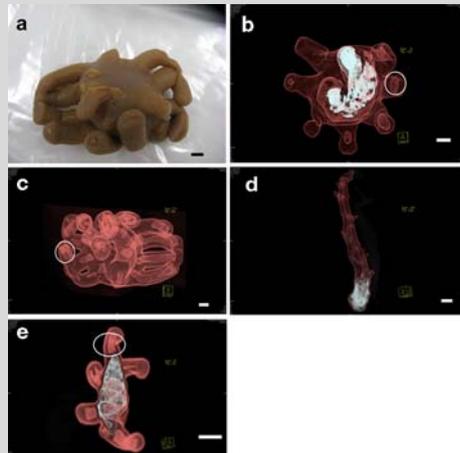

Fig. 1 *Epizoanthus* spp. associated with pagurid crabs (a–c), eunicid worm tubes (d), and molluscs (e). Specimens in b–e were examined using a computer tomography (CT) scanner (all scale bars = 1 cm)

Epizoic zoanthids are found from coral reef communities (e.g., *Acrozoanthus*) to the deep sea (*Epizoanthus* spp.) (Muirhead et al. 1986; Ates 2003). While often the substrate identity is obvious, in other associations only the zoanthid is visible from the outside, making invasive examination the only method to determine if a substrate is present, and what or where the substrate is within the zoanthid. While invasive sampling is often very easy to perform, for rare, unknown, or type specimens, this may not be a desirable option. Zoanthid internal examination is also made difficult by their uptake of sand and detritus to help form their structure.

In an attempt to solve these problems, several *Epizoanthus* spp. (Fig. 1; all scale bars = 1 cm) associated with pagurid crabs (Fig. 1a, b, c), eunicid worm tubes (Fig. 1d), and molluscs (Fig. 1e) were examined using a Somatom Spirit (Siemens Co., Tokyo, Japan) computer tomography (CT) scanner at Okinawa Churaumi Aquarium, Motobu, Japan. Results showed substrates clearly visible in some specimens (eunicid worm tube in Fig. 1d, shell in Fig. 1e), while some specimens had no apparent substrate except for a pagurid crab (white section in Fig. 1b, also Fig. 1c). Additionally, diagnostic taxonomic characters such as tentacles and mesenterial areas were also often distinguishable (e.g., circles in Fig. 1b, c, e), as was potential biomineralization (white sections in Fig. 1d).

As many CT scanners are designed to examine small animals, this method is not only potentially applicable to valuable specimens but also to many marine invertebrates with difficult to examine morphologies, such as sponges or octocorals and their spicule arrangement. Future examinations of zoanthids

would be well served by imaging the interior morphology of specimens using high-resolution CT scanners. CT scanner technology has recently begun to be applied to biological specimens (e.g., DigiMorph project at the University of Texas), and undoubtedly the use of such technology in morphological examinations will become more commonplace in the future as technology advances.
