution:** Where there are threats of serious or irreversible damage, lack of full scientific certainty shall not be used as a reason for postponing cost-effective measures to prevent environmental degradation.
- **Protection:** A healthy ocean underpins a sustainable ocean economy. A net gain approach must be applied to ocean uses in order to help sustain or restore the health of the ocean.
- **Resilience:** The resilience of the ocean and ocean economy must be enhanced.
- **Solidarity:** The need for access to finance, technology and capacity building for developing countries, especially Small Island Developing States and Least Developed Countries, must be recognised, taking into account their particular circumstances and vulnerabilities.
- **Sustainability:** The production and harvesting of ocean resources must be sustainable and support resilient ecosystems and future productivity.

We will leverage the UN Decade of Ocean Science for Sustainable Development and the body of knowledge commissioned by the Ocean Panel to build collective understanding and knowledge of ocean sustainability, ecosystem services and functions, and ensure that science underpins decision-making for building a sustainable ocean economy.

2 A 100% Approach

The ocean is a complex natural system that is inextricably linked to land-based activities and ecosystems. We must approach ocean management holistically in order to achieve the vision of protection, production and prosperity. We need a comprehensive approach to sustainably manage 100% of the ocean, starting with coastal and ocean states and working together regionally and globally to safeguard areas beyond national jurisdiction.

We Commit
To sustainably manage 100% of the ocean area under national jurisdiction, guided by Sustainable Ocean Plans, by 2025.

We Urge
All coastal and ocean states to join us in this commitment so that by 2030 all ocean areas under national jurisdiction are sustainably managed.

Sustainable Ocean Plans are providing a credible basis for safeguarding the long-term health and resilience of the ocean, attracting investment and creating jobs to the benefit of coastal communities and national economies.

A **Sustainable Ocean Plan** describes policies and mechanisms to facilitate sustainable use of the ocean and maximise benefits and value creation for current and future generations. It provides a framework to reconcile conflicting uses of the ocean and its resources and enable long-term sustainable growth in the ocean economy. It can include a range of mechanisms such as regulatory reform, strategic investments in emerging sectors, marine spatial planning, integrated coastal and watershed management, and the establishment and implementation of marine protected areas and other effective area-based conservation measures that can help deliver nature's contributions to people, economic and positive biodiversity conservation outcomes, climate change mitigation and adaptation, and sustainable fish stocks.

The Sustainable Ocean Plans should be in line with the 2030 Agenda for Sustainable Development, build on integrated ocean management and ecosystem knowledge, address pressures from all land- and sea-based sources, and take account of the predicted impacts of climate change. As the foundation for a sustainable ocean economy, these plans should be developed and implemented through an inclusive, participatory, transparent and accountable process.

We support a global target to protect 30% of the ocean by 2030. As a global target, it would not be binding on states individually. National decisions on marine spatial plans, marine protected areas and other effective area-based conservation measures will depend on the state and function of the ecosystem and the extent and quality of ocean management as well as the importance of addressing human well-being, sustainable ocean food and climate change. To achieve the global target, we also call for international cooperation, including supporting capacity building in this area. Detailed content of Sustainable Ocean Plans will vary according to national circumstances.

We will work with others to mobilise and facilitate support for coastal and ocean states in developing Sustainable Ocean Plans by 2030.

2.1 Getting to 100%

Our vision for protection, production and prosperity requires mutually reinforcing transformations in five critical areas: ocean wealth, ocean health, ocean equity, ocean knowledge and ocean finance. Action in all areas is required to achieve a sustainable ocean economy and build critical foundations for economic recovery and resilience.

The Ocean Panel presents a framework with outcomes for these five areas and a range of actions to achieve them. We commit to deliver these fully by 2030 or sooner. The framework is consistent with the existing target deadlines set in the Sustainable Development Goals, and particular effort is needed for the unfulfilled targets with a 2020 timeline. We will act with determination in accordance with national capacities and circumstances, and invite other leaders, industry and civil society to join us.

3 Ocean Wealth

In recent years, the ocean has produced US $2.5 trillion in goods and services each year, and the asset value of the ocean has been estimated at US $24 trillion. Many ocean-based industries have the potential to outperform the growth of the global economy, both in terms of additional value and employment. Unsustainable human activity—in the ocean and on land—is threatening the ocean's ability to regenerate and sustainably provide for people around the world. We must transform our relationship with the ocean to ensure that it can continue to produce sustainably for future generations.

3.1 Sustainable Ocean Food

Ocean food plays a critical role in feeding global populations. It supplies an essential and accessible source of animal protein and micronutrients, which are particularly important in low-income, food-deficit countries and Small Island Developing States and during times of economic or environmental crisis. The ocean can provide more abundant and diverse food than it currently does, thereby playing a bigger role in the global food system. To build resilience, ocean food production must meet national and local needs and be adapted to a changing climate. Doing so can enhance food security, improve nutrition, human health and well-being, create sustainable economic growth and jobs and prevent the widening of current inequities. This transition must include increased transparency in global ocean governance and supply chains and the elimination of inefficiencies and perverse incentives that undermine the sustainability of the food we derive from the ocean. We must seize opportunities to sustainably increase fisheries productivity and aquaculture production, including by strengthening opportunities for coastal communities, Indigenous Peoples, artisanal and small-scale fishers.

Wild fish stocks are restored and harvested at sustainable levels, aquaculture is sustainably grown to meet global needs, and waste is minimised and managed throughout the value chain.

Priority Actions

- Eliminate illegal, unreported and unregulated fishing by incentivising the use of the latest innovations and technologies—such as digital traceability—to increase transparency; strengthening monitoring, control and surveillance; improving flag state control; effectively implementing the Port State Measures Agreement; and enabling enhanced collaboration amongst all stakeholders in the supply chain.
- Prohibit harmful fisheries subsidies that contribute to overcapacity, overfishing, and illegal, unreported and unregulated fishing.
- Minimise bycatch, discards and waste in seafood supply chains.
- Develop, adopt and effectively implement science-based plans to rebuild depleted stocks, and ensure adaptive fisheries management to respond to climate change and the uncertainties of shifting ocean ecosystems, based on the UN Fish Stocks Agreement, in cooperation with multilateral bodies such as the Food and Agriculture Organisation and regional fisheries management organisations, and implement FAO's Voluntary Guidelines to Ensure Sustainable Small-Scale Fisheries.
- Strengthen regional fisheries management organisations, including by promoting the use of a precautionary approach, management that controls harvest levels based on scientific assessment, such as total allowable catch, meaningful consequences for exceeding quotas, and through regular and transparent performance reviews.
- Explore in a precautionary manner the potential to sustainably harvest new species from the ocean, without undermining ecosystem health.
- Put in place policies and management frameworks to minimise the environmental impacts of aquaculture, including inefficiencies in the feed supply chain, and enable the acceleration of fed and non-fed aquaculture production that fits local environmental, governance and economic priorities.

3.2 Sustainable Ocean Energy

The ocean holds tremendous potential to provide clean energy for the world. Scaling up ocean-based renewable energy will generate jobs and boost economic development while providing a pathway to decarbonisation. An ocean-based renewable energy revolution is in the making, and recovery efforts provide an opportunity to increase investment over the coming years. The pace and scope of development must match the state of the science, enable technology transfer and adoption, and minimise the impact on marine ecosystems to enable the delivery of sustainable ocean-based energy.

Ocean-based renewable energy is fast-growing and on the path to becoming a leading source of energy for the world.

Priority Actions

- Invest in research, technology development and demonstration projects to help make all forms of ocean-based renewable energy—including wind, wave, tidal, current, thermal and solar—cost-competitive, accessible to all and environmentally sustainable.
- Work collaboratively with industry and other stakeholders to develop clear frameworks addressing environmental impacts of ocean-based renewable energy, enabling capacity, co-existence and integration with other uses of the ocean.
- Set clear goals, commit to deliver appropriate policy and regulatory measures, and remove market impediments in order to accelerate sustainable ocean-based renewable energy deployment.

3.3 Sustainable Ocean-Based Tourism

Before the COVID-19 pandemic, tourism was projected to become the single-largest ocean- based industry by 2030. Tourism is one of the sectors hardest hit by the COVID-19 pandemic worldwide. At the same time, coastal and marine tourism remains vital to the economic prosperity of island and coastal communities. The continued viability of this sector remains at risk from climate change, disasters, pollution, urbanisation and ecosystem degradation. Sustainable ocean-based tourism can restore and protect the ocean while delivering jobs and prosperity. Achieving sustainable ocean tourism that can withstand future crises requires strategic public and private investments.

Coastal and ocean-based tourism is sustainable, resilient, addresses climate change, reduces pollution, supports ecosystem regeneration and biodiversity conservation and invests in local jobs and communities.

Priority Actions

- Invest in sustainable tourism that regenerates the ecosystems on which it depends, builds the resilience of coastal communities and Indigenous Peoples, reduces inequality through promoting equal opportunity and equitable distribution of benefits and addresses climate change and pollution.
- Implement sustainable tourism management strategies that advance environmental, social and economic priorities and enable monitoring and transparent reporting with the full participation of coastal communities and Indigenous Peoples.
- Implement mechanisms to increase the reinvestment of tourism revenue into local and indigenous communities to build capacity and skills for increasing local employment in tourism, diversify economic opportunities and increase resources for coastal and marine restoration and protection.
- Accelerate financial incentives for including nature-based solutions in sustainable tourism infrastructure.
- Invest in sewerage and wastewater infrastructure for coastal and marine tourism to improve the health of coastal communities and reduce the impacts on coastal and marine ecosystems.

3.4 Sustainable Ocean Transport

Shipping, the most energy-efficient form of transport, is vital to international trade and connectivity as it continues to move over 90% of global goods. Maintaining global supply chains will be critical to support recovery from the COVID-19 pandemic and future crises. Technology to decarbonise and minimise the negative environmental impacts of marine transport exists but must be brought to scale. To ensure the industry is resilient, we must move decisively towards reducing greenhouse gas emissions by investing in solutions now to support rapid decarbonisation. Such investments will create jobs and build connectivity and the long-term resilience of global supply chains and island and coastal communities to future crises.

Shipping investments have effectively accelerated the shift towards zero-emission and low-impact marine vessels.

Priority Actions

- Establish early national targets and strategies to support decarbonisation of vessels.
- Stimulate the development and adoption of technologies for producing and storing new zero-emission fuels.
- Incentivise sustainable, low-carbon ports that support the transition to decarbonised marine transport and shipping fleets through renewable energy and zero-carbon fuel supply chains.
- Promote the transition of the global fleet to modern modes of propulsion and renewable fuels, including through strengthened regulations within the International Maritime Organization (IMO) and support technical cooperation for international capacity building.
- Minimise the transfer of aquatic invasive species by ships through an effective IMO framework, including its robust implementation.
- Apply the global regime for safe and environmentally sound recycling of ships.

- Promote quiet vessel programs by ports in sensitive areas, and incentivise the use of vessel-quietening technologies taking into account international guidelines.
- Ban the use and carriage for use of heavy fuel oil in the Arctic through the IMO, and welcome other similar initiatives.

4 Sustainable New Ocean Industries

The ocean holds untapped opportunities to deliver medicines, animal feed, fuel, new materials and carbon-storage solutions, the need for which has been further evidenced and strengthened by the COVID-19 pandemic and its repercussions. We need to innovate and invest to scale up these opportunities based on science and environmentally responsible practices.

Innovation and investments in new ocean industries have boosted environmentally responsible and inclusive economic growth.

Priority Actions

- Scale up environmentally responsible commercial farming of seaweed and algae to provide food and create alternatives for products such as fuels, aquaculture and agriculture feedstocks, biotech, and viable and sustainable plastic alternatives.
- Explore and incentivise smart and sustainable cross-sectoral and co-located activities, such as ocean-based renewable energy sites to fuel zero-emission shipping and aquaculture farms.
- Promote fair and equitable sharing of benefits from research and development from marine genetic resources within national waters.
- Advance carbon capture and storage in the sub-seabed through international collaboration, appropriate incentives and mapping the storage potential of sub-seabed geological formations.

4.1 A Precautionary Approach to Seabed Mining

The deep ocean floor contains minerals that are useful for renewable energy technologies and may contribute to the transition to a low–carbon emission society. These areas are among the most isolated and poorly explored of all ocean ecosystems. The sensitivity of these ecosystems, our insufficient scientific knowledge and our limited understanding of the potential impacts of emerging ocean activities requires applying a precautionary approach, undertaking research and investigation, and developing a circular economy to reduce demand and help mitigate these risks.

Sufficient knowledge and regulations are in place to ensure that any activity related to seabed mining is informed by science and ecologically sustainable.

Priority Actions

- Build partnerships to increase research, innovation and deployment of urban mining (reclaiming and recycling metals from spent products, buildings and waste), and of innovative technologies that will reduce the need for new sources of metals and rare earth minerals.
- Initiate an international research agenda to improve understanding of the environmental impacts and risks of seabed mineral activities (especially regarding deep ocean ecosystems).
- Ensure that regulations for seabed mineral mining—under development by the International Seabed Authority—provide effective protection of marine environments by applying a precautionary and ecosystem-based approach, using science-based and transparent management, and ensuring effective compliance with a robust inspection mechanism.
- Ensure that all seabed mineral activities within and beyond national jurisdiction comply with robust environmental standards.
- Promote the participation of scientists from developing countries in research, and make the results from research and the analysis of research findings publicly available, including through the International Seabed Authority.

5 Ocean Health

The ocean is critical for the global climate system and planetary health. It has absorbed 25% of all carbon dioxide (CO_2) emissions and captured 90% of the additional heat generated from greenhouse gas emissions, but it is now warming and acidifying. The global community must act urgently to reduce greenhouse gas emissions, prevent biodiversity loss, restore and protect coastal and marine ecosystems, reduce pollution and take a precautionary approach to economic activity on the ocean floor.

5.1 Reduce Greenhouse Gas Emissions

The health of the ocean, and the livelihoods and economies that depend on it, requires the world to urgently reduce greenhouse gas emissions in line with the goals of the Paris Agreement. A sustainable ocean-based economy can play an essential role in this much needed emissions reduction, while providing jobs, supporting food security, sustaining biological diversity and enhancing resilience. Ocean-based climate actions can deliver up to one-fifth of the annual greenhouse *gas emission reductions needed by 2050 to limit warming to 1.5 °C.*

Ambitious climate action has set the world on track to achieve the goals of the Paris Agreement and restore ocean health.

Priority Actions

- Establish and implement ambitious emissions reductions, covering all sectors, consistent with the Paris Agreement goal of pursuing efforts to limit global temperature increases to 1.5 °C.
- Implement the Ocean Panel's Call to Ocean-Based Climate Action by scaling up investments in ocean-based renewable energy, green shipping, sustainable seafood production, nature-based solutions and carbon capture and storage in sub-seabed geological formations.
- Include ocean-based climate action in reporting under the Paris Agreement.

5.2 Protect and Restore Marine and Coastal Ecosystems

Marine and coastal ecosystems not only sequester and store vast amounts of CO_2 but also protect coasts and communities from climate impacts. They provide food, economic, medicinal and recreation opportunities, habitat and a range of ecosystem functions to support human well-being. An integrated approach that is climate-smart and focuses on nature-based solutions, integrating well-managed marine protected areas and other effective area-based conservation measures, alongside sustainable infrastructure development will be vital to protect coastal communities and marine habitats. This can support increased seafood production, enable pharmaceutical innovation, enhance climate change mitigation and adaptation, and protect and restore biodiversity and cultural values.

Marine and coastal ecosystems are healthy, resilient and productive, and nature-based solutions are key elements in developing coastal infrastructure.

Priority Actions

- Halt the net loss and increase the extent and improve the condition of coastal and marine ecosystems, in particular critical ecosystems such as mangroves, seagrasses, salt marshes, kelp beds, sand dunes, reefs and deep ocean ecosystems.
- Use nature-based solutions in planning and developing coastal infrastructure to reduce grey infrastructure where possible, and incentivise their use to sequester and store carbon and improve coastal resilience.
- Establish and effectively manage marine protected areas and other effective area- based conservation measures that conserve biodiversity while also delivering climate, food, socioeconomic and cultural benefits.
- Collaborate with all relevant partners, including local community, Indigenous Peoples, and stakeholders through relevant global and regional organisations to promote sustainable management of all marine and coastal ecosystems.
- Capitalise on knowledge and spatial analysis tools to identify carbon sequestration potential and optimal locations for marine protected areas, and other effective area-based conservation measures in the development of Sustainable Ocean Plans.

5.3 Reduce Ocean Pollution

The ocean has become a sink for pollutants including plastics, chemicals, nutrients and wastewater. While global awareness and action has been increasing, it has not been sufficient to prevent an increase in ocean pollution. The response to the COVID-19 pandemic has caused a surge in production and consumption of protective equipment, much of which contains single-use plastic. This response, although necessary, has further accentuated the need to stop waste from entering the ocean. Efforts to combat harmful land-to-sea pollution should not be scaled back under the guise of economic recovery after the pandemic. Urgent action is needed to target the sources and management of pollution. Through the UN Environment Assembly, governments have endorsed a long-term vision of eliminating the discharge of marine litter and microplastics into the ocean. The G20 Osaka Blue Ocean Vision and the Ocean Plastics Charter further recognise the importance of embracing a lifecycle and circular economy approach.

Nutrient runoff contributes to deoxygenation of the ocean but suffers from less attention and action; it should be treated with the same level of urgency. The connection between the land and the ocean must be understood to address systemic sources of ocean pollution.

The ocean is no longer a sink for pollution and ocean dead zones are minimised.

Priority Actions

- Incentivise the development, production and use of viable and sustainable alternatives to plastics to enable the phase out of problematic and unnecessary plastics, where warranted and where such alternatives exist.
- Use financial incentives, trade opportunities and extended producer responsibility to encourage sustainable product

design and promote standards to maximise reduction, reuse and recycling in pursuit of a circular economy, as well as research on new biodegradable materials that substitute plastics.
- Enforce rules on waste shipments and illegal exports of plastic waste.
- Promote a comprehensive life-cycle approach that includes improved waste management and innovative solutions towards reducing the discharge of marine plastic litter to zero.
- Eliminate discharges of plastic litter and microplastics from sea-based sources including ships, offshore installations and from land-based sources including ports and bridges, through stronger regulations, technology development, training programmes and capacity building.
- Eliminate ghost fishing gear through such means as reuse and retrieval, promoting gear marking and loss reporting, and supporting development of new environmentally friendly cost-effective gear.
- Promote public and private awareness of and investment in sewage and waste management infrastructure in developing countries, including as a means to stop diseases.
- Promote agriculture farming practices and technology that minimises the discharge of excess pesticides, fertilisers, manure and soil particles to eliminate eutrophication and ocean dead zones in coastal waters.
- Implement integrated watershed management practices.
- Encourage the aquaculture industry to apply best practices in order to reduce the amount of nutrient leakage in connection with feed formulation and application, and minimise the discharge of excess antibiotics.
- Strengthen measures to prevent pollution from mining and offshore oil and gas activities, including hazardous and noxious substance spills.

6 Ocean Equity

A sustainable ocean economy puts people at its centre, works for everyone, enables human rights, facilitates the equitable distribution of ocean wealth and ensures equality of opportunity for all. It promotes accountable and transparent business practices, addresses labour rights abuses, child labour, forced labour, trafficking in persons and contraband, as well as tax evasion, and it supports the fight against corruption. It also recognises the specific climate vulnerabilities and financing and capacity constraints of developing countries, in particular Small Island Developing States and Least Developed Countries. With the global population expected to grow by a further two billion people by 2050, effective planning undertaken today can assure the needs and rights of all.

6.1 Promote Equal Opportunity for People to Benefit from the Ocean

A sustainable ocean economy cannot be achieved while many millions of people remain in poverty and inequality is systemic. The COVID-19 pandemic has widened existing inequalities and placed millions of people in extreme poverty. There must be a fair and just transition out of the pandemic and to a sustainable ocean economy that leaves no one behind, enables equitable access to resources, supports fair distribution of benefits and protects the most vulnerable from further risks of harm.

People have equitable access to ocean resources, benefits are fairly distributed and the most vulnerable are protected from the risk of harm.

Priority Actions
- Require transparent, responsible business practices that engage and benefit coastal communities, including small-scale fishers, and protect the rights of all workers in ocean industries.
- Create the conditions to facilitate the full engagement of women in ocean activities to help unlock their economic and social potential, and empower them to safeguard natural resources while enhancing opportunities to access decent work.
- Recognise and respect the interests of coastal communities and rights of Indigenous Peoples, and implement policies that require consideration of the particular importance of marine resources for these groups.
- Create inclusive governance by incorporating indigenous and local community knowledge and interests, particularly those of women and youth, in planning and decision-making processes.
- Promote integrity across ocean governance and ocean industries, enforce transparency and accountability in public service and public finance and take robust action against corruption.
- Enhance domestic revenue administration through modernised, progressive tax systems, improved tax policy and more efficient tax collection.
- Promote international cooperation to combat child labour and forced labour and eliminate trafficking in persons and contraband along supply chains in the ocean economy.

7 Ocean Knowledge

The ocean is a vital and complex natural system. We need to build literacy and skills, and share and apply knowledge of how ocean ecosystems work, and how they respond to stressors to better inform decision-making. Accounting that captures the full value of ocean assets and the ocean economy is critical to guide the sustainable development of ocean industries. The UN Decade of Ocean Science for Sustainable Development (2021–2030) represents a unique opportunity to enhance the scientific understanding of the ocean.

7.1 Build Ocean Literacy and Skills

It is important for people to understand the significance and influence of the ocean on their well-being and the influence of their activities upon the ocean. People must be enabled to acquire the knowledge, skills and capacity necessary to participate in and benefit from ocean opportunities.

Through the UN Decade of Ocean Science ocean literacy has been enhanced worldwide. People understand the value of the ocean and have acquired the skills and knowledge to participate in the sustainable ocean economy.

Priority Actions

- Make ocean knowledge available to everyone and invest in building ocean literacy and awareness among citizens, including through formal education.
- Invest in knowledge, technology and skills training for ocean conservation and management and the sustainable ocean industries of the future to ensure a just transition for workers in the ocean economy.
- Increase cooperation, capacity building and transfer of knowledge and marine technology on mutually agreed terms to ensure that benefits from the sustainable development of the ocean are shared.

7.2 Account for the Value of the Ocean

Measurement of progress for the ocean economy is overly focused on production indicators such as contribution to gross domestic product. With current data and technology, it is now possible for all countries to account for the status of the natural wealth of the ocean—the most important measure of progress towards sustainability of the ocean economy. The development and integration of ocean accounts into national accounts can provide a dynamic evidence base that goes beyond a single indicator of production to reflect the full value of the ocean economy.

Decision-making affecting the ocean reflects the value of and impacts on the ocean's natural capital.

Priority Actions

- Develop a complete sequence of national ocean accounts that are actively used to inform decision-making.
- Align international standards for ocean accounting and best practices for implementation as soon as possible to develop and ensure interoperability, harmonisation and coherence of ocean accounts.
- Commit to global partnerships to share best practices and build capacity in national ocean accounting.
- Explore a process to develop a global approach for tracking national performance based on ocean accounts.

7.3 Harness Ocean Science, Technology and Data

Scientific research and monitoring are critical to decision-making and ocean management, and to understanding the impacts of stressors on the ocean. Advances in remote sensing technologies, big data management and modelling techniques provide new opportunities to improve the efficiency and cost-effectiveness of monitoring and managing activities in the ocean, including commercial and artisanal fisheries and protected area management. These technologies can revolutionise how ocean data are collected, stored and used for better ocean management, business development and job creation.

A globally shared data revolution has contributed to sustainable ocean management worldwide.

Priority Actions

- Incentivise the use of the latest innovations and technologies, such as satellites, autonomous vehicles, artificial intelligence for near real-time data collection, research, monitoring, and enforcement and decision-making.
- Promote transparent and open sharing and accessibility of ocean data.
- Scale up integrated local-to-global observation, including indigenous and local community knowledge, and research to better inform decision-making.
- Support marine science capacity building, information exchange, collaboration and appropriate technology transfer on mutually agreed terms, and mobilise capital for technologies where there are market gaps.
- Fill major data gaps and digitise information on coastal and marine ecosystems, such as mangroves, seagrasses, salt marshes, kelp beds, sand dunes, reefs, deep ocean ecosystems and the ocean floor.

8 Ocean Finance

Capital to finance the transformation to a sustainable ocean economy is readily available. US $90 trillion is projected to be invested over the next decade on infrastructure alone, much of which will be on the coast. If grounded in global principles and standards, finance can catalyse responsible policy and business practices across the land-sea interface. Strong examples of such principles include the UN Environment Programme Finance Initiative's Sustainable Blue Economy Finance Principles and the UN Global Compact's Sustainable Ocean Principles. We need to ensure that access to finance is equitable and supports sustainability, recognising the needs of developing countries, particularly Small Island Developing States and Least Developed Countries. Public sector finance can help unlock private sector financing.

Sustainable ocean finance is accessible for all and drives ecologically sustainable and socially equitable economic growth.

Priority Actions

- Direct public sector financing and development assistance to investments in the sustainable ocean economy, including for the development and implementation of Sustainable Ocean Plans, to unlock private sector financing.
- Support the use of sustainable ocean finance principles and other voluntary mechanisms led by the private sector and multilateral financial institutions in recovery and stimulus efforts, to guide, de-risk, incentivise and monitor investment in sustainable ocean activities to increase transparency and ensure reporting consistency.
- De-risk investments by creating focused blended finance capacity that combines concessional finance from the public and private sectors with innovative private insurance products.
- Support the development and application of a global 'ocean risk map' and 'risk index' to catalyse a responsible and sustainable ocean insurance market and investments in the resilience of islands and coastal communities.

Correction to: The Blue Compendium: From Knowledge to Action for a Sustainable Ocean Economy

Jane Lubchenco and Peter M. Haugan

Correction to: J. Lubchenco, P. M. Haugan (eds.), *The Blue Compendium*, https://doi.org/10.1007/978-3-031-16277-0

The original version of the book has been corrected, and the corrections are as follows:

1. Chapter author names are now listed under each chapter in the Table of Contents instead of Editors names. List of authors, lead authors and corresponding authors in each chapter have been added to each chapter.
2. About the Authors sections have been added to the end of Chapters 1 and 19.
3. At the beginning of each chapter, there was an error in the "Originally published in" section. It shows "World Research Institute" instead of "World Resources Institute'.
4. Following author names changes were carried over globally:
   a. Ca Vu Thanh—Vu Thanh Ca
   b. Rashid Sumaila—U. Rashid Sumaila
   c. Eddie H. Allison—Edward H. Allison
   d. Peter Haugen—Peter Haugan
   e. Catherine E Lovelock—Catherine E. Lovelock
5. On Page xi and in the Chapter 21 heading, the title is listed as: "Transformations for a Sustainable Ocean Economy: A Vision for Protection, Production and Prosperity".
6. In Chapter 5: the "period" after the term "Indonesian" has been removed: "Indonesian. Institute of Sciences in Indonesia and at the Research".
7. In Chapter 7: Page 218, Figure 7.1 description bracket was closed.
8. In Chapter 9: Louise Teh's name was listed after Durreen Shahnaz.
9. In Chapter 12: Page 473, heading of table "shipping" carried onto the next page—headings for each section were realigned.
10. In Chapter 13: Page 516, "Accessed 18 Nov" form Global Compact (2019) reference removed, same with IPBES reference "accessed 21 Nov"
11. In Chapter 14
    a. Line break has been removed in the affiliation of the author Minhan Dai.
    b. Page 543, Fig. 14.8. An additional bracket has been inserted at the end of the sentence.
12. In Chapter 15
    a. Page 559-560, Box 15.1: the activities were set in bullet points.
    b. Page 572, Table 15.1: last row set as a part of "Allowing at-sea transshipment".
    c. Page 579: colon (:) added after "these actions are".
    d. Page 590: added spaces between lettering of Ministry of Marine Affairs and Fisheries of the Republic of Indonesia.

The updated versions of the chapters can be found at https://doi.org/10.1007/978-3-031-16277-0

13. In Chapter 17:
    a. Formatting of boxes has been carried over.
    b. Page 625: full stop added at the end of “Governance” bullet point.
    c. Page 633: closing bracket included at the end of “….0.114 gigawatts (GW)”.
    d. Page 639: extra closing bracket removed from the final paragraph “(long))”.
    e. Page 640: “short term” and “medium term” titles were in bold font.
    f. Page 660: first sentence in the box has been changed to “CO2” instead of “CO”.
    g. Page 666: 8.3.3. the first subheading font is changed as per style
    h. Page 672: removed italics within the “about of expert authors”.
14. In Chapter 19: Affiliations added for Eliza Northrop, Manaswita Konar, Nicola Frost and Elizabeth Hollaway.
