ABSTRACT: We construct a complete basis of dimension-8 operators in the Low-Energy Effective Field Theory below the Electroweak Scale (LEFT). We find there are 35058 dimension-8 operators in the LEFT for two generations of up-type quarks and three generations of down-type quarks, charged leptons, and left-handed neutrinos. The existence of this operator basis is a necessary prerequisite for matching to the Standard Model Effective Field Theory at the dimension-8 level.

1 Introduction

The discovery of the Higgs boson at the Large Hadron Collider along the absence of an observation of physics beyond the Standard Model (SM) has left open questions surrounding the nature of electroweak (EW) symmetry breaking. One such question concerns the Higgs boson itself: is the Higgs boson part of an $SU(2)_L$ doublet with hypercharge $Y = 1/2$, or is it an electroweak singlet? Measurements at energies well below the electroweak scale interpreted in an effective field theory (EFT) framework provide one way of answering this question. The effective field theory approach to analyzing experimental data has become widely popular due to its model-independence and systematic improvability.

The Low-Energy Effective Field Theory below the Electroweak Scale (LEFT), as its name implies, is correct the EFT to use to interpret measurements below the EW scale [1–4]. The LEFT gauge group is the product of QCD and QED, $SU(3) \times U(1)_Q$, with field strengths $G_{\mu\nu}^A$ and $F_{\mu\nu}$, respectively. There are $n_u = 2$ generations of up-type quarks, u_L, u_R , and $n_d = n_e = n_\nu = 3$ generations of down-type quarks, charged leptons, and left-handed neutrinos, $d_L, d_R, e_L, e_R, \nu_L$. Through the lens of the LEFT the question concerning the Higgs boson can be restated as: what is the UV completion of the LEFT? A leading candidate is the Standard Model Effective Field Theory (SMEFT) in which the Higgs boson forms part of an $SU(2)_L$ doublet with $Y = 1/2$ [5–16]. The SMEFT has a larger gauge group, $SU(3) \times SU(2)_L \times U(1)_Y$, than the LEFT leading to the seven fermion fields of the LEFT (ignoring flavor) being encoded into only five SMEFT fermion fields, l, e, q, u, d . This leads to correlations among LEFT Wilson coefficients matching

to the SMEFT. For example, the dimension-6 SMEFT contribution to the LEFT operator $(\bar{\tau}_L \gamma_\mu \nu_{L\tau})(\bar{c}_R \gamma^\mu b_R)$ cannot induce lepton universality violation [17–19]. Ref. [1] tabulated the full set of correlations between dimension-6 LEFT coefficients that would arise if it is UV-completed by the SMEFT.

By measuring observables sensitive to these coefficients one can test whether the SMEFT is the correct completion of the LEFT. Here correlated coefficients means a linear combination of Wilson coefficients that generally should be $O(1/\Lambda^2)$, but is instead zero when matched to the SMEFT at dimension-6. However, as any measurement has a finite precision, it is important to first determine the size of the corrections to these correlations resulting from higher-order effects to design an experiment with the appropriate level of sensitivity. For correlated dimension-6 coefficients typically what will happen when the matching is extended to dimension-8 is that a correlated coefficient will no longer be zero, but instead will be of order $O(v^2/\Lambda^4)$.

Furthermore, many dimension-8 operators are subject to positivity bounds arising from fundamental principles of quantum field theory including unitarity and analyticity, see [20–29] for some recent applications. The LEFT is a valid EFT in its own right, independent of whatever its UV completion may be. As such the Wilson coefficients of the LEFT are subject to their own set of positivity bounds. In general, the constraints on the underlying physics from LEFT positivity bounds will not be identical to those arising from its UV completion, say, the SMEFT. This is due to the fact that the matching between the LEFT and the SMEFT is rich in nature, and is not simply a matter of setting the Higgs field to its vacuum expectation value (vev). In addition to these contact contributions to the matching there are also exchanges of SM particles with masses comparable to the EW scale, and the number possible exchange contributions to the matching increases with mass increasing dimension [1, 3, 4].

The first step in tackling these matching problems is to construct a complete basis of dimension-8 LEFT operators, which is the goal of this work. We find there are 35058 operators. The overwhelming majority of these operators, 34721 to be exact, contain four fermions along with either a field strength or two derivatives. In contrast the SMEFT has fewer operators belonging to classes $\psi^4 X$ or $\psi^4 D^2$, 21303 [10, 13, 14], which will lead to correlations among LEFT dimension-8 operators when matched to the SMEFT, repeating the behavior first seen at dimension-6.

2 LEFT dimension-8 operators

The LEFT consists of all the gauge invariant, non-redundant operators of dimension-3 and higher that can be formed out of the subset of SM fields whose masses are parametrically smaller than the electroweak scale. Additionally, the LEFT possesses an expansion in the mass dimension, d , of its operators with expansion parameter $1/v^{d-4}$ for $d > 4$ where v is the vev of the Higgs field *in the SM*. LEFT operators with two or more fermions can violate lepton number, and LEFT operators with four fermions can violate both baryon and lepton number. Ref. [1] constructed a LEFT operator basis for operators up to and including dimension-6. At dimension-5 there is one operator class $\psi^2 X$, while at dimension-

6 there are two classes, X^3 and ψ^4 . The one-loop anomalous dimension matrix for these operators was computed by the same authors in ref. [2]. Ref. [4] constructed a LEFT basis for dimension-7 operators. There are two classes of dimension-7 LEFT operators: $\psi^2 X^2$ and $\psi^4 D$.

Much effort has been devoted to counting the number of operators in an EFT [10, 30–35]. Specifically, we use the Mathematica program `Sym2Int` [34] to count the number of LEFT dimension-8 operators along with their baryon and lepton numbers. `Sym2Int` also provides the flavor structures of the Lagrangian terms up to ambiguities due to integration by parts relations between operators with repeated fields. We find the number of LEFT dimension-8 operators is

$$N_{\text{operators}} = 35058 = 21144|_{\Delta B=0}^{\Delta L=0} + 5442|_{\Delta B=0}^{\Delta L=2} + 4536|_{\Delta B=1}^{\Delta L=1} + 3888|_{\Delta B=1}^{\Delta L=-1} + 48|_{\Delta B=0}^{\Delta L=4} \quad (2.1)$$

for the SM case of $n_u = 2$ and $n_d = n_e = n_\nu = 3$. The counting for arbitrary $n_{\nu,e,u,d}$ is given in table 1 of appendix A.

In this work we construct a complete basis of dimension-8 LEFT operators. There are four operators classes to consider: X^4 , $\psi^2 X^2 D$, $\psi^4 X$, and $\psi^4 D^2$. Each class of operators contains subclasses with definite transformation properties under the Lorentz group. For example, $\{X_L^4, X_R^4, X_L^2 X_R^2\} \in X^4$ where $X_L \sim (1, 0)$ and $X_R \sim (0, 1)$ under $SU(2)_l \times SU(2)_r$ of the Lorentz group. The existence of complete bases of dimension-8 SMEFT operators [13, 14] aides in the construct of a LEFT dimension-8 basis as all of the LEFT operator classes are also present in the SMEFT at dimension-8. However not all of the types of LEFT operators are present in the SMEFT. For example, some LEFT operators involving four fermions can violate lepton number while preserving baryon number, but in the SMEFT even mass dimensions operators (below $d = 10$) conserve baryon minus lepton number, $\Delta B - \Delta L = 0$ [36, 37].

The LEFT Lagrangian terms with two or less fermions are a subset of their SMEFT counterparts, and can be constructed by relabeling some of the fields of the appropriate operators. For definiteness we use the SMEFT dimension-8 basis of ref. [13] when constructing these LEFT operators, and refer the reader there for more detail on the construction of the operator basis. Each of these Lagrangian terms has trivial flavor structure with X^4 and $\psi^2 X^2 D$ terms containing one and n_f^2 operators, respectively. In total there are 23 X^4 operators and $2n_\nu^2 + 4n_e^2 + 20n_u^2 + 20n_d^2 = 314$ $\psi^2 X^2 D$ operators. Table 5 of appendix B lists the X^4 operators, while tables 6 and 7 contain the $\psi^2 X^2 D$ operators.

As there are a large number of operators with four fermions it is convenient to break these operators classes into different cases. For operators that conserve both baryon and lepton number we again start from the SMEFT operators of ref. [13] and relabel fields as appropriate. However the counting of operators in Lagrangian terms with repeated field does not translate from the SMEFT to the LEFT as there are five fermion fields in the SMEFT, whereas there are seven fermion fields in the LEFT. The flavor structure and operator counting for each Lagrangian term with four fermions is given in tables 2, 3, and 4. We make one change from the approach of ref. [13], namely that all of the baryon and lepton number conserving operators in this work have lepton bilinear and/or quark bilinears, but they do not contain leptoquark bilinears. There is one baryon number conserving term

in [13] with a leptoquark bilinear, and we use a Fierz identity to eliminate it in favor of operators with the tensor Dirac matrix $\sigma^{\mu\nu}$. A special case are the subclass $\psi_L^4 D^2$ operators with all charged-lepton fields. The lack of color indices allows for a symmetric and antisymmetric flavor representation to be unambiguously combined into a single Lagrangian term. In equations, for up-quarks there is $D^\mu(\bar{u}_L u_R)D_\mu(\bar{u}_L u_R)$ and $D^\mu(\bar{u}_L T^A u_R)D_\mu(\bar{u}_L T^A u_R)$, whereas for charged-leptons there can clearly only be $D^\mu(\bar{e}_L e_R)D_\mu(\bar{e}_L e_R)$. Similarly, the lack of color indices on the lepton fields makes some operators of subclass $\psi_L^2 \psi_R^2 D^2$ redundant. One such example is

$$(\bar{e}_{Rp} \gamma^\mu \overleftrightarrow{D}^\rho e_{Rr})(\bar{e}_{Rs} \gamma_\mu \overleftrightarrow{D}^\rho e_{Rt}) = \mathcal{O}_{prst}^{(1,RR)} + 2\mathcal{O}_{ptsr}^{(1,RR)}. \quad (2.2)$$

For operators that violate baryon and/or lepton number we start from our operator counting and instead use set of Lorentz structures for each subclass of operator from ref. [14]. We then use Fierz identities to eliminate leptoquark bilinears from the $\Delta L = 2$ operators with two left-handed and two right-handed fermions. On the other hand, for $\Delta L = 2$ operators with four left-handed fermions (and their Hermitian conjugates) we only eliminate leptoquark bilinears when there are no repeated fields. That is, for operators with two left-handed neutrinos and two left-handed quarks we make the choice to have leptoquark bilinears to avoid writing Lagrangian terms as sum of two terms. As an example, the neutrinos in $\mathcal{O}_{\nu^2 d^2 F}^{(2,ST)}$ can be in a symmetric or an antisymmetric flavor representation.

$$\begin{aligned} L_{\nu^2 d^2 F}^{(2,ST)} \mathcal{O}_{prst}^{(2,ST)} &\sim L_{[pt]sr}^{(2a,ST)} \mathcal{O}_{ptsr}^{(2a,ST)} + L_{(pt)sr}^{(2s,ST)} \mathcal{O}_{ptsr}^{(2s,ST)}, \\ \mathcal{O}_{\nu^2 d^2 F}^{(2a,ST)} &= (\nu_{Lp}^\top C \nu_{Lr})(\bar{d}_{Rs} \sigma^{\mu\rho} d_{Lt}) F_{\mu\rho}, \\ \mathcal{O}_{\nu^2 d^2 F}^{(2s,ST)} &= (\nu_{Lp}^\top C \sigma^{\mu\lambda} \nu_{Lr})(\bar{d}_{Rs} \sigma_{\lambda\rho} d_{Lt}) F_\mu^\rho, \end{aligned} \quad (2.3)$$

where $[.]$ and (\cdot) indicate anti-symmetrization and symmetrization respectively.

There are 24108 $\psi^4 X$ LEFT operators and 10613 $\psi^4 D^2$ LEFT operators. These classes have more operators than their SMEFT counterparts despite the handicap of having one fewer generation of up-type quarks. As such there are correlations between LEFT Wilson coefficients when matching from the SMEFT. Measuring processes sensitive to these coefficients is way one to test whether the SMEFT is the correct UV completion of the LEFT.

The baryon and lepton number conserving operators of class $\psi^4 X$ and subclass $\psi_L^2 \psi_R^2 X$ are enumerated in tables 8, 9, 10, and 11, while table 12 contains the $\psi_L^4 X_L + \text{h.c.}$ operators. The baryon and lepton number conserving operators of class $\psi^4 D^2$ and subclass $\psi_L^2 \psi_R^2 D^2$ are given in tables 13 and 14, whereas table 15 lists the $\psi_L^4 D^2 + \text{h.c.}$ operators. The $\psi^4 X$ and $\psi^4 D^2$ operators that violate lepton number, but preserve baryon number are tabulated in tables 16 and 17, respectively. On the other hand, the $\psi^4 D^2$ and $\psi^4 X$ operators that violate baryon and lepton number, but preserve $\Delta B - \Delta L$ are listed in tables 18 and 19, respectively. Finally, table 20 contains all the $\Delta B = -\Delta L = 1$ operators.

3 Conclusions

In this work we constructed a complete basis of dimension-8 operators in the LEFT. We found there are 35058 operators, see eq. (2.1) or table 1. In addition to the operator

counting, the construction of the LEFT operator basis was aided by the existence of the dimension-8 bases of SMEFT operators as all of the LEFT dimension-8 operator classes are also found in the SMEFT.

The existence of an operator basis is a prerequisite for matching to the SMEFT at the dimension-8 level. For a given class of LEFT operators involving four fermions there are fewer SMEFT operators of the same class leading to correlations between LEFT Wilson coefficients when matched to the SMEFT. Measuring observables sensitive to these coefficients is one way to test whether the SMEFT is the correct EFT extension of the SM and the correct UV-completion of the LEFT. Additionally, the LEFT has its own set of positivity bounds on dimension-8 operators from unitarity, analyticity, and crossing symmetry. We encourage the study of these bounds as they are potentially complementary to those of the SMEFT.

Note added. As this work was being finalized ref. [38] appeared on the arXiv. It constructs bases of LEFT operators through mass dimension 9 by expanding on the technology developed in refs. [14, 15].

Ref. [38] makes a minor arithmetic error in counting the number of dimension-8 LEFT operators. The number of $d=8$ LEFT operators found in this work is 35058 in contrast to the 35060 reported in [38]. The origin of the discrepancy comes the counting of the $F_L^2 F_R^2$ operators in [38]. Based on the equations (3.154)-(3.158) in ref. [38] there are nine rather than 11 operators in that class. This brings the total count of ref. [38] down to 35058 and into agreement with what is found in this work. We thank Jiang-Hao Yu for confirming that the operator counting in this work is correct.

Note for the editor: Jiang-Hao Yu, on behalf of the authors of [38], said they would post an update to their work. I am happy to remove this comment when the update is posted.
