(Lett. Nuovo Cimento, 7, 221 (1973))

If one considers an isospin-zero pair of ρ 's, the probability of having a $\rho^+\rho^-$ pair is $\frac{2}{3}$ and that of a $\rho^0\rho^0$ pair is $\frac{1}{3}$, and not $\frac{1}{2}$ in both cases as written in our article. Our error leads to trivial changes in our formulae from formula (7) onwards, in particular the denominator in (7) is now $\frac{2}{3}$ and not 3, the coefficient of $\langle n_- \rangle$ in (9) is $\frac{1}{2}$ and not $\frac{2}{3}$, and the parameter $\beta = \frac{1}{2}$ and not $\frac{2}{3}$. As a consequence, the agreement of f_2^- with the data is not quite as good, but that of $\langle n_0 \rangle_n$ is better. More importantly, however, none of the qualitative features of our model is changed and except for point v), the important points made in our final discussion still hold.
