The author presents an interesting novel technique for labia majora augmentation using adipofascial flaps from the inner thigh. As expected, the technique is only suitable for patients who are candidates for both labia majora augmentation and thigh lift. Such patients are becoming very common in clinical practice. On the one hand, over recent years, the number of patients undergoing bariatric procedures has skyrocketed. The main reason for this is the acceptance and success of

laparoscopic techniques which require less recovery time. On the other hand however, the awareness of female genital esthetics has also increased owing to increased media attention, both from magazines and video. Many women feel self-conscious about the appearance of their labia majora and request surgical correction. In view of all of these, the presented technique seems a valuable addition to the plastic surgeon's armamentarium. The author should be congratulated for this contribution.
