

On the Undecidability of Asynchronous Session Subtyping

Julien Lange^(✉) and Nobuko Yoshida

Imperial College London, London, UK
j.lange@imperial.ac.uk

Abstract. Asynchronous session subtyping has been studied extensively in [9, 10, 28–31] and applied in [23, 32, 33, 35]. An open question was whether this subtyping relation is decidable. This paper settles the question in the negative. To prove this result, we first introduce a new sub-class of two-party communicating finite-state machines (CFSMs), called asynchronous duplex (ADs), which we show to be Turing complete. Secondly, we give a compatibility relation over CFSMs, which is sound and complete wrt. safety for ADs, and is equivalent to the asynchronous subtyping. Then we show that the halting problem reduces to checking whether two CFSMs are in the relation. In addition, we show the compatibility relation to be decidable for three sub-classes of ADs.

1 Introduction

Session types [22, 24, 34] specify the expected interaction patterns of concurrent systems and can be used to automatically determine whether communicating processes interact correctly with other processes. A crucial theory in session types is *subtyping* which makes the typing discipline more flexible and therefore easier to integrate in real programming languages and systems [1]. The first subtyping relations for session types targeted synchronous communications [6, 7, 18, 19], by allowing subtypes to make fewer selections and offer more branches. More recent relations treat asynchronous (buffered) communications [9, 10, 12, 13, 16, 28–31]. They include synchronous subtyping and additionally allow an optimisation by message permutations where outputs can be performed in advance without affecting correctness with respect to the delayed inputs (there are two buffers per session). Only the relative order of outputs (resp. inputs) needs to be preserved to avoid communication mismatches. The asynchronous subtyping is important in parallel and distributed session-based implementations [23, 32, 33, 35], as it reduces message synchronisations without safety violation.

Theoretically, the asynchronous subtyping has been shown to be *precise*, in the sense that: (i) if T is a subtype of U , then a process of type T may be used whenever a process of type U is required and (ii) if T is *not* a subtype of U , then there is a system, requiring a process of type U , for which using a process of type T leads to an error (e.g., deadlock). The subtyping is also denotationally

See [27] for a full version of this paper (with proofs and additional examples).

Fig. 1. Asynchronous subtyping and compatibility: examples.

precise taking the standard interpretation of type T as the set of processes typed by T [9, 16].

An open question in [9, 10, 28–31] was whether the asynchronous subtyping relation is decidable, i.e., is there an algorithm to decide whether two types are in the relation. The answer to that question was thought to be positive, see [10, Sect. 7] and Sect. 6.

Asynchronous Subtyping, Informally. In this work, we consider session types in the form of CFSMs [4], along the lines of [3, 14, 15, 25]. This enables us to characterise the asynchronous subtyping in CFSMs and reduce the undecidability problem to the Turing completeness of CFSMs. Consider a system of CFSMs consisting of machines M_s (server) and M_c (client) in Fig. 1, which communicate via two unbounded queues, one in each direction. A transition $!a$ represents the (asynchronous) emission of a message a , while $?a$ represents the receptions of a message a from a buffer. For instance, the transition labelled by $!req$ in M_c says that the client sends a request to the server M_s , later the server can consume this message from its buffer by firing the transition labelled by $?req$. We say that the system (M_s, M_c) , i.e., the parallel composition of M_s and M_c , is *safe* if (i) the pair never reaches a deadlock and (ii) whenever a message is sent by one party, it will eventually be received by the other.

The key property of session subtyping is that, e.g., if the system (M_s, M'_c) is safe and M_c is a subtype of M'_c , the system (M_s, M_c) is also safe. We write \leq_a for the asynchronous subtyping relation, which intuitively requires that, if, e.g., $M_c \leq_a M'_c$, then M_c is ready to receive no fewer messages than M'_c and it may not send more messages than M'_c . For instance, M_c can receive all the messages that M'_c can handle, plus the message *err*. Observe that M_c is an optimised version of M'_c wrt. asynchrony: the output action $!data$ is performed in advance of the branching. Thus in the system (M_s, M_c) , when both machines are in state 2 (respectively), both queues contain messages. Instead, in the system (M_s, M'_c) , it is never the case that both queues are non-empty. Note that anticipating the sending of *data* in M_c does not affect safety as it is sent in both branches of M'_c .

Our Approach. Using CFSMs, we give the first automata characterisation of asynchronous subtyping and the first proof of its undecidability. To do this, we introduce a new sub-class of CFSMs, called *asynchronous duplex* (AD) which let

us study directly the relationship between safety and asynchronous subtyping in CFSMs. Our development consists of the following steps:

- Step 1.** In Sect. 2, we define a new sub-class of (two-party) CFSMs, called asynchronous duplex (AD), which strictly includes *half-duplex* (HD) systems [8].
- Step 2.** In Sect. 3, we introduce a compatibility relation (\asymp) for CFSMs which is sound and complete wrt. safety in AD CFSMs, i.e., an AD system has no deadlocks nor orphan messages if and only if its machines are \asymp -related.
- Step 3.** Adapting the result of [17], we show in Sect. 4 that AD systems are Turing complete, hence membership of \asymp is generally undecidable.
- Step 4.** In Sect. 5, we show that the \asymp -relation for CFSMs is equivalent to the asynchronous subtyping for session types, thus establishing that the latter is also undecidable.

Throughout the paper, we also show that our approach naturally encompasses the correspondence between synchronous subtyping and safety in HD systems.

In Sect. 4.1, we show that the \asymp -relation is decidable for three sub-classes of CFSMs (HD, alternating [21], and non-branching) which are useful to specify real-world protocols. In Sect. 6, we discuss related works and conclude.

2 A New Class of CFSMs: Asynchronous Duplex Systems

This section develops **Step 1** by defining a new sub-class of CFSMs, called *asynchronous duplex*, which characterises machines that can only simultaneously write on their respective channels if they can only do so for finitely many consecutive send actions before executing a receive action. In Sect. 2.1, we recall definitions about CFSMs, then we give the definition of safety. In Sect. 2.2, we introduce the sub-class of AD systems and give a few examples of such systems.

2.1 CFSMs and Their Properties

Let \mathbb{A} be a (finite) alphabet, ranged over by a, b , etc. We let ω, π , and φ range over words in \mathbb{A}^* and write \cdot for the concatenation operator. The set of actions is $Act = \{!, ?\} \times \mathbb{A}$, ranged over by ℓ , $!a$ represents the emission of a message a , while $?a$ represents the reception of a . We let ψ range over Act^* and define $dir(!a) \stackrel{\text{def}}{=} !$ and $dir(?a) \stackrel{\text{def}}{=} ?$.

Since our ultimate goal is to relate CFSMs and session types, we only consider deterministic communicating finite-state machines, without mixed states (i.e., states that can fire both send and receive actions) as in [14, 15].

Definition 2.1 (Communicating machine). A (communicating) machine M is a tuple (Q, q_0, δ) where Q is the (finite) set of states, $q_0 \in Q$ is the initial state, and $\delta \subseteq Q \times Act \times Q$ is the transition relation such that $\forall q, q', q'' \in Q : \forall \ell, \ell' \in Act : (1) (q, \ell, q'), (q, \ell', q'') \in \delta \implies dir(\ell) = dir(\ell')$, and (2) $(q, \ell, q'), (q, \ell, q'') \in \delta \implies q' = q''$.

We write $q \xrightarrow{\ell} q'$ for $(q, \ell, q') \in \delta$, omit the label ℓ when unnecessary, and write \rightarrow^* for the reflexive transitive closure of \rightarrow .

Given $M = (Q, q_0, \delta)$, we say that $q \in Q$ is *final*, written $q \dashv$, iff $\forall q' \in Q : \forall \ell \in \text{Act} : (q, \ell, q') \notin \delta$. A state $q \in Q$ is *sending* (resp. *receiving*) iff q is not final and $\forall q' \in Q : \forall \ell \in \text{Act} : (q, \ell, q') \in \delta : \text{dir}(\ell) = !$ (resp. $\text{dir}(\ell) = ?$). The dual of M , written \bar{M} , is M where each sending transition $(q, !a, q') \in \delta$ is replaced by $(q, ?a, q')$, and vice-versa for receive transitions, e.g., $\bar{M}_s = M'_c$ in Fig. 1.

We write $q_0 \xrightarrow{\ell_1 \dots \ell_k} q_k$ iff there are $q_1, \dots, q_{k-1} \in Q$ such that $q_{i-1} \xrightarrow{\ell_i} q_i$ for $1 \leq i \leq k$. Given a list of messages $\omega = a_1 \dots a_k$ ($k \geq 0$), we write $? \omega$ for the list $?a_1 \dots ?a_k$ and $! \omega$ for $!a_1 \dots !a_k$. We write $q \xrightarrow{! \omega}^* q'$ iff $\exists \omega \in \mathbb{A}^* : q \xrightarrow{! \omega} q'$ and $q \xrightarrow{? \omega}^* q'$ iff $\exists \omega \in \mathbb{A}^* : q \xrightarrow{? \omega} q'$ (note that ω may be empty, in which case $q = q'$).

Definition 2.2 (System). A system $S = (M_1, M_2)$ is a pair of machines $M_i = (Q_i, q_{0_i}, \delta_i)$ with $i \in \{1, 2\}$.

Hereafter, we fix $S = (M_1, M_2)$ and assume $M_i = (Q_i, q_{0_i}, \delta_i)$ for $i \in \{1, 2\}$ such that $Q_1 \cap Q_2 = \emptyset$. Hence, for $q, q' \in Q_i$, we can write $q \xrightarrow{\ell} q'$ to refer unambiguously to δ_i .

We let λ range over the set $\{ij!a \mid i \neq j \in \{1, 2\}\} \cup \{ij?a \mid i \neq j \in \{1, 2\}\}$ and ϕ range over (possibly empty) sequences of $\lambda_1 \dots \lambda_k$.

Definition 2.3 (Reachable configuration). A configuration of S is a tuple $s = (q_1, \omega_1, q_2, \omega_2)$ such that $q_i \in Q_i$, and $\omega_i \in \mathbb{A}^*$. A configuration $s' = (q'_1, \omega'_1, q'_2, \omega'_2)$ is reachable from $s = (q_1, \omega_1, q_2, \omega_2)$, written $s \xRightarrow{\lambda} s'$, iff

1. $q_i \xrightarrow{!a} q'_i$, $\omega'_i = \omega_i \cdot a$, $q_j = q'_j$, and $\omega_j = \omega'_j$, $\lambda = ij!a$, for $i \neq j \in \{1, 2\}$, or
2. $q_i \xrightarrow{?a} q'_i$, $\omega_j = a \cdot \omega'_j$, $q_j = q'_j$, and $\omega_i = \omega'_i$, $\lambda = ji?a$, for $i \neq j \in \{1, 2\}$.

We write $s \Rightarrow s'$ when the label is irrelevant and \Rightarrow^* for the reflexive and transitive closure of \Rightarrow .

In Definition 2.3, (1) says that machine M_i puts a message on queue i , to be received by machine M_j , while (2) says that machine M_i consumes a message from queue j , which was sent by M_j .

Given a system S , we write s_0 for its initial configuration $(q_{0_1}, \epsilon, q_{0_2}, \epsilon)$ and let $RS(S) \stackrel{\text{def}}{=} \{s \mid s_0 \Rightarrow^* s\}$.

Definition 2.4 (Safety). A configuration $s = (q_1, \omega_1, q_2, \omega_2)$ is a deadlock iff $\omega_1 = \omega_2 = \epsilon$, q_i is a receiving state, and q_j is either receiving or final for $i \neq j \in \{1, 2\}$. System S satisfies eventual reception iff $\forall s = (q_1, \omega_1, q_2, \omega_2) \in RS(S) : \forall i \neq j \in \{1, 2\} : \omega_i \in a \cdot \mathbb{A}^* \implies \forall q'_j \in Q_j : q_j \xrightarrow{!}^* q'_j \implies q'_j \xrightarrow{?a}^*$.

S is safe iff (i) for all $s \in RS(S)$, s is not a deadlock, and (ii) S satisfies eventual reception (i.e., every sent message is eventually received).

Lemma 2.1 below shows that safety implies progress and that a configuration with at least one empty buffer is always reachable.

Lemma 2.1. If S is safe, then for all $s = (q_1, \omega_1, q_2, \omega_2) \in RS(S)$

1. Either (i) q_1 and q_2 are final and $\omega_1 = \omega_2 = \epsilon$, or (ii) $\exists s' \in RS(S) : s \Rightarrow s'$.
2. $\exists s', s'' \in RS(S) : s \Rightarrow^* s' = (q_1, \epsilon, q'_2, \omega_2 \cdot \omega'_2) \wedge s \Rightarrow^* s'' = (q''_1, \omega_1 \cdot \omega'_1, q_2, \epsilon)$.

Fig. 2. Examples of AD (left) and non-AD (right) systems.

2.2 Asynchronous Duplex Systems

We define asynchronous duplex systems, a sub-class of two-party CFSMs. Below we introduce a predicate which guarantees that when a machine is in a given state, it cannot send infinitely many messages without executing receive actions periodically. This predicate mirrors one of the premises of the defining rules of the asynchronous subtyping (\leq_a), cf. Lemma 5.1. Given $M = (Q, q_0, \delta)$ and $q \in Q$, we define $\text{fin}(q) \iff \text{fin}(q, \emptyset)$, where

$$\text{fin}(q, R) \stackrel{\text{def}}{=} \begin{cases} \text{true} & \text{if } q \xrightarrow{?a} \\ \forall q' \in \{q' \mid q \xrightarrow{!a} q'\} : \text{fin}(q', R \cup \{q\}) & \text{if } q \xrightarrow{!a} \wedge q \notin R \\ \text{false} & \text{otherwise} \end{cases}$$

Definition 2.5 (Asynchronous duplex). A system $S = (M_1, M_2)$ is Asynchronous Duplex (AD) if for each $s = (q_1, \omega_1, q_2, \omega_2) \in RS(S) : \omega_1 \neq \epsilon \wedge \omega_2 \neq \epsilon \implies \text{fin}(q_1) \wedge \text{fin}(q_2)$.

AD systems are a strict extension of half-duplex systems [8]: S is half-duplex (HD) if for all $(q_1, \omega_1, q_2, \omega_2) \in RS(S) : \omega_1 = \epsilon \vee \omega_2 = \epsilon$. AD requires that for any reachable configuration either (i) at most one channel is non-empty (i.e., it is a half-duplex configuration) or (ii) each machine is in a state where the predicate $\text{fin}(\cdot)$ holds, i.e., each machine will reach a receiving state after firing *finitely* many send actions. The AD restriction is reasonable for real-world systems. It intuitively amounts to say that if two parties are *simultaneously* sending data to each other, they should both ensure that they will periodically check what the other party has been sending.

Example 2.1. Consider the machines in Fig. 2. The system (M_1, M_2) is AD: $\text{fin}(\cdot)$ holds for each state in M_1 and M_2 . The system (\hat{M}_1, \hat{M}_2) is not AD. For instance, the configuration $(0, a, 0, c)$ is reachable but we have $\neg \text{fin}(0)$ for both initial states of \hat{M}_1 and \hat{M}_2 . Observe that both systems are *safe*, cf. Definition 2.4.

3 A Compatibility Relation for CFSMs

This section develops **Step 2**: we introduce a binary relation \succsim on CFSMs which is sound and complete wrt. safety (cf. Definition 2.4) for AD systems. That is $M_1 \succsim M_2$ holds if and only if (M_1, M_2) is a safe asynchronous duplex system.

Definition 3.1 (Compatibility). Let $M_i = (Q_i, q_{0_i}, \delta_i)$ for $i \in \{1, 2\}$ such that $Q_1 \cap Q_2 = \emptyset$, and let $p \in Q_1$, $q \in Q_2$, and $\pi \in \mathbb{A}^*$.

The compatibility relation is defined as follows: $\pi \blacktriangleright p \asymp_0 q$ always holds, and if $k \geq 0$, then $\pi \blacktriangleright p \asymp_{k+1} q$ holds iff

1. if $p \nrightarrow$ then $\pi = \epsilon$ and $q \nrightarrow$
2. if $p \xrightarrow{?a}$ then
 - (a) if $\pi = \epsilon$ then, $q \xrightarrow{!b}$ and $\forall b \in \mathbb{A} : q \xrightarrow{!b} q' \implies (p \xrightarrow{?b} p' \wedge \epsilon \blacktriangleright p' \asymp_k q')$,
 - (b) if $\pi = b \cdot \pi'$ then, $\exists p' \in Q_1 : p \xrightarrow{?b} p' \wedge \pi' \blacktriangleright p' \asymp_k q$
3. if $p \xrightarrow{!a} p'$ then either
 - (a) $\pi = \epsilon$ and $\exists q' \in Q_2 : q \xrightarrow{?a} q' \wedge \epsilon \blacktriangleright p' \asymp_k q'$, or
 - (b) $\text{fin}(p)$, $\text{fin}(q)$, and $\forall q' \in Q_2 : \forall \pi' \in \mathbb{A}^* : q \xrightarrow{! \pi'} q'$, there exist $\pi'' \in \mathbb{A}^*$ and $q'' \in Q_2$ such that $q' \xrightarrow{! \pi''} q'' \xrightarrow{?a} q''$ and $\pi \cdot \pi' \cdot \pi'' \blacktriangleright p' \asymp_k q''$

Define $\pi \blacktriangleright p \asymp q \stackrel{\text{def}}{=} \forall k \in \mathbb{N} : \pi \blacktriangleright p \asymp_k q$ and $M_1 \asymp M_2 \stackrel{\text{def}}{=} \epsilon \blacktriangleright q_{0_1} \asymp q_{0_2}$.

The relation $M_1 \asymp M_2$ checks that the two machines are compatible by executing M_1 while recording what M_2 asynchronously sends to M_1 in the π message list. The definition first differentiates the type of state p :

Final. Case (1) says that if M_1 is in a final state, then M_2 must also be in a final state and π must be empty (i.e., M_1 has emptied its input buffer).

Receiving. Case (2) says that if M_1 is in a receiving state, then either π is empty and M_1 must be ready to receive any message sent by M_2 , cf. case (2a); otherwise, case (2b) must apply: M_1 must consume the head of the message list π , this models the FIFO consumption of messages sent by M_2 .

Sending. Case (3) says that if M_1 is ready to send a , then either M_2 must be able to receive a directly, cf. case (3a). Otherwise, $\text{fin}(p)$ and $\text{fin}(q)$ must hold so that case (3b) applies. M_2 may delay the reception of a by sending messages (which are recorded in $\pi' \cdot \pi''$). Whichever sending path M_2 chooses, it must always eventually receive a .

We write \asymp_s for the *synchronous compatibility relation*, i.e., Definition 3.1 without cases (2b) and (3b).

Example 3.1. (1) Recall the machines from Fig. 1, we have $M_s \asymp M_c$, in particular: $\epsilon \blacktriangleright 0 \asymp 0$ and $\text{data} \blacktriangleright 2 \asymp 0$. The latter relation represents the fact that M_c and M_s have exchanged the messages *req* and *ko*, but M_s has yet to process the reception of *data*. Observe that we also have $M'_s \asymp M'_c$ and $M'_s \asymp_s M'_c$.

(2) Consider the systems in Fig. 2. We have $M_1 \asymp M_2$ and $\hat{M}_1 \not\asymp \hat{M}_2$. The latter does not hold since both initial states are sending states, but the predicate $\text{fin}(-)$ does not hold for either state, e.g., we have $\neg \text{fin}(0, \{0\})$ in \hat{M}_1 .

Soundness of \asymp . We show the soundness of the \asymp -relation wrt. safety. More precisely we show that if $M_1 \asymp M_2$ holds, then the system (M_1, M_2) is a safe AD system. We first give two auxiliary definitions which are convenient to relate safety with the definition of \asymp . Fixing $M = (Q, q_0, \delta)$, the predicate $A(q, \omega)$ asserts when a list of messages ω is “accepted” from a state $q \in Q$, which implies eventual reception of the messages in ω . The function $W(q, \omega)$ is used to connect a configuration to a triple in the \asymp -relation.

Definition 3.2. Let $q \in Q$ and $\omega \in \mathbb{A}^*$, we define

$$A(q, \omega) \iff \begin{cases} \forall q' : q \xrightarrow{!}^* q' : \exists \hat{q} : q' \xrightarrow{!}^* \xrightarrow{?a} \hat{q} \wedge A(\hat{q}, \omega') & \text{if } \omega = a \cdot \omega' \\ \text{true} & \text{if } \omega = \epsilon \end{cases}$$

Given $q \in Q$ and $\omega \in \mathbb{A}^*$, the predicate $A(q, \omega)$ is true iff the list of messages ω can always be consumed entirely from state q , for all paths reachable from q by send actions. Note the similarity with case (3b) of Definition 3.1.

Definition 3.3. Let $q \in Q$ and $\omega \in \mathbb{A}^*$, $W(q, \omega) \subseteq \mathbb{A}^* \times Q$ is the set such that

$$(\pi, \hat{q}) \in W(q, \omega) \iff \begin{cases} (\varphi, \hat{q}) \in W(q', \omega') & \text{if } \omega = a \cdot \omega', q \xrightarrow{! \pi' \cdot ?a} q', \pi = \pi' \cdot \varphi \\ \pi = \epsilon \wedge \hat{q} = q & \text{if } \omega = \epsilon \end{cases}$$

Each pair (π, \hat{q}) in $W(q, \omega)$ represents a state $\hat{q} \in Q$ reachable directly after having consumed the list of messages ω , while π is the list of messages that are sent along a path between q and \hat{q} . For example, consider M_c from Fig. 1. We have $A(0, ko \cdot ko \cdot err)$ and $W(0, ko \cdot ko \cdot err) = \{(req \cdot data \cdot req \cdot data, 3)\}$; instead, $\neg A(0, ok \cdot ko)$ and $\neg A(4, ko)$.

Lemma 3.1. Let $M = (Q, q_0, \delta)$, $q \in Q$ and $\omega \in \mathbb{A}^*$. If $A(q, \omega)$ and $\forall(\varphi, q') \in W(q, \omega) : A(q', a)$ then $A(q, \omega \cdot a)$.

Lemma 3.1, shown by induction on the size of ω , is useful in the proof of the main soundness lemma below.

Lemma 3.2. Let $S = (M_1, M_2)$. If $M_1 \asymp M_2$, then for all $s = (p, \omega_1, q, \omega_2) \in RS(S)$ the following holds: (1) s is not a deadlock, (2) $A(q, \omega_1)$, (3) $\forall(\varphi, q') \in W(q, \omega_1) : \omega_2 \cdot \varphi \blacktriangleright p \asymp q'$, and (4) $A(p, \omega_2)$.

Lemma 3.2 states that for any configuration s : (1) s is not a deadlock; (2) M_2 can consume the list ω_1 from state q ; (3) for each state q' , reached after consuming ω_1 , the relation $\omega_2 \cdot \varphi \blacktriangleright p \asymp q'$ holds, where φ contains the messages that M_2 sent while consuming ω_1 ; and (4) M_1 can consume the list ω_2 from state p . The proof of Lemma 3.2 is by induction on the length of an execution from s_0 to s , then by case analysis on the last action fired to reach s . Lemma 3.1 is used for the case $s_0 \Rightarrow^* \xrightarrow{12!a} s$, i.e., to show that $A(q, \omega_1 \cdot a)$ holds.

Lemma 3.3. Let $S = (M_1, M_2)$. If for all $s = (q_1, \omega_1, q_2, \omega_2) \in RS(S) : A(q_1, \omega_1)$ and $A(q_2, \omega_2)$, then S satisfies eventual reception.

Lemma 3.3 simply shows a correspondence between eventual reception and Definition 3.2. The proof essentially shows that if $A(q_i, \omega_j)$ holds, then we can always reach a configuration where the list ω_j has been entirely consumed.

Finally, we state our final soundness results. Theorem 3.1 is a consequence of Lemmas 2.1, 3.2, 3.3, and 3.4. Theorem 3.2 essentially follows from Theorem 3.1 and the fact that $\asymp_s \subseteq \asymp$.

Theorem 3.1. *If $M_1 \asymp M_2$, then (M_1, M_2) is a safe AD system.*

Theorem 3.2. *If $M_1 \asymp_s M_2$, then (M_1, M_2) is a safe HD system.*

Completeness of \asymp . Our completeness result shows that for any safe asynchronous duplex system $S = (M_1, M_2)$, $M_1 \asymp M_2$ holds. Below we show that any reachable configuration of S whose first queue is empty can be mapped to a triple that is in the relation of Definition 3.1.

Lemma 3.4. *Let S be safe and AD, then $\forall (p, \epsilon, q, \omega) \in RS(S) : \omega \blacktriangleright p \asymp q$.*

The proof of Lemma 3.4 is by induction on the k^{th} approximation of \asymp , i.e., assuming that $\omega \blacktriangleright p \asymp_k q$ holds, we show that $\omega \blacktriangleright p \asymp_{k+1} q$ holds. The proof is a rather straightforward case analysis on the type of p and whether or not $\omega = \epsilon$.

Theorem 3.3. *If (M_1, M_2) is a safe AD system, then $M_1 \asymp M_2$.*

Proof. Take $(q_{01}, \epsilon, q_{02}, \epsilon) \in RS(S)$, $\epsilon \blacktriangleright q_{01} \asymp q_{02}$ holds by Lemma 3.4. □

Following a similar (but simpler) argument, we have Theorem 3.4 below.

Theorem 3.4. *If (M_1, M_2) is a safe HD system, then $M_1 \asymp_s M_2$.*

Theorem 3.5. *If $M_1 \asymp M_2$ (resp. $M_1 \asymp_s M_2$), then $M_2 \asymp M_1$ (resp. $M_2 \asymp_s M_1$).*

Proof. We show the \asymp part. By Theorem 3.1, (M_1, M_2) is safe, hence by definition of safety, (M_2, M_1) is also safe. Thus by Theorem 3.3, we have $M_2 \asymp M_1$. □

4 Undecidability of the \asymp -relation

This section addresses **Step 3**: we show that the problem of checking $M_1 \asymp M_2$ is undecidable. We show that AD systems are Turing complete, then show that the halting problem reduces to deciding whether or not a system is safe.

Preliminaries. We adapt the relevant part of the proof of Finkel and McKenzie [17] to demonstrate that the problem of deciding whether two machines are \asymp -related is undecidable. For this we need to show that there is indeed a Turing machine encoding that is an AD system.

Definition 4.1 (Turing machine [17]). *A Turing machine (T.M.) is a tuple $TM = (V, \mathbb{A}, \Gamma, t_0, \mathbb{B}, \gamma)$ where V is the set of states, \mathbb{A} is the input alphabet, Γ is the tape alphabet, $t_0 \in V$ is the initial state, \mathbb{B} is the blank symbol, and $\gamma : V \times \Gamma \rightarrow V \times \Gamma \times \{\text{left}, \text{right}\}$ is the (partial) transition function.*

Assume TM accepts an input $\omega \in \mathbb{A}^*$ iff TM halts on ω , and if TM does not halt on ω , then TM eventually moves its tape head arbitrarily far to the right.

Definition 4.2 (Configuration of a T.M. [17]). *A configuration of the Turing machine TM is a word $\omega_1 t \omega_2 \#$ with $\omega_1 \omega_2 \in \mathbb{A}^*$, $t \in V$, and $\# \notin \Gamma$.*

The word $\omega_1 t \omega_2 \#$ represents TM in state $t \in V$ with the tape content set to $\omega_1 \omega_2$ and the rest blank, and TM 's head positioned under the first symbol to the right of ω_1 . Symbol $\#$ is a symbol used to mark the end of the tape.

T.M. Encoding. We present an AD system which encodes a Turing machine $TM = (V, \mathbb{A}, \Gamma, t_0, B, \gamma)$ with initial tape ω into a system of two CFSMs as in [17].

We explain the T.M. encoding. The two channels represent the tape of the Turing machine, with a marker $\#$ separating the two ends of the tape. Each machine represents the control of the Turing machine as well as a transmitter from a channel to another. The head is represented by writing the current control state $t \in V$ on the channel. Whenever a machine receives a message that is $t \in V$, then it proceeds with one execution step of the Turing machine. Any other symbol is simply consumed from one channel and sent on the other. The only difference wrt. [17] is that we construct machines which are deterministic and which do not contain mixed states, cf. Definition 2.1. We also do not require the machines to be identical hence we encode the initial tape content as a sequence of transitions in the first machine. These slight modifications do not affect the rest of Finkel and McKenzie's proof in [17]. The system consists of two CFSMs $A_i = (Q_i, q_{0_i}, \delta_i)$, $i \in \{1, 2\}$ over the alphabet $\mathbb{A} \cup \{\#\}$. The definitions of δ_i are given below, the sets Q_i are induced by δ_i . The transition relation δ_1 consists in a sequence of transitions from the initial state q_{0_1} to a central state q and a number of elementary cycles around state q , cf. Fig. 3; while δ_2 is like δ_1 without the initial sequence of transitions and $q = q_{0_2}$. The initial sequence of transitions in δ_1 is of the form:

$$q_{0_1} \xrightarrow{!t_0} q_1 \xrightarrow{!a_1} \cdots q_k \xrightarrow{!a_k} q \quad \text{such that } a_1 \cdots a_k = \omega \cdot \#$$

Both δ_1 and δ_2 contain six types of elementary cycles given in Fig. 3. For each type of cycle, we illustrate the behaviour of the system from the point view of machine A_2 by giving the type of configuration this cycle applies to as well the configuration obtained after A_2 has finished executing the cycle.

When computing each δ_i and Q_i from the description above, we assume that each “anonymous” state maintain its own identity, while “named” states, i.e., q , r_t , r_x and r_x^t from Fig. 3, are to be identified and redundant transitions to be removed. This ensures that each machine so obtained is deterministic. Besides this determinisation, the only changes from [17] concerns the copying cycles. (1) Each copying cycle is expanded to receive (then send) two symbols so to ensure the absence of mixed states once merged with left head motion cycles. (2) We add a cycle which only re-emits $\#$ symbols (to make up for absence of it in the first reception of the copying cycles). (3) We add another blank insertion cycle to deal with the special case where the head is followed by the $\#$ symbol.

Blank insertion cycles (1). For each $t \in V$, there is a cycle of the form:

Right head motion cycles. For each $(t, a, t', b) \in V \times \Gamma \times V \times \Gamma$ such that $\gamma(t, a) = (t', b, \text{right})$, there is a cycle of the form:

Blank insertion cycles (2). For each $x \in \Gamma$ and $t \in V$ there is a cycle of the form:

Left head motion cycles. For each $(x, t, a, t', b) \in \Gamma \times V \times \Gamma \times V \times \Gamma$ such that $\gamma(t, a) = (t', b, \text{left})$, there is a cycle of the form:

Copying cycles. For all $x \in \Gamma$ and $y \in \Gamma \cup \{\#\}$, there is a cycle of the form:

Marker transmission cycle. There is one cycle specified by:

Fig. 3. Definition of δ_i (elementary cycles).

Definition 4.3 (Turing machine encoding [17]). Given a Turing machine TM and an initial tape content ω , we write $S(TM, \omega)$ for the system (A_1, A_2) with each A_i constructed as described above.

The rest follows the proof of [17]. Here we recall informally the final result: any execution of a Turing machine TM with initial word ω can be simulated by $S(TM, \omega)$, and vice-versa.

Lemma 4.1. For any TM and word ω , $S(TM, \omega) = (A_1, A_2)$ is AD.

Proof. Take $A_i = (Q_i, q_{0i}, \delta_i)$, we show $\forall q \in Q_i : \mathbf{fin}(q)$, which implies that the system is AD. If there was $q \in Q_i$ such that $\neg \mathbf{fin}(q)$, there would be a cycle of send actions only, the construction of A_i clearly prevents this (see Fig. 3). \square

Theorem 4.1 (Undecidability of \asymp). Given two machines M_1 and M_2 , it is generally undecidable whether $M_1 \asymp M_2$ holds.

The proof of Theorem 4.1 shows that the following statements are equivalent: (1) TM accepts ω , (2) $S(TM, \omega) = (A_1, A_2)$ is *not* safe, and (3) $\neg(A_1 \asymp A_2)$. We show (1) \Rightarrow (2) by Lemma 2.1, (2) \Rightarrow (1) from the definition of safety, and (2) \Leftrightarrow (3) by Theorems 3.1 and 3.3 and the fact that (A_1, A_2) is AD.

4.1 Decidable Sub-classes of CFSMs

We now identify three sub-classes of CFSMs for which the \asymp -relation is decidable. We say that $M_1 \asymp M_2$ is decidable iff it is decidable whether or not $M_1 \asymp M_2$ holds. The first sub-class is HD systems: HD is a decidable property and safety is decidable within that class [8], hence \asymp is decidable in HD and it is equivalent to \asymp_s within HD. The second sub-class is taken from the CFSMs literature and the third is limited to systems that contain at least one machine that has no branching. We define the last two sub-classes below.

The following definition is convenient to formalise our decidability results. Given $M_i = (Q_i, q_{0_i}, \delta_i)$ for $i \in \{1, 2\}$, the *derivation tree* of a triple $\pi \blacktriangleright p \asymp q$ is a tree whose nodes are labelled by elements of $\mathbb{A}^* \times Q_1 \times Q_2$ such that the children of a node are exactly the triple generated by applying one step of Definition 3.1.

For example, consider the machines M_1 and M_2 from Fig. 2, we have a tree which consists of a unique (infinite) branch:

$$\epsilon \blacktriangleright 0 \asymp 0 \longrightarrow b \blacktriangleright 1 \asymp 0 \longrightarrow bb \blacktriangleright 2 \asymp 0 \longrightarrow b \blacktriangleright 0 \asymp 0 \longrightarrow bb \blacktriangleright 1 \asymp 0 \longrightarrow bbb \blacktriangleright 2 \asymp 0 \cdots$$

Lemma 4.2. *The derivation tree of $\pi \blacktriangleright p \asymp q$ is finitely branching.*

Lemma 4.2 follows from the fact that each machine is finitely branching and the predicate $\text{fin}(\cdot)$ guarantees finiteness for case (3b) of Definition 3.1.

Alternating Machines. Alternating machines were introduced in [21] where it is shown that the progress problem (corresponding to our notion of safety) is decidable for such systems. A machine is *alternating* if each of its sending transition is followed by a receiving transition, e.g., M_s and M'_s in Fig. 1 are alternating, as well as the specification of the alternating-bit protocol in [21]. Observe that alternating machines form AD systems.

Theorem 4.2. *If M_1 and M_2 are alternating, then $M_1 \asymp M_2$ is decidable.*

The proof simply shows that the π part of the relation (cf. Definition 3.1) is bounded by 1, by induction on the depth of the derivation tree.

Non-branching Machines. Given $M = (Q, q_0, \delta)$ we say that M is non-branching if each of its state has at most one successor, i.e., if $\forall q \in Q : |\delta(q)| \leq 1$. For example, M'_s in Fig. 1 is non-branching. Non-branching machines are used notably in [33, 35] to specify parallel programs which can be optimised through asynchronous message permutations.

Theorem 4.3. *Let M_1 and M_2 be two machines such that at least one of them is non-branching, then $M_1 \asymp M_2$ is decidable.*

The proof relies on the fact that (i) the derivation tree is finitely branching (Lemma 4.2), hence there is a semi-algorithm to check whether $\neg(M_1 \asymp M_2)$ and (ii) over any infinite branches we can find two nodes of the form $c = \pi^n \blacktriangleright p \asymp q$ and $c' = \pi^m \blacktriangleright p \asymp q$, with $n \leq m$. If n is large enough, this implies that the relation holds (i.e., the branch is indeed infinite).

5 Correspondence Between Compatibility and Subtyping

We show a precise correspondence between the asynchronous subtyping for session types and the \asymp -relation for CFSMs, i.e., **Step 4**. We first recall the syntax of session types and as well as the definition of asynchronous subtyping.

Session Types and Subtyping. The syntax of session types is given by

$$T, U ::= \text{end} \quad | \quad \oplus_{i \in I} !a_i. T_i \quad | \quad \&_{i \in I} ?a_i. T_i \quad | \quad \text{rec } \mathbf{x}. T \quad | \quad \mathbf{x}$$

where $I \neq \emptyset$ is finite and $a_i \neq a_j$ for $i \neq j$. Type **end** indicates the end of a session. Type $\oplus_{i \in I} !a_i. T_i$ specifies an *internal* choice, indicating that the program chooses to send one of the a_i messages, then behaves as T_i . Type $\&_{i \in I} ?a_i. T_i$ specifies an *external* choice, saying that the program waits to receive one of the a_i messages, then behaves as T_i . Types **rec** $\mathbf{x}. T$ and \mathbf{x} are used to specify recursive behaviours. We only consider closed types, i.e., without free variables.

Since our goal is to relate a binary relation defined on CFSMs to a binary relation on session types, we first introduce transformations from one to another.

Definition 5.1. *Given a type T , we write $\mathcal{M}(T)$ for the CFSM induced by T . Given a CFSM M , we write $\mathcal{T}(M)$ for the type constructed from M .*

We assume the existence of two algorithms such that $T = \mathcal{T}(\mathcal{M}(T))$ and $M = \mathcal{M}(\mathcal{T}(M))$ for any type T and machine M . These algorithms are rather trivial since each session type induces a finite automaton, see [15] for instance.

We write \bar{T} for the *dual* of type T , i.e., $\bar{\text{end}} = \text{end}$, $\bar{\mathbf{x}} = \mathbf{x}$, $\text{rec } \mathbf{x}. \bar{T} = \text{rec } \mathbf{x}. T$, $\bar{\oplus_{i \in I} !a_i. T_i} = \&_{i \in I} ?a_i. \bar{T}_i$, and $\bar{\&_{i \in I} ?a_i. T_i} = \oplus_{i \in I} !a_i. \bar{T}_i$.

Hereafter, we write \leq_a for the relation in [9] (abstracting away from carried types) which we recall below. An *asynchronous context* [9] is defined by

$$\mathcal{A} := []^n \quad | \quad \&_{i \in I} ?a_i. \mathcal{A}_i$$

We write $\mathcal{A}[]^{n \in N}$ to denote a context with holes indexed by elements of N and $\mathcal{A}[T_n]^{n \in N}$ to denote the same context when the hole $[]^n$ has been filled with T_n .

The predicate $\& \in T$ holds if it can be derived from the following rules:

$$\frac{}{\& \in \&_{i \in I} ?a_i. T_i} \quad \frac{\forall i \in I : \& \in T_i}{\& \in \oplus_{i \in I} !a_i. T_i} \quad \frac{\& \in T}{\& \in \text{rec } \mathbf{x}. T}$$

$\& \in T$ holds whenever T always eventually performs a receive action, i.e., it cannot loop on send actions only. It is the counterpart of the predicate $\mathbf{fin}(_)$ for CFSMs, cf. Lemma 5.1.

Definition 5.2 (\leq_a [9]). *The asynchronous subtyping, \leq_a , is the largest relation that contains the rules:¹*

$$\begin{array}{c} \frac{\forall i \in I : T_i \leq_a U_i}{\oplus_{i \in I} !a_i. T_i \leq_a \oplus_{i \in I \cup J} !a_i. U_i} \text{ [SEL]} \quad \frac{\forall i \in I : T_i \leq_a U_i}{\&_{i \in I \cup J} ?a_i. T_i \leq_a \&_{i \in I} ?a_i. U_i} \text{ [BRA]} \\[10pt] \frac{\forall i \in I : T_i \leq_a \mathcal{A}[U_i^n]^{n \in N} \quad \& \in T_i}{\oplus_{i \in I} !a_i. T_i \leq_a \mathcal{A}[\oplus_{i \in I \cup J_n} !a_i. U_i^n]^{n \in N}} \text{ [ASYNC]} \quad \frac{}{\mathbf{end} \leq_a \mathbf{end}} \text{ [END]} \end{array}$$

The double line in the rules indicates that the rules should be interpreted coinductively. We are assuming an equi-recursive view of types.

Rule [SEL] lets the subtype make fewer selections than its supertype, while rule [BRA] allows the subtype to offer more branches. Rule [ASYNC] allows safe permutations of actions, by which a protocol can be refined to maximise asynchrony without violating safety. Note that the *synchronous* subtyping \leq_s [11, 19, 20] is defined as Definition 5.2 without rule [ASYNC], hence $\leq_s \subseteq \leq_a$. In Fig. 1, $T(M'_s) \leq_s T(M_s)$, $T(M'_s) \leq_a T(M_s)$, and $T(M_c) \leq_a T(M'_c)$.

The correspondence between \asymp (Definition 3.1) and \leq_a (Definition 5.2) can be understood as follows. Case (1) of Definition 3.1 corresponds to rule [END]. Case (2a) corresponds to rule [BRA]. Case (3a) corresponds to rule [SEL]. Cases (2b) and (3b) together correspond to rule [ASYNC].

Correspondences. We show that \asymp on CFSMs and \leq_a on session types are equivalent, and, as a consequence, deciding whether two types are \leq_a -related is undecidable. We first introduce a few auxiliary lemmas and definitions.

Lemma 5.1. *Let $M = (Q, q_0, \delta)$ and T be a session type.*

1. *For each $q \in Q$, if $\mathbf{fin}(q)$, then $\& \in T(Q, q, \delta)$.*
2. *If $\& \in T$ and $\mathcal{M}(T) = (\hat{Q}, q, \hat{\delta})$, then $\mathbf{fin}(q)$.*
3. *If $T = \mathcal{A}[\oplus_{i \in I} !a_i. U_i^n]^{n \in N}$ then $\& \in T$.*

Lemma 5.1 states the relationship between $\& \in T$ and $\mathbf{fin}(_)$ (cf. Sect. 2.2).

We write $\pi \in \mathcal{A}$ if π is a branch in the context \mathcal{A} . Formally, given \mathcal{A} and $\pi \in \mathbb{A}^*$, we define the predicate $\pi \in \mathcal{A}$ as follows:

$$\pi \in \mathcal{A} \iff \begin{cases} \pi = \epsilon & \text{if } \mathcal{A} = [] \\ \pi = a_j \cdot \pi_j & \text{if } \mathcal{A} = \&_{i \in I} ?a_i. \mathcal{A}_i, \pi_j \in \mathcal{A}_j, \text{ with } j \in I \end{cases}$$

The next lemma shows that the \leq_a -relation implies the \asymp -relation.

¹ Note that in [9] rule [ASYNC] has a redundant additional premise, $\& \in \mathcal{A}$, which is only used to make the application of the rules deterministic.

Lemma 5.2. *Let T and U be two session types, such that $\mathcal{M}(T) = (Q^T, q_0^T, \delta^T)$ and $\mathcal{M}(U) = (Q^U, q_0^U, \delta^U)$, then $T \leq_a \mathcal{A}[\bar{U}] \implies \forall \pi \in \mathcal{A} : \pi \blacktriangleright q_0^T \asymp q_0^U$.*

The proof of Lemma 5.2 is by coinduction on the derivation of $\pi \blacktriangleright p \asymp q$. We use Lemma 5.1 to show that premise of rule [ASYNC] implies that $\text{fin}(q_0^T)$ and $\text{fin}(q_0^U)$ hold when necessary.

The next lemma shows that the \asymp -relation implies the \leq_a -relation.

Lemma 5.3. *Let $M_i = (Q_i, q_{0_i}, \delta_i)$, $i \in \{1, 2\}$ and $\pi = a_1 \cdots a_k \in \mathbb{A}^*$, for all $p \in Q_1$ and $q \in Q_2$, $\pi \blacktriangleright p \asymp q \implies \mathcal{T}(Q_1, p, \delta_1) \leq_a ?a_1 \cdots ?a_k. [\mathcal{T}(Q_2, q, \delta_2)]$.*

The proof of Lemma 5.3 is by coinduction on the rules of Definition 5.2, using Lemma 5.1 to match the requirements of the respective relations.

We are now ready to state the final equivalence result.

Theorem 5.1. *The relations \asymp and \leq_a are equivalent in the following sense:*

1. *Let T_1 and T_2 be two session types, then $T_1 \leq_a \bar{T}_2 \implies \mathcal{M}(T_1) \asymp \mathcal{M}(T_2)$.*
2. *Let M_1 and M_2 be two machines, then $M_1 \asymp M_2 \implies \mathcal{T}(M_1) \leq_a \mathcal{T}(M_2)$.*

Proof. (1) follows from Lemma 5.2, with $T_1 = T$, $T_2 = U$, and $\mathcal{A} = []$. (2) follows from Lemma 5.3, with $\pi = \epsilon$, $p = q_{0_1}$, and $q = q_{0_2}$. \square

A consequence of the correspondence between the two relations is that the \asymp -relation is transitive in the following sense:

Theorem 5.2. *If $M_1 \asymp \bar{M}$ and $M \asymp M_2$, then $M_1 \asymp M_2$.*

Proof. By Theorem 5.1 we have (1) $M_1 \asymp \bar{M} \iff M_1 \leq_a M$ (2) $M \asymp M_2 \iff M \leq_a \bar{M}_2$. Since \leq_a is transitive [10], we have $M_1 \leq_a \bar{M}_2$. Thus, using Theorem 5.1 again, we have $M_1 \leq_a \bar{M}_2 \iff M_1 \asymp M_2$. \square

As a consequence of Theorems 4.1 and 5.1, we have the undecidability of the asynchronous subtyping:

Theorem 5.3. (Undecidability of \leq_a). *Given two session types T_1 and T_2 , it is generally undecidable whether $T_1 \leq_a T_2$ holds.*

We state the equivalence between \asymp_s and \leq_s , and the transitivity of \asymp_s .

Theorem 5.4. *The relations \asymp_s and \leq_s are equivalent in the following sense:*

1. *Let T_1 and T_2 be two session types, then $T_1 \leq_s \bar{T}_2 \implies \mathcal{M}(T_1) \asymp_s \mathcal{M}(T_2)$.*
2. *Let M_1 and M_2 be two machines, then $M_1 \asymp_s M_2 \implies \mathcal{T}(M_1) \leq_s \mathcal{T}(M_2)$.*

Theorem 5.5. *If $M_1 \asymp_s \bar{M}$ and $M \asymp_s M_2$, then $M_1 \asymp_s M_2$.*

Theorem 5.1 together with the soundness and completeness of \asymp wrt. safety in AD systems (Theorems 3.1 and 3.3) imply a tight relationship between \leq_a and session types corresponding to AD systems. A similar correspondence between \leq_s and HD systems exists, by Theorems 3.2, 3.4, and 5.4.

6 Conclusions and Related Work

We have introduced a new sub-class of CFSMs (AD), which includes HD, and a compatibility relation \asymp (resp. \asymp_s) that is sound and complete wrt. safety within AD (resp. HD) and equivalent to asynchronous (resp. synchronous) subtyping. Our results in Sect. 4.1 suggest that \asymp is a convenient basis for designing safety checking algorithms for some sub-classes of CFSMs. Given the results in the present paper, we plan to study bounded approximations of \asymp that can be used for session typed applications. Such approximations would make asynchronous subtyping available for real-world programs and thus facilitate the integration of flexible session typing.

Related Work. The first (synchronous) subtyping for session types in the π -calculus was introduced in [19] and shown to be decidable in [20]. Its complexity was further studied in [26] which encodes synchronous subtyping as a model checking problem. The first version of asynchronous subtyping was introduced in [31] for multiparty session types and further studied in [28–30] for binary session types in the higher-order π -calculus. These works and [10] stated or conjectured the decidability of the relations. The technical report [5] (announced after the submission of the present paper) independently studied the undecidability of these relations. Note that the subtyping relation in [28, 30] only differs from the one in [9, 10] by the omission of the premise $\& \in T_i$ in rule [ASYNC]. This subtyping is not sound wrt. our definition of safety as it does not guarantee eventual reception [9, 10]. We conjecture that it is sound and complete wrt. progress (either both machines are in a final state or one can eventually make a move) in (the full class of) CFSMs, hence it is also undecidable since progress corresponds to rejection of a word by a Turing machine, cf. Sect. 4.

The operational and denotational preciseness of (synchronous and asynchronous) subtyping for session types was studied in [9, 10] where the authors give soundness and completeness of each subtyping through the set of π -calculus processes a type T can type. In this paper, we study the soundness and completeness of \asymp (resp. \asymp_s) in CFSMs through AD (resp. HD) systems.

CFSMs have long been known to be Turing complete [4, 17] even when restricted to deterministic machines without mixed states [21]. The first paper to relate formally CFSMs and session types was [14], which was followed by a series of work using CFSMs as session types [3, 15, 25]. The article [2] shows, in a similar fashion to [17], that the compliance of contracts based on asynchronous session types is undecidable. Here, we show that the encoding of [17] is indeed AD and that safety is equivalent to word acceptance by a Turing machine.

Acknowledgements. We thank A. Scalas, B. Toninho and G. Zavattaro for their comments on earlier versions of this paper, in particular G. Zavattaro for identifying the need for additional blank insertion cycles (in Fig. 3).
