ABSTRACT: We introduce a new information-theoretic measure of multipartite correlations Δ_P , by generalizing the entanglement of purification to multipartite states. We provide proofs of its various properties, focusing on several entropic inequalities, in generic quantum systems. In particular, it turns out that the multipartite entanglement of purification gives an upper bound on multipartite mutual information, which is a generalization of quantum mutual information in the spirit of relative entropy. After that, motivated by a tensor network description of the AdS/CFT correspondence, we conjecture a holographic dual of multipartite entanglement of purification Δ_W , as a sum of minimal areas of codimension-2 surfaces which divide the entanglement wedge into multi-pieces. We prove that this geometrical quantity satisfies all properties we proved for the multipartite entanglement of purification. These agreements strongly support the $\Delta_P = \Delta_W$ conjecture. We also show that the multipartite entanglement of purification is larger than multipartite squashed entanglement, which is a promising measure of multipartite quantum entanglement. We discuss potential saturation of multipartite squashed entanglement onto multipartite mutual information in holographic CFTs and its applications.

1 Introduction

Quantum entanglement has recently played significant roles in condensed matter physics [1–3], particle physics [4–8] and string theory [9–11]. To study the quantum entanglement in states of a quantum system, we often divide the total system into a subsystem A and its complement A^c , and then compute the entanglement entropy $S_A := -\text{Tr} \rho_A \log \rho_A$, where ρ_A is the reduced density matrix of a given total state $\rho_A := \text{Tr}_{A^c} \rho_{\text{tot}}$. In the gauge/gravity correspondence [12], the Ryu-Takayanagi formula [9–11] allows one to compute the entanglement entropy in CFTs by a minimal area of codimension-2 surface in AdS. This discovery opens a new era of studying precise relations between spacetime geometry and quantum entanglement [13–22].

Recently the holographic counterpart of a new quantity independent of entanglement entropy, called the entanglement of purification E_P [23], has been conjectured [24, 25]. The entanglement of purification quantifies an amount of total correlation, including quantum entanglement, for bipartite mixed states ρ_{AB} acting on $\mathcal{H}_{AB} \equiv \mathcal{H}_A \otimes \mathcal{H}_B$. On the other hand, the entanglement entropy truly measures quantum entanglement only for pure states $|\psi\rangle_{AB}$. Indeed, it is not even a correlation measure if a given total state is mixed. Thus, so called $E_P = E_W$ conjecture fills a gap between correlations in mixed states and spacetime geometry. This has been further studied in the literature [26–30].

Figure 1. An example of minimal surfaces which gives Δ_W for a tripartite setup.

Another important direction is to explore multipartite correlation measure and its geometric dual. It is well known that there are richer correlation structures in quantum systems consisting of three or more subsystems, especially about quantum entanglement (see e.g. [31]). For example, there appear different separability criteria for multipartite states. To understand operational aspects of an amount of entanglement by means of (S)LOCC, one needs (infinitely) many kinds of standard states, such as W and GHZ states. Therefore multipartite entanglement is much more sophisticated than bipartite entanglement.

On the other hand, the holographic interpretation of multipartite correlations is less known, though it can play a crucial role to understand the emergence of bulk geometry out of boundary renormalization group flows as well as the idea of ER=EPR [15, 32–34]. In the literature, one quantity $\tilde{I}_3$ called tripartite information, which is one particular generalization of mutual information $I(A : B) = S_A + S_B - S_{AB}$, attracts a lot of attention in holography [32, 35–38]. However, it can be either positive or negative, which makes it a bit hard to use it to diagnose physical properties of the system at times.

In this paper, we first introduce a new measure of multipartite quantum and classical correlations Δ_P in generic quantum systems. It is given by generalizing the entanglement of purification to multipartite states. We study its information-theoretic properties, especially focusing on various entropic inequalities. It turns out that Δ_P gives an upper bound on another generalization of quantum mutual information introduced in [39, 40], the so called multipartite mutual information.

We then propose a holographic dual of multipartite entanglement of purification Δ_W , as a sum of minimal areas of codimension-2 surfaces in the entanglement wedge [41–43], motivated by the tensor network description of the AdS/CFT correspondence [13, 17–20]. One typical example of Δ_W was drawn in figure 1. We demonstrate that it satisfies all the properties of the multipartite entanglement of purification by geometrical proofs. These agreements tempt us to provide a new conjecture $\Delta_P = \Delta_W$.

We clarify in the appendix that Δ_P is larger than the multipartite generalization [39, 40] of squashed entanglement, which is a promising measure of genuine quantum entanglement [44–46]. We also discuss the holographic counterpart of squashed entanglement.

This paper is organized as follows: in section 2, we give the definition of multipartite entanglement of purification Δ_P and prove its information-theoretic properties. In sec-

tion 3, we introduce a multipartite generalization of the entanglement wedge cross-section Δ_W in holography and study its properties geometrically, and find full agreement with those we proved in section 2. Based on these facts, we propose the conjecture $\Delta_P = \Delta_W$. In section 4, we conclude and discuss future questions. In appendix A, the universal relation between Δ_P and multipartite squashed entanglement was clarified and the holographic counterpart of squashed entanglement was also discussed.

Note added. After all the results in this paper were obtained, [47] appeared in which the authors defined the same multipartite generalization of E_P (up to a normalization factor) and tested a holographic dual which is different from Δ_W .

2 Multipartite entanglement of purification

In this section, we will define a generalization of entanglement of purification for multipartite correlations and prove its various information-theoretic properties.

Let us start from recalling the definition and basic properties of the entanglement of purification [23, 48]. We consider a quantum state ρ_{AB} on a bipartite quantum system $\mathcal{H}_{AB} = \mathcal{H}_A \otimes \mathcal{H}_B$. The entanglement of purification E_P for a bipartite state ρ_{AB} is defined by

$$E_P(\rho_{AB}) := \min_{|\psi\rangle_{AA'BB'}} S_{AA'}, \quad (2.1)$$

where the minimization is taken over purifications $\rho_{AB} = \text{Tr}_{A'B'}[|\psi\rangle\langle\psi|_{AA'BB'}]$. This is an information-theoretic measure of total correlations, namely, it captures both quantum and classical correlations between A and B . In this point of view, it is similar as the quantum mutual information $I(A : B) = S_A + S_B - S_{AB}$. Nevertheless, it is known that the regularized version of entanglement of purification $E_P^\infty(\rho_{AB}) := \lim_{n \rightarrow \infty} E_P(\rho_{AB}^{\otimes n})/n$ has an operational interpretation in terms of EPR pairs and local operation and asymptotically vanishing communication [23]. From the definition, we can see that E_P measures the value of quantum entanglement between AA' and BB' in the optimally purified system.

We simply write $E_P(\rho_{AB})$ as $E_P(A : B)$ unless otherwise a given state specified. We summarize some known properties of E_P for the reader's convenience:

(I) It reduces to the entanglement entropy for pure state $\rho_{AB} = |\psi\rangle\langle\psi|_{AB}$,

$$E_P(A : B) = S_A = S_B, \text{ for pure states.} \quad (2.2)$$

(II) It vanishes if and only if a given state ρ_{AB} is a product,

$$E_P(A : B) = 0 \Leftrightarrow \rho_{AB} = \rho_A \otimes \rho_B. \quad (2.3)$$

(III) It monotonically decreases upon discarding ancilla,

$$E_P(A : BC) \geq E_P(A : B). \quad (2.4)$$

(IV) It is bounded from above by the entanglement entropy,

$$E_P(A : B) \leq \min\{S_A, S_B\}. \quad (2.5)$$

(Va) It is bounded from below by a half of mutual information,

$$E_P(A : B) \geq \frac{I(A : B)}{2}. \quad (2.6)$$

(Vb) For tripartite state ρ_{ABC} , it has a lower bound,

$$E_P(A : BC) \geq \frac{I(A : B) + I(A : C)}{2}. \quad (2.7)$$

(VI) For tripartite pure state $|\psi\rangle_{ABC}$, it is polygamous,

$$E_P(A : BC) \leq E_P(A : B) + E_P(A : C). \quad (2.8)$$

(VIIa) For a class of states that saturate the subadditivity, i.e. $S_{AB} = S_B - S_A$, it reduces to the entanglement entropy,

$$E_P(A : B) = S_A \text{ when } S_{AB} = S_B - S_A. \quad (2.9)$$

(VIIb) For a class of states that saturate the strong subadditivity, i.e. $S_{AB} + S_{AC} = S_B + S_C$, it reduces to the entanglement entropy,

$$E_P(A : B) = S_A \text{ when } S_{AB} + S_{AC} = S_B + S_C. \quad (2.10)$$

These properties are not independent from each other and one can prove (VI) from (I) and (Va), and also prove (VIIa) (or (VIIb)) from (III) and (Va) (or (Vb)). All these properties are proven in generic quantum systems. (I) allows us to regard E_P as a generalization of entanglement entropy for quantifying an amount of correlations for mixed states. We refer to [23, 48] for detailed proofs and discussion.

2.1 Definition

We define a new quantity that captures total multipartite correlations by generalizing the entanglement of purification. We first note that we can rewrite the definition of E_P (2.1) as

$$E_P(\rho_{AB}) = \frac{1}{2} \min_{|\psi\rangle_{AA'BB'}} [S_{AA'} + S_{BB'}], \quad (2.11)$$

because $S_{AA'} = S_{BB'}$ holds for any purifications $|\psi\rangle_{AA'BB'}$. This form of E_P motivate us to define a generalization of entanglement of purification for a n -partite state $\rho_{A_1 \dots A_n}$ as follows.

Definition 1. For n -partite quantum states $\rho_{A_1 \dots A_n}$, we define the multipartite entanglement of purification Δ_P as¹

$$\Delta_P(\rho_{A_1 \dots A_n}) := \min_{|\psi\rangle_{A_1 A'_1 \dots A_n A'_n}} \sum_{i=1}^n S_{A_i A'_i}, \quad (2.12)$$

where the minimization is taken over all possible purifications of $\rho_{A_1 \dots A_n}$.

---

¹The normalization factor is not essential in our discussion, so we take it so that the entropic inequalities below become simple. We remark that it is common and even operationally meaningful at times in quantum information theory to define a multipartite generalization of some measure with $\frac{1}{2}$ prefactor regardless to n . If we follow this convention for Δ_P , some results in this paper will seemingly change e.g. from $\Delta_P \geq I$ to $\Delta_P \geq I/2$.

We call it multipartite entanglement of purification and write $\Delta_P(\rho_{A_1 \dots A_n}) = \Delta_P(A_1 : \dots : A_n)$ unless we need to specify a given state. Δ_P can be regarded as the value of sum of quantum entanglement in an optimal purification $|\psi\rangle_{A_1 A'_1 \dots A_n A'_n}$, between one of n -parties and the other $n - 1$ parts. For example, for tripartite state ρ_{ABC} , it can be represented as

$$\Delta_P(A : B : C) := \min_{|\psi\rangle_{AA'BB'CC'}} [S_{AA'} + S_{BB'} + S_{CC'}], \quad (2.13)$$

and the entanglement entropies $S_{AA'}$, $S_{BB'}$ and $S_{CC'}$ in the brackets characterize quantum entanglement between $AA' : BB'CC'$, $BB' : AA'CC'$ and $CC' : AA'BB'$, respectively. We also note that a purification that gives the optimal value in (2.13) may not be unique in general, as is so for the entanglement of purification E_P .

2.2 Other measures

Besides the entanglement of purification, there have been a lot of measures of quantum and/or classical correlations which quantify bipartite correlations for mixed states - including mutual information and squashed entanglement [44, 45]. Their generalization for multipartite cases have also been proposed in the literature [39, 40]. To see that multipartite entanglement is not just a sum of bipartite one, let us consider the famous GHZ state in a 3-qubit system:

$$|\text{GHZ}\rangle = \frac{1}{\sqrt{2}}(|000\rangle + |111\rangle). \quad (2.14)$$

For this state, the three qubits are strongly correlated by genuine tripartite entanglement. The point is that, after one of the subsystems is traced out, the remaining bipartite state is just a separable state and there is no quantum entanglement. This is an example which shows that the structure of multipartite quantum entanglement is much richer than bipartite ones.

To quantify an amount of correlations for multipartite states, there have been several proposals by generalizing the mutual information. One well known quantity, the so-called tripartite information is defined as (based on Ven diagram)

$$\begin{aligned} \tilde{I}_3(A : B : C) &:= S_A + S_B + S_C - S_{AB} - S_{BC} - S_{CA} + S_{ABC} \\ &= I(A : C) + I(A : B) - I(A : BC). \end{aligned} \quad (2.15)$$

This quantity plays an important role in holography and has been studied e.g. in [32, 35–37]. The tripartite information $\tilde{I}_3$, however, can take all of negative, zero, or positive values in generic quantum systems, and especially it always vanishes for all pure states. These facts make it hard to be regarded as a standard measure of correlations.

An alternative approach is introduced in [39, 40] and the authors called the generalization as multipartite mutual information, defined by the relative entropy between a given original state and its local product state:

$$I(A : B : C) := S(\rho_{ABC} || \rho_A \otimes \rho_B \otimes \rho_C) = S_A + S_B + S_C - S_{ABC}, \quad (2.16)$$

where $S(\rho || \sigma) = \text{Tr} \rho \log \rho - \text{Tr} \rho \log \sigma$. This definition is motivated by an expression of the bipartite mutual information,

$$I(A : B) = S(\rho_{AB} || \rho_A \otimes \rho_B). \quad (2.17)$$

In general, the multipartite mutual information for n -partite state $\rho_{A_1 \dots A_n}$ is defined in the same manner:

$$I(A_1 : \dots : A_n) := S(\rho_{A_1 \dots A_n} \| \rho_{A_1} \otimes \dots \otimes \rho_{A_n}) = \sum_{i=1}^n S_{A_i} - S_{A_1 \dots A_n}. \quad (2.18)$$

This is clearly positive semi-definite and is monotonic under local operations [39]. Thus one may consider it as a more promising measure than $\tilde{I}$ for the purpose of total multipartite correlations. Note that we can rewrite $I(A_1 : \dots : A_n)$ as a suggestive form, which is a summation of bipartite mutual information:

$$I(A_1 : \dots : A_n) = I(A_1 : A_2) + I(A_1 A_2 : A_3) + \dots + I(A_1 \dots A_{n-1} : A_n). \quad (2.19)$$

We will carefully distinguish these two types of generalizations of mutual information, $\tilde{I}$ and I , and we mainly discuss the latter one in the following context.

2.3 Properties of multipartite entanglement of purification

Here we explore properties of Δ_P in generic quantum systems. Firstly, we can immediately see the following property from the definition.

Lemma 2. *If one of the subsystems is decoupled $\rho_{A_1 \dots A_n} = \rho_{A_1 \dots A_{n-1}} \otimes \rho_{A_n}$, then $\Delta_P(A_1 : \dots : A_{n-1} : A_n) = \Delta_P(A_1 : \dots : A_{n-1})$.*

Proof. One can separately purify ρ_{A_n} and the remaining parts, and then it directly follows by definition. $\square$

Especially, for bipartite state ρ_{AB} , it reduces to the twice of entanglement of purification: $\Delta_P(A : B) = 2E_P(A : B)$. This guarantees that Δ_P is a generalization of E_P to multipartite states.

We expect that Δ_P is a natural generalization of E_P for multipartite correlations and has similar properties. Indeed, one can prove the following properties which are the counterparts of those of E_P mentioned above.

Proposition 3. *If a given n -partite state $|\phi\rangle_{A_1 \dots A_n}$ is pure, then the multipartite entanglement of purification is given by the summation of entanglement entropy of each single subsystem,*

$$\Delta_P(A_1 : \dots : A_n) = \sum_{i=1}^n S_{A_i} \text{ for pure states.} \quad (2.20)$$

Proof. Notice that $|\phi\rangle_{A_1 \dots A_n}$ itself is a purification, and that all the other purifications should have a form $|\psi\rangle_{A_1 A'_1 \dots A_n A'_n} = |\phi\rangle_{A_1 \dots A_n} \otimes |\phi'\rangle_{A'_1 \dots A'_n}$. Thus adding ancillary systems always increases the sum of entanglement entropy of purified systems, and the minimum is achieved by the original state $|\psi\rangle_{A_1 A'_1 \dots A_n A'_n} = |\phi\rangle_{A_1 \dots A_n}$. $\square$

This is a generalization of property (I) and makes it easy to calculate Δ_P for pure states. Note that in the case of pure state, the multipartite mutual information also reduces to the sum of entanglement entropy: $I(A_1 : \dots : A_n) = \sum_{i=1}^n S_{A_i} - S_{A_1 \dots A_n} = \sum_{i=1}^n S_{A_i}$. Thus we have $\Delta_P = I$ for any pure multipartite states.

Proposition 4. Δ_P vanishes if and only if a given n -partite state is fully product,

$$\Delta_P(A_1 : \cdots : A_n) = 0 \Leftrightarrow \rho_{A_1 \cdots A_n} = \rho_{A_1} \otimes \cdots \otimes \rho_{A_n}. \quad (2.21)$$

Even though it can be directly proven, we postpone its proof after the proposition 8. This property indicates that Δ_P is not a measure of merely quantum entanglement but of both quantum and classical correlations. This is expected since it is a generalization of E_P . Note that Δ_P is not a measure of genuine n -partite correlations, but also includes $2, \dots, n-1$ -partite correlations in $\rho_{A_1 \cdots A_n}$.

As a measure of correlations, it is natural to expect that Δ_P decreases when we trace out a part of one subsystem. Actually, this is true as we can see in the following.

Proposition 5. Δ_P monotonically decrease upon discarding ancilla,

$$\Delta_P(XA_1 : \cdots : A_n) \geq \Delta_P(A_1 : \cdots : A_n). \quad (2.22)$$

Proof. It follows from the fact that all purifications of $\rho_{XA_1 \cdots A_n}$ are included in these of $\rho_{A_1 \cdots A_n}$. Namely, if $|\psi\rangle_{XX'A_1A'_1 \cdots A_nA'_n}$ is a optimal purification for $\rho_{XA_1 \cdots A_n}$, then it is also one of the (not optimal in general) purification of $\rho_{A_1 \cdots A_n}$, thus

$$\Delta_P(XA_1 : \cdots : A_n) = S_{A_1(A'_1 XX')} + S_{A_2 A'_2} + \cdots + S_{A_n A'_n} \geq \Delta_P(A_1 : \cdots : A_n). \quad (2.23)$$

□

Now we give an upper bound on Δ_P in terms of a certain sum of entanglement entropy. This is a generalization of property (IV).

Proposition 6. Δ_P is bounded from above by

$$\Delta_P(A_1 : \cdots : A_n) \leq \min_i [S_{A_1} + \cdots + S_{A_1 \cdots A_{i-1} A_{i+1} \cdots A_i} + \cdots + S_{A_n}]. \quad (2.24)$$

Proof. For simplicity, we will first prove this bound for tripartite state ρ_{ABC} . Let us consider a standard purification of a given state $\rho_{ABC} = \sum p_k |\phi^k\rangle \langle \phi^k|_{ABC}$ such that

$$|\psi\rangle_{AA'BB'CC'} = \sum_{k=1}^{\text{rank}[\rho_{ABC}]} \sqrt{p_k} |\phi^k\rangle_{ABC} \otimes |0\rangle_{A'} \otimes |0\rangle_{B'} \otimes |k\rangle_{C'}. \quad (2.25)$$

For this purification we have $\Delta_P(A : B : C) \leq S_{AA'} + S_{BB'} + S_{CC'}$. Note that $\rho_{AA'} = \rho_A \otimes |0\rangle \langle 0|_{A'}$ and the same for B , and $S_{CC'} = S_{AA'BB'}$, it can be easily shown that

$$S_{AA'} = S_A, \quad S_{BB'} = S_B, \quad S_{CC'} = S_{AB}, \quad (2.26)$$

for the state (2.25). Thus we get $\Delta_P(A : B : C) \leq S_A + S_B + S_{AB}$. Commuting A, B, C , we get three upper bounds on Δ_P ,

$$\Delta_P(A : B : C) \leq \min\{S_A + S_B + S_{AB}, S_B + S_C + S_{BC}, S_C + S_A + S_{CA}\}. \quad (2.27)$$

The generalization of this proof to n -partite cases is straightforward. □

These upper bounds indicates that if we have a bipartite state ρ_{AB} , and consider extensions ρ_{ABC} , the upper bound of $\Delta_P(A : B : C)$ is totally determined by the information included in ρ_{AB} . In other words, we can not arbitrarily increase the multipartite correlations by adding ancillary systems (the upper bound can be reached by any purification $|\psi\rangle_{ABC}$ of ρ_{AB} , though it is not the only way to saturate these bounds as we will see in corollary 10 and 11).

Next we state universal lower bounds on Δ_P . We first show the following inequality satisfied for any tripartite state ρ_{ABC} .

Proposition 7. *Tripartite entanglement of purification $\Delta_P(A : B : C)$ is bounded from below by*

$$\Delta_P(A : B : C) \geq \max\{S_A + S_B + S_C - S_{ABC}, 2(S_A + S_B + S_C) - S_{AB} - S_{BC} - S_{CA}\}. \quad (2.28)$$

Proof. Let us take an optimal purification $|\psi\rangle_{AA'BB'CC'}$. For this state we have

$$\begin{aligned} \Delta_P(A : B : C) &= S_{AA'} + S_{BB'} + S_{CC'} \\ &= I(AA' : BB') + I(AA'BB' : CC') \\ &\geq I(A : B) + I(AB : C) \\ &= S_A + S_B + S_C - S_{ABC}, \end{aligned} \quad (2.29)$$

where in the third line we used the monotonicity of mutual information

$$I(AX : B) \geq I(A : B). \quad (2.30)$$

Moreover, for tripartite pure states $|\psi\rangle_{AA'BB'CC'}$, we have $I(AA'BB' : CC') = I(AA' : CC') + I(BB' : CC')$. Thus we get

$$\begin{aligned} \Delta_P(A : B : C) &= I(AA' : BB') + I(BB' : CC') + I(CC' : AA') \\ &\geq I(A : B) + I(B : C) + I(C : A) \\ &= 2(S_A + S_B + S_C) - S_{AB} - S_{BC} - S_{CA}. \end{aligned} \quad (2.31)$$

□

These bounds have a suggestive form in terms of tripartite mutual information:²

$$\Delta_P(A : B : C) \geq \max\{I(A : B : C), I(A : B : C) + \tilde{I}_3(A : B : C)\}. \quad (2.32)$$

In particular, Δ_P is always greater or equal to the multipartite mutual information $I(A : B : C)$. We will see that this is also true for n -partite states in the following proposition.

Proposition 8. *The multipartite entanglement of purification $\Delta_P(A_1 : \dots : A_n)$ is bounded from below by the multipartite mutual information,*

$$\Delta_P(A_1 : \dots : A_n) \geq I(A_1 : \dots : A_n). \quad (2.33)$$

---

²Note that it leads to a general relationship $\Delta_P(A : B : C) \geq \tilde{I}_3(A : B : C)$ for any quantum states.

Proof. The proof is essentially the same as that in tripartite case. Let us consider an optimal purification $|\psi\rangle_{A_1 A'_1 \dots A_n A'_n}$ for $\rho_{A_1 \dots A_n}$. Then we have

$$\begin{aligned}\Delta_P(A_1 : \dots : A_n) &= \sum_{i=1}^n S_{A_i A'_i} = \sum_{i=1}^n S_{A_i A'_i} - S_{A_1 A'_1 \dots A_n A'_n} \\ &= I(A_1 A'_1 : \dots : A_n A'_n) \\ &\geq I(A_1 : \dots : A_n),\end{aligned}\tag{2.34}$$

where we used the property of multipartite mutual information [39]

$$I(A_1 X : \dots : A_n) \geq I(A_1 : \dots : A_n).\tag{2.35}$$

□

This is a generalization of property (Va), (Vb) and provides general relationship between two types of multipartite total correlation measures I and Δ_P . It is worth to point out that these two quantities behave very similarly. Indeed, the propositions 2, 3, 4, 5, and 6 are also true for multipartite mutual information. One exception is, the lower bound of tripartite case, $\Delta_P(A : B : C) \geq I(A : B : C) + \tilde{I}_3(A : B : C)$, which is obviously violated for $I(A : B : C)$ when $\tilde{I}_3(A : B : C)$ is positive.

The proposition 8 also allows us to give a simple proof of the proposition 4.

Proof. If a n -partite state is totally product $\rho_{A_1 \dots A_n} = \rho_{A_1} \otimes \dots \otimes \rho_{A_n}$, then one can get $\Delta_P = 0$ by purifying each subsystems independently. On the other hand, if $\Delta_P(A_1 : \dots : A_n) = 0$, then $I(A_1 : \dots : A_n) = S(\rho_{A_1 \dots A_n} || \rho_{A_1} \otimes \dots \otimes \rho_{A_n}) = 0$ following the proposition 8. Thus, the non-degeneracy of relative entropy leads to $\rho_{A_1 \dots A_n} = \rho_{A_1} \otimes \dots \otimes \rho_{A_n}$. □

Using the above arguments, some properties of Δ_P follow as corollaries.

Corollary 9. *For any pure n -partite state, Δ_P is polygamous:*

$$\Delta_P(A_1 : \dots : A_{n-1} : BC) \leq \Delta_P(A_1 : \dots : A_{n-1} : B) + \Delta_P(A_1 : \dots : A_{n-1} : C).\tag{2.36}$$

Proof. For any pure state $|\phi\rangle_{A_1 \dots A_n BC}$ it follows from the proposition 3 that

$$\begin{aligned}\Delta_P(A_1 : \dots : A_{n-1} : BC) &= \sum_{i=1}^{n-1} S_{A_i} + S_{BC} = \sum_{i=1}^{n-1} S_{A_i} + S_{A_1 \dots A_{n-1}} \\ &\leq 2 \sum_{i=1}^{n-1} S_{A_i} \\ &= \sum_{i=1}^{n-1} S_{A_i} + S_B - S_{A_1 \dots A_{n-1} B} + \sum_{i=1}^{n-1} S_{A_i} + S_C - S_{A_1 \dots A_{n-1} C} \\ &\leq \Delta(A_1 : \dots : A_{n-1} : B) + \Delta(A_1 : \dots : A_{n-1} : C),\end{aligned}\tag{2.37}$$

where in the first inequality we used the subadditivity of von Neumann entropy recursively, in the third line $S_B = S_{A_1 \dots A_{n-1} C}$, $S_C = S_{A_1 \dots A_{n-1} B}$ for pure states, and in the last inequality the proposition 8. □

As E_P is so, the multipartite entanglement of purification is difficult to calculate in general because of the minimization over infinitely many purifications. Nevertheless, there is a class of quantum states for which one can rigorously calculate Δ_P in terms of entanglement entropy.

Corollary 10. *For a class of tripartite states ρ_{ABC} that saturate the subadditivity $S_{ABC} = S_C - S_{AB}$, we have $\Delta_P(A : B : C) = S_A + S_B + S_{AB}$.*

Proof. From proposition 6 and 7, we have

$$S_A + S_B + S_C - S_{ABC} \leq \Delta_P(A : B : C) \leq S_A + S_B + S_{AB}. \quad (2.38)$$

Therefore $S_C - S_{ABC} = S_{AB}$ leads $\Delta_P(A : B : C) = S_A + S_B + S_{AB}$. $\square$

Corollary 11. *For a class of tripartite states ρ_{ABC} that saturate both of the two forms of the strong subadditivity, $S_A + S_C = S_{AB} + S_{BC}$ and $S_B + S_C = S_{AB} + S_{AC}$, then we have $\Delta_P(A : B : C) = S_A + S_B + S_{AB}$.*

Proof. From proposition 6 and 7, we have

$$2(S_A + S_B + S_C) - S_{AB} - S_{BC} - S_{CA} \leq \Delta_P(A : B : C) \leq S_A + S_B + S_{AB}, \quad (2.39)$$

where the lower bound can be expressed as

$$\begin{aligned} & 2(S_A + S_B + S_C) - S_{AB} - S_{BC} - S_{CA} \\ &= S_A + S_B + S_{AB} + (S_A + S_C - S_{AB} - S_{BC}) + (S_B + S_C - S_{AB} - S_{AC}). \end{aligned} \quad (2.40)$$

Thus if the two strong subadditivity are simultaneously saturated, we get $\Delta_P(A : B : C) = S_A + S_B + S_{AB}$. $\square$

We also provide another lower bound on Δ_P in terms of bipartite entanglement of purification.

Proposition 12. Δ_P is bounded from below by

$$\Delta_P(A_1 : \cdots : A_n) \geq \sum_{i=1}^n E_P(A_i : A_1 \cdots A_{i-1} A_{i+1} \cdots A_n). \quad (2.41)$$

Proof. Let us prove it for tripartite cases for simplicity. For a state ρ_{ABC} , we have

$$\begin{aligned} \Delta_P(A : B : C) &= \min_{|\psi\rangle_{AA'BB'CC'}} [S_{AA'} + S_{BB'} + S_{CC'}] \\ &\geq \min_{|\psi\rangle_{AA'BB'CC'}} S_{AA'} + \min_{|\psi\rangle_{AA'BB'CC'}} S_{BB'} + \min_{|\psi\rangle_{AA'BB'CC'}} S_{CC'} \\ &= E_P(A : BC) + E_P(B : CA) + E_P(C : AB), \end{aligned} \quad (2.42)$$

then the bound follows. $\square$

3 Holography: multipartite entanglement wedge cross section

In this section, we define a multipartite generalization of entanglement wedge cross-section introduced in [24, 25], motivated by the tensor network description of AdS geometry [13, 17–20].

3.1 Definition

We start by setting our conventions in holography. To compute entanglement entropy in quantum field theories, we often choose a (maybe disconnected) subsystem A on a time slice, and the Hilbert space of the field theory is factorized into $\mathcal{H}_{\text{tot}} = \mathcal{H}_A \otimes \mathcal{H}_{A^c}$. Then the entanglement entropy for subsystem A in a state ρ_{tot} , is defined as the von Neumann entropy of the reduced density matrix ρ_A ,

$$S_A := -\text{Tr} \rho_A \log \rho_A, \quad \rho_A = \text{Tr}_{A^c} \rho_{\text{tot}}. \quad (3.1)$$

In the AdS/CFT correspondence, the holographic entanglement entropy formula [9–11] tells us how to calculate entanglement entropy in dual gravity side. Consider a state in d -dimensional holographic CFT which has a classical $d+1$ dimensional gravity dual. In the present paper, we will restrict ourselves to static cases³. The dual gravity solution of the given state ρ_{tot} will be a canonical time slice M in gravity side. To compute the entanglement entropy for a chosen subsystem $A \subset \partial M$, we are looking for a $d-1$ -dimensional surface Γ_A in M with minimal area, under the conditions that $\partial \Gamma_A = \partial A$ and Γ_A is homologous to A . Then the holographic entanglement entropy is determined by the minimal area,⁴

$$S_A = \frac{\text{Area}(\Gamma_A^{\min})}{4G_N}. \quad (3.2)$$

Let us start to define our main interest, i.e. a multipartite generalization of entanglement wedge cross-section Δ_W . We mostly focus on tripartite case for simplicity, though the generalization to more partite cases is rather straightforward. We take subsystems A , B and C on the boundary ∂M . In general ρ_{ABC} is a mixed state. Then one can compute the holographic entanglement entropy S_A, S_B, S_C and also S_{ABC} following (3.2). The corresponding minimal surfaces are denoted by $\Gamma_A^{\min}, \Gamma_B^{\min}, \Gamma_C^{\min}, \Gamma_{ABC}^{\min}$, respectively. The entanglement wedge M_{ABC} [41–43] is defined as a region of M ⁵ with boundary A, B, C and $\Gamma_{ABC}^{\min}$:

$$\partial M_{ABC} = A \cup B \cup C \cup \Gamma_{ABC}^{\min}. \quad (3.3)$$

Notice that M_{ABC} gets disconnected when some of A, B, C or all of them are decoupled. Also note that ∂M_{ABC} may include bifurcation surfaces in the bulk such as in AdS black hole geometry.

³Even though we can define a covariant version of multipartite entanglement wedge cross-section in a similar way for E_W [24], the holographic proofs of its entropic inequalities for more than 4-partite cases is not straightforward [50]. We leave it as a future problem.

⁴We work at the leading order of large N limit through the whole of present paper.

⁵More precisely, we consider a constant time slice of entanglement wedge and call it also entanglement wedge, while the former is codimension-0 and the latter is codimension-1.

Figure 2. An example of tripartite entanglement wedge cross-section. The black bold dashed lines represents the minimal surface $\Gamma_{ABC}^{\min}$, giving a part of the boundary of M_{ABC} . The yellow thin dashed lines represents $\Sigma_{ABC}^{\min}$ whose area (divided by $4G_N$) is Δ_W .

Next, we divide arbitrarily the boundary ∂M_{ABC} (not M_{ABC} itself) into three parts $\tilde{A}, \tilde{B}, \tilde{C}$ so that they satisfy

$$\tilde{A} \cup \tilde{B} \cup \tilde{C} = \partial M_{ABC}, \quad (3.4)$$

and

$$A \subset \tilde{A}, B \subset \tilde{B}, C \subset \tilde{C}. \quad (3.5)$$

The boundary of $\tilde{A}, \tilde{B}, \tilde{C}$ is denoted by $\mathcal{D}_{ABC}$. Regarding each $\tilde{A}, \tilde{B}, \tilde{C}$ as a subsystem of a geometric pure state, we can calculate

$$S_{\tilde{A}} + S_{\tilde{B}} + S_{\tilde{C}}, \quad (3.6)$$

by using holographic entanglement entropy formula (3.2). This is performed by finding a minimal surface $\Sigma_{ABC}^{\min}$ that consists of three parts $\Sigma_A, \Sigma_B, \Sigma_C$, which share the boundary $\mathcal{D}_{ABC}$, such that

$$\Sigma_{ABC}^{\min} = \Sigma_A \cup \Sigma_B \cup \Sigma_C, \quad \partial \Sigma_{ABC}^{\min} = \mathcal{D}_{ABC}, \quad (3.7)$$

and

$$\Sigma_{A,B,C} \text{ is homologous to } \tilde{A}, \tilde{B}, \tilde{C} \text{ inside } M_{ABC}. \quad (3.8)$$

Since ∂M_{ABC} is codimension-2, the surfaces $\mathcal{D}_{ABC}$ which plays the role of the division of $\partial M_{ABC} = \tilde{A} \cup \tilde{B} \cup \tilde{C}$, is codimension-3. In the case of $\text{AdS}_3/\text{CFT}_2$, $\mathcal{D}_{ABC}$ is in general three separated points on $\Gamma_{ABC}^{\min}$, see figure 2, 3.

Finally we minimize the area of $\Sigma_{ABC}^{\min}$ over all possible divisions $\tilde{A}, \tilde{B}, \tilde{C}$ that satisfy the conditions (3.4) and (3.5). This gives now a quantity we call the multipartite entanglement wedge cross section

$$\Delta_W(\rho_{ABC}) := \min_{\tilde{A}, \tilde{B}, \tilde{C}} \left[\frac{\text{Area}(\Sigma_{ABC}^{\min})}{4G_N} \right]. \quad (3.9)$$

For n -partite boundary subsystems, in general, the multipartite entanglement wedge cross-section is defined in the same manner. Notice that when it is reduced to the bipartite case, this definition is actually twice of the bipartite entanglement wedge cross-section defined

Figure 3. An example of tripartite entanglement wedge cross-section in a black hole geometry. Each surface of $\Sigma_{ABC}^{\min}$ is doubled.

in [24, 25]. We sometimes write $\Delta_W(\rho_{ABC}) = \Delta_W(A : B : C)$ to clarify a way of partition of subsystems.

In summary, Δ_W computes the multipartite cross-sections of the entanglement wedge M_{ABC} and it is a natural generalization of the bipartite entanglement wedge cross-section. This can be used as a total measure of how strongly multiple parties are holographically connected with each other. Below we study the properties of Δ_W .

3.2 Properties of multipartite entanglement wedge cross-section and the conjecture $\Delta_W = \Delta_P$

In the following, we investigate holographic properties of Δ_W , inspired by those of Δ_P . To avoid unnecessary complexity, we mostly consider tripartite case only, and it should be understood that the properties are easily generalized for n -partite cases in somewhat trivial ways unless otherwise emphasized.

First, if ρ_{ABC} is pure, from the definition (3.7), $\Sigma_{ABC}^{\min}$ coincides with $\Gamma_A^{\min} \cup \Gamma_B^{\min} \cup \Gamma_C^{\min}$. Therefore Δ_W is equal to the sum of the entanglement entropy of A , B and C :

$$\Delta_W(A : B : C) = S_A + S_B + S_C. \quad (3.10)$$

As we mentioned above, for a partly decoupled entanglement wedges i.e. if $M_{ABC} = M_{AB} \sqcup M_C$, where $\sqcup$ denote that the geometries M_{AB}, M_C are totally separated, then Δ_W is reduced to (twice of) entanglement wedge cross-section. This clearly leads that $\Delta_W = 0$ if and only if the entire entanglement wedge is totally decoupled $M_{A_1 \dots A_n} = \sqcup_{i=1}^n M_{A_n}$ for multipartite setups.

One can easily show that Δ_W decreases when we reduce one of the subregions in $A, B, C \equiv C_1 \cup C_2$:

$$\Delta_W(A : B : C_1 \cup C_2) \geq \Delta_W(A : B : C_1), \quad (3.11)$$

by using the so-called entanglement wedge nesting,

$$M_X \subset M_{XY}, \quad (3.12)$$

which holds for any boundary subregions X, Y [41–43].

Figure 4. The proof of an upper bound of Δ_W . The sum of blue real lines is $S_A + S_B + S_{AB}$ and the sum of dashed yellow lines are $\Delta_W(\rho_{ABC})$. Clearly $\Delta_W(\rho_{ABC}) \leq S_A + S_B + S_{AB}$ holds somewhat trivially since $S_A + S_B + S_{AB}$ has UV divergences while Δ_W does not. When two of subsystems share the boundary, Δ_W also diverges, but it is always weaker than $S_A + S_B + S_{AB}$ shown by a graph.

One can also easily show an upper bound of Δ_W by a graph proof (figure 4):

$$\Delta_W(A : B : C) \leq S_A + S_B + S_{AB}, \quad (3.13)$$

By commuting A, B, C , one can further get

$$\Delta_W(A : B : C) \leq \min[S_A + S_B + S_{AB}, S_B + S_C + S_{BC}, S_A + S_C + S_{AC}]. \quad (3.14)$$

Furthermore, for tripartite setups, one can show two lower bounds of Δ_W also by graph proofs (figure 5, figure 6):

$$\Delta_W(A : B : C) \geq I(A : B : C) = S_A + S_B + S_C - S_{ABC}. \quad (3.15)$$

$$\Delta_W(A : B : C) \geq I(A : B : C) + \tilde{I}_3(A : B : C) = 2(S_A + S_B + S_C) - S_{AB} - S_{BC} - S_{AC}. \quad (3.16)$$

Note that, however, in holography we always have $I(A : B : C) \geq I(A : B : C) + \tilde{I}_3(A : B : C)$ because of negative tripartite information $\tilde{I}_3 \leq 0$ [32]. Therefore the former is always tighter.

Similarly, for n -partite setup, one can easily show that

$$\Delta_W(A_1 : \dots : A_n) \geq I(A_1 : \dots : A_n), \quad (3.17)$$

by drawing graphs.

Note that the corollaries in the previous section automatically follows for Δ_W from the above discussion, while we can also show them by drawing graphs. We also note that the proposition 12 for Δ_W can be easily shown by graphs.

One can view the above properties are the multipartite generalization of the holographic properties of bipartite entanglement wedge cross-section. Motivated by the same

Figure 5. The proof of a lower bound of Δ_W . The sum of dashed yellow lines is $\Delta_{ABC} + S_{ABC}$ and the sum of real blue lines are $S_A + S_B + S_C$. Clearly $\Delta_W(\rho_{ABC}) + S_{ABC} \geq S_A + S_B + S_C$ follows since the entanglement entropy are defined as minimal surfaces.

Figure 6. The proof of a lower bound of Δ_W . The sum of dashed yellow lines is $\Delta_{ABC} + S_{AB} + S_{BC} + S_{CA}$, and the sum of real doubled blue lines are $2(S_A + S_B + S_C)$. Clearly $\Delta_W + S_{AB} + S_{BC} + S_{CA} \geq 2(S_A + S_B + S_C)$ follows, since the entanglement entropy are defined as minimal surfaces.

properties of Δ_W and Δ_P , we now make a conjecture that, the multipartite entanglement wedge cross-section Δ_W we defined in this section is nothing but the holographic counterpart of the multipartite entanglement of purification Δ_P we defined in the last section (at the leading order $O(N^2)$):

$$\Delta_W = \Delta_P . \quad (3.18)$$

3.3 Computation of Δ_W in pure AdS_3

Now we compute Δ_W in the simple examples of $\text{AdS}_3/\text{CFT}_2$. We work in Poincaré patch, and a static ground state of a CFT_2 on a infinite line is described by a bulk solution with the metric

$$ds^2 = \frac{dx^2 + dz^2}{z^2} , \quad x \in (-\infty, +\infty), z \in [0, +\infty) . \quad (3.19)$$

Figure 7. The computation of Δ_W in pure AdS_3 .

The three subsystems we choose are the intervals $A = [-b, -a - r]$, $B = [-a + r, a - r]$, $C = [a + r, b]$, where $b > a > 0$ and r is relatively small compared to both a and b . We require that the entanglement wedge of ABC is connected, as shown in figure 7. Following the definition of Δ_W given in (3.9), in this set up the problem becomes to find a triangle type configuration with the minimal length of three connected geodesics, where the ending points of the geodesics are located on 3 semi-circles separately, as shown in figure 7. Since we focus on the case of 3 intervals A, B, C which have a reflection symmetry $x \rightarrow -x$, the reasonable minimal configuration should also keep the reflection symmetry. This consideration reduces the problem to find a special angle θ such that the length of 3 geodesics is minimal. Then, the tripartite entanglement wedge cross-section Δ_W is given by

$$\Delta_W(A : B : C) = \min_{\theta} \left[\frac{L(\theta)}{4G_N} \right]. \quad (3.20)$$

We obtained a compact formula of the length L as a function of a, b, r and θ , however this formula is rather complicated. We instead show numerical θ dependence of L as plotted in figure 8 and evaluate the special values of both θ and L satisfying the minimal length condition for a given a, b, r .

It is also straightforward to check the properties of Δ_W studied before in this particular setup.

3.4 Computation of Δ_W in BTZ black hole

Now we turn to the BTZ black holes. A planar BTZ black hole describes a 2d CFT on a infinite line at finite temperature. The metric of a fixed time slice of BTZ is given by

$$ds^2 = \frac{1}{z^2} \left(\frac{dz^2}{f(z)} + dx^2 \right), \quad f(z) = 1 - \frac{z^2}{z_H^2}, \quad (3.21)$$

where the temperature is related to the horizon by $\beta = 2\pi z_H$. For simplicity we choose 3 subsystems A, B, C as intervals $[-\ell, 0]$, $[0, \ell]$ and the remaining part of the infinite line, respectively, as shown in figure 9.

Figure 8. $L - \theta$ plot in the computation of Δ_W with different parameters. From top to bottom, the parameters of (a, b, r) are $(10, 100, 0.05)$, $(10, 100, 0.1)$, $(10, 100, 0.5)$, $(10, 100, 0.75)$. $\Delta_W * 4G_N$ and the optimal value of θ are $(27.2046, \theta \rightarrow 1.56818)$, $(24.432, \theta \rightarrow 1.5657)$, $(17.9942, \theta \rightarrow 1.54531)$, $(16.3723, \theta \rightarrow 1.53255)$, respectively.

Figure 9. The computation of Δ_W in BTZ.

As studied in [24], the geodesic length between the boundary and the horizon is

$$L_1 = \log \frac{\beta}{\pi\epsilon}, \quad (3.22)$$

where ϵ is the UV cutoff. The geodesic length between $(-\ell, 0)$ and $(0, 0)$ is⁶

$$L_2 = 2 \log \frac{\beta \sinh(\pi\ell/\beta)}{\pi\epsilon}, \quad (3.23)$$

and the geodesic length between $(-\ell, 0)$ and $(\ell, 0)$ is

$$L_3 = 2 \log \frac{\beta \sinh(2\pi\ell/\beta)}{\pi\epsilon}. \quad (3.24)$$

At high temperature, Σ_{ABC} consists of six short lines of length L_1 , so the tripartite cross-section is given by

$$\Delta_W = 6L_1 = 6 \log \frac{\beta}{\pi\epsilon} =: A^{(1)}. \quad (3.25)$$

⁶It is the same as the geodesic length between $(0, 0)$ and $(\ell, 0)$.

At low temperature, Σ_{ABC} consists of 3 geodesic lines connecting $(-\ell, 0)$, $(0, 0)$ and $(\ell, 0)$, so the Δ_W is given by

$$\Delta_W = 2L_2 + L_3 = 4 \log \frac{\beta \sinh(\pi\ell/\beta)}{\pi\epsilon} + 2 \log \frac{\beta \sinh(2\pi\ell/\beta)}{\pi\epsilon} =: A^{(2)} . \quad (3.26)$$

The tripartite entanglement wedge cross-section Δ_W is thus given by

$$\Delta_W(A : B : C) = \frac{1}{4G_N} \min[A^{(1)}, A^{(2)}] . \quad (3.27)$$

We compare $A^{(1)}$ and $A^{(2)}$ and find the critical temperature

$$\beta_* = \frac{\log \sqrt{y_*}}{\pi\ell} , \quad (3.28)$$

where y_* is the positive root of

$$(y + y^{-1} - 2)(y - y^{-1}) = 8 . \quad (3.29)$$

Furthermore, one can confirm that there are only two phases $A^{(1)}, A^{(2)}$ separated by the above critical temperature. When $\beta < \beta_*$, $A^{(1)}$ is favored and when $\beta > \beta_*$, $A^{(2)}$ is favored.

4 Conclusion

In this paper, we defined a generalization of entanglement of purification to multipartite states denoted by Δ_P , and proved its various properties focusing on bounds described by other entropic quantities. We demonstrate that Δ_P satisfies desired properties as a generalization of E_P and provides an upper bound on the multipartite mutual information introduced in [39, 40]. In particular, we show that the tripartite entanglement of purification $\Delta_P(A : B : C)$ is bounded from below by a sum of two different generalizations of mutual information. We also show that for a class of tripartite quantum states which saturate the subadditivity or the strong subadditivity, there is a closed expression of Δ_P in terms of entanglement entropy.

Based on the holographic conjecture of entanglement of purification [24, 25], we defined a generalization of entanglement wedge cross-section as the holographic counterpart of the multipartite entanglement of purification Δ_W , and show that all the properties Δ_P has are indeed satisfied by Δ_W . It leads us to propose a new conjecture $\Delta_P = \Delta_W$ at the leading order $O(N^2)$ of large N limit. Alternatively speaking, this implies the naive picture of purified geometry based on tensor network description [17–20] still works for multipartite cases. As explicit examples, we calculated Δ_W for several simple setups in $\text{AdS}_3/\text{CFT}_2$ including pure AdS_3 and black hole geometry.

Several future questions are in order: first, proof of Δ_W properties in time-dependent background geometry. The properties in this case are expected to be very useful in understanding the dynamical process in quantum gravity systems, since many interesting physical set up go beyond the bi-partite pattern. The entropic inequalities for multipartite cases were actually discussed in [50] for covariant cases, there they argued that new techniques apart from the maximin surfaces [42] are needed to prove them for 5 or more partite

cases. Second, we expect that there is an operational interpretation for Δ_P just like E_P has, such as the one based on SLOCC for multipartite qubits. Third, looking for the new properties satisfied by Δ_W but not always by Δ_P is certainly interesting, because these are essentially the new constraints on holographic states, such as the conjectured strong superadditivity of entanglement of purification in holography. We shall report the progress in future publications.

A The multipartite squashed entanglement and holography

There have been a lot of measures of genuine quantum entanglement proposed. In particular, the squashed entanglement [44, 45] is the most promising measure of quantum entanglement for mixed states, as it satisfies all known desirable properties e.g. additivity. The squashed entanglement is defined by

$$E_{\text{sq}}(\rho_{AB}) := \frac{1}{2} \inf_{\rho_{ABE}} I(A : B|E), \quad (\text{A.1})$$

where $I(A : B|E) = I(A : BE) - I(A : E) = S_{AE} + S_{BE} - S_{ABE} - S_E$ is the conditional mutual information, and the minimization is taken over all possible extensions $\rho_{AB} = \text{Tr}_E[\rho_{ABE}]$. By taking E is trivial we see that by definition E_{sq} is less than or equal to half of the mutual information: $E_{\text{sq}} \leq I/2$.

In [39, 40], multipartite generalizations of E_{sq} were also introduced. To define the one we are interested, we first introduce a conditional multipartite mutual information,

$$I(A_1 : \dots : A_n|E) = I(A_1 : A_2|E) + I(A_1 A_2 : A_3|E) + \dots + I(A_1 \dots A_{n-1} : A_n|E). \quad (\text{A.2})$$

Using this, the (q -)multipartite squashed entanglement for n -partite state $\rho_{A_1 \dots A_n}$ is defined by⁷

$$E_{\text{sq}}^q(A_1 : \dots : A_n) := \inf_{\rho_{A_1 \dots A_n E}} I(A_1 : \dots : A_n|E), \quad (\text{A.3})$$

where the minimization is taken over all possible extensions of $\rho_{A_1 \dots A_n}$.

Noting that a trivial extension $\rho_{A_1 \dots A_n E} = \rho_{A_1 \dots A_n} \otimes |0\rangle\langle 0|_E$ gives $I(A_1 : \dots : A_n|E) = I(A_1 : \dots : A_n)$, we get a generic bound,

$$E_{\text{sq}}^q(A_1 : \dots : A_n) \leq I(A_1 : \dots : A_n). \quad (\text{A.4})$$

Combining it with the proposition 8, we get a generic order of three different measures of multipartite correlations.

---

⁷Here we also define the multipartite squashed entanglement without $\frac{1}{2}$ prefactor following our convention for Δ_P .

Corollary 13. *It holds for any n -partite quantum states that*

$$E_{\text{sq}}^q(A_1 : \cdots : A_n) \leq I(A_1 : \cdots : A_n) \leq \Delta_P(A_1 : \cdots : A_n). \quad (\text{A.5})$$

Note that for any pure n -partite state these bounds are saturated and we have $E_{\text{sq}}^q = I = \Delta_P$. Generally, $E_{\text{sq}}^q \leq \Delta_P$ is a desirable property, since Δ_P is expected to be a measure of both quantum and classical correlations while E_{sq}^q is only of quantum ones.

A.1 Holographic counterpart of E_{sq}

The definition of squashed entanglement (A.1) is similar to that of the entanglement of purification (2.1). Both of them use a certain type of extension, indeed, purification is a special set of extension. This observation motivates us to seek for a holographic counterpart of E_{sq} in the same spirit of E_P or Δ_P .

Let us regard a time slice of AdS as a tensor network which describes a quantum state of CFT. In a gravity background with a tensor network description, one can define a pure or mixed state for any codimension two convex surface, called the surface/state correspondence [17–20]. Let us now take use of this picture to study what the holographic counterpart of squashed entanglement could be if it indeed exists.⁸

First, we consider a class of extensions from ρ_{AB} to ρ_{ABE} which have classical gravity duals described by tensor networks. The extensions are not necessarily on the original AdS boundary, but each extended geometry should include the entanglement wedge M_{AB} and its boundary should be convex [17]. We assume that there exists an optimal extension for (A.1) in this class. Then we find that all nontrivial such extensions give $I(A : B|E) \geq I(A : B)$. Indeed this is equivalent to say that the holographic tripartite information is always negative: $\tilde{I}_3(A : B : E) \leq 0$. This eventually leads that the optimal solution in (A.1) is given by half of the mutual information in holography

$$E_{\text{sq}}(A : B) = \frac{1}{2} I(A : B). \quad (\text{A.6})$$

In the remaining text, we illustrate our argument in details.

To compute the squashed entanglement (A.1), we want to consider how much correlation one can reduce between A and B by knowing the ancillary system E . This is appropriately quantified by the tripartite information

$$\tilde{I}_3(A : B : E) = I(A : B) - I(A : B|E). \quad (\text{A.7})$$

This quantity has been widely studied in holography. In particular, the so called monogamy of mutual information (MMI) shows that $\tilde{I}_3(A : B : E)$ is always negative in holography in the case E is on the original AdS boundary [32]

$$I(A : BE) \geq I(A : B) + I(A : E) \Leftrightarrow \tilde{I}_3(A : B : E) \leq 0. \quad (\text{A.8})$$

Hence one can never reduce the correlation between A and B by knowing the extension E located on the original AdS boundary, i.e. $I(A : B|E) \geq I(A : B)$ holds in this case

---

⁸We are grateful to Tadashi Takayanagi for lots of fruitful comments on the following discussion.

Figure 10. A proof of $I(A : B|E) \geq I(A : B)$ for an extension ρ_{ABE} , where E is on the original boundary [32]. The difference $I(A : B|E) - I(A : B)$ is given by the area of dashed orange codimension-2 surfaces minus that of solid blue ones, which is clearly non-negative by the minimal property of RT-surfaces.

(figure 10). Note that (A.8) is a characteristic property of holographic states, since it is not generally satisfied by arbitrary tripartite quantum states.

Now, we would like to assert that this type of monogamy (A.8) is still true in more general holographic states we consider, as long as the entanglement entropy is still given by a minimal area functional in dual geometry.⁹ This is because the proof of MMI in [32] does not rely on any peculiarity of asymptotic AdS boundary. In particular, it does not concern whether the boundary is at the asymptotic infinity or not. This fact tempts us to assume that all extensions with classical gravity duals satisfy the monogamy of mutual information (or equivalently $\tilde{I}_3(A : B : E) \leq 0$). This situation can be graphically illustrated for example in figure 11.

From the above argument we conjecture that one cannot reduce the correlation between A and B by measuring an ancillary system E i.e. $I(A : B|E) \geq I(A : B)$ holds for any extension with classical gravity dual. With the assumption that in (A.1) there exists an optimal extension with a classical geometrical description, the squashed entanglement in holography will be given by just half of the mutual information (at $O(N^2)$):

$$E_{\text{sq}}(A : B) = \frac{1}{2}I(A : B), \quad (\text{A.9})$$

which can clearly be achieved by a trivial extension. This tells that the inequality $E_{\text{sq}}(A : B) \leq I(A : B)/2$ is saturated in holography.¹⁰

As a consistency check of this saturation conjecture, one can test whether the holographic properties of them (such as the additivity) coincide or not. As mentioned above,

⁹One can replace in this argument the area functional to any geometrical functional as long as it is extensive [32]. In particular, the authors of [32] showed that higher curvature corrections does not affect the MMI, and conjectured that it will be a common property of all large- N field theories.

¹⁰This saturation can also be observed in a tensor network model of holography [34].

Figure 11. A proof of $I(A : B|E) \geq I(A : B)$ for an extension ρ_{ABE} , where E is on the minimal purification (i.e. RT-surface of S_{AB}). The difference $I(A : B|E) - I(A : B)$ in this case is given by the area of the orange codimension-2 surfaces minus that of the blue ones, which is certainly non-negative. For simplicity here we assumed that E is relatively small, but the same result is true for large E (i.e. near the purification).

the mutual information does not always satisfy the monogamy, while the squashed entanglement does for any tripartite state [46]. The fact that the mutual information becomes monogamous in holography actually provides a non-trivial check of (A.6). One might also regard (A.6) as the origin of the MMI in holography.

Note that the saturation (A.6) is already implicated in [32], motivated by the MMI itself.

Moreover, we expect that this kind of saturation also happens for multipartite cases. Namely, we are tempted to test the saturation of (A.4) in holography (at $O(N^2)$):

$$E_{\text{sq}}^q(A_1 : \dots : A_n) \stackrel{?}{=} I(A_1 : \dots : A_n). \quad (\text{A.10})$$

One of such non-trivial tests is given by the strong superadditivity of multipartite squashed entanglement [39]:

$$E_{\text{sq}}^q(A_1 B_1 : \dots : A_n B_n) \geq E_{\text{sq}}^q(A_1 : \dots : A_n) + E_{\text{sq}}^q(B_1 : \dots : B_n). \quad (\text{A.11})$$

This is true in any $2n$ -partite state $\rho_{A_1 B_1 \dots A_n B_n}$. Note that the multipartite mutual information does not satisfy this property in general. For example, if one considers a quantum state

$$\rho_{A_1 B_1 A_2 B_2 A_3 B_3} = \frac{1}{\sqrt{2}} (|000000\rangle \langle 000000|_{A_1 B_1 A_2 B_2 A_3 B_3} + |111111\rangle \langle 111111|_{A_1 B_1 A_2 B_2 A_3 B_3}), \quad (\text{A.12})$$

This will lead to $I(A_1 B_1 : A_2 B_2 : A_3 B_3) = I(A_1 : A_2 : A_3) = I(B_1 : B_2 : B_3)$, which clearly violates the inequality.

However, in holographic CFTs, one can show that the multipartite mutual information does satisfy the strong superadditivity. This comes as follows:

$$\begin{aligned}
I(A_1 B_1 : \cdots : A_n B_n) &= I(A_1 B_1 : A_2 B_2) + I(A_1 B_1 A_2 B_2 : A_3 B_3) + \cdots \\
&\quad \cdots + I(A_1 B_1 A_2 B_2 \cdots A_{n-1} B_{n-1} : A_n B_n) \\
&\geq I(A_1 : A_2) + I(A_1 A_2 : A_3) + \cdots + I(A_1 A_2 \cdots A_{n-1} : A_n) \\
&\quad + I(B_1 : B_2) + I(B_1 B_2 : B_3) + \cdots + I(B_1 B_2 \cdots B_{n-1} : B_n) \\
&= I(A_1 : \cdots : A_n) + I(B_1 : \cdots : B_n), \tag{A.13}
\end{aligned}$$

where we have used the monogamy of holographic mutual information recursively. This observation gives us further evidence for our conjectured saturation in holography (A.10).

To our best knowledge, there is no counter example for such saturation conjecture. If there is a property which E_{sq} always satisfies but I does not always, then one can try to test whether it holds for holographic mutual information. If it does, this can be considered as additional positive evidence for our conjecture.¹¹
