Efficient Zero-Knowledge Arguments from Two-Tiered Homomorphic Commitments

Jens Groth*

University College London, UK j.groth@ucl.ac.uk

Abstract. We construct practical and efficient zero-knowledge arguments with sublinear communication complexity. The arguments have perfect completeness, perfect special honest verifier zero-knowledge and computational soundness. Our zero-knowledge arguments rely on two-tiered homomorphic commitments for which pairing-based constructions already exist.

As a concrete application of our new zero-knowledge techniques, we look at the case of range proofs. To demonstrate a committed value belongs to a specific N-bit integer interval we only need to communicate $O(N^{\frac{1}{3}})$ group elements.

Keywords: Zero-knowledge arguments, sublinear communication, circuit satisfiability, range proofs, two-tiered homomorphic commitments.

1 Introduction

Zero-knowledge proofs introduced by Goldwasser, Micali and Rackoff [18] are fundamental building blocks in cryptography that are used in secure multi-party computation and numerous other protocols. Zero-knowledge proofs enable a prover to convince a verifier of the truth of a statement without leaking any other information. The central properties are captured in the notions of completeness, soundness and zero-knowledge.

Completeness: The prover can convince the verifier if the prover knows a witness testifying to the truth of the statement.

Soundness: A malicious prover cannot convince the verifier if the statement is false. We distinguish between computational soundness that protects against polynomial time cheating provers and statistical or perfect soundness where even an unbounded prover cannot convince the verifier of a false statement. We will call computationally sound proofs for *arguments*.

Zero-knowledge: A malicious verifier learns nothing except that the statement is true. We distinguish between computational zero-knowledge, where a polynomial time verifier learns nothing from the proof and statistical or perfect zero-knowledge, where even a verifier with unlimited resources learns nothing from the proof.

Recent works on zero-knowledge proofs [25] give us proofs with a communication complexity that grows linearly in the size of the statement to be proven and [25,26]

^{*} Supported by EPSRC grant number EP/G013829/1.

also give us proofs where the communication complexity depends quasi-linearly on the witness-length. These works rely on standard assumptions; if one is willing to assume the existence of fully homomorphic encryption [15] the communication complexity can be reduced to the witness-length plus a small additive overhead [14,23].

For zero-knowledge *arguments* the communication complexity can be even lower. Kilian [27] gave a zero-knowledge argument for circuit satisfiability with polylogarithmic communication. His argument goes through the PCP-theorem [3,2,11] and uses a collision-free hash-function to build a hash-tree that includes the entire PCP though. Even with the best PCP constructions known to date [4] Kilian's argument has high computational complexity for practical parameters. Goldwasser, Kalai and Rothblum [17] improve that state of affairs by constructing arguments that have both low communication complexity and highly efficient verification.

A large body of research starting with Schnorr's identification protocols [32] deals with zero-knowledge proofs and arguments over prime order groups. A class of zero-knowledge proofs and arguments known as Σ -protocols [8] is often used in practical applications. Groth [22] also used prime order groups to develop practical sublinear size zero-knowledge arguments for statements relating to linear algebra over \mathbb{Z}_p for large primes p.

One particular example of zero-knowledge arguments that has appeared in several applications, e.g., e-voting [10] and auctions [30] are range proofs. Here the prover holds a commitment to a value w and wants to convince the verifier that the value belongs to a specific integer interval [A;B). Boudot [5], Lipmaa [29] and Groth [20] have given constant size zero-knowledge argument for interval membership based on the strong RSA assumption.

In prime order groups the best range proof technique known was for a long time to commit to the bits of the value and use OR-proofs [8] to show that the committed bits were 0 or 1. For N-bit integers this communicates O(N) group elements. Camenisch, Chaabouni and Shelat [6] improved this in the bilinear group setting by giving a zero-knowledge range proof with communication complexity $O(\frac{N}{\log N})$. Chaabouni, Lipmaa and Shelat [7] improved this complexity with a factor 2.

Our contribution. We construct zero-knowledge arguments for circuit satisfiability and range proofs that have perfect completeness and perfect zero-knowledge. For simplicity our constructions are in the common reference string model, but typically the common reference string can be chosen by the verifier at the cost of one extra round in the beginning to get zero-knowledge arguments in the plain model; we refer to the remarks at end of Section 2.2 for further discussion.

The circuit satisfiability argument has communication complexity $O(N^{\frac{1}{3}})$ group elements when the circuit has N gates. The range proof has a size of $O(N^{\frac{1}{3}})$ group elements for N-bit intervals. The arguments have quasi-linear computational complexity for the prover and very efficient verification. An efficiency comparison of the arguments can be found in Tables 1 and 2.

In the tables we give the conservative estimate of $O(N\log^2 N)$ estimate for the prover's computation, but as we will discuss at the end of Section 3 it can often be reduced to $O(N\log N)$ using Fast Fourier Transform techniques. When comparing the range proofs, we are assuming a common reference string is available. This permits the

incorporation of the initial messages in [6,7] into the common reference string such that their range proofs only use 3 rounds instead of 4 rounds.

Our zero-knowledge arguments can be instantiated in asymmetric bilinear groups where the computational double pairing assumption (Section 2.1) holds. In comparison, the range proofs [6,7] are based on the q-SDH assumption in bilinear groups.

Techniques. Our main technical contribution is the batch product argument that can be found in Section 3. Using homomorphic commitments to group elements [1,22] we can in combination with Pedersen commitments to multiple elements commit to N elements in \mathbb{Z}_p using only $N^{\frac{1}{3}}$ group elements. Given 3N committed elements $u_i, v_i, w_i \in \mathbb{Z}_p$ we generalize techniques from [24,22] to develop a communication-efficient zero-knowledge argument for proving that the committed values all satisfy $u_i v_i = w_i$.

Since the commitments are homomorphic we can now do both additions and multiplications on the committed elements. This enables the prover to commit to the wires in a circuit and prove that they respect the NAND-gates.

For the range proof we commit to the bits w_1,\ldots,w_N of the committed value. Using the batch product argument we can show with a communication complexity of $O(N^{\frac{1}{3}})$ group elements that the committed bits satify $w_iw_i=w_i$, which can only be true if $w_i\in\{0,1\}$. Once we have the committed bits, we can then use the homomorphic properties of the commitment schemes to compute $w=\sum_{i=1}^N w_i 2^{i-1}$. This shows that w belongs to the range $[0;2^N)$ and can be generalized to a range of the form [A;B).

2 Preliminaries

We write y = A(x; r) when the algorithm A on input x and randomness r, outputs y. We write $y \leftarrow A(x)$ for the process of picking randomness r at random and setting y = A(x; r). We also write $y \leftarrow S$ for sampling y uniformly at random from the set S.

We give a security parameter λ written in unary as input to all parties in our protocols. Intuitively, the higher the security parameter the more secure the protocol. We say a function $f: \mathbb{N} \to [0,1]$ is negligible if $f(\lambda) = O(\lambda^{-c})$ for every constant c>0. We write $f\approx g$ when $|f(\lambda)-g(\lambda)|$ is negligible. We say f is overwhelming if $f\approx 1$.

2.1 Two-tiered Homomorphic Commitments

A commitment scheme allows Alice to compute and send a commitment to a secret message a. Later Alice may open the commitment and reveal to Bob that she committed to a. Commitments must be binding and hiding. Binding means that Alice cannot change her mind; a commitment can only be opened to one message a. Hiding means that Bob does not learn which message Alice committed to.

In the Pedersen commitment scheme [31] the public key contains the description of a group of prime order p and group elements g,h. A commitment to $a\in\mathbb{Z}_p$ is constructed by picking $r\leftarrow\mathbb{Z}_p$ and computing $c=g^ah^r$. This commitment scheme is very useful because it is homomorphic, i.e., the product of two commitments is $c\cdot c'=(g^ah^r)(g^bh^s)=g^{a+b}h^{r+s}$, which is a commitment to a+b. The Pedersen commitment can be generalized such that the public key contains g_1,\ldots,g_n,h and a commitment to $(a_1,\ldots,a_n)\in\mathbb{Z}_p^n$ is computed as $h^r\prod_{k=1}^ng_k^{a_k}$.

Abe, Fuchsbauer, Groth, Haralambiev and Ohkubo [1,21] proposed commitment schemes for group elements. One of the commitment schemes uses a bilinear group with a pairing $e: \mathbb{G} \times \hat{\mathbb{G}} \to \mathbb{T}$. Here $\mathbb{G}, \hat{\mathbb{G}}, \mathbb{T}$ are cyclic groups of prime order p where we call $\mathbb{G}, \hat{\mathbb{G}}$ the base groups and \mathbb{T} the target group. The pairing is efficiently computable, non-trivial and bilinear, i.e., for all x,y,a,b we have $e(x^a,y^b)=e(x,y)^{ab}$. The commitment scheme specifies non-trivial group elements $v,u_1,\ldots,u_m\in \hat{\mathbb{G}}$ and a commitment to $(c_1,\ldots,c_m)\in \mathbb{G}$ is computed by picking at random $t\in \mathbb{G}$ and computing $C=e(t,v)\prod_{j=1}^m e(c_j,u_j)$. The commitment scheme is computationally binding under the computational double pairing assumption, which states that given random $u,v\in \hat{\mathbb{G}}$ it is hard to find non-trivial $s,t\in \mathbb{G}$ such that e(s,u)=e(t,v). The hardness of the computational double pairing assumption is implied by the decision Diffie-Hellman assumption in $\hat{\mathbb{G}}$ [1,21]. Furthermore, the bilinearity of the pairing means that the commitment scheme is homomorphic in the sense that

$$C \cdot C' = \left(e(t, v) \prod_{j=1}^{m} e(c_j, u_j) \right) \left(e(t', v) \prod_{j=1}^{m} e(c'_j, u_j) \right) = e(tt', v) \prod_{j=1}^{m} e(c_j c'_j, u_j)$$

is a commitment to the entry-wise product of the messages.

Combining the two types of commitment schemes it is possible to commit to commitments. If we compute $c_j = h^{r_j} \prod_{k=1}^n g_k^{a_{jk}}$ and $C = e(t,v) \prod_{j=1}^m e(c_j,u_j)$ we have a single target group element that is a commitment to mn values $\{a_{jk}\}_{j=1,k=1}^{m,n}$. Since both commitment schemes are homomorphic the product of two commitments $C \cdot C'$ is a commitment to the sums of the messages $a_{jk} + a'_{jk}$. In our zero-knowledge arguments

¹ Galbraith, Paterson and Smart [12] classified bilinear groups into 3 types. The commitment scheme described above uses type II or type III bilinear groups. In a type I bilinear group we could instead use the decisional linear assumption based commitment scheme from [21].

the homomorphic and the length-reducing properties allow the prover to do computations on committed values in a verifiable manner and with little communication.

The commitment schemes described above provide an example of what we will call a two-tiered commitment scheme. With the Pedersen commitment scheme in mind we will for simplicity assume the randomness is drawn from \mathbb{Z}_p but it would be easy to generalize to other randomizer spaces. Furthermore, in the example given above the Pedersen commitments are perfectly hiding and we can therefore use trivial randomness t=1 in the commitments to Pedersen commitments. This observation is incorporated in the following definition of a two-tiered commitment scheme.

A two-tiered commitment scheme has three polynomial time algorithms $(\mathcal{K}, \operatorname{com}, \operatorname{com}^{(2)})$. \mathcal{K} is a key generator that on security parameter λ and integers m, n returns a public key ck. The commitment key specifies cyclic groups \mathbb{Z}_p , \mathbb{G} and \mathbb{T} of prime order p. It also specifies how to efficiently compute $\operatorname{com}_{ck}: \mathbb{Z}_p^n \times \mathbb{Z}_p \to \mathbb{G}$ and $\operatorname{com}_{ck}^{(2)}: \mathbb{G}^m \to \mathbb{T}$.

Definition 1 (Homomorphic). We say the two-tiered commitment scheme is homomorphic, when the maps $com_{ck}^{(2)}$ and $com_{ck}^{(2)}$ are \mathbb{Z}_p -linear.

Definition 2 (Computationally binding). The two-tiered commitment scheme $(\mathcal{K}, \text{com}, \text{com}^{(2)})$ is computationally binding if for all non-uniform polynomial time adversaries \mathcal{A} and for all $m, n = \lambda^{O(1)}$

$$\Pr\left[ck \leftarrow \mathcal{K}(1^{\lambda}, m, n); (\boldsymbol{a}, \boldsymbol{b}, r, s, \boldsymbol{c}, \boldsymbol{d}) \leftarrow \mathcal{A}(ck) : \boldsymbol{a} \neq \boldsymbol{b} \in \mathbb{Z}_p^n \ r, s \in \mathbb{Z}_p \ \boldsymbol{c} \neq \boldsymbol{d} \in \mathbb{G}^m \right.$$

$$\operatorname{com}_{ck}(\boldsymbol{a}; r) = \operatorname{com}_{ck}(\boldsymbol{b}; s) \quad \text{or} \quad \operatorname{com}_{ck}^{(2)}(\boldsymbol{c}) = \operatorname{com}_{ck}^{(2)}(\boldsymbol{d}) \right] \approx 0.$$

Definition 3 (Perfectly hiding). The two-tiered commitment scheme $(K, \text{com}, \text{com}^{(2)})$ is perfectly hiding if for all stateful adversaries A and all $m, n \in \lambda^{O(1)}$

$$\Pr\left[ck \leftarrow \mathcal{K}(1^{\lambda}, m, n); \boldsymbol{a}_0, \boldsymbol{a}_1 \leftarrow \mathbb{Z}_p^n; b \leftarrow \{0, 1\}; c \leftarrow \text{com}_{ck}(\boldsymbol{a}_b) : \mathcal{A}(ck, \boldsymbol{a}_0, \boldsymbol{a}_1, c) = b\right] = \frac{1}{2}.$$

The zero-knowledge arguments we describe will work over any two-tiered homomorphic commitment scheme with a large prime p. When giving concrete efficiency estimates we will assume we are using the bilinear group based scheme described earlier in this section. The public key for this commitment scheme consists of a description of a bilinear group $(p, \mathbb{G}, \hat{\mathbb{G}}, \mathbb{T}, e)$ and m+n+2 group elements in \mathbb{G} and $\hat{\mathbb{G}}$. We will be looking at statements of size N and the minimal communication complexity will be obtained when $m=O(N^{\frac{1}{3}})$ and $n=O(N^{\frac{1}{3}})$ giving a public key size of $O(N^{\frac{1}{3}})$ group elements.

2.2 Special Honest Verifier Zero-knowledge Arguments of Knowledge

We will for simplicity describe how our arguments work in the common reference string model and how to obtain zero-knowledge against honest-but-curious verifiers. Both of these restrictions can be removed at very small cost to get full zero-knowledge in the plain model as described in the remarks at the end.

Consider a triple of probabilistic polynomial time interactive algorithms $(\mathcal{K}, \mathcal{P}, \mathcal{V})$ called the common reference string generator, the prover and the verifier. The common reference string generator takes the security parameter λ as input in unary and some auxilliary input m,n that specifies the size of the statements and generates a common reference string. In the zero-knowledge arguments in this paper, the common reference string will contain the public key ck for a two-tiered commitment scheme.

Let R be a polynomial time decidable ternary relation. For a statement x we call w a witness if $(ck, x, w) \in R$. We define a corresponding common reference string dependent language L_{ck} consisting of statements x that have a witness w such that $(ck, x, w) \in R$. This is a natural generalization of NP-languages; when R ignores ck we have the standard notion of an NP-language.

We write $\operatorname{tr} \leftarrow \langle \mathcal{P}(s), \mathcal{V}(t) \rangle$ for the public transcript produced by \mathcal{P} and \mathcal{V} when interacting on inputs s and t. This transcript ends with \mathcal{V} either accepting or rejecting. We sometimes shorten the notation by saying $\langle \mathcal{P}(s), \mathcal{V}(t) \rangle = b$, where b = 0 corresponds to \mathcal{V} rejecting and b = 1 corresponds to \mathcal{V} accepting.

Definition 4 (Argument). The triple (K, P, V) is an argument for relation R with perfect completeness if for all non-uniform polynomial time interactive adversaries A and all $m, n = \lambda^{O(1)}$ we have

Perfect completeness:

$$\Pr\Bigl[ck\leftarrow\mathcal{K}(1^{\lambda},m,n);(x,w)\leftarrow\mathcal{A}(ck):(ck,x,w)\notin R \text{ or } \langle\mathcal{P}(ck,x,w),\mathcal{V}(ck,x)\rangle=1\Bigr]=1.$$

Computational soundness:

$$\Pr\left[ck \leftarrow \mathcal{K}(1^{\lambda}, m, n); x \leftarrow \mathcal{A}(ck) : x \notin L_{ck} \text{ and } \langle \mathcal{A}, \mathcal{V}(ck, x) \rangle = 1\right] \approx 0.$$

Definition 5 (Public coin argument). An argument (K, P, V) is public coin if the verifier's messages are chosen uniformly at random independently of the messages sent by the prover.

We shall define an argument of knowledge through witness-extended emulation [19,28]. Informally, the definition says: given an adversary that produces an acceptable argument with probability ϵ , there exists an emulator that produces a similar argument with roughly the same probability ϵ and at the same time provides a witness.

Definition 6 (Witness-extended emulation). We say the public coin argument $(\mathcal{K}, \mathcal{P}, \mathcal{V})$ has computational witness-extended emulation if for all deterministic polynomial time \mathcal{P}^* there exists an expected polynomial time emulator \mathcal{X} such that for all non-uniform polynomial time adversaries \mathcal{A} and all $m, n = \lambda^{O(1)}$

$$\begin{split} & \text{Pr}\left[ck \leftarrow \mathcal{K}(1^{\lambda}, m, n); (x, s) \leftarrow \mathcal{A}(ck); \text{tr} \leftarrow \langle \mathcal{P}^*(ck, x, s), \mathcal{V}(ck, x) \rangle : \mathcal{A}(\text{tr}) = 1\right] \\ & \approx \text{Pr}\left[ck \leftarrow \mathcal{K}(1^{\lambda}, m, n); (x, s) \leftarrow \mathcal{A}(ck); (\text{tr}, w) \leftarrow \mathcal{X}^{\langle \mathcal{P}^*(ck, x, s), \mathcal{V}(ck, x) \rangle}(ck, x) : \\ & \mathcal{A}(\text{tr}) = 1 \text{ and if tr is accepting then } (ck, x, w) \in R\right], \end{split}$$

where \mathcal{X} has access to a transcript oracle $\langle \mathcal{P}^*(ck,x,s), \mathcal{V}(ck,x) \rangle$ that can be rewound to a particular round and run again with the verifier using fresh randomness.

We think of s as being the state of \mathcal{P}^* , including the randomness. Then we have an argument of knowledge in the sense that the emulator can extract a witness whenever \mathcal{P}^* is able to make a convincing argument. This shows that the definition implies soundness. We remark that the verifier's randomness is part of the transcript and the prover is deterministic. So combining the emulated transcript with ck, x, s gives us the view of both the prover and the verifier and at the same time gives us the witness.

We define special honest verifier zero-knowledge (SHVZK) [8] for a public coin argument as the ability to simulate the transcript without access to the witness as long as the challenges are known in advance.

Definition 7 (Perfect special honest verifier zero-knowledge). The public coin argument $(\mathcal{K}, \mathcal{P}, \mathcal{V})$ is a perfect special honest verifier zero-knowledge argument for R if there exists a probabilistic polynomial time simulator \mathcal{S} such that for all non-uniform polynomial time adversaries \mathcal{A} and all $m, n = \lambda^{O(1)}$

$$\begin{split} \Pr\Big[ck \leftarrow \mathcal{K}(1^{\lambda}, m, n); (x, w, \rho) \leftarrow \mathcal{A}(ck); \operatorname{tr} \leftarrow \langle \mathcal{P}(ck, x, w), \mathcal{V}(ck, x; \rho) \rangle : \\ (ck, x, w) \in R \text{ and } \mathcal{A}(\operatorname{tr}) = 1 \Big] \\ = & \Pr\Big[ck \leftarrow \mathcal{K}(1^{\lambda}, m, n); (x, w, \rho) \leftarrow \mathcal{A}(ck); \operatorname{tr} \leftarrow \mathcal{S}(ck, x, \rho) : (ck, x, w) \in R \text{ and } \mathcal{A}(\operatorname{tr}) = 1 \Big]. \end{split}$$

The plain model. We will describe our arguments in the common reference string model where the prover and verifier have a trusted setup. If we want to work in the plain model we can add an initial round where the verifier picks the common reference string and sends it to the prover. Provided it can be verified that the verifier's initial message describes a valid common reference string this will still be perfect SHVZK because we do not rely on the simulator knowing any trapdoor information associated with the common reference string.

Full zero-knowledge. For simplicity, we focus on SHVZK arguments in this paper. There are very efficient standard techniques [9,13,19] to convert an SHVZK argument into a public-coin full zero-knowledge argument with a cheating verifier when a common reference string is available.

If we work in the plain model and let the verifier choose the common reference string, we can use coin-flipping techniques (for the full zero-knowledge property the coin-flips should be simulatable against a dishonest verifier) for the challenges to get private-coin² full zero-knowledge arguments against a cheating verifier. Challenges in our SHVZK arguments are very short so both in the case with and without a common reference string the overhead of getting full zero-knowledge is insignificant compared to the cost of the SHVZK arguments.

3 Batch Product Argument

We will now present our main technical contribution, which is a batch product argument for committed values $\{u_{ijk},v_{ijk},w_{ijk}\}_{i=1,j=1,k=1}^{M,m,n}$ satisfying $u_{ijk}v_{ijk}=w_{ijk}$. More

² Goldreich and Krawczyk [16] have shown that only languages in BPP have constant-round public-coin arguments.

precisely, the statement consists of commitments $C_{U_1}, C_{V_1}, C_{W_1}, \ldots, C_{U_M}, C_{V_M}, C_{W_M}$. The prover argues knowledge of openings $u_{ijk}, r_{ij}, v_{ijk}, s_{ij}, w_{ijk}, t_{ij} \in \mathbb{Z}_p$ satisfying

$$c_{u_{ij}} = com_{ck}(u_{ij1}, \dots, u_{ijn}; r_{ij}) \qquad C_{U_i} = com_{ck}^{(2)}(c_{u_{i1}}, \dots, c_{u_{im}})$$

$$c_{v_{ij}} = com_{ck}(v_{ij1}, \dots, v_{ijn}; s_{ij}) \qquad C_{V_i} = com_{ck}^{(2)}(c_{v_{i1}}, \dots, c_{v_{im}})$$

$$c_{w_{ij}} = com_{ck}(w_{ij1}, \dots, w_{ijn}; t_{ij}) \qquad C_{W_i} = com_{ck}^{(2)}(c_{w_{i1}}, \dots, c_{w_{im}})$$

$$u_{ijk}v_{ijk} = w_{ijk}.$$

The argument will have communication complexity O(M+m+n). In order to explain the idea behind the argument let us first focus on soundness and for now postpone the question of how to get SHVZK. In the argument, the prover will demonstrate that she knows openings of $C_{U_i}, C_{V_i}, C_{W_i}$ to $c_{u_{ij}}, c_{v_{ij}}, c_{w_{ij}}$ and that she knows openings of $c_{u_{ij}}, c_{v_{ij}}, c_{w_{ij}}$ using standard techniques. She will also know openings $a_{\alpha}, \rho_{\alpha}, b_{\beta}, \sigma_{\beta} \in \mathbb{Z}_p$ of intermediate commitments $c_{a_{\alpha}} = \mathrm{com}_{ck}(a_{\alpha}; \rho_{\alpha}), c_{b_{\beta}} = \mathrm{com}_{ck}(b_{\beta}, \sigma_{\beta})$ that she sends during the argument and which will be specified later. The argument runs over 7 moves with the prover getting challenges $x, y, z \in \mathbb{Z}_p^*$ in round 2, 4 and 6. The commitments $c_{a_{\alpha}}$ are sent in round 3 and the commitments $c_{b_{\beta}}$ are sent in round 5. This means a_{α} may depend on x but is independent of y and z, and b_{β} may depend on both x and y but is independent of z.

The prover will demonstrate to the verifier that

$$\sum_{i=1}^{M} \sum_{j=1}^{m} \sum_{k=1}^{n} (u_{ijk}v_{ijk} - w_{ijk})x^{i(m+1)n+jn+k} = 0.$$
 (1)

Unless $u_{ijk}v_{ijk}=w_{ijk}$ for all choices of i,j,k this has negligible probability of holding over a randomly chosen challenge $x\in\mathbb{Z}_p^*$. Our main obstacle is to build up this polynomial and convince the verifier that the equality (1) holds true using only O(M+m+n) communication.

We carefully choose appropriate linear combinations of the commitments and by the homomorphic property get corresponding linear combinations of the $u_{ijk}, v_{ijk}, w_{ijk}$ values such that the equality (1) emerges. During this process, we will also use exponentiations of some of the commitments to powers of x such that we get linear combinations of $u_{ijk}x^{i(m+1)n+jn+k}$ and $w_{ijk}x^{i(m+1)n+jn+k}$. Suppose for instance that the prover after seeing x computes and opens

$$\begin{split} &\prod_{i=1}^{M} C_{U_i}^{x^{i(m+1)n}} = \mathrm{com}_{ck}^{(2)}(c_{u_1}, \dots, c_{u_m}) & \text{where} & c_{u_j} = \prod_{i=1}^{M} c_{u_{ij}}^{x^{i(m+1)n}} \\ &\prod_{i=1}^{M} C_{V_i} = \mathrm{com}_{ck}^{(2)}(c_{v_1}, \dots, c_{v_m}) & \text{where} & c_{v_j} = \prod_{i=1}^{M} c_{v_{ij}} \\ &\prod_{i=1}^{M} C_{W_i}^{x^{i(m+1)n}} = \mathrm{com}_{ck}^{(2)}(c_{w_1}, \dots, c_{w_m}) & \text{where} & c_{w_j} = \prod_{i=1}^{M} c_{w_{ij}}^{x^{i(m+1)n}} \end{split}$$

and at the same time computes and opens

$$\prod_{j=1}^{m} c_{u_{j}}^{x^{jn}} = \text{com}_{ck}(u_{1}, \dots, u_{n}; r) \qquad \text{where} \qquad u_{k} = \sum_{i=1}^{M} \sum_{j=1}^{m} u_{ijk} x^{i(m+1)n+jn}$$

$$\prod_{j=1}^{m} c_{v_{j}} = \text{com}_{ck}(v_{1}, \dots, v_{n}; s) \qquad \text{where} \qquad v_{k} = \sum_{i=1}^{M} \sum_{j=1}^{m} v_{ijk}$$

$$\prod_{j=1}^{m} c_{w_{j}}^{x^{jn}} = \text{com}_{ck}(w_{1}, \dots, w_{n}; t) \qquad \text{where} \qquad w_{k} = \sum_{i=1}^{M} \sum_{j=1}^{m} w_{ijk} x^{i(m+1)n+jn}$$

Using only 3m commitments and 3m + 3 elements in \mathbb{Z}_p this tells the verifier

$$u_k x^k = \sum_{i=1}^M \sum_{j=1}^m u_{ijk} x^{i(m+1)n+jn+k} \qquad v_k = \sum_{i=1}^M \sum_{j=1}^m v_{ijk}$$
$$w_k x^k = \sum_{i=1}^M \sum_{j=1}^m w_{ijk} x^{i(m+1)n+jn+k}.$$

We now have that

$$\begin{split} &\sum_{k=1}^{n}(u_{k}v_{k}-w_{k})x^{k} \\ &=\sum_{k=1}^{n}\left((\sum_{i=1}^{M}\sum_{j=1}^{m}u_{ijk}x^{i(m+1)n+jn+k})(\sum_{i'=1}^{M}\sum_{j'=1}^{m}v_{i'j'k})-\sum_{i=1}^{M}\sum_{j=1}^{m}w_{ijk}x^{i(m+1)n+jn+k}\right) \end{split}$$

contains the desired polynomial from (1) but there are some cross-terms corresponding to $i \neq i'$ or $j \neq j'$ so the polynomial given above may be non-zero.

We will choose the a_{α} and b_{β} values such that they cancel out the cross-terms. However, we have to be careful that there are only O(M+m+n) of them and that they are feasible to compute. We will therefore use an interactive technique that will enable the verifier to pick a_{α} and b_{α} after seeing x. This introduces a second concern, namely to choose them in a way such that they do not affect the original equality we wish to get. We accomplish this by making sure that a_{α} and b_{β} are modified by factors y^{α} and z^{β} for $\alpha, \beta \neq 0$ while the desired equality does not contain any such factors. To make this happen we will modify the opening process of the commitments C_{U_i} and C_{V_i} described above to open

$$\prod_{i=1}^{M} C_{U_i}^{x^{i(m+1)n}y^i} = \operatorname{com}_{ck}^{(2)}(c_{u_1}, \dots, c_{u_m}) \qquad \prod_{j=1}^{m} c_{u_j}^{x^{jn}z^j} = \operatorname{com}_{ck}(u_1, \dots, u_n; r)
\prod_{i=1}^{M} C_{V_i}^{y^{-i}} = \operatorname{com}_{ck}^{(2)}(c_{u_1}, \dots, c_{u_m}) \qquad \prod_{j=1}^{m} c_{v_j}^{z^{-j}} = \operatorname{com}_{ck}(v_1, \dots, v_n; r)$$

This gives us

$$u_k x^k = \sum_{i=1}^M \sum_{j=1}^m u_{ijk} x^{i(m+1)n+jn+k} y^i z^j$$
 $v_k = \sum_{i=1}^M \sum_{j=1}^m v_{ijk} y^{-i} z^{-j}.$

We now have

$$\sum_{k=1}^{n} u_k x^k v_k = \sum_{k=1}^{n} \left(\sum_{i=1}^{M} \sum_{j=1}^{m} u_{ijk} x^{i(m+1)n+jn+k} y^i z^j \right) \left(\sum_{i'=1}^{M} \sum_{j'=1}^{m} v_{i'j'k} y^{-i'} z^{-j'} \right)$$

$$= \sum_{k=1}^{n} \sum_{i=1}^{M} \sum_{i'=1}^{M} \sum_{j=1}^{m} \sum_{j'=1}^{m} u_{ijk} x^{i(m+1)n+jn+k} v_{i'j'k} y^{i-i'} z^{j-j'}$$

By splitting the sum into three parts corresponding to the three cases j=j', i=i' and $j=j', i\neq i'$ and $j\neq j'$ and subtracting the w_kx^k 's we get

$$\sum_{k=1}^{n} (u_{k}v_{k} - w_{k})x^{k} = \sum_{k=1}^{n} \sum_{i=1}^{M} \sum_{j=1}^{m} (u_{ijk}v_{ijk} - w_{ijk})x^{i(m+1)n+jn+k}$$

$$+ \sum_{k=1}^{n} \sum_{i=1}^{M} \sum_{i'=1}^{M} \sum_{j=1}^{m} u_{ijk}x^{i(m+1)n+jn+k} v_{i'jk}y^{i-i'}$$

$$+ \sum_{k=1}^{n} \sum_{i=1}^{M} \sum_{i'=1}^{M} \sum_{j=1}^{m} \sum_{j'=1}^{m} u_{ijk}x^{i(m+1)n+jn+k} v_{i'j'k}y^{i-i'}z^{j-j'}$$

$$= \sum_{k=1}^{n} \sum_{i=1}^{M} \sum_{j=1}^{m} (u_{ijk}v_{ijk} - w_{ijk})x^{i(m+1)n+jn+k}$$

$$+ \sum_{\substack{\alpha = -M \\ \alpha \neq 0}}^{M} \sum_{i=1,i'=1}^{M,M} \sum_{k=1}^{n} \sum_{j=1}^{m} u_{ijk}x^{i(m+1)n+jn+k} v_{i'jk}y^{\alpha}$$

$$+ \sum_{\substack{\beta = -m \\ \beta \neq 0}}^{m} \sum_{i=i'=n}^{m,m} \sum_{k=1}^{n} (\sum_{i=1}^{M} u_{ijk}x^{i(m+1)n+jn+k}y^{i})(\sum_{i'=1}^{M} v_{i'j'k}y^{-i'})z^{\beta}$$

The prover will select

$$a_{\alpha} = \sum_{\substack{i=1,i'=1\\i-i'=\alpha}}^{M,M} \sum_{k=1}^{n} \sum_{j=1}^{m} u_{ijk} x^{i(m+1)n+jn+k} v_{i'jk}$$

$$b_{\beta} = \sum_{\substack{j=1,j'=1\\i-j'=\beta}}^{m,m} \sum_{k=1}^{n} (\sum_{i=1}^{M} u_{ijk} x^{i(m+1)n+jn+k} y^{i}) (\sum_{i'=1}^{M} y^{i} v_{i'j'k} y^{-i'})$$

and send the commitments $\{c_{a_{\alpha}}\}_{\alpha}$ before seeing y and send $\{c_{b_{\beta}}\}_{\beta}$ before seeing z. She will reveal randomness $R \in \mathbb{Z}_p$ such that

$$\prod_{\substack{\alpha=-M\\\alpha\neq 0}}^{M} c_{a_{\alpha}}^{y^{\alpha}} \cdot \prod_{\substack{\beta=-m\\\beta\neq 0}}^{m} c_{b_{\beta}}^{z^{\beta}} = \operatorname{com}_{ck}(\sum_{k=1}^{n} (u_{k}v_{k} - w_{k})x^{k}; R).$$

This corresponds to the values in the commitments satisfying

$$\sum_{\substack{\alpha = -M \\ \alpha \neq 0}}^{M} a_{\alpha} y^{\alpha} + \sum_{\substack{\beta = -m \\ \beta \neq 0}}^{m} b_{\beta} z^{\beta} = \sum_{k=1}^{n} (u_k v_k - w_k) x^k.$$

Keeping in mind the expansion of the right hand side (2) we get that with overwhelming probability over y, z this can only be true if equation (1) holds.

In order to make the protocol SHVZK we add some commitments and values such that $c_{u_j}, c_{v_j}, c_{w_j}$ and u_k, v_k, w_k cannot reveal anything about $u_{ijk}, v_{ijk}, w_{ijk}$. Furthermore, we add some d_k values and c_{d_k} commitments to cancel out new cross-terms arising from the added values. This gives us the full batch product argument below.

Common reference string: Two-tiered commitment key ck.

Statement: Commitments $C_{U_1}, C_{V_1}, C_{W_1}, \dots, C_{U_M}, C_{V_M}, C_{W_M} \in \mathbb{T}$.

Prover's witness: Values $u_{111}, v_{111}, w_{111}, \dots, u_{Mmn}, v_{Mmn}, w_{Mmn} \in \mathbb{Z}_p$ and randomness $r_{11}, s_{11}, t_{11}, \dots, r_{Mm}, s_{Mm}, t_{Mm} \in \mathbb{Z}_p$ such that for all $i \in \{1, \dots, M\}, j \in \{1, \dots, m\}, k \in \{1, \dots, n\}$:

$$c_{u_{ij}} = com_{ck}(u_{ij1}, \dots, u_{ijn}; r_{ij}) \qquad C_{U_i} = com_{ck}^{(2)}(c_{u_{i1}}, \dots, c_{u_{im}})$$

$$c_{v_{ij}} = com_{ck}(v_{ij1}, \dots, v_{ijn}; s_{ij}) \qquad C_{V_i} = com_{ck}^{(2)}(c_{v_{i1}}, \dots, c_{v_{im}})$$

$$\prod_{k=1}^{n} c_{d_{k}}^{x^{k}} \cdot \prod_{\substack{\alpha = -M \\ \alpha \neq 0}}^{M} c_{a_{\alpha}}^{y^{\alpha}} \cdot \prod_{\beta = -m \\ \beta \neq 0}^{m} c_{b_{\beta}}^{z^{\beta}} = \operatorname{com}_{ck}(\sum_{k=1}^{n} (u_{k} v_{k} - w_{k}) x^{k}; R)$$

Theorem 1 (Full paper). The argument given above has perfect completeness, perfect SHVZK and witness-extended emulation if the two-tiered commitment scheme is binding.

Complexity. The communication complexity of the batch product argument is 3 elements in \mathbb{T} , 2M + 5m + n + 1 elements in \mathbb{G} and 3n + 7 elements in \mathbb{Z}_p .

Let us estimate the computation complexity assuming that we use the two-tiered commitment scheme we described in Section 2.1 in an asymmetric bilinear group with base groups \mathbb{G} , $\hat{\mathbb{G}}$ and target group \mathbb{T} . The verifier's computation is 3m pairings and exponentiations in the target group \mathbb{T} and 5M+2m+4n exponentiations in the base group \mathbb{G} . Using standard techniques for batch verification some of the equations can be combined in a randomized manner and we may also use multi-exponentiation techniques to reduce the complexity further to $O(\frac{M+m+n}{\log(M+m+n)})$ exponentiations.

A naïve implementation of the prover would require 3m pairings and O(M+m+n) exponentiations and O(N(M+m)) multiplications in \mathbb{Z}_p , where N-Mmn. When M or m are large the latter complexity dominates.

We can use techniques for polynomial multiplication to reduce the prover's computation. Consider as an example the computation in round 3, where the prover computes

$$a_{\alpha} = \sum_{\substack{i=0, i'=0\\ i-i'=\alpha}}^{M,M} \sum_{j=0}^{m} \sum_{k=1}^{n} (u_{ijk} x^{i(m+1)n+jn+k}) v_{i'jk}$$

for $\alpha = -M, \ldots, -1, 1, \ldots, M$. Define $\boldsymbol{u}_i = (u_{i01}x^{i(m+1)n+0n+1}, \ldots, u_{imn}x^{i(m+1)n+mn+n})$ and $\boldsymbol{v}_{i'} = (v_{i'01}, \ldots, v_{i'mn})$, which allows us to rewrite it as

$$a_{\alpha} = \sum_{\substack{i=0,i'=0\\i-i'=\alpha}}^{M,M} \boldsymbol{u}_{i} \boldsymbol{v}_{i'}^{\top}.$$

Observe that a_{α} is the $M + \alpha$ 'th coefficient of the polynomial

$$p(\omega) = \left(\sum_{i=0}^{M} \omega^{i} \boldsymbol{u}_{i}\right) \left(\sum_{i'=0}^{M} \omega^{M-i'} \boldsymbol{v}_{i'}^{\top}\right) \in \mathbb{Z}_{p}[\omega].$$

The degree of the polynomial is 2M so if we evaluate it in 2M+1 different points $\omega_1,\ldots,\omega_{2M+1}\in\mathbb{Z}_p$ we can use polynomial interpolation to recover the coefficients. The evaluation of $\sum_{i=0}^M \omega^i u_i$ and $\sum_{i'=0}^M \omega^{M-i'} v_{i'}^\top$ in 2M+1 different points can be done using $O(N\log^2 M)$ multiplications. If 2M|p-1 and M is a power of 2 we can pick $\omega_1,\ldots,\omega_{2M}$ as 2M-roots of unity, i.e., $\omega_k^{2M}=1$ and use the Fast Fourier Transform to reduce the cost further down to $O(N\log M)$ multiplications. Similarly, we can compute $b_{-m},\ldots,b_{-1},b_1,\ldots,b_m$ using $O(N\log^2 m)$ multiplications or $O(N\log m)$ multiplications if 2m|p-1 and m is a power of 2.

Known values. Sometimes it will be useful to use publicly known values u_{ijk} in the argument. The trivial way to handle this is to use commitments $c_{u_{ij}} = \cos_{ck}(u_{ij1},\ldots,u_{ijn};0)$. Since they use trivial randomness, the verifier can check directly that C_{U_1},\ldots,C_{U_M} contain the correct values. A more careful inspection reveals

³ It takes a while before the assymptotic behaviour kicks in, so for small M it may be better to use Toom-Cook related methods for computing the coefficients a_{-M}, \ldots, a_{M} .

444

that some efficiency savings can be made by abandoning the commitments $c_{u_{ij}}$ altogether. Since the u_{ijk} values are public we do not need to hide them, so the prover may choose $u_{0ik} = 0$. The verifier can now herself compute the resulting u_k values without using the commitments at all.

A similar analysis reveals that when w_{ijk} are known the prover does not need to communicate any C_{W_i} or c_{w_i} commitments since the verifier can compute w_k himself. In the special case where $w_{ijk} = 0$ this simplifies to fixing $w_k = 0$.

Inner Product Argument

A slight modification of the batch product argument allows the prover to demonstrate instead $\sum_{i=1}^{M}\sum_{j=1}^{m}\sum_{k=1}^{n}u_{ijk}v_{ijk}=\sum_{i=1}^{M}\sum_{j=1}^{m}\sum_{k=1}^{n}w_{ijk}$. The main observation is that we can fix x=1 instead of letting the verifier choose it, in which case equation (1) gives us the desired equality.

The only issue in following this idea is the cross-terms arising from u_{0jk},v_{0jk},w_{0jk} . We therefore compute $C^x_{U_0},C^x_{V_0},C^x_{W_0},c^x_{u_{00}},c^x_{v_{00}},c^x_{w_{00}}$ giving us commitments to $u_{0jk}x, v_{0jk}x, w_{0jk}x$. Since $x \in \mathbb{Z}_p^*$ these values will still ensure that $c_{u_i}, c_{v_i}, c_{w_i}, u_k, v_k, w_k$ do not leak any information about $u_{ijk}, v_{ijk}, w_{ijk}$. But since they are modified by a random factor x throughout the argument they will not interfere with the equation $\sum_{i=1}^{M}\sum_{j=1}^{m}\sum_{k=1}^{n}u_{ijk}v_{ijk}=\sum_{i=1}^{M}\sum_{j=1}^{m}\sum_{k=1}^{m}w_{ijk}$. To get perfect completeness, we use two commitments to d_1 and d_2 values to cancel out crossterms corresponding to x and x^2 .

Arguments for Circuit Satisfiability

Using the batch product argument from Section 3 we can give a 7-move SHVZK argument for circuit satisfiability. Consider a boolean circuit consisting of N-1 NANDgates where the prover wants to convince the verifier that there is a satisfying assignment making the circuit output 1. If the output wire is w, we can add a new variable uand add a self-looping gate of the form $w = \neg(w \land u)$, which can only be satisfied if w=1. The prover now has a circuit with N NAND-gates and no output and wants to demonstrate that there is an internally consistent assignment to the wires that respects all gates.

Let us without loss of generality consider a circuit with N = Mmn NAND-gates for which the prover wants to demonstrate that there is a consistent assignment. The prover enumerates the two inputs and the output of each gate as $u_{ijk}, v_{ijk}, w_{ijk}$. The task is now to show that the committed values correspond to a satisfying assignment for the circuit.

The prover first shows that all the committed values are either 0 or 1 corresponding to truth values. This is done by using batch product arguments to show $u_{ijk}u_{ijk} =$ $u_{ijk}, v_{ijk}v_{ijk} = v_{ijk}$ and $w_{ijk}w_{ijk} = w_{ijk}$, which can only be true if $u_{ijk}, v_{ijk}, w_{ijk} \in$ $\{0,1\}.$

The prover then uses the homomorphic property of the commitment scheme to compute commitments to $1 - w_{ijk}$. Using another batch product argument it can show $u_{ijk}v_{ijk} = 1 - w_{ijk}$, which means the committed values respect the NAND-gates.

Finally, using a technique from [22] it uses an inner product argument to show that all committed values u_{ijk}, v_{ijk} and w_{ijk} corresponding to the same wire x_ℓ are consistent with each other. We describe this technique in the full circuit satisfiability argument below.

Common reference string: Two-tiered commitment key ck.

Statement: N = Mmn NAND-gates $x_{\ell_2} = \neg (x_{\ell_0} \land x_{\ell_1})$ over variables x_{ℓ} .

Prover's witness: An assignment to $\{x_{\ell}\}$ respecting all NAND-gates.

Argument: Label the inputs and outputs of the gates $\{u_{ijk}, v_{ijk}, w_{ijk}\}_{i=1,j=1,k=1}^{M,m,n}$. Pick $r_{ij}, s_{ij}, t_{ij} \leftarrow \mathbb{Z}_p$ and compute the commitments

$$c_{u_{ij}} = com_{ck}(u_{ij1}, \dots, u_{ijn}; r_{ij}) \qquad C_{U_i} = com_{ck}^{(2)}(c_{u_{i1}}, \dots, c_{u_{im}})$$

$$c_{v_{ij}} = com_{ck}(v_{ij1}, \dots, v_{ijn}; s_{ij}) \qquad C_{V_i} = com_{ck}^{(2)}(c_{v_{i1}}, \dots, c_{v_{im}})$$

$$c_{w_{ij}} = com_{ck}(w_{ij1}, \dots, w_{ijn}; t_{ij}) \qquad C_{W_i} = com_{ck}^{(2)}(c_{w_{i1}}, \dots, c_{w_{im}})$$

Send $\{C_{U_i}, C_{V_i}, C_{W_i}\}_{i=1}^M$ to the verifier.

Engage in three batch product arguments with statements $\{C_{U_i}, C_{U_i}, C_{U_i}\}_{i=1}^M$, $\{C_{V_i}, C_{V_i}, C_{V_i}\}_{i=1}^M$ and $\{C_{W_i}, C_{W_i}, C_{W_i}\}_{i=1}^M$ in order to show that $u_{ijk}, v_{ijk}, w_{ijk} \in \{0, 1\}$.

Define $c_1=\mathrm{com}_{ck}(1,\ldots,1;0)$ and $C_1=\mathrm{com}_{ck}^{(2)}(c_1,\ldots,c_1)$. Engage in a batch product proof with statement $\{C_{U_1},C_{V_1},C_1C_{W_i}^{-1}\}_{i=1}^M$ to show that the NAND-gates are respected.

There are 3N=3Mmn committed values $u_{ijk}, v_{ijk}, w_{ijk}$. Let us rename them $\{b_i\}_{i=1}^{3N}$ and the corresponding commitments to $\{C_{B_i}\}_{i=1}^{3M}$. The same variable x_ℓ may appear n_ℓ times in the circuit as $b_{i_1},\ldots,b_{i_{n_\ell}}$. Define π as the permutation in S_{3N} such that for each variable x_ℓ appearing n_ℓ times in the circuit the permutation makes a complete cycle $i_1 \to i_2 \to \ldots \to i_{n_\ell} \to i_1$ corresponding to those appearances.

The prover receives a challenge y from the verifier and defines $a_i = y^i - y^{\pi(i)}$. It uses the inner product argument⁴ from Section 3.1 to demonstrate $\sum_{i=1}^{3N} a_i b_i = 0$. This shows that for random y

$$\sum_{i=1}^{3N} a_i b_i = \sum_{i=1}^{3N} (y^i - y^{\pi(i)}) b_i = \sum_{i=1}^{3N} y^i (b_i - b_{\pi^{-1}(i)}) = 0.$$

With overwhelming probability over y this shows $b_{\pi(i)} = b_i$ for all i thus proving that the values b_i and hence the values $u_{ijk}, v_{ijk}, w_{ijk}$ are consistent with the wires x_{ℓ} .

Verification: Verify the 4 batch product proofs and the inner product argument.

Theorem 2 (Full paper). The argument for circuit satisfiability has perfect completeness, perfect SHVZK and witness-extended emulation.

 $^{^4}$ The first round of the inner product argument can be run independently of y such that the total round complexity remains 7.

Arithmetic circuits. Using similar techniques as in the circuit satisfiability argument, we can also get an argument for the satisfiability of arithmetic circuits consisting of addition and multiplication gates over \mathbb{Z}_p . The prover commits to the values and uses the homomorphic property of the commitment scheme to show that addition gates are respected and the batch product argument to show that multiplication gates are respected. If there are publicly known constants (without loss of generality a multiple of mn) involved in the circuit, the prover commits to these using randomness 0 so the verifier can check directly that they are correct. As in the circuit satisfiability argument the prover also demonstrates that the committed values are consistent with the wiring of the arithmetic circuit. This gives an arithmetic circuit argument with communication complexity O(M+m+n).

5 Range Arguments

As a concrete application of our batch product argument we will give a communicationefficient range proof. The prover has a commitment c and wants to convince the verifier that she knows an opening w, t such that $c = com_{ck}(w;t)$ and $w \in [A;B)$. Since the commitment is homomorphic, the problem can be simplified to demonstrating that she knows an opening of $c \cdot \text{com}_{ck}(-A; 0)$ in the range [0; B - A). Let $N = \lfloor \log(B - A) \rfloor$. The prover can construct a commitment $c_{0/1} = \mathrm{com}_{ck}(b;s)$ and show that it contains 0or 1 using standard techniques. By showing that $c \cdot \mathrm{com}_{ck}(-A;0) \cdot c_{0/1}^{A-B+2^N}$ contains a value in the range $[0; 2^N)$ she convinces the verifier that $w \in [A; B]$.

We can therefore without loss of generality focus on demonstrating that a committed value w belongs to the interval $[0; 2^N)$. We will now give such a range argument that only communicates $O(N^{\frac{1}{3}})$ elements. The idea is that the prover will commit to the bit representation of w. Using a batch product argument the prover can demonstrate that the committed bits are 0 or 1. Furthermore, using techniques similar to the buildup of w_k in the batch product argument the prover will demonstrate that $w=\sum_{i=1}^M\sum_{j=1}^m\sum_{k=1}^nw_{ijk}2^{imn+jn+k-1}$ using O(M+m+n) communication. If $M = O(N^{\frac{1}{3}})$, $m = O(N^{\frac{1}{3}})$, $n = O(N^{\frac{1}{3}})$ the communication complexity is $O(N^{\frac{1}{3}})$ elements.

Common reference string: ck.

Statement: $c \in \mathbb{G}$.

Prover's witness: $w,t\in\mathbb{Z}_p$ such that $w\in[0;2^N)$ and $c=\mathrm{com}_{ck}(w;t)$. Argument: Let $\{w_{ijk}\}_{i=1,j=1,k=1}^{M,m,n}$ be the bits of w. Pick $r_{ij}\leftarrow\mathbb{Z}_p$ and compute

$$c_{w_{ij}} = \operatorname{com}_{ck}(w_{ij1}, \dots, w_{ijn}; r_{ij}) \ C_{W_i} = \operatorname{com}_{ck}^{(2)}(c_{w_{i1}}, \dots, c_{w_{im}}) \ c_{w_j} = \prod_{i=1}^{M} c_{w_{ij}}^{2^{imn}}.$$

Pick $w_{01},\ldots,w_{0n}\leftarrow\mathbb{Z}_p$ and $r_0,s_d\leftarrow\mathbb{Z}_p$ and compute $c_{w_0}=\mathrm{com}_{ck}(w_{01},\ldots,w_{0n};r_0)$ and $c_d=\mathrm{com}_{ck}(\sum_{k=1}^n w_{0k}2^{k-1};s_d)$. Send $\{C_{W_i}\}_{i=1}^M,\{c_{w_j}\}_{j=0}^m$ and c_d to the verifier and get a challenge $x\leftarrow\mathbb{Z}_p^*$ back. Compute

$$w_k = xw_{0k} + \sum_{i=1}^{M} \sum_{j=1}^{m} w_{ijk} 2^{imn+jn}$$
 $r = xr_0 + \sum_{i=1}^{M} \sum_{j=1}^{m} r_{ij} 2^{imn+jn}$ $s = s_d x + t$

and send them to the verifier.

In parallel, engage in a batch product argument with statement $\{C_{W_i}, C_{W_i}, C_{W_i}\}_{i=1}^M$ to show that each w_{ijk} satisfies $w_{ijk}w_{ijk} = w_{ijk}$, which implies $w_{ijk} \in \{0,1\}$.

Verification: Verify that the batch product argument is valid and

$$\prod_{i=1}^{M} C_{W_i}^{2^{imn}} = \operatorname{com}_{ck}^{(2)}(c_{w_1}, \dots, c_{w_m}) \qquad c_{w_0}^x \prod_{j=1}^m c_{w_j}^{2^{jn}} = \operatorname{com}_{ck}(w_1, \dots, w_n; r)$$

$$c_d^x c = \operatorname{com}_{ck}(\sum_{k=1}^n w_k 2^{k-1}; s).$$

Theorem 3 (Full paper). The range argument given above has perfect completeness, perfect SHVZK and witness-extended emulation.
