HIPP Human Islet Phenotyping Program
IIDP Integrated Islet Distribution Program
NIH National Institutes of Health

To the Editor: In recent years, the need for enhanced rigour, reproducibility and transparency in biomedical research has been the topic of much discussion. The National Institutes of Health (NIH) led the way in this conversation with issuance of the NIH guidelines for rigour and reproducibility, which have been mandated for all grant applications since 2016 [1, 2]. In support of this initiative, a recent review article by Hart and Powers, published in *Diabetologia* [3], with an accompanying editorial co-published in *Diabetes* and *Diabetologia* by Poitout et al [4, 5] highlighted the need for improved standardisation of human islet data and its reporting in scientific publications. *Diabetologia* and *Diabetes* have initiated a

checklist that is now required at the time of manuscript submission. At a minimum, the source and isolation centre, a unique identifier number for each human islet preparation, and key demographic/clinical data must be included. Although not mandatory, the editorial encourages the inclusion of additional data, such as the cause of donor death, measurements of islet purity and viability, functional measures, ischaemia duration and culture time.

Since 2004, the Integrated Islet Distribution Program (IIDP) has served as the main source of human islets for research in the USA [6–8]. Directed by Joyce C. Niland at the City of Hope in Duarte, CA, the IIDP is funded by the National Institutes of Diabetes and Digestive and Kidney Diseases (NIDDK) and the JDRF. To date, the IIDP has distributed over 250 million islets, serving more than 400 islet studies across nine different countries, with the resulting research yielding more than 700 publications. Thus, the IIDP is a major contributor to the ‘human islet research ecosystem’ as described by Hart and Powers [3], as well as an avid supporter of improved standards for reporting of human islet data.

In recognition of the growing need for improved assessment of human islet function and quality, the NIH and IIDP initiated the Human Islet Phenotyping Program (HIPP) in 2016. The HIPP programme is located at Vanderbilt University in Nashville, TN, and is directed by Marcela Brissova, with Carmella Evans-Molina, Co-Principal Investigator of the IIDP, serving as the HIPP liaison. The HIPP receives a sample of human islets from each IIDP-supported islet isolation. As depicted in the analysis workflow (Fig. 1a), the HIPP conducts post-shipment assessment of islet morphology, viability, and software-guided measurement of islet purity and number. These data are then integrated with in vitro islet functional analysis by perfusion, which simultaneously captures insulin and glucagon secretory profiles with high temporal resolution. Because human islet preparations

This Editorial is being simultaneously published in *Diabetologia* and *Diabetes*.

Fig. 1 The IIDP–HIPP integrates a broad spectrum of islet phenotypic features with donor characteristics. **(a)** Analysis workflow performed by the HIPP on human islets from each IIDP-supported islet isolation. Human islets from the same preparation are distributed to HIPP and IIDP-affiliated investigators. **(b)** The IIDP–HIPP database contains data from a large and demographically diverse pool of islet donors. Shown is the racial background of islet donors for 198 preparations analysed by HIPP since 2016. **(c)** Steps required for automated publication checklist generation from the IIDP Data Center. The IIDP–HIPP database and the automated online tool for checklist generation can be accessed by authorised IIDP users through the dashboard of the IIDP password-protected website (<https://iidp.coh.org/secure/isletavail/>)

vary in terms of their composition, the islet functional data can be further correlated with composition of three major islet cell types, alpha, beta, and delta cells, measured independently by immunofluorescence. When possible, the HIPP also collects and stores samples for future investigation, including frozen samples of handpicked islets (for RNA and protein analysis) and frozen samples of islet preparations (for DNA analysis). The sample resource is under development and will become available in the near future. In December 2018, the HIPP data were released to IIDP-affiliated investigators. To date, the

HIPP has analysed nearly 200 islet preparations from a demographically diverse pool of donors (Fig. 1b). Synthesis of the rich data set generated by this unique resource can be leveraged by investigators to provide context for their own experiments and analyses, and their resulting data could potentially be integrated with IIDP–HIPP data in the future. Most importantly, the HIPP workflow yields standardised data that will enhance transparency and quality in human islet research.

As another recent enhancement to assist investigators in meeting the new mandatory criteria for reporting of human

islet data as put forth by *Diabetologia* and *Diabetes*, the IIDP has developed an automated online tool to compile and export the mandated information for manuscript submission. All of the required data have been collected by IIDP-affiliated islet isolation centres since January 2010, and are available to investigators so that the information can be provided when submitting manuscripts to *Diabetes/Diabetologia* (and, possibly, additional journals in the future). Data on the functional assessment of the islet preparations, classed as ‘recommended information’ in the reporting checklist, have been provided by the HIPP since July 2016. Using this online reporting tool, investigators will be able to directly export islet checklist data into an Excel spreadsheet that can be uploaded to the journal. Islet preparations are selected for inclusion in the checklist based on a unique Research Resource Identifier [RRID] [9] (Fig. 1c). Both the IIDP–HIPP database and the automated online tool for checklist generation can be accessed by authorised IIDP users through the dashboard of the IIDP password-protected website (<https://iidp.coh.org/secure/isletavail/>).

Whereas efforts towards standardised reporting of human islet data are a critical first step in ensuring rigour and reproducibility in diabetes research, an unintended consequence of any new mandate can be an additional burden on investigators both in time and resources. Our hope is that the data provided by the IIDP isolation centres pre-shipment and the rich phenotyping data provided by the HIPP post-shipment can assist investigators in meeting these new requirements. Other programmes have begun similar initiatives to share phenotyping and multi-omics data from isolated islets, including the Human Pancreas Analysis Program (HPAP) of the Human Islet Research Network (HIRN) and the Islet Core at the Alberta Diabetes Institute. Making these types of centrally collected data available can both enhance rigour and reproducibility and accelerate scientific discoveries. In addition, they provide cost savings to the diabetes research community by reducing the need for individual investigators to collect the same type of information and/or perform redundant assays. We believe that the recent IIDP–HIPP initiatives described here will help to set new standards in human islet research, and we are pleased to offer solutions that improve human islet research and satisfy new journal reporting requirements, without adding undue burden to individual investigators.

Acknowledgements The authors would like to acknowledge R. Aramandla, V. DiBacco, H. Durai, A. Coldren, S. Mei, G. Poffenberger and C. Reihsmann at the Vanderbilt University Medical Center, for their assistance with the development of HIPP workflows and the design of the IIDP–HIPP database. The authors acknowledge J.-N. Chuang (Database Administrator), and M. Pineda and H. Sibley (Senior Software

Developers), all from the Department of Diabetes & Cancer Discovery Science, Diabetes and Metabolism Research Institute, City of Hope, for their work in developing the IIDP–HIPP database and the Islet Data Checklist for Publication. In addition, the authors would like to acknowledge K. Abraham (Project Scientist for the IIDP) of NIDDK, for her advice and guidance on this project.

Funding The Integrated Islet Distribution Program is funded by the NIDDK (UC4DK098085) with additional support from JDRF (1-RSC-2019-712-S-B). The authors also acknowledge support from the Vanderbilt Diabetes Research and Training Center (DK020593) in providing resources, core infrastructure and support for HIPP-related activities.

Duality of interest The authors declare that there is no duality of interest associated with this manuscript.

Contribution statement All authors were responsible for drafting the article and revising it critically for important intellectual content. All authors approved the version to be published.
