A 32-week gestational age female neonate, born by caesarean section, presented with respiratory distress, and a chest x-ray was performed (Fig. 1). Physical examination showed large fontanelles and open sutures, micrognathia and glossoptosis, facial dysmorphisms, pectus excavatum, and bulging eyes.

At 11 months of corrected age, due to palpable clavicular discontinuity on physical examination, the proband performed a second X-ray (Fig. 2).

## Declarations

**Ethics approval** Informed consent was obtained from all individual participants included in the study. This study was conducted in accordance with the ethical standards of the institutional and/or national research committee and with the 1964 Helsinki declaration and its later amendments or comparable ethical standards.

**Conflict of interest** The authors declare no competing interests.

**Publisher's note** Springer Nature remains neutral with regard to jurisdictional claims in published maps and institutional affiliations.
