Abstract

Purpose The purpose of this prospective randomized clinical trial is to compare the clinical outcomes of three injections of leukocyte-poor platelet-rich plasma (LP-PRP) and hyaluronic acid (HA) to a single dose of autologous microfragmented adipose tissue (AMAT) in patients with mild osteoarthritis at a two-year follow-up.

Methods Eighty symptomatic knees in fifty patients (mean age: 62.38 ± 11.88 years) with Kellgren-Lawrence grade 0 to 2 osteoarthritis were non blinded, randomly allocated into two equal groups. Group 1 consisted of 40 knees that received autologous LP-PRP + HA; Group 2 consisted of 40 knees treated with a single dose of AMAT injection. The outcomes were measured by Tegner, Marx, Visual Analogue Scale (VAS) for pain, International Knee Documentation Committee, and Knee Injury and Osteoarthritis Outcome Score (KOOS) at 6 (T_1), 12 (T_2), and 24 (T_3) months. Adverse events were recorded at each follow-up timepoint. To assess score differences among subjects of the same gender and age, a subgroup analysis was performed.

Results Both groups had significant clinical and functional improvement at 6, 12, and 24 months ($p < 0.05$). Comparing the two groups, the AMAT groups showed significantly higher pre-operative Marx score (3.35 ± 4.91 vs. 1.78 ± 3.91) and VAS score (5.03 ± 2.02 vs. 3.85 ± 1.68) ($p < 0.05$), higher VAS (3.89 ± 2.51 vs. 2.64 ± 2.00) at T_2 and KOOS-ADL (79.60 ± 20.20 vs. 65.68 ± 23.62), and lower KOOS-Sports (50.30 ± 30.15 vs. 68.35 ± 30.39) at T_3 ($p < 0.05$). No patient from either group had experienced major adverse effects. In the LP-PRP group 12 (30%) patients presented swelling, redness, and mild pain for one day after injection and two patients had synovitis for two days and required paracetamol and local ice. In AMAT group 5 (12.5%) patients had ecchymosis and bruising at the fat aspiration site for three days.

Conclusion AMAT did not show significant superior clinical improvement compared with three LP-PRP combined with HA injections in terms of functional improvement at different follow-up points. Both procedures were safe with no major complications reporting good results at mid-term follow-up, improving knee function, pain, and quality of life regardless of age and gender.

Introduction

There is a growing recognition of the importance of identifying the early stages of degenerative processes in knee osteoarthritis (OA), the period of the disease during which there may still be some ability to regenerate articular cartilage, which is permanently lost in the late stage of the disease

✉ Riccardo D'Ambrosi
riccardo.dambrosi@hotmail.it

[1, 2]. A definition of the early stage of OA is important for the proper identification and treatment of patients at risk of progression, enabling better design of trials for assessing the potential and indications of available and new treatments, and therefore better allocate resources and manage patients affected by symptomatic lesions of knee cartilage [1, 2].

Hyaluronic acid (HA) is a polysaccharide, formed from numerous disaccharide subunits of D-glucuronic acid and N-acetylglucosamine, which belongs to the glycosaminoglycan family [3]. In joints, hyaluronic acid plays a key role in maintaining close functional and metabolic interdependencies between synovial membrane, synovial fluid, articular cartilage, and indirectly subchondral bone [3]. In vitro studies have shown that hyaluronic acid is able to interact with several cellular receptors, modulating both acute and chronic inflammatory processes. Intra-articularly administered HA aims to positively affect both the symptomatology and delayed progression of OA through anti-inflammatory, chondroprotective, analgesic, and stimulating effects on the production of endogenous HA [3].

Platelet-rich plasma (PRP) represents a simple, inexpensive and minimally invasive option for obtaining a concentrate of autologous-derived growth factors and other bioactive molecules capable of stimulating tissue healing and regeneration, as well as anti-inflammatory and anti-catabolic molecules [4]. Pre-clinical studies have shown promising results, supporting the use of PRP also for the treatment of OA [4]. Indeed, by infiltrative application, PRP acts on the entire joint environment with a homeopathic action, as can be seen from the effects exerted in vitro on different cell types (synovial, stem, and meniscus) and in vivo in different pathological models (focal or degenerative lesions) [4].

When PRP and HA are used in combination these effects are enhanced and prolonged. HA creates a bioactive scaffolding in which the platelets progressively release their growth factors [5]. Regen PRP does not negatively affect the mechanical, elastic or viscous properties of HA [5]. Adipose-derived stem cells (ADSCs) have attracted attention in recent years due to their high availability and less invalidity of the harvesting procedure [6]. In addition to their ability to differentiate, i.e., acquire the phenotype of the cells of the tissue to be treated, it has been shown in recent years that the therapeutic potential of adipose-derived stem cells lies primarily in their ability to interact with the surrounding microenvironment [7]. Numerous in vitro and proclitic studies have, in fact, shown how these mechanisms are able to modulate the activity of resident cells, leading to an improvement, or in some cases a restoration of tissue/organ homeostasis [6, 7]. Some clinical in vivo human studies were performed, which have shown encouraging results in the treatment of OA [6, 7]

Given that all these modalities are potentially promising, this study primarily aimed to compare clinical outcomes of

a single dose of autologous microfragmented adipose tissue (AMAT) against three repeated doses of leucocyte-poor platelet-rich plasma (LP-PRP) in association with HA in the treatment of mild symptomatic knee OA; the secondary purpose is to assess whether demographic factors such as age and sex may affect the final outcome; finally to evaluate the adverse reactions of the two treatments. Currently, only one study reported one-year follow-up comparing AMAT versus LP-PRP + HA [8]. It was hypothesized that a single AMAT injections will improve patients' quality of life and functional status and will decrease pain level significantly more than LP-PRP + HA injections in patients with symptomatic early knee OA with a 24-month follow-up.

Materials and methods

Study design

In this prospective randomized trial, patients were recruited from November 2015 to December 2017. This study has been approved by the Institutional Review Board OASI Foundation and conforms to Helsinki and Good Clinical's declaration Practice: Consolidate Guideline. The study was conducted following the CONSORT Guidelines for randomized clinical trials (RCT) and has been registered in the Research Registry [9].

Eligibility criteria

All patients were provided with a specific written consent form to sign before treatment. Detailed inclusion and exclusion criteria are reported in Table 1. Pre-operative radiographs were evaluated according to the Kellgren-Lawrence OA classification [10]. Each patient was studied using a standing anteroposterior (AP) long-leg radiograph, standing AP and lateral views, skyline patellofemoral, and standing 45° flexion knee views. Furthermore, magnetic resonance imaging (MRI) was also performed in all treated knees [11]. Mild knee OA was classified based on radiographic findings as Kellgren-Lawrence grade 0 to 2. A complete hematology screening was performed before testing.

Allocation and procedures

Randomization was performed using an online software (www.randomization.com) and patients were randomly assigned at a 1:1 ratio to 1 of 2 treatment groups [12].

Leucocyte-Poor Platelet-Rich Plasma (LP-PRP) in association with Hyaluronic Acid (HA)

The first group received a LP-PRP + HA injection into the osteoarthritic knee (Cellular Matrix; Regen Lab,

Table 1 Inclusion and exclusion criteria*Inclusion criteria*

1. Symptomatic knee osteoarthritic (Kellgren-Lawrence Grade 1–2 cartilage lesions on radiographs or early OA on MRI)
2. Aged over 40 years with BMI < 30 kg/m²
3. Pain without relief with oral anti-inflammatory agents > 3 months
4. Patients with stable knees without malalignment
5. Patients who consented to either treatment modality as per the protocol
6. Normal blood results and coagulation profile (Platelets between 150,000 and 450,000/uL)
7. Patients who had not undergone any surgery on the affected knee in the 2 years before enrolment into the study

Exclusion criteria

1. Tricompartmental osteoarthritis, rheumatoid arthritis, or concomitant severe hip osteoarthritis
2. Previous High Tibial Osteotomy or cartilage transplantation
3. Patients with blood diseases, systemic metabolic disorders, immunodeficiency, Hepatitis B or C, HIV positive status, local or systemic infection
4. Ingestion of anti-platelet medications within 7 days before the treatment, or intra-articular or oral corticosteroids in the 3 months before initiating therapy
5. Smokers
6. Inflammatory arthritis
7. Severe cardiovascular disease

Switzerland). One cycle involved three injections one month apart. For PRP preparation, 6 mL of whole blood were obtained by venipuncture from the antecubital vein and centrifuged for 5 min at 1,500 g relative centrifugal field and 3,500 revolutions per minute. A mix was prepared of PRP with HA at a concentration of 3 mL of PRP for every 2 mL of HA. As per the PAW classification system, the final PRP product was classified as P2 B β [13–15]. The system provides a 1.6–1.8-fold increase in platelets [16–18]. PRP was active just before injection.

Autologous microfragmented adipose tissue preparation (AMAT)

The second group received a single dose of AMAT (Lipogems International S.p.A., Milan, Italy). After aseptic precautions and under local anesthesia, adipose tissue was harvested with an abdominal lipo-harvest procedure. The subcutaneous fat was injected with up to 300 ml of tumescent fluid. Then, up to 60 ml of adipose tissue and tumescent fluid were retrieved through a 4 mm lipoaspirate cannula and collected within a sterile medical grade single-use Shippert Tissu-Trans Collection filter (Shippert Medical Technologies, Colorado, USA). The lipoaspirate was transferred directly to an AMAT device. This is a full-immersion, and low-pressure cylindrical system in order to obtain fluid with a concentrated population of pericytes signaling cells [19]. The processed fat is subjected only to slight mechanical forces, with no detrimental effects.

Intra-articular injection

For both groups A single physician, with more than 5 years of experience in intra-articular knee injections, performed all procedures in this study using a supra-patellar approach. The injecting physician was not involved in clinical assessment of the patients. After treatment, weight bearing was allowed in both groups; ice application was recommended for the next 24 h (15 min every 3 h) [20, 21].

Rehabilitation protocol

Vigorous knee exercises were discouraged for the next 2 days. During all the follow-up period, was recommended to patients to perform isometric knee exercises [22]. In case of pain, redness or swelling, it has been suggested that patients use acetaminophen by mouth with a maximum dosage of up to 3000 mg per day (1000 mg every 8 h).

Outcomes of interest

All patients were evaluated by two blinded-independent clinicians not involved in the procedure.

Subjects' demographics (age and sex) were recorded at the screening visit after study enrollment was confirmed. Clinical outcomes were assessed by means of the Knee Injury and Osteoarthritis Outcome Score (KOOS), Visual Analogue Scale (VAS), Marx Knee Measure, and Tegner scoring systems [23–26]. The patients completed

questionnaires and all scores were tabulated before the commencement of treatment (T_0), at 6 (T_1), 12 (T_2), and 24 (T_3) months after treatment.

Complications and adverse events

Undesirable clinical developments which were not present at baseline or which increased in severity after treatment were classified as Adverse Events (AEs). Duration, type, and severity of adverse events (AEs) are recorded as defined in Table 2 [27].

Injections-related complications were defined as any deviation from the normal postoperative course due to the implants [28].

Sample size estimation

The sample analysis was conducted on the primary outcome of the study (i.e., clinical outcomes as IKDC/KOOS), given the presence in literature of several studies on the effects of regenerative treatment injections on knee function. Starting from two homogeneous groups with similar IKDC/KOOS values at the baseline, a sample of 78 knees—39 for each group—was estimated to be adequate to detect a 10-point difference of IKDC/KOOS score between LP-PRP+HA and AMAT groups, assuming a standard deviation (SD) of 15, an 80% power and a 5% type I error, and using the Wilcoxon-Mann Whitney test. The estimated sample also has an 80% power to detect a five-point-score difference between time points, assuming an SD of 15, a 5% alpha, and using the Wilcoxon signed rank-sum test. To ensure statistical significance in the case of unexpected events, we recruited 40 patients for each group.

Statistical analysis

The summary statistics were presented by absolute numbers and percentages or means and SDs. A comparison between the LP-PRP+HA and AMAT was performed with a chi-square test for categorical variables and/or t-test or Wilcoxon-Mann Whitney test, based on continuous variable distribution. Additionally, mean scores were compared at

each point of time: preoperative (T_0), at T_1 , at T_2 , and at T_3 between the two groups. Furthermore, to compare the same score between the time points within the same group, we performed a repeated measure mixed model with a first-order autoregressive covariance structure of errors. In case of a deviation from normality assumption, a Wilcoxon signed rank-sum test was performed. Bonferroni correction was applied for multiple comparisons [29]. To assess score differences among subjects of the same gender and age, a subgroup analysis was performed. Age groups were defined with the dichotomizing age at its average higher rounded value. Correlations among scores and socio-demographic variables were estimated and tested. A two-tailed p -value less than 0.05 was considered statistically significant. Statistical analyses were performed using the SAS System Version 9.

Results

Patient recruitment

Seventeen patients were excluded: four had severe knee OA, two had done previous cartilage transplantation, one had hepatitis, two were with infection, one had intra-articular corticosteroids in the three months post treatment, four were smokers, two had inflammatory arthritis, and one had severe cardiovascular disease. Fifty patients for a total of eighty knees completed the entire follow-up, of which 40 were placed in the LP-PRP+HA group and 40 in AMAT group (Fig. 1) [30]. No pre-operative differences were found between the two groups regarding age, gender, alignment, and knee OA ($p > 0.05$). Detailed results are reported in Table 3.

Patient demographic

Between group comparability at baseline was found in age, gender, alignment degree, Kellgren-Lawrence OA degree, and all clinical scores except VAS and Marx Score. Baseline demographic and comparability is shown in Table 3. Clinical outcomes are reported in Table 4.

Table 2 Definitions of adverse event (AE) severity with required interventions

Severity	Definition	Additional medication required?	Physicians advice required?
Mild	Minor discomfort noticed but does not interfere with normal daily activity	No	No
Moderate	Discomfort reducing or affecting normal daily activity	Yes	Potentially
Severe	Incapacitating with inability to work or perform normal daily activity	Yes	Yes
Serious	Permanent damage, life-threatening or death	Yes	Yes

CONSORT 2010 Flow Diagram

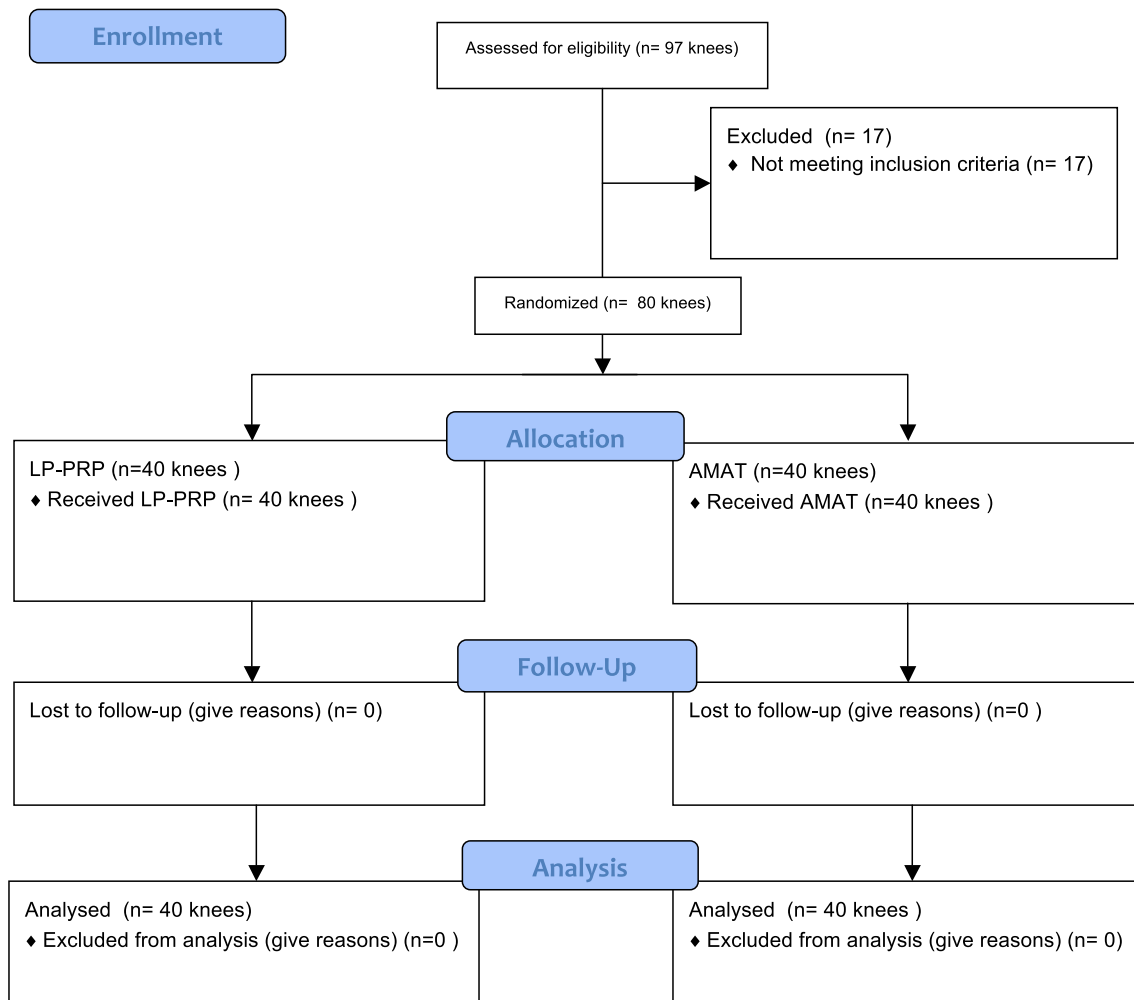

Fig. 1 Flowchart showing the patients assessed for eligibility, excluded, enrolled, and analyzed in the study

Results synthesis

The AMAT groups showed significantly higher pre-operative Marx score (3.35 ± 4.91 vs. 1.78 ± 3.91) and VAS score (5.03 ± 2.02 vs. 3.85 ± 1.68) ($p < 0.05$), higher VAS (3.89 ± 2.51 vs. 2.64 ± 2.00) at T₂ and KOOS-ADL (79.60 ± 20.20 vs. 65.68 ± 23.62), and lower KOOS-Sports (50.30 ± 30.15 vs. 68.35 ± 30.39) at T₃ ($p < 0.05$). Detailed results are reported in Table 4.

Subgroup analysis

Gender

Female

Female patients in the AMAT group reported a higher pre-operative Marx score, a higher VAS at T₂, and a higher KOOS-ADL at the final follow-up ($p < 0.05$). In the

Table 3 Characteristics of the patient study population

Variables	LP-PRP + HA N=40	AMAT N=40	Overall N=80	p-value

Values are presented as n (%) or mean ± SD

LP-PRP + HA = leucocyte-poor platelet-rich plasma plus hyaluronic acid (HA); AMAT—autologous microfragmented adipose tissue

*Statistical significant difference

LP-PRP + HA group, a significant improvement was noted for IKDC, KOOS-ADL, KOOS-Sports, KOOS-QOL, and VAS ($p < 0.05$). A significant improvement was noted in the AMAT group for Marx score, KOOS-symptoms, KOOS-ADL, KOOS-Sports, KOOS-QOL, and VAS ($p < 0.05$). Detailed results are reported in Appendix.

Male

Male patients in the AMAT group reported a lower pre-operative KOOS-Pain, KOOS-ADL, KOOS-Sports, KOOS-QOL, higher VAS, and a lower Marx score at the final follow-up ($p < 0.05$). In the LP-PRP + HA group, an improvement was noted for Marx score and KOOS-Sports, while in the AMAT group, only VAS at T₁ showed a significant improvement ($p < 0.05$). Detailed results are reported in Appendix.

Age

Patients < 65 years of age Young patients in the AMAT group showed a higher pre-operative Marx score, a lower pre-operative KOOS-ADL, and at final follow-up, a higher KOOS-ADL and lower KOOS-Sports ($p < 0.05$). Young patients in the LP-PRP + HA group reported significant improvement regarding Marx score, KOOS-ADL, and KOOS-Sports. In contrast, patients in the AMAT group showed significant improvement in IKDC, KOOS-symptoms, KOOS-pain, KOOS-ADL, KOOS-Sports, and VAS ($p < 0.05$). Detailed results are reported in Appendix.

Patients ≥ 65 years of age The only difference between the two groups involved VAS at each time-point, with a

significantly higher value in the AMAT group ($p < 0.05$). LP-PRP + HA patients reported significant improvement in KOOS-Pain and KOOS-Sports ($p < 0.05$), while no improvement was noted in the AMAT group ($p > 0.05$). Detailed results are reported in Appendix.

Adverse reactions

No patient from either group had experienced major adverse effects from the injection or during the final follow-up. In the LP-PRP group 12 (30%) patients presented swelling, redness, and mild pain for one day after injection and two patients had synovitis for two days and required paracetamol and local ice. In AMAT group 5 (12.5%) patients had ecchymosis and bruising at the fat aspiration site for three days. No statistical difference in rate of complications was found between the two groups ($p = 0.06$).

Discussion

The main findings of the current study found that both treatments lead to significant clinical improvement in several parameters with only slight differences were between the two different treatments. These results have also been confirmed by performing a subgroup analysis, by age and gender, confirming the treatments' efficacy without significant difference among the two groups regardless of age and gender. The two groups were homogeneous as regarding all pre-operative scores, but it is interesting to note that early-mid-term follow-up (T₂) LP-PRP reported a lower VAS score, confirming how the three injections can lead to a beneficial long-lasting effect [13].

*Statistical significant difference

This study has some limitations; it was not possible to conduct a prospective randomized and double-blinded study for ethical and practical reasons, as PRP does not require liposuction.

Furthermore, to avoid bias in the study, several restricted inclusion and exclusion criteria were followed, starting from age; in fact, the number of chondrocytes and bone-marrow-derived MSCs and their proliferative and matrix-forming potential may decrease as the years go by [31]. This might reduce the healing capacity of cartilage in older patients, and this is a common exclusion criterion [31]. In addition, patients with signs of joint-wide OA were excluded.

Finally, we excluded patients with BMI greater than 30, tricompartmental OA, inflammatory arthritis, previous cartilage transplantation, and ligamentous instability [31]. All these comorbidities or previous surgeries can increase the risk of excessive focal or abnormal loading and the likelihood of degeneration. Active inflammatory processes would be expected to interfere with any repair status and could limit the efficacy of tissue engineering strategies [31].

Another limitation is the lack of imaging evaluation that we tried to overcome with exhaustive clinical scores repeated over time. The study presents mid-term clinical results and a long follow-up may be necessary to confirm these results. The study did not include a placebo control group to compare results, as it is not ethically acceptable in the institution. More extensive research with long-term follow-up and biological outcomes will be of great interest for future studies.

The development of these new regenerative procedures opens up interesting scenarios in treating mild cases of arthrosis, where surgery has no place but has a significant social and QOL impact [32n]. OA is one of the leading causes of functional impairment in daily living activities among older adults and a serious issue in public health throughout the world. Pain and limitations result primarily from mechanical changes in the knee [32]. Patients with OA may also suffer from various psychological problems such as sleep disturbance, depressive mood, and individual's subjective assessment of their mental and physical well-being manifested by health-related QOL [33, 34].

Currently, only a few studies have analyzed the efficacy of PRP in association with HA, reporting good to excellent outcomes; Saturveithan et al. in 2015 analyzed the efficacy of PRP in association with HA in knee OA of grades III and IV, reporting improvement in terms of functional outcome and pain for up to six months [35].

In 2017, Yu et al. treated more than 350 patients with knee OA randomizing into four blinded different groups: PRP (2–14 ml), HA (0.1–0.3 mg), PRP plus HA, and placebo groups [36]. At the final follow-up, the authors confirmed that PRP in association with HA significantly improved pain, reduced cellular immune responses, and

promoted angiogenesis, with beneficial effects on histological parameters compared with PRP or HA treatment alone [36].

Recently, Lana et al. confirmed previous findings, analyzing 105 patients with moderate knee OA and randomized to one of three interventions: HA ($n = 36$), PRP ($n = 36$), or HA + PRP ($N = 33$) [37]. The combination of HA plus PRP resulted in better outcomes than isolated HA for up to one year and isolated PRP for up to three months.

Despite the demonstrated efficacy of PRP, there remains a great deal of doubt about its classification and preparation, making it difficult to analyze clinical outcomes.

Multiple variables comprise the formulations of PRP, with the predominant categories involving platelet concentration, white blood cell concentration, and growth factor quantity [38–40]. Riboh et al. performed a meta-analysis of the current literature and found LP-PRP resulted in significantly better functional outcomes when compared with LR-PRP [41].

In the other groups, treatment of patients with AMAT was decided; in fact, these cells contain immunomodulatory properties, making them a promising candidate for OA's regenerative treatment [7]. The ADSCs in the SVF secrete several anti-inflammatory substances such as IL-1RA, nitric oxide, TGF β 1, SDF-1, and LL37, among others. These alleviate the inflammatory state and relieve in the affected joint [7].

Furthermore, AMAT is present in a huge amount in the human body (more than 5% of nucleated cells in adipose tissue), with the relative simplicity of harvesting and lower donor-site morbidity, and its rapid expansion and high proliferative capabilities [7]. Moreover, ADSCs are able to maintain their features even if manipulated through different cell cultures compared to different cell lines [7].

A recent systematic review reported good to excellent clinical results after AMAT injection, with minimal complication rates [42]. Gobbi et al., in a multi-centric, international, and open-label study published in 2021, show that a single-dose of AMAT injection leads to clinical and functional, improvement at two years in seventy-five patients with KL grades two, three or four [43].

Conclusions

AMAT did not show significant superior clinical improvement compared with three LP-PRP combined with HA injections in terms of functional improvement at different follow-up points. Both procedures were safe with no major complications reporting good results at mid-term follow-up, improving knee function, pain, and quality of life regardless of age and gender.
