Received: 19 August 1997 / In revised form: 15 December 1997

Summary. We address the following problem from the intersection of dynamical systems and stochastic analysis: Two SDE $d x_{t}=$ $\sum_{j=0}^{m} f_{j}\left(x_{t}\right) \circ d W_{t}^{j}$ and $d x_{t}=\sum_{j=0}^{m} g_{j}\left(x_{t}\right) \circ d W_{t}^{j}$ in $\mathbb{R}^{d}$ with smooth coefficients satisfying $f_{j}(0)=g_{j}(0)=0$ are said to be smoothly equivalent if there is a smooth random diffeomorphism (coordinate transformation) $h(\omega)$ with $h(\omega, 0)=0$ and $D h(\omega, 0)=$ id which conjugates the corresponding local flows,

$$
\varphi(t, \omega) \circ h(\omega)=h\left(\theta_{t} \omega\right) \circ \psi(t, \omega),
$$

where $\theta_{t} \omega(s)=\omega(t+s)-\omega(t)$ is the (ergodic) shift on the canonical Wiener space. The normal form problem for SDE consists in finding the "simplest possible" member in the equivalence class of a given SDE, in particular in giving conditions under which it can be linearized $\left(g_{j}(x)=D f_{j}(0) x\right)$.

We develop a mathematically rigorous normal form theory for SDE which justifies the engineering and physics literature on that problem. It is based on the multiplicative ergodic theorem and uses a uniform (with respect to a spatial parameter) Stratonovich calculus which allows the handling of non-adapted initial values and coefficients in the stochastic version of the cohomological equation. Our

[^0]main result (Theorem 3.2) is that an SDE is (formally) equivalent to its linearization if the latter is nonresonant.

As a by-product, we prove a general theorem on the existence of a stationary solution of an anticipative affine SDE.

The study of the Duffing-van der Pol oscillator with small noise concludes the paper.

Mathematics Subject Classification: (1991) primary 60H10, 34F05; secondary 58F11, 93E03

## 1 Introduction

Normal form theory was initiated by Poincaré in 1892 and is a technique of fundamental importance for dynamical systems, in particular for bifurcation theory. It aims at simplifying a nonlinear deterministic or random dynamical system in the neighborhood of a reference solution by means of a smooth change of coordinates. In this paper, we consider dynamical systems in $\mathbb{R}^{d}$, and the reference solution is assumed to be the fixed point $x=0$.

We briefly recall those facts from deterministic normal form theory relevant to the stochastic case. For recent presentations of the deterministic theory see e.g. Anosov and V. I. Arnold [1], Vanderbauwhede [23], or Katok and Hasselblatt [14].

Two smooth vector fields $f$ and $g$ in $\mathbb{R}^{d}$ with $f(0)=g(0)=0$ are called smoothly equivalent, if the local flows $\varphi$ and $\psi$ generated by $\dot{x}=f(x)$ and $\dot{x}=g(x)$ are smoothly equivalent, i.e., if there is a $C^{\infty}$ diffeomorphism (also called coordinate transformation) ${ }^{1} h: \mathbb{R}^{d} \rightarrow \mathbb{R}^{d}$ with $h(0)=0$ for which

$$
\varphi(t) \circ h=h \circ \psi(t) \quad \text { locally } .
$$

Differentiating this with respect to $t$ gives the equivalent infinitesimal form

$$
\begin{equation*}
f \circ h=D h g \tag{1.1}
\end{equation*}
$$

Normal form theory for vector fields now seeks an $h$ for which $g$ is "simplest possible", in other words: we look for the "simplest possible" element in the $C^{\infty}$ equivalence class of $f$.

[^1]Since (1.1) implies $B=\operatorname{Dh}(0)^{-1} A D h(0)$, where $A=D f(0)$ and $B=D g(0)$ are the Jacobians of $f$ and $g$ at $x=0$, respectively, and since a linear mapping is considered simplest possible if its matrix representation is in Jordan canonical form (which requires the choice of a basis in $\mathbb{R}^{d}$ ) it is reasonable to assume without loss of generality that $A$ is in Jordan canonical form, and $h$ is near-identity, i.e., $D h(0)=\mathrm{id}$. Then $B=A$ for any such $h$. The normal form of $f$ at the fixed point 0 is thus the natural generalization of the Jordan canonical form to the nonlinear case.

The ultimate aim of normal form theory is the linearization of $f$, i.e., to find an $h$ such that $g(x)=A x$, or $f \sim A$, against which there are obstructions in the form of "resonances".

Formal normal form theory now expands $f, g$ and $h$ into formal Taylor series at $0, f(x) \sim A x+\sum_{n=2}^{\infty} f_{n}(x), g(x) \sim A x+\sum_{n=2}^{\infty} g_{n}(x)$, $h(x) \sim x+\sum_{n=2}^{\infty} h_{n}(x)$, inserts those expansions into equation (1.1), equates coefficients of order $n \geq 2$ (which are homogeneous polynomials), and tries to successively determine $h_{n}$ such that $g_{n}$ is zero, or at least "simplest possible". For this purpose we introduce spaces of homogeneous polynomials.

Let for $n \in \mathbb{N}$

$$
\mathbb{N}_{n}^{d}:=\left\{\tau=\left(\tau_{1}, \ldots, \tau_{d}\right) \in\left(\mathbb{Z}^{+}\right)^{d}:|\tau|:=\sum_{i=1}^{d} \tau_{i}=n\right\}
$$

be the set of multi-indices of length $n$. Denote by $x^{\tau}:=x_{1}^{\tau_{1}} x_{2}^{\tau_{2}} \cdots x_{d}^{\tau_{d}}$ the scalar monomial in $d$ variables of degree $|\tau|=n$. Then

$$
H_{n, d}:=H_{n, d}\left(\mathbb{R}^{d}\right)=\left\{f=\sum_{\tau \in \mathbb{N}_{n}^{d}} x^{\tau} f_{\tau}: f_{\tau} \in \mathbb{R}^{d}\right\}
$$

is the vector space of homogeneous polynomials of degree $n$ in $d$ variables with values in $\mathbb{R}^{d}$. We also write $|\tau|=n$ for $\tau \in \mathbb{N}_{n}^{d}$. Observe that

$$
\Delta:=\Delta(n, d)=\# \mathbb{N}_{n}^{d}=\binom{n+d-1}{n}
$$

so that

$$
D=\operatorname{dim} H_{n, d}\left(\mathbb{R}^{d}\right)=\Delta \cdot d,
$$

in particular

$$
\Delta=\operatorname{dim} H_{n, d}\left(\mathbb{R}^{1}\right) .
$$

A basis $F=\left(u_{1}, \ldots, u_{d}\right)$ of $\mathbb{R}^{d}$ and the basis $\left(x^{\tau}\right)_{|\tau|=n}$ of $H_{n, d}\left(\mathbb{R}^{1}\right) \cong \mathbb{R}^{\Delta}$ give a basis $\left(x^{\tau} F\right):=\left(x^{\tau} u_{i}\right)_{i=1, \ldots, d ;|\tau|=n}$ of $H_{n, d}\left(\mathbb{R}^{d}\right)$, and

$$
H_{n, d} \ni f=\sum_{|\tau|=n} \sum_{i=1}^{d} f_{i, \tau} x^{\tau} u_{i} \cong k_{F}(f)=\left(k_{F}\left(f_{\tau}\right)\right)_{|\tau|=n}=\left(f_{i, \tau}\right) \in \mathbb{R}^{D}
$$

(column vectors, ordered lexicographically) identifies $H_{n, d}$ with $\mathbb{R}^{D}$, where $k_{F}$ is the mapping which assigns $F$ coordinates (respectively $\left(x^{\tau} F\right)$ coordinates) to an element of $\mathbb{R}^{d}$ (respectively $\left.H_{n, d}\right)$. We can identify $H_{n, d}\left(\mathbb{R}^{d}\right)$ with the tensor product of $H_{n, d}\left(\mathbb{R}^{1}\right)$ and $\mathbb{R}^{d}$,

$$
H_{n, d}\left(\mathbb{R}^{d}\right)=H_{n, d}\left(\mathbb{R}^{1}\right) \otimes \mathbb{R}^{d} \cong \mathbb{R}^{\Delta} \otimes \mathbb{R}^{d}
$$

where the above choice of bases induces the basis with elements $x^{\tau} \otimes u_{i}$ in $H_{n, d}\left(\mathbb{R}^{d}\right)$, and the isomorphism induced by the coordinate mappings maps this basis to the standard basis $f_{j} \otimes e_{i} \in \mathbb{R}^{\Delta} \otimes \mathbb{R}^{d}$.

Inserting the above Taylor expansions into (1.1) and equating coefficients gives the cohomological equations

$$
g_{n}(x)=\left(\operatorname{ad}_{n} A\right) h_{n}(x)+k_{n}(x), \quad n \geq 2
$$

where the linear operator

$$
\begin{equation*}
\operatorname{ad}_{n} A: H_{n, d} \rightarrow H_{n, d}, \quad h_{n} \mapsto\left(\operatorname{ad}_{n} A\right) h_{n}(x):=A h_{n}(x)-D h_{n}(x) A x \tag{1.2}
\end{equation*}
$$

is called cohomological operator. Further,

$$
k_{n}=f_{n}+P_{n}\left(f_{k}, g_{k}, h_{k}, 2 \leq k \leq n-1\right)
$$

where

$$
\begin{equation*}
P_{n}=T_{n}\left\{S_{n-1}(f-A) \circ S_{n-1}(h-\mathrm{id})-D S_{n-1}(h-\mathrm{id}) S_{n-1}(g-A)\right\} \tag{1.3}
\end{equation*}
$$

is a polynomial of the lower order terms $f_{k}, g_{k}, h_{k}, 2 \leq k \leq n-1$, of $f$, $g$, and $h$. Here $T_{n}(f)$ denotes the term of order $n$ of $f, S_{n}(f)$ is the $n$-jet (Taylor polynomial of order $n$ ) of $f$. For example, $k_{2}=f_{2}$, $k_{3}=f_{3}-D h_{2} g_{2}, k_{4}=f_{4}+f_{2} \circ g_{2}-D h_{2} g_{3}-D h_{3} g_{2}$, etc.

The operator $\operatorname{ad}_{n} A$ depends linearly on the entries of $A$, and its $D \times D$ matrix representation is

$$
\begin{equation*}
\operatorname{ad}_{n} A=I_{1} \otimes A-T(A)_{n} \otimes I_{2} \tag{1.4}
\end{equation*}
$$

where $I_{1}$ and $I_{2}$ are $\Delta \times \Delta$ and $d \times d$ unit matrices, respectively, $T(A)_{n}$ is the $\Delta \times \Delta$ matrix describing the linear mapping on $H_{n, d}\left(\mathbb{R}^{1}\right) \cong \mathbb{R}^{\Delta}$ given by

$$
h=\sum_{|\tau|=n} h_{\tau} x^{\tau} \mapsto \sum_{|\tau|=n} \sum_{j, k=1}^{d} h_{\tau} \frac{\partial\left(x^{\tau}\right)}{\partial x_{j}} a_{j k} x_{k}=: T(A)_{n}(h),
$$

and $A \otimes B=\left(a_{i j} B\right)$ is the Kronecker product of $A$ and $B$.

Remark 1.1. One easily checks that if $A$ is diagonal, then so is $\operatorname{ad}_{n} A$ for any $n \geq 2$.

We will now present a treatment of the normal form problem for stochastic differential equations (SDE). It deals with the basic question of how many "essentially different" (modulo a $C^{\infty}$ near-identity coordinate transformation) SDE exist.

Our effort is motivated by the fact that many dynamical systems in engineering and physics are perturbed by noise. The desire to simplify those systems prompted numerous publications (see, e.g., Coullet, Elphick and Tirapegui [12], Nicolis and Nicolis [15], Schöner and Haken [20, 21], Sri Namachchivaya and Lin [22], and the references therein). All those authors work with a smallness parameter multiplying the noise terms, hence obtaining the stochastic normal form as a small perturbation of the deterministic one.

Normal form theory without any smallness assumption was developed for random diffeomorphisms by Arnold and Xu in [8], and for random differential equations in [9, 10].

However, normal form theory for SDE has so far defied rigorous analysis for the following technical reason: When solving the stochastic version of the cohomological equation one is forced to consider coefficients as well as solutions which at time $t$ are not adapted to the natural forward filtration $\mathscr{F}_{-\infty}^{t}$ of the (two-sided) Wiener process. This fact, which is a "conflict" between (multiplicative) ergodic theory and classical stochastic analysis, has been clearly seen but not rigorously handled by the pioneers of stochastic normal form theory quoted above. It is the aim of this paper to dissolve this "conflict" and present a rigorous treatment on the basis of multiplicative ergodic theory and of a uniform Stratonovich and anticipative calculus. Our main result is that an SDE is formally equivalent to its linearization provided the latter is nonresonant (Theorem 3.2). We also show by way of an example the usefulness of the stochastic normal form.

## 2 The stochastic cohomological equation

We consider the SDE

$$
\begin{equation*}
d x_{t}=\sum_{j=0}^{m} f_{j}\left(x_{t}\right) \circ d W_{t}^{j}, \quad t \in \mathbb{R}, \quad f_{j}(0)=0 \tag{2.1}
\end{equation*}
$$

in $\mathbb{R}^{d}$, where as usual, $d W_{t}^{0}$ stands for $d t, f_{j} \in C^{\infty}$ for $0 \leq j \leq m$, $(\Omega, \mathscr{F}, \mathbb{P})$ is the canonical two-sided Wiener space, $W_{t}=\left(W_{t}^{1}, \ldots, W_{t}^{m}\right), t \in \mathbb{R}$, the canonical two-sided Wiener process,
$\mathscr{F}_{-\infty}^{t}$ the $\sigma$-algebra generated by $W_{s}, s \leq t$, completed by $\mathbb{P}$-null sets, and $\theta_{t} \omega(s):=\omega(t+s)-\omega(t), s, t \in \mathbb{R}$. In the following $\omega$ will denote an arbitrary element of $\Omega$, whenever it appears in the argument of a random variable.

Equation (2.1) uniquely generates a local $C^{\infty}$ random dynamical system (RDS) (or cocycle) $\varphi$ over the ergodic dynamical system $\left(\Omega, \mathscr{F}, \mathbb{P},\left(\theta_{t}\right)_{t \in \mathbb{R}}\right)$, (see Arnold and Scheutzow [6], Arnold [3, Theorem 2.3.36], for a survey see Arnold [2]). The domain $D(t, \omega)$ and range $R(t, \omega)$ of $\varphi(t, \omega): D(t, \omega) \rightarrow R(t, \omega)$ are neighborhoods of 0 . How many different such local RDS do exist modulo a smooth random conjugacy?

The linear cocycle $\Phi_{1}(t, \omega):=\Phi(t, \omega)=D \varphi(t, \omega, 0)$ on $T_{0} \mathbb{R}^{d} \cong \mathbb{R}^{d}$ is then generated by the linearized SDE

$$
\begin{equation*}
d v_{t}=\sum_{j=0}^{m} A_{j} v_{t} \circ d W_{t}^{j}, \quad A_{j}:=D f_{j}(0), \quad 0 \leq j \leq m . \tag{2.2}
\end{equation*}
$$

The multiplicative ergodic theorem holds for (2.2) (without any further integrability assumptions, see [3, Proposition 6.2.11]), giving the Lyapunov spectrum

$$
\Sigma\left(\Phi_{1}\right):=\Sigma\left(\theta, A_{0}, \ldots, A_{m}, W\right)=\left\{\Lambda_{1} \geq \cdots \geq \Lambda_{d}\right\}
$$

and the splitting $\mathbb{R}^{d}=E_{1}(\omega) \oplus \cdots \oplus E_{p}(\omega)$ which is invariant, $\Phi(t, \omega) E_{i}(\omega)=E_{i}\left(\theta_{t} \omega\right), t \in \mathbb{R}$, and in which the different Lyapunov exponents $\lambda_{1}>\cdots>\lambda_{p}$ from the spectrum are realized as exponential growth rates forward and backward in time,

$$
v \in E_{i}(\omega) \backslash\{0\} \Longleftrightarrow \lim _{t \rightarrow \pm \infty} \frac{1}{t} \log \|\Phi(t, \omega) v\|=\lambda_{i},
$$

and for which $\operatorname{dim} E_{i}(\omega)=d_{i}, d_{i}$ the multiplicity of $\lambda_{i}, 1 \leq i \leq p$.
Definition 2.1 (Random coordinate transformation). A measurable mapping $h: \Omega \times \mathbb{R}^{d} \rightarrow \mathbb{R}^{d}$ is called (near-identity) random coordinate transformation if
(i) $h(\omega, \cdot) \in \operatorname{Diff}^{\infty}\left(\mathbb{R}^{d}\right)$,
(ii) $h(\omega, 0)=0$,
(iii) $\operatorname{Dh}(\omega, 0)=$ id.

The diffeomorphism $h(\omega, \cdot)$ is also denoted by $h(\omega)$.
We now conjugate the local $\operatorname{RDS} \varphi$ generated by (2.1) with another local RDS $\psi$ by means of a random coordinate transformation,

$$
\begin{equation*}
\varphi(t, \omega) \circ h(\omega)=h\left(\theta_{t} \omega\right) \circ \psi(t, \omega) \quad \text { (locally) }, \tag{2.3}
\end{equation*}
$$

where $\psi$ is generated by an SDE

$$
\begin{equation*}
d x_{t}=\sum_{j=0}^{m} g_{j}\left(\theta_{t} \cdot, x_{t}\right) \circ d W_{t}^{j} \tag{2.4}
\end{equation*}
$$

and $h$ is chosen such that the $\operatorname{SDE}$ (2.4) makes sense, and its coefficients $g_{j}$ are "as simple as possible", the ultimate aim being linearization, i.e.,

$$
d x_{t}=\sum_{j=0}^{m} A_{j} x_{t} \circ d W_{t}^{j}
$$

It is important to realize that, while the diffeomorphisms $\varphi(t, \omega)$ and $\psi(t, \omega)$ map the fiber over $\omega$ to the fiber over $\theta_{t} \omega$, the coordinate transformation $h$ is "static" and maps each fiber to itself, hence the $h(\omega)$ on the left-hand side, and the $h\left(\theta_{t} \omega\right)$ on the right-hand side of (2.3).

Although it will turn out that the transformation $\bar{h}(t, \cdot, x)=h\left(\theta_{t} \cdot, x\right)$ to be applied at time $t$ is in general not adapted to the filtration of $W$ at $t$, we proceed formally (and justify later): Applying the Stratonovich lemma to (2.3) gives

$$
\begin{equation*}
d \varphi_{t}=d h_{t}+D h\left(\theta_{t} \cdot, \psi_{t}\right) \circ d \psi_{t} \tag{2.5}
\end{equation*}
$$

where $d h_{t}$ denotes the $t$-differential of $h\left(\theta_{t} \cdot, x\right)$, and $d \varphi_{t}$ the $t$-differential of $\varphi(t, \cdot)$, etc. Inserting the differentials of $\varphi_{t}$ and $\psi_{t}$ into (2.5) yields

$$
\begin{equation*}
\sum_{j=0}^{m} f_{j}\left(h\left(\theta_{t} \cdot, x_{t}\right) \circ d W_{t}^{j}=d h_{t}+\sum_{j=0}^{m} \operatorname{Dh}\left(\theta_{t} \cdot, x_{t}\right) g_{j}\left(\theta_{t} \cdot, x_{t}\right) \circ d W_{t}^{j}\right. \tag{2.6}
\end{equation*}
$$

equivalently

$$
\begin{align*}
d x_{t} & =\sum_{j=0}^{m} g_{j}\left(\theta_{t} \cdot, x_{t}\right) \circ d W_{t}^{j} \\
& =-D h\left(\theta_{t} \cdot, x_{t}\right)^{-1} d h_{t}+\sum_{j=0}^{m} \operatorname{Dh}\left(\theta_{t^{\cdot}}, x_{t}\right)^{-1} f_{j}\left(h\left(\theta_{t} \cdot, x_{t}\right)\right) \circ d W_{t}^{j} \tag{2.7}
\end{align*}
$$

This is an equation for $h$ and the $g_{j}$, where the choice of $h$ is made such that the $g_{j}$ are simplest possible.

We now make the simplifying assumption that we choose the canonical basis in $\mathbb{R}^{d}$. In other words, we leave the linearized SDE (2.2) untouched and refrain from making it "as simple as possible" by choosing an appropriate (necessarily non-adapted) random basis. See the treatment of the resonant case in subsection 4.1.

As in the deterministic case, we make the formal Taylor series Ansatz

$$
\begin{gathered}
f_{j}(x) \sim A_{j} x+\sum_{n=2}^{\infty} f_{j, n}(x), \quad j=0, \ldots, m \\
g_{j}(\omega, x) \sim A_{j} x+\sum_{n=2}^{\infty} g_{j, n}(\omega, x), \quad j=0, \ldots, m \\
h(\omega, x) \sim x+\sum_{n=2}^{\infty} h_{n}(\omega, x),
\end{gathered}
$$

where $f_{j, n} \in H_{n, d}$, while $g_{j, n}(\cdot)$ and $h_{n}(\cdot) \in \mathscr{H}_{n, d}$ are $H_{n, d}$-valued random variables.

Plugging this into equation (2.6) and equating coefficients yields (calculations are as in the deterministic case) an identity for the linear part, and for $n \geq 2$

$$
\begin{align*}
\sum_{j=0}^{m} g_{j, n}\left(\theta_{t} \cdot\right) \circ d W_{t}^{j}= & \sum_{j=0}^{m}\left(\operatorname{ad}_{n} A_{j}\right) h_{n}\left(\theta_{t} \cdot\right) \circ d W_{t}^{j}-d h_{n}\left(\theta_{t} \cdot\right) \\
& +\sum_{j=0}^{m} k_{j, n}\left(\theta_{t} \cdot\right) \circ d W_{t}^{j} \tag{2.8}
\end{align*}
$$

where $\operatorname{ad}_{n} A_{j}: H_{n, d} \rightarrow H_{n, d}$ is the linear operator defined in (1.2) by $h_{n} \mapsto\left(\operatorname{ad}_{n} A_{j}\right) h_{n}(x):=A_{j} h_{n}(x)-D h_{n}(x) A_{j} x$, in matrix form $\operatorname{ad}_{n} A_{j}=$ $I_{1} \otimes A_{j}-T\left(A_{j}\right)_{n} \otimes I_{2}$ on $H_{n, d}\left(\mathbb{R}^{d}\right) \cong H_{n, d}\left(\mathbb{R}^{1}\right) \otimes \mathbb{R}^{d}$, and

$$
\begin{equation*}
k_{j, n}=f_{j, n}+P_{n}\left(f_{j, k}, g_{j, k}, h_{k}, 2 \leq k \leq n-1\right), \quad j=0, \ldots, m \tag{2.9}
\end{equation*}
$$

Here $P_{n}$ is a deterministic polynomial of the lower order terms of $f_{j, k}$, $g_{j, k}$ and $h_{k}, 2 \leq k \leq n-1$, which is independent of $j$ and explicitly given in (1.3).

We now define the stochastic cohomological operator by

$$
\begin{equation*}
d L_{n}\left(h_{n}\right):=d h_{n}-\sum_{j=0}^{m}\left(\operatorname{ad}_{n} A_{j}\right) h_{n} \circ d W_{t}^{j} \tag{2.10}
\end{equation*}
$$

acting on those $H_{n, d}$-valued stationary stochastic processes $h_{n}\left(\theta_{t} \omega\right)$ for which the expression in (2.10) makes sense. With this definition, (2.8) turns into the system of stochastic cohomological equations (suppressing the $\left(\theta_{t} \omega\right)$ argument)

$$
\begin{equation*}
d L_{n}\left(h_{n}\right)=\sum_{j=0}^{m}\left(k_{j, n}-g_{j, n}\right) \circ d W_{t}^{j}=: d K_{n}-d G_{n} \tag{2.11}
\end{equation*}
$$

which have to be solved successively for $n=2, \ldots$, for $d K_{n}$ known from previous steps, and $h_{n}$ choosen to make $d G_{n}$ simplest possible. The most desirable choice is $d G_{n} \equiv 0$, resulting in the task of solving the cohomological equations

$$
d L_{n}\left(h_{n}\right)=d K_{n}, \quad n \geq 2
$$

or, equivalently, looking for stationary solutions of the affine SDE

$$
\begin{equation*}
d h_{n}=\sum_{j=0}^{m}\left(\left(\operatorname{ad}_{n} A_{j}\right) h_{n}+k_{j, n}\left(\theta_{t} \cdot\right)\right) \circ d W_{t}^{j}, \quad n \geq 2 \tag{2.12}
\end{equation*}
$$

where $k_{j, n}$ depends on the solutions of (2.12) of lower order $2 \leq k \leq n-1$. We have $k_{j, 2}=f_{j, 2}$ deterministic, but for $n \geq 3, k_{j, n}$ is typically random and not adapted to the filtration of $W$.

Let $\Phi_{n}$ be the linear cocycle on $H_{n, d}$ generated by the SDE

$$
\begin{equation*}
d v_{t}=\sum_{j=0}^{m}\left(\operatorname{ad}_{n} A_{j}\right) v_{t} \circ d W_{t}^{j}, \quad n \geq 2 . \tag{2.13}
\end{equation*}
$$

The multiplicative ergodic theorem holds for $\Phi_{n}$ (again without additional assumptions) and gives the spectrum

$$
\Sigma\left(\Phi_{n}\right)=\left\{\Lambda_{i}-(\Lambda, \tau): \Lambda_{i} \in \Sigma\left(\Phi_{1}\right),|\tau|=n\right\}
$$

where $(\Lambda, \tau):=\sum_{i=1}^{d} \Lambda_{i} \tau_{i}$. This can be deduced from the form of $\operatorname{ad}_{n} A_{j}$ given in (1.4) and the following facts: If the linear cocycles $\Psi_{1}$ and $\Psi_{2}$ are generated by the linear SDE $d \Psi_{i}=\sum_{j=0}^{m} A_{j}^{(i)} \Psi_{i} \circ d W_{t}^{j}, i=1,2$, then the linear cocycle $\Psi_{1} \otimes \Psi_{2}$ is generated by the linear SDE

$$
d\left(\Psi_{1} \otimes \Psi_{2}\right)_{t}=\sum_{j=0}^{m}\left(A_{j}^{(1)} \otimes I_{2}+I_{1} \otimes A_{j}^{(2)}\right)\left(\Psi_{1} \otimes \Psi_{2}\right)_{t} \circ d W_{t}^{j}
$$

the spectrum of $\Psi_{1} \otimes \Psi_{2}$ is

$$
\Sigma\left(\Psi_{1} \otimes \Psi_{2}\right)=\Sigma\left(\Psi_{1}\right)+\Sigma\left(\Psi_{2}\right)
$$

[3, Theorem 5.4.2] and, finally, the spectrum of the cocycle generated by $d v_{t}=\sum_{j=0}^{m}\left(-T\left(A_{j}\right)_{n}\right) v_{t} \circ d W_{t}^{j}$ is $\{-(\Lambda, \tau):|\tau|=n\}$ (see Arnold and Xu [10, Theorem 3.1]).

It turns out that we have a chance of finding a (unique) stationary solution of (2.12) provided the linear $\operatorname{SDE}(2.13)$ is hyperbolic, i.e., $0 \notin \Sigma\left(\Phi_{n}\right)$. We call the linear cocycle $\Phi=\Phi_{1}$ generated by (2.2) nonresonant of order $\mathbf{n}$ if $0 \notin \Sigma\left(\Phi_{n}\right)$, resonant of order $\mathbf{n}$ otherwise, $n \geq 2$.

## 3 The nonresonant case

The crucial property of the stationary processes $k_{j, n}\left(\theta_{t} \cdot\right)$ in the cohomological equation (2.12) to ensure the existence of a stationary solution in case the linear $\operatorname{SDE}(2.13)$ is hyperbolic, and which is in fact inherited by the solution, is the property of temperedness.

Definition 3.1 (Tempered random vector). A random vector $X$ with values in $\mathbb{R}^{d}$ is called tempered with respect to the metric dynamical system $\left(\Omega, \mathscr{F}, \mathbb{P},\left(\theta_{t}\right)_{t \in \mathbb{R}}\right)$ if

$$
\begin{equation*}
\lim _{t \rightarrow \pm \infty} \frac{1}{|t|} \log ^{+}\left|X\left(\theta_{t} \omega\right)\right|=0 \tag{3.1}
\end{equation*}
$$

The assumption (3.1) excludes the case $\lim \sup _{t \rightarrow \pm \infty} \frac{1}{|t|} \log ^{+}\left|X\left(\theta_{t} \omega\right)\right|$ $=\infty$, and is implied by the integrability condition $\sup _{0 \leq t \leq 1} \log ^{+}\left|X\left(\theta_{t} \cdot\right)\right| \in L^{1}(\mathbb{P})$. We will also make use of the fact that the set of real-valued tempered random variables is a commutative ring with unit element.

Theorem 3.2 (Formal linearization of an SDE). Given the $S D E$

$$
d x_{t}=\sum_{j=0}^{m} f_{j}\left(x_{t}\right) \circ d W_{t}^{j}, \quad f_{j}(0)=0, \quad 0 \leq j \leq m
$$

and assume that the linear cocycle generated by

$$
d v_{t}=\sum_{j=0}^{m} A_{j} v_{t} \circ d W_{t}^{j}, \quad A_{j}:=D f_{j}(0), \quad 0 \leq j \leq m
$$

is nonresonant of any order $n \geq 2$. Then there is a random coordinate transformation $h$ whose formal Taylor series $h(\omega, x) \sim x+$ $\sum_{n \geq 2} h_{n}(\omega, x)$ is uniquely determined and has tempered coefficients $h_{n}$, such that $h$ formally linearizes the above $S D E$.
Remark. 3.3. (i) It is quite remarkable that at the beginning and at the end of the above procedure we have two bona fide classical SDE, while the transformation converting the solutions of the first into the solutions of the second is anticipative.
(ii) With the above procedure, infinitely flat terms of the $f_{j}$ at 0 cannot be detected as they do not appear in formal power series. A random version of Sternberg's linearization theorem would assert that in the above situation the nonlinear $\operatorname{SDE}$ (2.1) and its linearization (2.2) are indeed smoothly (and not just formally) conjugate by a random coordinate transformation $h(\omega, x)$. However, such a theorem is still lacking.

The proof of Theorem 3.2 is quite complicated and is divided into three steps, of which the first two are of technical nature, while the third one (on invariant measures of affine SDE) is of independent interest. The result will be a formal random Taylor series for $h$. To find a random coordinate transformation corresponding to this formal random Taylor series is accomplished by the following theorem.

Theorem 3.4 (Borel's theorem). Given $h_{0}=0, h_{1}(\omega, x)=x, h_{n} H_{n, d^{-}}$ valued random variables, $n \geq 2$. Then there is a random coordinate transformation $h$ whose formal random Taylor series expansion has the coefficients $h_{n}$.

The proof is just an $\omega$-wise version of the deterministic proof given by Vanderbauwhede [23, page 142] and is thus omitted.

### 3.1 Step 1: Boundedness of moments of solutions of a hierarchical system of affine SDE

Our main task here will consist in proving that all processes in our hierarchical system of affine SDE obtained by solving the cohomological equations (2.12) step by step for fixed initial conditions satisfy the conditions of the following lemma.
Lemma 3.5 Let $u=(u(t, x))_{t \in[0,1], x \in \mathbb{R}^{d}}$ be an $\mathbb{R}^{k}$-valued stochastic process which for fixed $x$ is $\mathbb{P}$-a.s. continuous with respect to $t$, is adapted to $\left(\mathscr{F}_{-\infty}^{t}\right), 0 \leq t \leq 1$, and satisfies the following two conditions which from now on are called

Conditions (C): For any $p \geq 2$ and any compact set $K \subset \mathbb{R}^{d}$ there exist constants $c_{p}$ and $c_{p, K} \in \mathbb{R}^{+}$such that

$$
\begin{gathered}
\mathbb{E}\left(\sup _{0 \leq t \leq 1}|u(t, 0)|^{p}\right) \leq c_{p}, \\
\mathbb{E}\left(\sup _{0 \leq \leq \leq 1}|u(t, x)-u(t, y)|^{p}\right) \leq c_{p, K}|x-y|^{p / 2} \quad \text { for all } x, y \in K .
\end{gathered}
$$

Then $u$ is $\mathbb{P}$-a.s. jointly continuous with respect to $(t, x)$, and for $p>d$ and any compact set $K \subset \mathbb{R}^{d}$ there exist constants $C_{p} \in \mathbb{R}^{+}$and $q \geq 1$ such that

$$
\begin{equation*}
\mathbb{E}\left(\sup _{x \in K} \sup _{0 \leq t \leq 1}|u(t, x)|^{p}\right) \leq C_{p}(\operatorname{diam} K)^{q} . \tag{3.2}
\end{equation*}
$$

Proof. The joint continuity of $u$ follows from (C) by Kolmogorov's continuity criterion, applied to the $C[0,1]$-valued process $x \mapsto u(\cdot, x)$, and with $p / 2>d$.
(3.2) is a well-known implication of the fundamental continuity lemma of Garsia, Rodemich and Rumsey, see for example Barlow and Yor [11, formula (3.b),] or Arnold and Imkeller [5].

We now prove that conditions (C) are passed on from $u$ to processes obtained from $u$ by reasonable operations.

Lemma 3.6 Let u satisfy conditions ( $C$ ), and let

$$
v(t, x)=\int_{0}^{t} u(s, x) d W_{s}, \quad w(t, x)=\int_{0}^{t} u(s, x) d s
$$

where $W$ is a scalar Wiener process. Then $v$ and $w$ satisfy conditions $(C)$. Proof. This is an immediate consequence of Burkholder's and Hölder's inequalities.

The following considerations will be crucial for the algorithm by which we solve our hierarchical system of affine SDE. Let $d_{1}, d_{2} \in \mathbb{N}$, and for $0 \leq i \leq m$ suppose that $\left(u_{i}\left(t, x_{1}\right)\right)_{t \in[0,1], x_{1} \in \mathbb{R}^{d_{1}}}$ is a parametrized semimartingale with decomposition

$$
\begin{equation*}
u_{i}\left(t, x_{1}\right)=\int_{0}^{t} w_{i}\left(s, x_{1}\right) d s+\sum_{j=1}^{m} \int_{0}^{t} v_{i}^{j}\left(s, x_{1}\right) d W_{s}^{j} \tag{3.3}
\end{equation*}
$$

with values in $\mathbb{R}^{d_{2}}$. Let, moreover, $B_{0}, B_{1}, \ldots, B_{m}$ be $d_{2} \times d_{2}$ matrices, and denote by $(\Phi(t))_{t \in \mathbb{R}}$ the linear flow in $\mathbb{R}^{d_{2}}$ generated by the linear SDE

$$
\begin{equation*}
d y_{t}=\sum_{j=0}^{m} B_{j} y_{t} \circ d W_{t}^{j} \tag{3.4}
\end{equation*}
$$

We now consider the SDE

$$
\begin{equation*}
d x_{t}=\sum_{j=0}^{m}\left(B_{j} x_{t}+u_{j}\left(t, x_{1}\right)\right) \circ d W_{t}^{j}, \quad x_{0}=x_{2} \in \mathbb{R}^{d_{2}} \tag{3.5}
\end{equation*}
$$

Let $\left(\varphi\left(t, x_{1}\right)\right)_{t \in \mathbb{R}}$ be the flow generated by (3.3), the value of which at $x_{2} \in \mathbb{R}^{d_{2}}$ will be written as $\varphi\left(t, x_{1}\right) x_{2}$.

Lemma 3.7 Let $u_{i}=\left(u_{i}\left(t, x_{1}\right)\right)_{t \in[0,1], x_{1} \in \mathbb{R}^{d_{1}}}$ be given by (3.3). Assume that $w_{i}$ and $v_{i}^{j}$ (hence $\left.u_{i}\right), 0 \leq i \leq m, 1 \leq j \leq m$, satisfy conditions $(C)$. Let

$$
\varphi\left(t, x_{1}\right) x_{2}=\int_{0}^{t} \rho\left(s, x_{1}, x_{2}\right) d s+\sum_{j=1}^{m} \int_{0}^{t} \psi^{j}\left(s, x_{1}, x_{2}\right) d W_{s}^{j}
$$

be the semimartingale decomposition of the solution flow of (3.5). Then $\varphi, \rho$, and $\psi^{j}, 1 \leq j \leq m$, satisfy conditions $(C)$.
Proof. (i) We only prove the second of the conditions (C) for $\varphi$.
Let us start by writing the Itô form of (3.5). We have

$$
\begin{align*}
d y_{t}= & \sum_{j=1}^{m}\left(B_{j} y_{t}+u_{j}\left(t, x_{1}\right)\right) d W_{t}^{j} \\
& +\left(\left(B_{0}+\frac{1}{2} \sum_{j=1}^{m} B_{j}^{2}\right) y_{t}+\frac{1}{2} \sum_{j=1}^{m} v_{j}^{j}\left(t, x_{1}\right)\right) d t \tag{3.6}
\end{align*}
$$

Now fix $p \geq 2$ and a compact set $K \subset \mathbb{R}^{d_{1}} \times \mathbb{R}^{d_{2}}$. Then for any $\left(x_{1}, x_{2}\right),\left(y_{1}, y_{2}\right) \in \mathbb{R}^{d_{1}} \times \mathbb{R}^{d_{2}}$, Burkholder's and Jensen's inequalities as well as the hypothesis yield, with suitable constants $c_{1}, c_{2}, c_{3, K}$ and with the abbreviation

$$
\begin{align*}
& f(t):=\mathbb{E}\left(\sup _{s \in[0, t]}\left|\varphi\left(s, x_{1}\right) x_{2}-\varphi\left(s, y_{1}\right) y_{2}\right|^{p}\right)^{1 / p} \\
& f(1) \leq c_{1}\left\{\left|x_{2}-y_{2}\right|\right. \\
&+\sum_{j=1}^{m} \mathbb{E}\left(\sup _{t \in[0,1]}\left|\int_{0}^{t} B_{j}\left(\varphi\left(s, x_{1}\right) x_{2}-\varphi\left(s, y_{1}\right) y_{2}\right) d W_{s}^{j}\right|^{p}\right)^{1 / p} \\
&+\sum_{j=1}^{m} \mathbb{E}\left(\sup _{t \in[0,1]}\left|\int_{0}^{t}\left(u_{j}\left(s, x_{1}\right)-u_{j}\left(s, y_{1}\right)\right) d W_{s}^{j}\right|^{p}\right)^{1 / p} \\
&+\mathbb{E}\left(\sup _{t \in[0,1]}\left|\int_{0}^{t}\left(B_{0}+\frac{1}{2} \sum_{j=1}^{m} B_{j}^{2}\right)\left(\varphi\left(s, x_{1}\right) x_{2}-\varphi\left(s, y_{1}\right) y_{2}\right) d s\right|^{p}\right)^{1 / p} \\
&\left.+\sum_{j=1}^{m} \mathbb{E}\left(\sup _{t \in[0,1]}\left|\int_{0}^{t}\left(v_{j}^{j}\left(s, x_{1}\right)-v_{j}^{j}\left(s, y_{1}\right)\right) d s\right|^{p}\right)^{1 / p}\right\} \\
& \leq c_{2}\left(\left|x_{2}-y_{2}\right|+\int_{0}^{t} f(s) d s+\left|x_{1}-y_{1}\right|^{1 / 2}\right) \\
& \leq c_{3, K}\left(\left|\left(x_{1}, x_{2}\right)-\left(y_{1}, y_{2}\right)\right|^{1 / 2}+\int_{0}^{1} f(t) d t\right) . \tag{3.7}
\end{align*}
$$

To (3.7) we have to apply Gronwall's lemma to obtain with a suitable constant $c_{p, K} \in \mathbb{R}^{+}$

$$
\begin{equation*}
\mathbb{E}\left(\sup _{t \in[0,1]}\left|\varphi\left(t, x_{1}\right) x_{2}-\varphi\left(t, y_{1}\right) y_{2}\right|^{p}\right) \leq c_{p, K}\left|\left(x_{1}, x_{2}\right)-\left(y_{1}, y_{2}\right)\right|^{p / 2} \tag{3.8}
\end{equation*}
$$

This is the second of the conditions (C) for $\varphi$.
(ii) Next observe that according to (3.6) for any $t \in[0,1]$ and $\left(x_{1}, x_{2}\right) \in \mathbb{R}^{d_{1}} \times \mathbb{R}^{d_{2}}$

$$
\begin{gathered}
\psi^{j}\left(t, x_{1}, x_{2}\right)=B_{j} \varphi\left(t, x_{1}\right) x_{2}+u_{j}\left(t, x_{1}\right), \\
\rho\left(t, x_{1}, x_{2}\right)=\left(B_{0}+\frac{1}{2} \sum_{j=1}^{m} B_{j}^{2}\right) \varphi\left(t, x_{1}\right) x_{2}+\frac{1}{2} \sum_{j=1}^{m} v_{j}^{j}\left(t, x_{1}\right) .
\end{gathered}
$$

Hence by our hypotheses and (3.8), $\psi^{j}$ and $\rho$ satisfy the conditions (C) as well.

Next we show that conditions (C) are inherited from $u$ and its characteristics to a polynomial of $u$ and its characteristics.

Lemma 3.8 Let

$$
u(t, x)=\sum_{j=1}^{m} \int_{0}^{t} v^{j}(s, x) d W_{s}^{j}+\int_{0}^{t} w(s, x) d s, \quad t \in[0,1], x \in \mathbb{R}^{d_{1}}
$$

take values in $\mathbb{R}^{d_{2}}$, and assume that $u, v^{j}$ and $w$ satisfy conditions $(C)$. Let $p$ be a polynomial in the variable $y \in \mathbb{R}^{d_{2}}$. Then, if

$$
(p \circ u)(t, x)=\sum_{j=1}^{m} \int_{0}^{t} q^{j}(s, x) d W_{s}^{j}+\int_{0}^{t} r(s, x) d s
$$

also $p \circ u, q^{j}$ and $r$ satisfy conditions $(C)$.
Proof. First note that, by Itô's formula, $q^{j}$ and $r$ are of the same structure as $p \circ u$. Hence it suffices to prove the conditions for $p \circ u$.

Due to Hölder's inequality, it is evidently enough to consider the case of a real-valued $u$ and a polynomial $p$ of the form $p(y)=y^{l}$ for some $l \in \mathbb{N}$. Then for $y_{1}, y_{2} \in \mathbb{R}$

$$
\begin{equation*}
p\left(y_{1}\right)-p\left(y_{2}\right)=\left(y_{1}-y_{2}\right) \sum_{k=0}^{l-1} y_{1}^{k} y_{2}^{l-1-k} \tag{3.9}
\end{equation*}
$$

Now observe that by conditions (C) for any $x \in \mathbb{R}^{d_{1}}$

$$
\begin{equation*}
\mathbb{E}\left(\sup _{t \in[0,1]}|u(t, x)|^{p}\right) \leq c_{p} \tag{3.10}
\end{equation*}
$$

for a suitable constant $c_{p} \in \mathbb{R}^{+}$. Then (3.9) and an application of Hölder's inequality obviously allow us to deduce conditions (C) for $p \circ u$ from (3.10) and the condition (C) for $u$.

Lemma 3.9 Let $u=(u(t, x))_{t \in[0,1], x \in \mathbb{R}^{d}}$ with values in $\mathbb{R}^{d}$ satisfy conditions $(C)$, let $(\Phi(t))_{t \in \mathbb{R}}$ be the linear flow generated by (3.4) for $d_{2}=d$, and let $W$ be a scalar Wiener process. Then the processes

$$
v(t, x)=\int_{0}^{t} \Phi(s)^{-1} u(s, x) d W_{s}, \quad w(t, x)=\int_{0}^{t} \Phi(s)^{-1} u(s, x) d s
$$

satisfy conditions (C).
Proof. $\Phi(t)^{-1}$ satisfies the SDE

$$
d \Phi(t)^{-1}=-\sum_{j=0}^{m} \Phi(t)^{-1} B_{j} \circ d W_{t}^{j}, \quad \Phi(0)=I .
$$

Hence for any $p \geq 1$ we have

$$
\begin{equation*}
\mathbb{E}\left(\sup _{t \in[0,1]}\left\|\Phi(t)^{-1}\right\|^{p}\right)<\infty \tag{3.11}
\end{equation*}
$$

Then it is clear that Burkholder's inequality, Hölder's inequality and (3.11) imply that $v$ and $w$ satisfy conditions (C).

We finally come to the announced hierarchical system of affine SDE. Let $\left(d_{n}\right)_{n \in \mathbb{N}}$ be a sequence of integers. For $0 \leq j \leq m$ and each $n \in \mathbb{N}$, let $A_{j, n}$ be a $d_{n} \times d_{n}$ matrix, and let $p_{j, n}$ be a polynomial in the variables $\left(x_{1}, \ldots, x_{n-1}\right) \in \mathbb{R}^{d_{1}} \times \cdots \times \mathbb{R}^{d_{n-1}}$, with $p_{j, 1}=b_{j} \in \mathbb{R}^{d_{1}}$ a fixed vector. Then our hierarchical system of affine SDE is as follows:

$$
\begin{align*}
d x_{t}^{1} & =\sum_{j=0}^{m}\left(A_{j, 1} x_{t}^{1}+p_{j, 1}\right) \circ d W_{t}^{j}, \quad x_{0}^{1}=x_{1} \in \mathbb{R}^{d_{1}}  \tag{3.12}\\
d x_{t}^{2} & =\sum_{j=0}^{m}\left(A_{j, 2} x_{t}^{2}+p_{j, 2}\left(x_{t}^{1}\right)\right) \circ d W_{t}^{j}, \quad x_{0}^{2}=x_{2} \in \mathbb{R}^{d_{2}}  \tag{3.13}\\
\ldots & \cdots  \tag{3.14}\\
d x_{t}^{n}= & \sum_{j=0}^{m}\left(A_{j, n} x_{t}^{n}+p_{j, n}\left(x_{t}^{1}, \ldots, x_{t}^{n-1}\right)\right) \circ d W_{t}^{j} \\
& x_{0}^{n}=x_{n} \in \mathbb{R}^{d_{n}}
\end{align*}
$$

The algorithm for successively solving this system is as follows: Let $\left(\Phi_{n}(t)\right)_{t \in \mathbb{R}}$ be the linear cocycle in $\mathbb{R}^{d_{n}}$ generated by the linear SDE

$$
\begin{equation*}
d y_{t}^{n}=\sum_{j=0}^{m} A_{j, n} y_{t}^{n} \circ d W_{t}^{j}, \quad y_{0}^{n}=y_{n} \in \mathbb{R}^{d_{n}} \tag{3.15}
\end{equation*}
$$

We first solve the first affine $\operatorname{SDE}$ (3.12). Denote the resulting affine cocycle by $\left(\varphi_{1}(t)\right)_{t \in \mathbb{R}}$ which by the variation of constants formula is given by

$$
\varphi_{1}(t) x=\Phi_{1}(t)\left(x+\sum_{j=0}^{m} \int_{0}^{t} \Phi_{1}(s)^{-1} p_{j, 1} \circ d W_{s}^{j}\right) .
$$

Then insert the cocycle $\varphi_{1}(t) x_{1}$ into the second equation (3.13) in place of $x_{t}^{1}$ which gives a non-autonomous affine SDE whose solution flow is denoted by $\varphi_{2}\left(t, x_{1}\right)$, etc. At step $n$ insert $\varphi_{1}(t) x_{1}, \ldots$, $\varphi_{n-1}\left(t, x_{1}, \ldots, x_{n-2}\right) x_{n-1}$ into the $n$th equation (3.14) which gives a nonautonomous affine SDE

$$
\begin{align*}
d x_{t}^{n}= & \sum_{j=0}^{m}\left(A_{j, n} x_{t}^{n}+p_{j, n}\left(\varphi_{1}(t) x_{1}, \ldots, \varphi_{n-1}\left(t, x_{1}, \ldots, x_{n-2}\right) x_{n-1}\right) \circ d W_{t}^{j}\right. \\
& x_{0}^{n}=x_{n} \in \mathbb{R}^{d_{n}} \tag{3.16}
\end{align*}
$$

with solution flow $\varphi_{n}\left(t, x_{1}, \ldots, x_{n-1}\right)$.
Note that the first $n$ affine SDE considered as one equation generate the $C^{\infty}$ RDS

$$
\begin{equation*}
\varphi(t)\left(x_{1}, \ldots, x_{n}\right)=\left(\varphi_{1}(t) x_{1}, \varphi_{2}\left(t, x_{1}\right) x_{2}, \ldots, \varphi_{n}\left(t, x_{1}, \ldots, x_{n-1}\right) x_{n}\right) . \tag{3.17}
\end{equation*}
$$

Proposition 3.10 For $n \in \mathbb{N}$, represent the solution of the nth equation (3.16) as

$$
\begin{aligned}
\varphi_{n}\left(t, x_{1}, \ldots, x_{n-1}\right) x_{n}= & \int_{0}^{t} v^{n}\left(s, x_{1}, \ldots, x_{n}\right) d s \\
& +\sum_{j=1}^{m} \int_{0}^{t} u_{j}^{n}\left(s, x_{1}, \ldots, x_{n}\right) d W_{s}^{j}
\end{aligned}
$$

Then for any $n \in \mathbb{N}, \varphi_{n}$ as well as $v^{n}$ and $u_{j}^{n}, 1 \leq j \leq m$, satisfy conditions (C).
Proof. We use induction on $n$.
The assertion holds for $n=1$. This is an immediate consequence of Lemma 3.7, choosing $u_{j}=b_{j}$.

Let us now assume that the assertion holds for $\varphi_{1}, \ldots, \varphi_{n-1}$ and their characteristics. Consequently, Lemma 3.8 yields that all the components of $p_{j, n-1}\left(\varphi_{1}(t) x_{1}, \ldots, \varphi_{n-1}\left(t, x_{1}, \ldots, x_{n-2}\right) x_{n-1}\right)$ and their semimartingale characteristics satisfy conditions (C). Hence Lemma 3.7 applies and gives condition (C) for $\varphi_{n}$ as well as for $u_{j}^{n}$ and $v^{n}$.

Proposition 3.11 Let for $t \in \mathbb{R}$

$$
X_{1}(t)=\sum_{j=0}^{m} \int_{0}^{t} \Phi_{1}(s)^{-1} b_{j} \circ d W_{s}^{j},
$$

and for $n \geq 2$ and $\left(x_{1}, \ldots, x_{n-1}\right) \in \mathbb{R}^{d_{1}} \times \cdots \times \mathbb{R}^{d_{n-1}}$

$$
\begin{align*}
& X_{n}\left(t, x_{1}, \ldots, x_{n-1}\right)  \tag{3.18}\\
& \quad=\sum_{j=0}^{m} \int_{0}^{t} \Phi_{n}(s)^{-1} p_{j, n}\left(\varphi_{1}(t) x_{1}, \ldots, \varphi_{n-1}\left(t, x_{1}, \ldots, x_{n-2}\right) x_{n-1}\right) \circ d W_{s}^{j} .
\end{align*}
$$

Then $X_{n}$ satisfies conditions (C).
Proof. This is an immediate consequence of Proposition 3.10 and Lemmas 3.8 and 3.9.

Here is our final and main result of step 1.
Theorem 3.12 Consider the hierarchical system of affine SDE introduced in (3.12) to (3.14). Then for any $n \geq 2$, any $p>d_{1}+\cdots+d_{n-1}$, and any compact set $K \subset \mathbb{R}^{d_{1}} \times \cdots \times \mathbb{R}^{d_{n-1}}$ there exist constants $c_{n, p} \in \mathbb{R}^{+}$and $q \geq 1$ such that

$$
\begin{equation*}
\mathbb{E}\left(\sup _{\left(x_{1}, \ldots, x_{n-1}\right) \in K} \sup _{t \in[0,1]}\left|X_{n}\left(t, x_{1}, \ldots, x_{n-1}\right)\right|^{p}\right) \leq c_{n, p}(\operatorname{diam} K)^{q} \tag{3.19}
\end{equation*}
$$

where $X_{n}$ is defined by (3.18).
Proof. Combine Proposition 3.11 with Lemma 3.5.

### 3.2 Step 2: Inheritance of temperedness

We first study the inheritance of temperedness in case tempered vectors (see Definition 3.1) are inserted into random fields. Property (3.2) will play a crucial role hereby, as indicated by the following lemma.

Lemma 3.13 Let $(X(y))_{v \in \mathbb{R}^{d_{1}}}$ be a $\mathbb{P}$-a.s. continuous random field with values in $\mathbb{R}^{d_{2}}$ for which the following condition holds: For $p>d_{1}$ and for any compact set $K \subset \mathbb{R}^{d_{1}}$ there exist $c_{p} \in \mathbb{R}^{+}$and $q \geq 1$ such that

$$
\begin{equation*}
\mathbb{E}\left(\sup _{y \in K}|X(y)|^{p}\right) \leq c_{p}(\operatorname{diam} K)^{q} . \tag{3.20}
\end{equation*}
$$

Let $Y$ be a random vector with values in $\mathbb{R}^{d_{1}}$, and for $\varepsilon>0$ and $m \in \mathbb{N}$ let

$$
A_{\varepsilon, m}:=\left\{\omega \in \Omega:\left|Y\left(\theta_{t} \omega\right)\right| \leq m \exp (t \varepsilon), t \in \mathbb{R}^{+}\right\} .
$$

Then there exists a constant $c_{\varepsilon, m} \in \mathbb{R}^{+}$such that for any $n \in \mathbb{Z}^{+}$

$$
\mathbb{E}\left(1_{A_{\varepsilon, m}} \sup _{t \in[n, n+1]}\left|X(Y)\left(\theta_{t} \cdot\right)\right|^{p}\right) \leq c_{\varepsilon, m} \exp (n \varepsilon q),
$$

where $p$ and $q$ are related by (3.20).

Proof. For $\omega \in A_{\varepsilon, m}$ and $t \in[n, n+1]$ we have

$$
\left|Y\left(\theta_{t} \omega\right)\right| \leq m \exp (t \varepsilon) \leq m \exp (\varepsilon) \exp (n \varepsilon)
$$

Hence due to (3.20)

$$
\begin{align*}
\left.\left.\mathbb{E}\left(1_{A_{\varepsilon, m}} \sup _{t \in[n, n+1]} \mid X(Y)\left(\theta_{t} \cdot\right)\right)\right|^{p}\right) & \leq \mathbb{E}\left(1_{A_{\varepsilon, m}} \sup _{y \in B_{\varepsilon, m, n}}|X(y)|^{p}\right) \\
& \leq c_{p}\left(\operatorname{diam} B_{\varepsilon, m, n}\right)^{q} \tag{3.21}
\end{align*}
$$

where

$$
B_{\varepsilon, m, n}:=\left\{y \in \mathbb{R}^{d_{1}}:|y| \leq m \exp (\varepsilon) \exp (n \varepsilon)\right\}
$$

But diam $B_{\varepsilon, m, n} \leq c_{d_{1}, \varepsilon, m} \exp (n \varepsilon)$, with a constant depending just on $d_{1}$, $\varepsilon$ and $m$. Hence the desired inequality follows readily from (3.21).

Theorem 3.14 Let $(X(y))_{y \in \mathbb{R}^{d_{1}}}$ be a $\mathbb{P}$-a. s. continuous random field with values in $\mathbb{R}^{d_{2}}$ for which the following condition holds: For $p>d_{1}$ and for any compact set $K \subset \mathbb{R}^{d_{1}}$ there exist a $c_{p} \in \mathbb{R}^{+}$and a $q \geq 1$ such that

$$
\begin{equation*}
\mathbb{E}\left(\sup _{y \in K}|X(y)|^{p}\right) \leq c_{p}(\operatorname{diam} K)^{q} \tag{3.22}
\end{equation*}
$$

Let $Y$ be a tempered random vector with values in $\mathbb{R}^{d_{1}}$. Then the $\mathbb{R}^{d_{2}}$ valued random vector $X(Y)$ is tempered.

Proof. Define $A_{\varepsilon, m}$ as in Lemma 3.13. We shall prove that

$$
\left.\left.\lim _{t \rightarrow \infty} \frac{1}{t} \log ^{+} \right\rvert\, X(Y)\left(\theta_{t} \omega\right)\right) \mid=0
$$

remarking that the behavior for $t \rightarrow-\infty$ can be treated similarly. Since $Y$ is tempered, $A_{\varepsilon, m} \uparrow \Omega(m \uparrow \infty) \mathbb{P}-$ a.s. for any $\varepsilon>0$.

Let $\varepsilon>0$ be given. We have to prove that there exists a $\delta(\varepsilon)>0$ such that for any $m \in \mathbb{N}$ we have

$$
\begin{equation*}
1_{A_{\delta(\varepsilon), m}} \limsup _{t \rightarrow \infty} \frac{1}{t} \log ^{+}\left|X(Y)\left(\theta_{t} \omega\right)\right| \leq \varepsilon, \quad \mathbb{P}-\text { a.s. } \tag{3.23}
\end{equation*}
$$

(3.23) will indeed imply temperedness since $A_{\delta(\varepsilon), m} \uparrow \Omega$, $\mathbb{P}$-a.s., for $m \uparrow \infty$ and any $\varepsilon>0$.

To prove (3.23), let $\varepsilon, \delta>0, m, n \in \mathbb{N}$ be given. Then by (3.22) and Lemma 3.13

$$
\mathbb{P}\left(A_{\delta, m} \bigcap\left\{\sup _{t \in[n, n+1]} \frac{1}{t} \log ^{+}\left|X(Y)\left(\theta_{t} \cdot\right)\right|>\varepsilon\right\}\right)
$$

$$
\begin{aligned}
& \leq \mathbb{P}\left(A_{\delta, m} \bigcap\left\{\sup _{t \in[n, n+1]}\left|X(Y)\left(\theta_{t} \cdot\right)\right|>\exp (n \varepsilon)\right\}\right) \\
& \leq \mathbb{E}\left(1_{A_{\delta, m}} \exp (-n p \varepsilon) \sup _{t \in[n, n+1]}\left|X(Y)\left(\theta_{t} \cdot\right)\right|^{p}\right) \\
& \leq c_{m, \delta} \exp (n q \delta-n p \varepsilon)=c_{m, \delta} \exp (n(q \delta-p \varepsilon))
\end{aligned}
$$

Now choose $\delta<\frac{p \varepsilon}{q}$. Then for all $m \in \mathbb{N}$ the Borel Cantelli lemma yields

$$
\left.\left.1_{A_{\delta, m}} \limsup _{n \rightarrow \infty} \sup _{t \in[n, n+1]} \frac{1}{t} \log ^{+} \right\rvert\, X(Y)\left(\theta_{t} \cdot\right)\right) \mid \leq \varepsilon .
$$

This clearly implies (3.23) and completes the proof.
As a second issue we study the inheritance of temperedness by geometric series.

Theorem 3.15 Suppose $X$ is an $\mathbb{R}^{d}$-valued tempered random vector. Let $\left(T_{n}\right)_{n \in \mathbb{N}}$ be a sequence of random linear operators in $\mathbb{R}^{d}$ with negative Lyapunov index, i.e., for some deterministic $\beta>0$

$$
\limsup _{n \rightarrow \infty} \frac{1}{n} \log \left\|T_{n}\right\| \leq-\beta
$$

Then

$$
Y=\sum_{n=0}^{\infty} T_{n}(X \circ \theta(n))
$$

is absolutely and geometrically convergent and tempered.
Proof. Choose $\varepsilon>0$ such that $2 \varepsilon<\beta$. Then by the assumptions, from a certain index $n$ on, $\left\|T_{n}\right\|(X \circ \theta(n))<\exp ((2 \varepsilon-\beta) n)$ from which the convergence statements follow. As to the temperedness of $Y$, there exists a random variable $R_{\varepsilon}$ such that for $t \in \mathbb{R}$

$$
\begin{aligned}
\left|Y \circ \theta_{t}\right| & \leq \sum_{n=0}^{\infty}\left\|T_{n}\right\|| | X \circ \theta(n+t) \mid \\
& \leq R_{\varepsilon} \sum_{n=0}^{\infty} \exp (\varepsilon n-\beta n) \exp (\varepsilon(n+|t|)) \\
& =R_{\varepsilon} \frac{1}{1-\exp (2 \varepsilon-\beta)} \exp (\varepsilon|t|),
\end{aligned}
$$

which clearly implies that $Y$ is tempered.

### 3.3 Step 3: Invariant measures of a hierarchical system of affine SDE

We return to the setting of a hierarchical system of affine SDE introduced above (see Theorem 3.12), and determine its invariant measures.

So let $\left(\Phi_{n}(t)\right)_{t \in \mathbb{R}}$ be the linear cocycle in $\mathbb{R}^{d_{n}}$ generated by (3.15). The multiplicative ergodic theorem holds for $\Phi_{n}$, giving its Lyapunov spectrum $\Sigma\left(\Phi_{n}\right)$. Having in mind our cohomological equations in the nonresonant case, we assume that all these cocycles are hyperbolic, i.e., $0 \notin \Sigma\left(\Phi_{n}\right)$ for all $n \in \mathbb{N}$. Then $\mathbb{R}^{d_{n}}=E_{n}^{s}(\omega) \oplus E_{n}^{u}(\omega)$, where $E_{n}^{s}(\omega)=\oplus_{\lambda_{i, n}<0} E_{i, n}(\omega)$ is the stable space, and $E_{n}^{u}(\omega)=\oplus_{\lambda_{i, n}>0} E_{i, n}(\omega)$ is the unstable space of $\Phi_{n}$. Denote by $\pi_{n}^{u}\left(\pi_{n}^{s}\right)$ the projection whose range is $E_{n}^{u}\left(E_{n}^{s}\right)$, and whose kernel is $E_{n}^{s}\left(E_{n}^{u}\right)$.

For convenience we recall the following facts [3, Section 4.3].
Lemma 3.16 Assume that the cocycle $\Phi_{n}$ is hyperbolic. Then there exists a constant $\beta_{n}>0$ such that

$$
\limsup _{k \rightarrow \infty} \frac{1}{k} \log \left\|\pi_{n}^{u} \Phi_{n}(k)^{-1}\right\| \leq-\beta_{n}
$$

and

$$
\limsup _{k \rightarrow \infty} \frac{1}{k} \log \left\|\pi_{n}^{s} \Phi_{n}(-k)^{-1}\right\| \leq-\beta_{n} .
$$

We first consider the affine SDE of order one. We recall that a probability measure $\mu(d \omega, d x)=\mu_{\omega}(d x) \mathbb{P}(d \omega)$ on $\left(\Omega \times \mathbb{R}^{d}, \mathscr{F} \otimes \mathscr{B}\right)$ with marginal $\mathbb{P}$ on $(\Omega, \mathscr{F})$ is called invariant for the $\operatorname{RDS} \varphi$ if $\varphi(t, \omega) \mu_{\omega}=\mu_{\theta_{t} \omega} \mathbb{P}$-a.s.
Theorem 3.17 Consider the affine $S D E$ in $\mathbb{R}^{d_{1}}$

$$
\begin{equation*}
d x_{t}^{1}=\sum_{j=0}^{m}\left(A_{j, 1} x_{t}^{1}+b_{j}\right) \circ d W_{t}^{j}, \tag{3.24}
\end{equation*}
$$

and assume that the corresponding linear cocycle $\Phi_{1}$ generated by $d y_{t}^{1}=\sum_{j=0}^{m} A_{j, 1} y_{t}^{1} \circ d W_{t}^{j}$ is hyperbolic. Then the affine cocycle $\varphi_{1}$ generated by (3.24) has a unique invariant measure, namely the random Dirac measure $\mu_{\omega}=\delta_{\kappa_{1}(\omega)}$, i.e., we have $\varphi_{1}(t, \cdot) \kappa_{1}=\kappa_{1} \circ \theta_{t}$. Here $\kappa_{1}=\kappa_{1}^{s} \oplus \kappa_{1}^{u}$, and

$$
\begin{align*}
& \kappa_{1}^{s}=\sum_{k=0}^{\infty} \pi_{1}^{s} \circ \Phi_{1}(-k)^{-1}\left(X_{1}^{-} \circ \theta_{-k}\right),  \tag{3.25}\\
& \kappa_{1}^{u}=-\sum_{k=0}^{\infty} \pi_{1}^{u} \circ \Phi_{1}(k)^{-1}\left(X_{1}^{+} \circ \theta_{k}\right), \tag{3.26}
\end{align*}
$$

where

$$
X_{1}^{-}:=\sum_{j=0}^{m} \int_{-1}^{0} \Phi_{1}(t)^{-1} b_{j} \circ d W_{t}^{j}, \quad X_{1}^{+}:=\sum_{j=0}^{m} \int_{0}^{1} \Phi_{1}(t)^{-1} b_{j} \circ d W_{t}^{j}
$$

The sequences in (3.25) and (3.26) converge $\mathbb{P}$-a.s. absolutely and geometrically, and the limits $\kappa_{1}^{s}$ and $\kappa_{1}^{u}$ as well as $\kappa_{1}=\kappa_{1}^{s} \oplus \kappa_{1}^{u}$ are tempered random vectors.

Proof. (i) We first prove the statements on temperedness. $X_{1}^{-}$and $X_{1}^{+}$ are tempered by Theorem 3.14 since a constant vector is tempered. Hence Theorem 3.15 and Lemma 3.16 yield that $\kappa_{1}^{s}$ and $\kappa_{1}^{u}$ exist and are tempered. Thus $\kappa_{1}$ is tempered.
(ii) We now check that $\delta_{\kappa_{1}}$ is invariant, i.e., that $\varphi_{1}(t, \cdot) \kappa_{1}=\kappa_{1} \circ \theta_{t}$. This is equivalent with $\pi_{1}^{s, u}\left(\theta_{t} \cdot\right) \varphi_{1}(t, \cdot) \kappa_{1}=\kappa_{1}^{s, u}\left(\theta_{t} \cdot\right)$ for $t \in \mathbb{R}$. Using the variation of constants representation of $\varphi_{1}$ and the fact that for $k \in \mathbb{Z}^{+}$

$$
\sum_{j=0}^{m} \int_{k}^{k+1} \Phi_{1}(s)^{-1} b_{j} \circ d W_{s}^{j}=\Phi_{1}(k)^{-1}\left(X_{1}^{+} \circ \theta_{k}\right)
$$

we obtain, after some rather lengthy, but elementary manipulations,

$$
\begin{aligned}
\varphi_{1}(t, \cdot) \kappa_{1}^{u} & =\lim _{N \rightarrow \infty} \varphi_{1}(t, \cdot)\left(-\sum_{k=0}^{N-1} \pi_{1}^{u} \circ \Phi_{1}(k)^{-1}\left(X_{1}^{+} \circ \theta_{k}\right)\right) \\
& =\kappa_{1}^{u} \circ \theta_{t}+\pi_{1}^{s} \sum_{j=0}^{m} \int_{0}^{t} \Phi_{1}(s)^{-1} b_{j} \circ d W_{s}^{j}
\end{aligned}
$$

A similar argument holds for the stable component.
(iii) The uniqueness of the invariant measure is a consequence of hyperbolicity and is proved in [3 Theorem 5.6.1].

Now suppose that $\kappa_{1}, \ldots, \kappa_{n-1}$ are tempered random vectors with values in $\mathbb{R}^{d_{1}}, \ldots, \mathbb{R}^{d_{n-1}}$, respectively such that $\mu^{i}=\delta_{\kappa_{i}}, 1 \leq i \leq n-1$ is the unique invariant measure of the $i$ th equation of our hierarchical system of affine SDE. We now study the $n$th SDE

$$
\begin{equation*}
d x_{t}^{n}=\sum_{j=0}^{m}\left(A_{j, n} x_{t}^{n}+p_{j, n}\left(\varphi_{1}(t) \kappa_{1}, \ldots, \varphi_{n-1}\left(t, \kappa_{1}, \ldots, \kappa_{n-2}\right) \kappa_{n-1}\right)\right) \circ d W_{t}^{j} \tag{3.27}
\end{equation*}
$$

in $\mathbb{R}^{d_{n}}$. Note the fundamental fact that the validity of Lemma 3.5 entails the famous substitution rule for Stratonovich integrals (see Arnold and Imkeller [5 Corollary 1]): If $\eta$ is any random variable and $W$ a scalar Wiener process, then $u(t, \eta)$ (though nonadapted) is Stratonovich integrable, and

$$
\begin{equation*}
\int_{0}^{t} u(s, \eta) \circ d W_{s}=\left.\int_{0}^{t} u(s, x) \circ d W_{s}\right|_{x=\eta}, \quad t \in \mathbb{R} \tag{3.28}
\end{equation*}
$$

Hence the anticipative affine SDE (3.27) makes sense, and it generates an affine cocycle $\varphi_{n}\left(t, \kappa_{1}, \ldots, \kappa_{n-1}\right)$. We now determine its invariant measure.

Theorem 3.18 Suppose all equations of the hierarchical system of affine SDE have a hyperbolic linear part. Then each of the equations has a unique invariant measure. This measure is a random Dirac measure (stationary solution) whose supporting random variable can be obtained step by step by determining $\kappa_{1}$ according to Theorem 3.17, inserting $\varphi_{1}(t) \kappa_{1}$ into the second $S D E$, etc., where the stable and unstable component of $\kappa_{n}$ of the nth equation (3.27) is given by

$$
\begin{align*}
& \kappa_{n}^{s}=\sum_{k=0}^{\infty} \pi_{n}^{s} \circ \Phi_{n}(-k)^{-1}\left(X_{n}^{-} \circ \theta_{-k}\right),  \tag{3.29}\\
& \kappa_{n}^{u}=-\sum_{k=0}^{\infty} \pi_{n}^{u} \circ \Phi_{n}(k)^{-1}\left(X_{n}^{+} \circ \theta_{k}\right), \tag{3.30}
\end{align*}
$$

where

$$
\begin{aligned}
X_{n}^{-}:= & \sum_{j=0}^{m} \int_{-1}^{0} \Phi_{n}(t)^{-1} p_{j, n} \\
& \times\left(\varphi_{1}(t) \kappa_{1}, \ldots, \varphi_{n-1}\left(t, \kappa_{1}, \ldots, \kappa_{n-2}\right) \kappa_{n-1}\right) \circ d W_{t}^{j}, \\
X_{n}^{+}:= & \sum_{j=0}^{m} \int_{0}^{1} \Phi_{n}(t)^{-1} p_{j, n} \\
& \times\left(\varphi_{1}(t) \kappa_{1}, \ldots, \varphi_{n-1}\left(t, \kappa_{1}, \ldots, \kappa_{n-2}\right) \kappa_{n-1}\right) \circ d W_{t}^{j} .
\end{aligned}
$$

The sequences in (3.29) and (3.30) converge $\mathbb{P}$-a.s. absolutely and geometrically, and the limits $\kappa_{n}^{s}$ and $\kappa_{n}^{u}$ as well as $\kappa_{n}=\kappa_{n}^{s} \oplus \kappa_{n}^{u}$ are tempered random vectors.

Proof. Since Theorem 3.12 holds, and since $\left(\kappa_{1}, \ldots, \kappa_{n-1}\right)$ is a tempered vector, Theorem 3.14 applies and entails that $X_{n}^{-}$and $X_{n}^{+}$are tempered. Hence by Lemma 3.16 and Theorem 3.15, the series in equations (3.29) and (3.30) have the convergence properties claimed, and the limits $\kappa_{n}^{s, u}$ are tempered. Hence finally $\kappa_{n}$ is tempered.

Invariance and uniqueness of $\kappa_{n}$ are proved as in Theorem 3.17 .

Remark 3.19. (i) By means of the substitution rule (3.28), $\kappa_{1}$ can also be written as

$$
\begin{aligned}
& \kappa_{1}^{s}=\sum_{j=0}^{m} \int_{-\infty}^{0} \Phi_{1}(t)^{-1}\left(\pi_{1}^{s}\left(\theta_{t} \cdot\right) b_{j}\right) \circ d W_{t}^{j}, \\
& \kappa_{1}^{u}=-\sum_{j=0}^{m} \int_{0}^{\infty} \Phi_{1}(t)^{-1}\left(\pi_{1}^{u}\left(\theta_{t} \cdot\right) b_{j}\right) \circ d W_{t}^{j},
\end{aligned}
$$

where the integrals exist as the $\mathbb{P}$-a.s. limits of the non-adapted Stratonovich integrals $\int_{-T}^{0}$ and $\int_{0}^{T}$ for $T \rightarrow \infty$. Similarly for $\kappa_{n}$.
(ii) Again by the substitution rule (3.28), the cocycle (3.17) evaluated at $\kappa:=\left(\kappa_{1}, \ldots, \kappa_{n}\right)$ is equal to the solution of the first $n$ equations with non-adapted initial value $\kappa$, and is the unique stationary solution of these equations, $\varphi(t) \kappa=\kappa \circ \theta_{t}, t \in \mathbb{R}$.

This completes the proof of Theorem 3.2. We close with an example.
Example 3.20. (The one-dimensional case). For $d=1, H_{n, 1} \cong \mathbb{R}^{1}$ (choose the basis $x^{n} e_{1}$ ) for all $n \geq 2$. The linearization of the SDE $d x=\sum_{j=0}^{m} f_{j}(x) \circ d W^{j}$ is $d v=\sum_{j=0}^{m} A_{j} v \circ d W^{j}$ whose explicit solution is

$$
\Phi(t, \omega)=\exp \left(A_{0} t+\sum_{j=1}^{m} A_{j} W_{t}^{j}(\omega)\right)
$$

Hence $\lambda=A_{0}$ is the Lyapunov exponent. Further, $\operatorname{ad}_{n} A_{j}=-(n-1) A_{j}$, and $\Sigma\left(\Phi_{n}\right)=\{-(n-1) \lambda\}$. We have nonresonance for all $n$ if and only if $\lambda \neq 0$. The unique stationary solution of the $n$th cohomological SDE

$$
d h_{n}=\sum_{j=0}^{m}\left(\left(\operatorname{ad}_{n} A_{j}\right) h_{n}+k_{j, n}\left(\theta_{t} \cdot\right)\right) \circ d W_{t}^{j}
$$

is

$$
h_{n}= \begin{cases}\sum_{j=0}^{m} \int_{-\infty}^{0} \exp \left((n-1) \sum_{l=0}^{m} A_{l} W_{t}^{l}\right) k_{j, n}\left(\theta_{t} \cdot\right) \circ d W_{t}^{j}, & \lambda>0 \\ -\sum_{j=0}^{m} \int_{0}^{\infty} \exp \left((n-1) \sum_{l=0}^{m} A_{l} W_{t}^{l}\right) k_{j, n}\left(\theta_{t} \cdot\right) \circ d W_{t}^{j}, & \lambda<0\end{cases}
$$

## 4 The resonant and small noise case

### 4.1 Resonant case

If $0 \in \Sigma\left(\Phi_{n}\right)$ we cannot guarantee anymore that the cohomological equation (2.11) of order $n$ has a solution for any right-hand side.

Assume for simplicity that $\Phi$ has simple spectrum (all Lyapunov exponents $\Lambda_{i}$ are different, equivalently all $E_{i}$ are one-dimensional). Then by [5, Theorem 9], the linear SDE (2.1) can be diagonalized by means of a random (anticipative) coordinate transformation $w_{t}=P\left(\theta_{t} \omega\right) v_{t}$, so that the linear cocycle

$$
\Psi(t, \omega)=P\left(\theta_{t} \omega\right) \Phi(t, \omega) P(\omega)^{-1}=\operatorname{diag}\left(\psi_{1}(t, \omega), \ldots, \psi_{d}(t, \omega)\right)
$$

has the same spectrum as $\Phi$, is diagonal, and has generator

$$
\begin{equation*}
d w_{t}=\sum_{j=0}^{m} \operatorname{diag}\left(Q_{j}\left(u_{1}\left(\theta_{t} \cdot\right)\right), \ldots, Q_{j}\left(u_{d}\left(\theta_{t} \cdot\right)\right)\right) w_{t} \circ d W_{t}^{j} \tag{4.1}
\end{equation*}
$$

where $Q_{j}(u)=\left\langle A_{j} u, u\right\rangle$, and $F=\left(u_{1}, \ldots, u_{d}\right)$ is a basis of random eigenvectors such that $u_{i} \in E_{i}$. The anticipative Stratonovich SDE (4.1) makes sense. Further, all $\mathrm{ad}_{n} A_{j}$ become diagonal matrices in this basis (see Remark 1.1), so that the random cohomological equation (2.11) decouples into $D$ scalar SDE. Recall that for $n \geq 2$, $\Sigma\left(\Phi_{n}\right)=\left\{\Lambda_{i}-(\Lambda, \tau): \Lambda_{i} \in \Sigma(\Phi),|\tau|=n\right\}$.

If $(i, \tau)$ is such that $\Lambda_{i}-(\Lambda, \tau) \neq 0$ we put $d G_{n}^{i, \tau}=0$, and solve the corresponding affine cohomological equation as usual. If for some $(i, \tau), \Lambda_{i}-(\Lambda, \tau)=0$ (resonance of order $n$ ) we make the convention to choose $h_{n}^{i, \tau}=0$, hence $d G_{n}^{i, \tau}=d K_{n}^{i, \tau}$, i.e., we will not try to simplify $G_{n}^{i, \tau}$ (which will only be possible in rare exceptions anyway). We call the result of this procedure after $N$ steps normal form of order $N$. The formal handling of the hierarchical system of anticipative SDE can be justified as in the nonresonant case which we refrain from making explicit here.

### 4.2 Small noise: a case study

The engineering and physics literature on stochastic normal forms has worked exclusively in a center/stable situation, and with a smallness parameter multiplying the noise terms, thus obtaining a stochastic normal form as a small perturbation of the deterministic one.

We will now connect our general approach developed in the previous sections (which is independent of any smallness assumptions) with the existing physics and engineering literature by presenting a stochastic analogue of a very successful procedure proposed by Elphick et al. [13] for simultaneously obtaining the normal form, eliminating the stable variables from the center equation, and determining the center manifold. This was done for random differential equations by Arnold and Xu [9].

We are now in a position to carry this procedure over to the SDE case. We will, however, not repeat details and just emphasize that all nonresonant (anticipative Stratonovich) cohomological equations in the SDE analogues of Theorems 2.1 and 3.1 of [9] are solved as in the nonresonant case of section 3 , and, following our convention made in subsection 4.1, for all resonant equations we make the trivial choice $h_{n}=0$ for the random transformation. This mathematically rigorous procedure finally justifies earlier important work on normal forms for SDE quoted at the beginning of this article.

We now discuss the following application: In stochastic bifurcation theory one needs to study an SDE

$$
\begin{equation*}
d x_{t}=f_{0}\left(x_{t}, \alpha\right) d t+\sigma \sum_{j=1}^{m} f_{j}\left(x_{t}, \alpha\right) \circ d W_{t}^{j} \tag{4.2}
\end{equation*}
$$

in $\mathbb{R}^{d}$, where the smooth vector fields $f_{j}(x, \alpha)$ smoothly depend on a parameter $\alpha \in \mathbb{R}^{m}$, and $\sigma \in \mathbb{R}$ is a (small) intensity parameter. We assume that $f_{j}(0, \alpha)=0$ for all $\alpha \in \mathbb{R}^{m}$, so that the linearization of (4.2) is

$$
\begin{array}{r}
d v_{t}=A_{0}(\alpha) v_{t} d t+\sigma \sum_{j=1}^{m} A_{j}(\alpha) v_{t} \circ d W_{t}^{j}, A_{j}(\alpha):=\left.D_{x} f_{j}(x, \alpha)\right|_{x=0}, \\
0 \leq j \leq m .
\end{array}
$$

Assume further that for $(\alpha, \sigma)=(0,0)$ the deterministic linear equation

$$
\dot{v}=A_{0} v, \quad A_{0}=\left.D_{x} f_{0}(x, 0)\right|_{x=0}
$$

is in a center/stable situation (no eigenvalues with positive real part) and has been brought into Jordan canonical form by a (deterministic!) coordinate transformation, so that $\mathbb{R}^{d}=\mathbb{R}^{d_{c}} \times \mathbb{R}^{d_{s}}$ is the invariant splitting for $A_{0}=\left(\begin{array}{cc}A_{0}^{c} & 0 \\ 0 & A_{0}^{s}\end{array}\right)$ into a center and stable part.

We treat $(\alpha, \sigma) \in \mathbb{R}^{m+1}$ as a small parameter and seek the normal form and center manifold reduction for small $(x, \alpha, \sigma)$ as a polynomial in $\left(x^{c}\right)^{p}\left(x^{s}\right)^{q} \alpha^{l} \sigma^{r}$. All cohomological operators (hence all linear cocycles) are now deterministic and of the form

$$
d L_{n}\left(h_{n}\right)=d h_{n}-\left(\mathrm{ad}_{n} A_{0}\right) h_{n} d t .
$$

We add the trivial equations $d \alpha=0$ and $d \sigma=0$. The result is given by the (rather obvious) white noise analogue of Theorem 3.1 of [9] and is (omitting remainder terms) as follows: The center variable satisfies

$$
d x_{t}^{c}=A_{0}^{c} x_{t}^{c} d t+\sum_{j=0}^{m} g_{j}^{c}\left(\theta_{t}, x_{t}^{c}, \alpha, \sigma\right) \circ d W_{t}^{j}, \quad d \alpha_{t}=0, \quad d \sigma_{t}=0
$$

where $g_{j}^{c}$ is a random polynomial of order $N$ in $x^{c}$ and $M$ in $(\alpha, \sigma)$, and the (approximate) stochastic center manifold is given by its graph

$$
\mathbb{R}^{d_{c}} \times \mathbb{R}^{m+1} \ni\left(x^{c}, \alpha, \sigma\right) \mapsto m_{c}\left(\cdot, x^{c}, \alpha, \sigma\right) \in \mathbb{R}^{d_{s}},
$$

where $m_{c}$ is a random polynomial of order $N$ in $x^{c}$ and $M$ in $(\alpha, \sigma)$.
The prototypical Duffing-van der Pol oscillator

$$
\begin{equation*}
\ddot{y}=\alpha y+\beta \dot{y}-y^{3}-y^{2} \dot{y} \tag{4.3}
\end{equation*}
$$

under the influence of parametric and additive noise has been the subject of numerous investigations (see Arnold, Sri Namachchivaya and Schenk-Hoppé [7], Schenk-Hoppé [17, 18, 19] and the references therein). For $\alpha<0$ fixed and $\beta$ the bifurcation parameter, the system (4.3) exhibits a Hopf bifurcation for $\beta=0$. For $\beta<0$ fixed and $\alpha$ the bifurcation parameter, it undergoes a pitchfork bifurcation at $\alpha=0$.

To reduce complexity, we will treat a particular case of parametric noise: Let the parameter $\alpha$ be replaced by $\alpha+\sigma \dot{W}$, where $\dot{W}$ stands, as usual, for white noise, and $\sigma$ is a strength parameter. With $x=\binom{y}{\dot{y}}$, the perturbed version of (4.3) is

$$
d x_{t}=\left(\left(\begin{array}{cc}
0 & 1  \tag{4.4}\\
\alpha & \beta
\end{array}\right) x_{t}+\binom{0}{-x_{1, t}^{3}-x_{1, t}^{2} x_{2, t}}\right) d t+\sigma\left(\begin{array}{ll}
0 & 0 \\
1 & 0
\end{array}\right) x_{t} \circ d W_{t} .
$$

Here $W$ is a two-sided one-dimensional Wiener process. The linearization of (4.4) at $x=0$ is

$$
d v_{t}=\left(\begin{array}{cc}
0 & 1  \tag{4.5}\\
\alpha & \beta
\end{array}\right) v_{t} d t+\sigma\left(\begin{array}{ll}
0 & 0 \\
1 & 0
\end{array}\right) v_{t} \circ d W_{t} .
$$

## The pitchfork scenario under small random perturbations

Put for simplicity $\beta=-1$. Then the eigenvalues of the linear part of the deterministic equation (4.4) $(\sigma=0)$ are $(-1 \pm \sqrt{1+4 \alpha}) / 2$. We treat $(\alpha, \sigma)$ as a small two-dimensional parameter and will determine the simultaneous stochastic normal form and center manifold reduction of (4.4) for small $x, \alpha$ and $\sigma$.

The (formidable) calculations are formally the same as in the real noise case (just replace in [9] $\xi(t)$ by $\dot{W}$, with all the obvious consequences). We introduce the auxiliary processes $U, V, X$, and $Y$ which are the unique stationary solutions of the scalar SDE

$$
d U_{t}=-U_{t} d t+d W_{t}, \quad d V_{t}=V_{t} d t+d W_{t},
$$

and

$$
d X_{t}=-X_{t} d t+d U_{t}, \quad d Y_{t}=-Y_{t} d t+U_{t} \circ d W_{t} .
$$

Note that $V$ anticipates the future of $W$. The resulting center SDE (up to terms of order 3 in $x^{c}$ and 2 in $(\alpha, \sigma)$ ) is

$$
\begin{align*}
d x_{t}^{c}= & \left(\alpha-\alpha \sigma U_{t}-\alpha^{2}\right) x_{t}^{c} d t+\left(\sigma-\sigma^{2} U_{t}-\alpha \sigma\right) x_{t}^{c} \circ d W_{t} \\
& +\left(-1+2 \sigma U_{t}-\sigma^{2}\left(3 U_{t} V_{t}+4 Y_{t}+2 U_{t}+U_{t}^{2}\right)\right. \\
& \left.+3 \alpha-\alpha \sigma\left(15 U_{t}+7 X_{t}+4 V_{t}\right)-18 \alpha^{2}\right)\left(x_{t}^{c}\right)^{3} d t \\
& +\left(\sigma-\sigma^{2}\left(4 U_{t}+3 X_{t}+V_{t}\right)-10 \alpha \sigma\right)\left(x_{t}^{c}\right)^{3} \circ d W_{t} . \tag{4.6}
\end{align*}
$$

Note that this is an anticipative SDE since $V$ is anticipative.
The approximate center manifold is the random function $\left(x^{c}, \alpha, \sigma\right) \mapsto m_{c}\left(\cdot, x^{c}, \alpha, \sigma\right)=x^{s}$ given by

$$
\begin{aligned}
m_{c}\left(\cdot, x^{c}, \alpha, \sigma\right)= & \left(-\sqrt{2} \sigma U_{0}+2 \sqrt{2} \sigma^{2} Y_{0}-\sqrt{2} \alpha\right. \\
& \left.+2 \sqrt{2} \alpha \sigma\left(U_{0}+X_{0}\right)+2 \sqrt{2} \alpha^{2}\right) x^{c} \\
& +\left(\sqrt{2}-\sqrt{2} \sigma\left(4 U_{0}+3 X_{0}\right)\right. \\
& \left.+\sigma^{2} H_{3002}^{s}-7 \sqrt{2} \alpha+\alpha \sigma H_{3011}^{s}-47 \sqrt{2} \alpha^{2}\right)\left(x^{c}\right)^{3},
\end{aligned}
$$

where $H_{3002}^{s}$ and $H_{3011}^{s}$ are certain anticipative random variables which are very complicated functions of lower order terms.

The computational effort for these results is enormous and could only be accomplished by using the computer algebra program MAPLE. There are 106 cohomological equations to be solved to determine the coefficients. For the real noise case, these cohomological equations fill 18 pages and can be found in an appendix to a reprint version of [9].

The scalar SDE (4.6) can now be utilized for stochastic bifurcation theory of the two-dimensional SDE (4.4), similarly as in Arnold and Boxler [4].

For example, linearizing the $\operatorname{SDE}$ (4.6) at $x_{c}=0$ gives the scalar SDE

$$
d v_{t}=\left(\alpha-\alpha \sigma U_{t}-\alpha^{2}\right) v_{t} d t+\left(\sigma-\sigma^{2} U_{t}-\alpha \sigma\right) v_{t} \circ d W_{t}
$$

which can be explicitly solved to give its Lyapunov exponent

$$
\lambda_{c}(\alpha, \sigma)=\alpha-\alpha^{2}-\sigma^{2} \lim _{t \rightarrow \infty} \frac{1}{t} \int_{0}^{t} U_{s} \circ d W_{s}=\alpha-\alpha^{2}-\frac{\sigma^{2}}{2}
$$

where we have used

$$
\int_{0}^{t} U_{s} \circ d W_{s}=\int_{0}^{t} U_{s} d W_{s}+\frac{t}{2}
$$

and $\int_{0}^{t} U_{s} d W_{s} / t \rightarrow 0 \mathbb{P}$-a.s. This is in full agreement with an asymptotic formula for the top Lyapunov exponent $\lambda_{1}(\alpha, \sigma)$ of the two-dimen-
sional linear SDE (4.5) (for $\beta=-1$ ) by Pardoux and Wihstutz [16, Theorem 5.3] which gives

$$
\lambda_{1}(\alpha, \sigma)=\lambda_{c}(\alpha, \sigma)+O\left(\sigma^{4}\right) .
$$

In particular $\lambda_{1}(0, \sigma)=-\frac{\sigma^{2}}{2}+O\left(\sigma^{4}\right)$, hence the disturbed system is still stable at the deterministic critical value $\alpha=0$, and the stochastic pitchfork bifurcation (bifurcation of two new invariant measures from the trivial reference measure $\delta_{0}$ ) is delayed to the parameter value

$$
\alpha_{c}=\frac{\sigma^{2}}{1+\sqrt{1-2 \sigma^{2}}}+\cdots=\frac{\sigma^{2}}{2}+\cdots .
$$

at which $\lambda_{1}\left(\alpha_{c}, \sigma\right)=0$.

## The Hopf scenario under small random perturbations

We now assume that $\alpha<0$ is fixed and $\beta$ is the bifurcation parameter which varies in the interval $|\beta|<\sqrt{-4 \alpha}$ so that the frequency

$$
\omega_{d}:=\sqrt{-\alpha-\beta^{2} / 4}
$$

is well-defined. We follow [7] and obtain the normal form for small $x$, $\beta$ and $\sigma$. The linearized $\operatorname{SDE}$ (4.5) is for $\sigma=0$

$$
\dot{v}=\left(\begin{array}{ll}
0 & 1 \\
\alpha & \beta
\end{array}\right) v,
$$

with eigenvalues $\frac{\beta}{2} \pm i \omega_{d}$ which are purely imaginary for $\beta=0$. We have dimension $d=d_{c}=2$ for the center space, while the stable component is not present. All cohomological equations are hence resonant (in the random sense, i.e., all Lyapunov exponents vanish). Our recipe for their solution is as follows: If in a cohomological equation the right-hand side is random, we choose $h_{n}=0$ (hence do not simplify $g_{n}$ ), while if the right-hand side is nonrandom we search for a nonrandom $h_{n}$ for which $g_{n}$ is "as simple as possible" by means of deterministic normal form theory.

The truncated stochastic normal form for $N=3$ and $M=1$ in polar coordinates $(r, \varphi), x_{1}=r \cos \varphi, x_{2}=r \sin \varphi$, is as follows (again after formidable computational efforts which we omit):

$$
\begin{aligned}
d r_{t}= & \left(\frac{\beta}{2} r_{t}-\frac{1}{2} r_{t}^{3}\right) d t \\
& +\frac{r_{t}}{8 \omega_{d}^{2}}\left(-2 r_{t}^{2}+\left(\frac{5 r_{t}^{2}}{\omega_{d}}-4 \omega_{d}\right) \sin 2 \varphi_{t}-\frac{2 r_{t}^{2}}{\omega_{d}} \sin 4 \varphi_{t}\right. \\
& \left.+r_{t}^{2} \cos 2 \varphi_{t}\right) \sigma \circ d W_{t}
\end{aligned}
$$

$$
\begin{aligned}
d \varphi_{t}= & \left(\omega_{d}+\frac{6+3 \beta}{4 \omega_{d}} r_{t}^{2}\right) d t \\
& +\frac{1}{2 \omega_{d}}\left(-1+\frac{3 r_{t}^{2}}{\omega_{d}^{2}}+\left(-1+\frac{5 r_{t}^{2}}{2 \omega_{d}^{2}}\right) \cos 2 \varphi_{t}-\frac{r_{t}^{2}}{2 \omega_{d}^{2}} \cos 4 \varphi_{t}\right. \\
& \left.-\frac{3 r_{t}^{2}}{2 \omega_{d}} \sin 2 \varphi_{t}\right) \sigma \circ d W_{t}
\end{aligned}
$$

For $\sigma=0$ we recover the deterministic truncated normal form, from which the Hopf bifurcation at $\beta=0$ can be read off. For $\sigma \neq 0$, the corresponding Pardoux-Wihstutz formula [16, Theorem 4.1] for the Lyapunov exponents of (4.5) yields for fixed $\alpha<0$

$$
\lambda_{1,2}(\beta, \sigma)=\frac{\beta}{2} \pm \frac{\sigma^{2}}{8 \omega_{d}^{2}}+O\left(\sigma^{4}\right)
$$

At $\beta=0, \lambda_{2}(0, \sigma)<0<\lambda_{1}(0, \sigma)$, so that the trivial solution has already lost its stability. Stochastic Hopf bifurcation consists of the premature bifurcation of a first invariant measure from the trivial one at $\beta_{1}<0$ where $\lambda_{1}\left(\beta_{1}, \sigma\right)=0$, and then of a second measure at $\beta_{2}>0$ where $\lambda_{2}\left(\beta_{2}, \sigma\right)=0$.
