#### Abstract

It has been demonstrated that apart from the known compounds $\mathrm{YbVO}_{4}$ and $\mathrm{Yb}_{8} \mathrm{~V}_{2} \mathrm{O}_{17}$, a substitutive solid solution is also formed in the binary oxide system $\mathrm{V}_{2} \mathrm{O}_{5}-\mathrm{Yb}_{2} \mathrm{O}_{3}$. This solid solution is characterized by limited solubility of vanadium $(\mathrm{V})$ oxide in the crystal lattice of ytterbium oxide, and its general formula is $\mathrm{Yb}_{2-5 x} \square_{2 x} \mathrm{~V}_{3 x} \mathrm{O}_{3}$, where $0.00<x<0.1667$. The new solid solution was obtained from the mixtures of $\mathrm{V}_{2} \mathrm{O}_{5}$ and $\mathrm{Yb}_{2} \mathrm{O}_{3}$ oxides, containing vanadium $(\mathrm{V})$ oxide in the amounts not exceeding $30 \mathrm{~mol} \%$, by high-energy ball milling in a planetary ball mill. The solid solution obtained was characterized using the methods XRD, DTA-TG, SEM, IR and UV-Vis-DR. It was found to crystallize in cubic system and to show a structure of $\mathrm{Yb}_{2} \mathrm{O}_{3}$. This solid solution was stable in air atmosphere at least up to $\sim 800^{\circ} \mathrm{C}$, and the temperature of its decomposition decreased with increasing $x$, so with increasing degree of $\mathrm{Yb}^{3+}$ replacement with $\mathrm{V}^{5+}$ in the crystal lattice of $\mathrm{Yb}_{2} \mathrm{O}_{3}$. The energy gap estimated for this solid solution varied from $\sim 2.5 \mathrm{eV}$ for $x=0.0322$ to $\sim 2.6 \mathrm{eV}$ for $x=0.1176$, which means that this new solid solution is a semiconductor.

## Introduction

Intensive search for new advanced materials for application in, e.g., optics, electronics and informatics has been conducted for many years. Of great importance is to devise simple and economically and ecologically justified methods for their syntheses to
meet the increasingly stringent rules for the environment protection. Such methods can be also applied for the modification of physicochemical properties of these new materials as well as other already known compounds. Different methods for syntheses of new materials have been proposed, including the solid-state reactions, co-precipitation,

[^0]sol-gel method, suspension, combustion, Pechini method, hydrothermal method, sonochemical method and still too little appreciated mechanochemical method. Each of the abovementioned methods has its specific advantages and disadvantages, and the choice of the suitable one depends on the type of products and their desired properties for particular applications (morphology and size of crystallites, degree of crystallinity, absorption properties, surface area, degree of homogeneity, etc.). The mechanochemical method meets a high degree the requirements of "green chemistry" as it does not generate troublesome wastes which are difficult for utilization and it does not need the use of toxic organic solvents [1-4]. The high-energy ball milling has been successfully used for syntheses of many new functional materials such as alloys, intermetallic compounds, polymer or inorganic composites, ceramic materials [1-6]. According to the hitherto-published literature on the binary oxides of our concern, $\mathrm{V}_{2} \mathrm{O}_{5}-\mathrm{Yb}_{2} \mathrm{O}_{3}$, the formation of two compounds $\mathrm{YbVO}_{4}$ and $\mathrm{Yb}_{8} \mathrm{~V}_{2} \mathrm{O}_{17}$ in this oxide system has been documented [7-16]. They have been obtained as a result of high-temperature treatment of the oxides mixture containing $\mathrm{V}_{2} \mathrm{O}_{5}$ and $\mathrm{Yb}_{2} \mathrm{O}_{3}$ of the contents chosen to match the stoichiometry of these compounds [11, 13-16]. To the best of our knowledge, there is no information on the solid solutions forming in the binary system of $\mathrm{V}_{2} \mathrm{O}_{5}$ and $\mathrm{Yb}_{2} \mathrm{O}_{3}$ oxides showing the structures of vanadium $(\mathrm{V})$ oxide and/or ytterbium oxide. In contrast to the scarce data on ytterbium divanadate(V), the synthesis and physicochemical properties of ytterbium orthovanadate $(\mathrm{V})$ have been thoroughly described [7-12]. $\mathrm{YbVO}_{4}$ has been obtained by different methods: solid-state, hydrothermal and co-precipitation [7-12] and mechanochemical method [21]. Detailed crystal structure of this compound as well as its optical, electric, magnetic, thermal and chemical properties is known [7-12]. It has been proved that as a result of $\mathrm{YbVO}_{4}$ doping with such lanthanide ions as $\mathrm{Nd}^{3+}$ and $\mathrm{Er}^{3+}$, a number of optically active laser materials can be obtained $[13,14]$. The information on the other of the two compounds, i.e., $\mathrm{Yb}_{8} \mathrm{~V}_{2} \mathrm{O}_{17}$, is scarce $[15,16]$ and ambiguous. This compound was for the first time obtained in 1973 by Brusset et al. [15] as a result of heating of a mixture of oxides $\mathrm{Yb}_{2} \mathrm{O}_{3} / \mathrm{V}_{2} \mathrm{O}_{5}$ at a molar ratio $4: 1$, up to $1550{ }^{\circ} \mathrm{C}$. These authors claimed that it crystallized in monoclinic system and gave its elementary cell parameters [15]; however,
according to our recent study, this compound obtained by the solid-solid reactions crystallizes in triclinic system and its elementary cell parameters are different from those given by Brusset et al. [16]. Recently, the authors from our group have also shown that $\mathrm{Yb}_{8} \mathrm{~V}_{2} \mathrm{O}_{17}$ is the matrix (solid solvent) of the limited substitutive solid solution of the formula $\mathrm{Yb}_{8-x} \mathrm{Y}_{x} \mathrm{~V}_{2} \mathrm{O}_{17}$ and $0.0<x<4.0$. In such a solid solution, the $\mathrm{Y}^{3+}$ ions are built into the crystalline lattice of $\mathrm{Yb}_{8} \mathrm{~V}_{2} \mathrm{O}_{17}$, replacing $\mathrm{Yb}^{3+}$ ones, with no damage to the crystal structure [16].

Taking into account the hitherto knowledge on the compounds forming in the system $\mathrm{V}_{2} \mathrm{O}_{5}-\mathrm{Yb}_{2} \mathrm{O}_{3}$, and in particular, the lack of information on the synthesis of $\mathrm{YbVO}_{4}$ and $\mathrm{Yb}_{8} \mathrm{~V}_{2} \mathrm{O}_{17}$ by mechanochemical method (MChS), the aim of the study reported here was to establish the type of compounds and/or phases forming in this system in the entire range of concentration of its components as a result of reactions induced by high-energy ball milling. If as a result of this process new compounds and/or solid solutions are obtained, our additional objectives will be to characterize their structures and properties, in particular thermal stability and optical properties, and to compare them with the properties of the phases obtained in the high-temperature reactions (HTS) taking place in the system studied in solid state.

## Experimental

The following reagents were used in our experiments: $\mathrm{Yb}_{2} \mathrm{O}_{3}$, a.p. (Alfa Aesar, Germany), and $\mathrm{V}_{2} \mathrm{O}_{5}$, a.p. (POCh, Poland). For the experiments, 14 samples were prepared (Tables 1, 2) by using two different methods, namely:
(a) Mechanochemical synthesis (MChS) using laboratory planetary ball mill Pulverisette-6 (Fritsch GmbH , Germany) with vessel and balls of zirconia, $\quad \mathrm{rpm}=500, \quad \mathrm{BPR}=1: 20, \quad$ time $=3.0$ and once again 3.0 h under air atmosphere.
(b) High-temperature synthesis (HTS) in a horizontal tube furnace PRC 50/170/M (Czylok, Poland) equipped with a stationary optical pyrometer MARATHON MM (Raytek, Germany). Reagents weighed in suitable proportions were homogenized and calcined in air atmosphere in the temperature range

$600-1500^{\circ} \mathrm{C}$. After each heating stage, the samples were gradually cooled in the furnace to room temperature and weighed (changes in their mass and their color were recorded) by the method described, e.g., in [16-19].

The powder diffraction patterns of the samples obtained were recorded on a diffractometer EMPYREAN II (PANalytical, Netherlands) using $\mathrm{CuK}_{\alpha}$ with graphite monochromator. The phases were identified on the basis of XRD (X-ray diffraction) characteristics contained in the PDF (Powder Diffraction File) cards [20].The parameters of selected unit cell solid solutions were refined using the REFINEMENT program of DHN/PDS package.

Selected samples were examined using the following methods: SEM (scanning electron microscopy) using FE-SEM Hitachi SU-70 microscope and EDX (X-ray microanalysis) using NORAN ${ }^{\mathrm{TM}}$ System 7 of Thermo Fisher Scientific (UltraDry X-ray detector). SEM analyses were performed at accelerating voltage of 5 and 15 kV , and secondary electron images were acquired. The samples were coated with palladium-gold alloy thin film using thermal evaporation PVD (physical vapor deposition) method to provide electric conductivity.
The densities of solid solutions were determined in argon ( 5 N purity) with the help of an Ultrapyc 1200e ultrapycnometer (Quantachrome Instruments, USA). Initial mixtures and monophasic samples were examined by IR (infrared spectroscopy). The
measurements were made within the wavenumber range of $1200-250 \mathrm{~cm}^{-1}$, using a spectrophotometer SPECORD M-80 (Carl Zeiss, Jena, Germany). The technique of pressing pellets with KBr at the mass ratio of 1:300 was applied. Selected samples were also subjected to examination by the DTA-TG (differential thermal analysis and thermogravimetry) method with the use of a SDT 2960 apparatus (TA Instruments Company, USA). The measurements were taken in air atmosphere, within the temperature range $20-1400^{\circ} \mathrm{C}$, at the heating rate of $10 \mathrm{deg} / \mathrm{min}$. The tests were conducted in corundum crucibles. The samples had the same mass of $\sim 20 \mathrm{mg}$.

The UV-Vis-DR (ultraviolet-visible with diffuse reflectance) spectra were measured using a UV-Vis spectrometer V-670 (JASCO, Japan) equipped with a reflecting attachment for the solid-state investigation (integrating sphere attachment with horizontal sample platform PIV-756/(PIN-757). The spectra were recorded in the wavelength region of $200-750 \mathrm{~nm}$ at room temperature.

## Results and discussion

## Mechanochemical synthesis

Investigation of the binary oxide system $\mathrm{V}_{2} \mathrm{O}_{5}-\mathrm{Yb}_{2} \mathrm{O}_{3}$ was started from preparation of mixtures of the substrates $\mathrm{Yb}_{2} \mathrm{O}_{3}$ and $\mathrm{V}_{2} \mathrm{O}_{5}$, of the compositions specified in Table 1. The compositions were chosen to
represent the range of substrate concentrations in which the literature-known compounds $\mathrm{Yb}_{8} \mathrm{~V}_{2} \mathrm{O}_{17}$ and $\mathrm{YbVO}_{4}$ are formed [7-16]. Mixtures of the ytterbium and vanadium oxides were homogenized and subjected to mechanochemical synthesis in a planetary ball mill in air atmosphere. XRD analysis of the phase composition revealed that already after the first stage of the 3-h milling, all the samples studied changed their phase composition. Diffractograms of samples 1-3 no longer showed the XRD reflections characteristic of one of the substrates- $\mathrm{V}_{2} \mathrm{O}_{5}$, but included a set of reflections evidencing the presence of $\mathrm{Yb}_{2} \mathrm{O}_{3}$. Analysis of these diffractograms also indicated that with an increasing content of $\mathrm{V}_{2} \mathrm{O}_{5}$ in the initial mixtures of the reagents, the reflections were slightly shifted toward lower $2 \Theta$ angles, which corresponds to greater interplanar distances $d_{\text {hkl }}$ with respect to those in the diffractograms of the pure compound $\mathrm{Yb}_{2} \mathrm{O}_{3}$. This result implied that in the range of concentration of up to $20.00 \mathrm{~mol} \% \mathrm{~V}_{2} \mathrm{O}_{5}$ in the system $\mathrm{Yb}_{2} \mathrm{O}_{3}-\mathrm{V}_{2} \mathrm{O}_{5}$, a new solid solution, showing the structure of $\mathrm{Yb}_{2} \mathrm{O}_{3}$, was formed. The lack of foreign lines in XRD patterns of these samples proved that the new solid solution was substitutive, with $\mathrm{V}^{5+}$ ions taking place of $\mathrm{Yb}^{3+}$ ions in the crystal lattice of $\mathrm{Yb}_{2} \mathrm{O}_{3}$. Analysis of the phase composition of samples 4 and 5 revealed that after 3 -h milling, these samples were biphasic and, besides the solid solution of the structure of $\mathrm{Yb}_{2} \mathrm{O}_{3}$, contained also the known orthovanadate $\mathrm{YbVO}_{4}$ (Table 1). The 3-h milling of the equimolar mixture of the reagents (sample 6) made the sample monophasic, with only $\mathrm{YbVO}_{4}$ in its content (Table 1) [21]. This result indicated that ytterbium orthovanadate( V ) could also be obtained by the way of mechanochemical synthesis [21], besides other known methods [7-12]. Sample 7 represented the initial system composition with more than $50.00 \mathrm{~mol} \% \mathrm{~V}_{2} \mathrm{O}_{5}$. After 3-h ball milling, the sample was biphasic and, besides the compound $\mathrm{YbVO}_{4}$, contained also small amounts of $\mathrm{V}_{2} \mathrm{O}_{5}$. The subsequent 3-h milling of all samples studied did not change their phase composition. The phase compositions of all samples after the last stage of their ball milling, as presented in Table 1, prove that the new substitutive solid solution forming in the system studied is characterized by limited solubility of components. The fact that $\mathrm{V}^{5+}$ ions are incorporated into the crystal lattice of ytterbium oxide replacing $\mathrm{Yb}^{3+}$ ions leads to the generation of excessive positive charge which can be compensated by the extension of
the anionic lattice or by the formation of vacancies in the cationic $\mathrm{Yb}^{3+}$ sublattice. In the former case, the general formula of the solution can be written as $\mathrm{Yb}_{2-x} \mathrm{~V}_{x} \mathrm{O}_{3+x}$, while in the latter case as $\mathrm{Yb}_{2-5 x} \square_{2 x} \mathrm{~V}_{3 x} \mathrm{O}_{3}$.

Charge compensation by the generation of vacancies in crystal lattice (the second formula) is supported by the values of experimental density of obtained phase in comparison with its X -ray density, as described later in this work. The data presented in Table 1 also imply that the maximum incorporation of $\mathrm{V}^{5+}$ into the lattice of $\mathrm{Yb}_{2} \mathrm{O}_{3}$, when expressed in the contents of components of the system studied, reaches at least $20.00 \mathrm{~mol} \%$ ( $x=0.1176$ ) and does not exceed $30.00 \mathrm{~mol} \%$.

Analysis of the results obtained leads to a conclusion that in the reaction mixtures containing up to $50.00 \mathrm{~mol} \% \mathrm{~V}_{2} \mathrm{O}_{5}$, the following reaction took place:

$$
\begin{align*}
& (2-5 x) / 2 \mathrm{Yb}_{2} \mathrm{O}_{3(\mathrm{~s})}+3 x / 2 \mathrm{~V}_{2} \mathrm{O}_{5(\mathrm{~s})} \\
& =\mathrm{Yb}_{2-5 x} \square_{2 x} \mathrm{~V}_{3 x} \mathrm{O}_{3 \text { (s.s. } .)} \tag{1}
\end{align*}
$$

Figure 1 presents a fragment of XRD diffractogram of the commercial $\mathrm{Yb}_{2} \mathrm{O}_{3}$ (Fig. 1a) and the diffractograms of the newly obtained solid solution

Fig. 1 Fragments of diffractograms of $\mathbf{a} \mathrm{Yb}_{2} \mathrm{O}_{3}(\boldsymbol{\wedge}), \mathbf{b} \mathrm{Yb}_{1.839}$ $\left.\square_{0.064} \mathrm{~V}_{0.097} \mathrm{O}_{3}()^{*}\right)$, $\mathrm{Yb}_{1.412} \square_{0.235} \mathrm{~V}_{0.353} \mathrm{O}_{3}$ ( $\square$ ), d $\mathrm{Yb}_{2-5 x} \square_{2 x}$ $\mathrm{V}_{3 x} \mathrm{O}_{3}(\odot)$ and $\mathrm{YbVO}_{4}(\square)$.
$\mathrm{Yb}_{2-5 x} \square_{2 x} \mathrm{~V}_{3 x} \mathrm{O}_{3}$ for $x=0.0322$ (Fig. 1b), $x=0.1176$ (Fig. 1c) and sample 4 containing the solid solution $\mathrm{Yb}_{2-5 x} \square_{2 x} \mathrm{~V}_{3 x} \mathrm{O}_{3}$ and $\mathrm{YbVO}_{4}$.

The aim of the next stage of our study was to confirm that the newly obtained solid solution $\mathrm{Yb}_{2-5 x} \square_{2 x} \mathrm{~V}_{3 x} \mathrm{O}_{3}$ shows the matrix structure, i.e., that it crystallizes in the cubic system. In order to check this, the powder diffractograms of the solution $\mathrm{Yb}_{2-5 x} \square_{2 x} \mathrm{~V}_{3 x} \mathrm{O}_{3}$ for $x=0.0322,0.0625$ or 0.1176 were refined using the program REFINEMENT. The results confirmed that the new solid solution crystallizes in the cubic system and permitted calculation of its unit cell parameters as a function of the content of incorporated $\mathrm{V}^{5+}$ replacing $\mathrm{Yb}^{3+}$ in the crystal lattice of $\mathrm{Yb}_{2} \mathrm{O}_{3}$. Table 2 presents the unit cell parameters, volumes and densities of $\mathrm{Yb}_{2-5 x} \square_{2 x} \mathrm{~V}_{3 x}$ $\mathrm{O}_{3}$ with $x=0.0322,0.0625$ and 0.1176 .

According to the data displayed in Table 2, with an increasing value of $x$ in the formula $\mathrm{Yb}_{2-5 x} \square_{2 x} \mathrm{~V}_{3 x} \mathrm{O}_{3}$, so with an increasing number of $\mathrm{V}^{5+}$ incorporated in the crystal lattice and replacing $\mathrm{Yb}^{3+}$ ions, the crystal lattice expands, although the radius of $\mathrm{V}^{5+}$ in coordination (VI) is smaller than that of $\mathrm{Yb}^{3+}$ in the same coordination. The lattice expansion can be a result of greater electric charge of vanadium ion or generation of vacancies in the $\mathrm{Yb}^{3+}$ sublattice. The same tendency has been observed in [22]. Analysis of the same data from Table 2 also shows that the density of the new solid solution, determined by an ultrapycnometer or by X-ray method, is always smaller than that of pure $\mathrm{Yb}_{2} \mathrm{O}_{3}$ and decreases with increasing $x$, which additionally supports the assumed model of the solution structure. With an increasing $x$ in $\mathrm{Yb}_{2-5 x} \square_{2 x} \mathrm{~V}_{3 x} \mathrm{O}_{3}$, the color of the solid solution changed from dark orange to yellow. The mixture of the substrates composed of $50 \mathrm{~mol} \% \quad \mathrm{Yb}_{2} \mathrm{O}_{3}$ and $50 \mathrm{~mol} \% \mathrm{~V}_{2} \mathrm{O}_{5}$ and the solid solution $\mathrm{Yb}_{2-5 x} \square_{2 x} \mathrm{~V}_{3 x} \mathrm{O}_{3}$ for $x=0.0625$ were also studied by scanning electron microscopy (SEM/EDX). The relevant images are presented in Figs. 2 and 3.

Figure 2 shows a clear distinction between the two types of crystallites, which can also be distinguished on the basis of their different interaction with a beam of electrons. The crystallites look like irregular deformed polyhedrons. As follows from EDX analysis, the brighter polygons correspond to $\mathrm{Yb}_{2} \mathrm{O}_{3}(\Delta)$, while the darker and slightly bigger ones to $\mathrm{V}_{2} \mathrm{O}_{5}(\mathrm{O})$. The crystallites of the solid solution $\mathrm{Yb}_{2-5 x} \square_{2 x} \mathrm{~V}_{3 x} \mathrm{O}_{3}$ presented in Fig. 3 have morphology similar to that of the matrix crystallites $\left(\mathrm{Yb}_{2} \mathrm{O}_{3}\right)$. They look like

Fig. 2 SEM image of $\mathrm{Yb}_{2} \mathrm{O}_{3}(\Delta)+\mathrm{V}_{2} \mathrm{O}_{5}(\bigcirc)$.

Fig. 3 SEM image of $\mathrm{Yb}_{2-5 x} \square_{2 x} \mathrm{~V}_{3 x} \mathrm{O}_{3}(x=0.0625)$.
deformed polyhedrons of irregular shapes and sizes varying from $\sim 40$ to $\sim 270 \mathrm{~nm}$ (Fig. 3). X-ray microanalysis (EDX) informing about the content of metals and oxygen in the crystals of $\mathrm{Yb}_{2-5 x} \square_{2 x} \mathrm{~V}_{3 x} \mathrm{O}_{3}$ for all monophase samples is presented in Table 3.

Taking into account the average error in determination of the content of oxygen, the results provided by SEM/EDX results are in good agreement with the values calculated from the formula $\mathrm{Yb}_{2-5 x} \square_{2 x} \mathrm{~V}_{3 x} \mathrm{O}_{3}$ for $x=0.0625$, which confirms its correctness.

In order to check whether the solid solution obtained shows the structure of the matrix, that is of $\mathrm{Yb}_{2} \mathrm{O}_{3}$, IR spectra were taken of selected monophasic samples. Figure 4, besides the IR spectrum of the commercial oxide $\mathrm{Yb}_{2} \mathrm{O}_{3}$ (Fig. 4a), also presents the IR spectra of the solid solution $\mathrm{Yb}_{2-5 x} \square_{2 x} \mathrm{~V}_{3 x} \mathrm{O}_{3}$ for $x=0.0322$ and $x=0.1176$ (Fig. 4 , spectra b and c ).

Table 3 Content of elements in monophase samples determined by X-ray microanalysis (EDX) and calculated from formula $\mathrm{Yb}_{2-5 x}$ $\square_{2 x} \mathrm{~V}_{3 x} \mathrm{O}_{3}$ where $x=0.0322,0.0625$ and 0.1176

| Formula of solid solution | X-ray microanalysis of elements (mas\%) |  |  | Contents of elements calculated from the formula (mas\%) |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Yb | V | O | Yb | V | O |
| $\mathrm{Yb}_{1.839} \square_{0.064} \mathrm{~V}_{0.097} \mathrm{O}_{3}$ | 89.2 | 1.3 | 9.5 | 85.7 | 1.4 | 12.9 |
| $\mathrm{Yb}_{1.688} \square_{0.125} \mathrm{~V}_{0.188} \mathrm{O}_{3}$ | 87.2 | 2.3 | 10.4 | 83.5 | 2.7 | 13.7 |
| $\underline{\mathrm{Yb}_{1.412} \square_{0.235} \mathrm{~V}_{0.353} \mathrm{O}_{3}}$ | 83.3 | 5.7 | 10.9 | 78.70 | 5.8 | 15.47 |

The IR spectrum of $\mathrm{Yb}_{2} \mathrm{O}_{3}$ (Fig. 4a) shows a broad absorption band in the wavenumber range from 645 to $300 \mathrm{~cm}^{-1}$, of distinct extremes at 565,395 and $335 \mathrm{~cm}^{-1}$ and an inflection point at $\sim 500 \mathrm{~cm}^{-1}$. These bands can be assigned to the stretching vibrations of $\mathrm{Yb}-\mathrm{O}$ in the deformed $\mathrm{YbO}_{6}$ octahedrons [23-26] and the stretching vibrations of the deformation bridge bonds $\mathrm{Yb}-\mathrm{O}-\mathrm{Yb}$ or $\mathrm{O}-\mathrm{Yb}-\mathrm{O}$ [23-26]. In the IR spectra of the solid solution (Fig. 4b,c), the absorption bands appear in a very narrow range of wavenumbers similar to those in the spectrum of $\mathrm{Yb}_{2} \mathrm{O}_{3}$, i.e., from 650 to $300 \mathrm{~cm}^{-1}$, but they are more broadened and show much less distinct maxima at $450 \mathrm{~cm}^{-1}$ (for $x=0.0322$ ) and $465 \mathrm{~cm}^{-1}$ (for $x=0.0322$ ). In contrast to the spectrum of $\mathrm{Yb}_{2} \mathrm{O}_{3}$, the spectra of the solid solution $\mathrm{Yb}_{2-5 x} \square_{2 x} \mathrm{~V}_{3 x} \mathrm{O}_{3}$ show also a broad and low-intensity band in the range $1000-600 \mathrm{~cm}^{-1}$, which on the basis of the literature can be assigned to the stretching vibrations of symmetric and asymmetric $\mathrm{V}-\mathrm{O}$ bonds in $\mathrm{VO}_{6}$ octahedrons [23]. The absorption band in the range 650$300 \mathrm{~cm}^{-1}$ is interpreted as corresponding to the stretching vibrations of $\mathrm{Yb}-\mathrm{O}$ bonds in $\mathrm{YbO}_{6}$ octahedra and vibrations of the bridging bonds $\mathrm{O}-\mathrm{Yb}-\mathrm{O}$ and $\mathrm{O}-\mathrm{V}-\mathrm{O}$ [23-26]. With an increasing number of $\mathrm{V}^{5+}$ replacing $\mathrm{Yb}^{3+}$ in the crystal lattice of $\mathrm{Yb}_{2} \mathrm{O}_{3}$, the absorption bands are shifted toward higher wavenumbers relative to their positions in the spectrum of the matrix. The results confirmed that the solid solution $\mathrm{Yb}_{2-5 x} \square_{2 x} \mathrm{~V}_{3 x} \mathrm{O}_{3}$ has a structure of $\mathrm{Yb}_{2} \mathrm{O}_{3}$ and is composed of $\mathrm{YbO}_{6}$ and $\mathrm{VO}_{6}$ octahedrons. In order to establish the thermal stability of the solid solution $\mathrm{Yb}_{2-5 x} \square_{2 x} \mathrm{~V}_{3 x} \mathrm{O}_{3}$ obtained by mechanochemical method, three monophasic samples, 1-3 (Table 1), were heated in the range from 500 to $1500 \pm 10^{\circ} \mathrm{C}$ in air atmosphere, in a horizontal tube furnace equipped with an optical pyrometer, in a few $12-\mathrm{h}$ stages. The samples heated at $500,600,700$ and $800^{\circ} \mathrm{C}$ did not show signs of melting, and their phase composition was not changed. Heating at

Fig. 4 Fragments of IR spectra of: a $\mathrm{Yb}_{2} \mathrm{O}_{3}$, $\mathbf{b} \mathrm{Yb}_{1.839} \square_{0.064}$ $\mathrm{V}_{0.097} \mathrm{O}_{3}$ and $\mathrm{c} \mathrm{Yb}_{1.412} \square_{0.235} \mathrm{~V}_{0.353} \mathrm{O}_{3}$.
$900^{\circ} \mathrm{C}(12 \mathrm{~h})$ caused changes in the phase composition of sample 3. The XRD diffractogram of this sample, besides the diffraction signals characteristic of $\mathrm{Yb}_{2} \mathrm{O}_{3}$, revealed also a set of XRD lines that, according to PDF card no. 00-017-0338, are assigned to $\mathrm{YbVO}_{4}$. The phase composition of the other samples ( 1 and 2 ) changed only after their heating at $\sim$ $1500{ }^{\circ} \mathrm{C}(12 \mathrm{~h})$. After this stage of heating, the samples were biphasic and besides $\mathrm{Yb}_{2} \mathrm{O}_{3}$ contained the literature-known compound $\mathrm{Yb}_{8} \mathrm{~V}_{2} \mathrm{O}_{17}[15,16]$. Sample 3 after annealing at this temperature was monophasic and contained only $\mathrm{Yb}_{8} \mathrm{~V}_{2} \mathrm{O}_{17}$. As follows from the results of this experiment, the solid

Fig. 5 Kubelka-Munk transformation of the UV-VisDR spectra of $\mathrm{Yb}_{2} \mathrm{O}_{3}$ and the solid solution
$\mathrm{Yb}_{2-5 x} \square_{2 x} \mathrm{~V}_{3 x} \mathrm{O}_{3}$ for $x=0.0322,0.0625$ and 0.1176 .

solution obtained is thermally stable in air atmosphere to at least $800^{\circ} \mathrm{C}$ (for $x=0.1176$ ); the lower the number of $\mathrm{V}^{5+}$ ions replacing $\mathrm{Yb}^{3+}$ ions in the lattice of $\mathrm{Yb}_{2} \mathrm{O}_{3}$, the higher its thermal stability, and the solid solution is stable in the range $900-1500{ }^{\circ} \mathrm{C}$. At higher temperatures, the solid solution undergoes decomposition to the oxides $\mathrm{V}_{2} \mathrm{O}_{5}$ and $\mathrm{Yb}_{2} \mathrm{O}_{3}$, which then react with formation of $\mathrm{YbVO}_{4}$. In the range of components of the system $\mathrm{Yb}_{2} \mathrm{O}_{3}-\mathrm{V}_{2} \mathrm{O}_{5}$, in which the oxide $\mathrm{Yb}_{2} \mathrm{O}_{3}$ is in excess to the stoichiometry of ytterbium orthovanadate $(\mathrm{V})$, the reagents react with formation of $\mathrm{Yb}_{8} \mathrm{~V}_{2} \mathrm{O}_{17}$ :
$2 \mathrm{YbVO}_{4(\mathrm{~s})}+3 \mathrm{Yb}_{2} \mathrm{O}_{3(\mathrm{~s})}=\mathrm{Yb}_{8} \mathrm{~V}_{2} \mathrm{O}_{17(\mathrm{~s})}$
The results obtained at this stage confirmed that $\mathrm{V}_{2} \mathrm{O}_{5}$ was initially built in $\mathrm{Yb}_{2} \mathrm{O}_{3}$, making the earlier unknown solid solution.

Physicochemical characterization of the matrix $\mathrm{Yb}_{2} \mathrm{O}_{3}$ and the solid solution $\mathrm{Yb}_{2-5 x} \square_{2 x} \mathrm{~V}_{3 x} \mathrm{O}_{3}$ was supplemented with UV-Vis-DR measurements that permitted estimation of the energy gap. Figure 5 presents the plots of $K^{2}=f(E)$, where $K$ is obtained from the Kubelka-Munk transformation (Spectra Analysis Program) and in the plot is marked as K/M. The energy gap values were read off as the points of intersection of the tangent to a given curve and the abscissa axis.

The energy gap ( $E_{\mathrm{g}}$ ) determined for $\mathrm{Yb}_{2} \mathrm{O}_{3}$ was $\sim$ 5.00 eV , while the energy gap for the solid solution decreased with an decreasing $x$ in $\mathrm{Yb}_{2-5 x} \square \square_{2 x} \mathrm{~V}_{3 x} \mathrm{O}_{3}$ from $E_{g}=\sim 2.5 \mathrm{eV}$ for $\mathrm{Yb}_{1.839} \square_{0.064} \mathrm{~V}_{0.097} \mathrm{O}_{3}$ to $\sim$ 2.6 eV for $\mathrm{Yb}_{1.412} \square_{0.235} \mathrm{~V}_{0.353} \mathrm{O}_{3}$. On the basis of the obtained energy gap values, the solid solution $\mathrm{Yb}_{2-5 x} \square_{2 x} \mathrm{~V}_{3 x} \mathrm{O}_{3}$ was classified as a semiconductor.

## High-temperature synthesis

In parallel with the mechanochemical synthesis of samples representing the system $\mathrm{Yb}_{2} \mathrm{O}_{3}-\mathrm{V}_{2} \mathrm{O}_{5}$, we carried out their syntheses by the classical method of high-temperature reactions taking place in solid state. The samples prepared for this procedure had the same compositions as those studied in the first part of this work, as shown in Tables 1 and 4. The mixtures of $\mathrm{Yb}_{2} \mathrm{O}_{3}$ and $\mathrm{V}_{2} \mathrm{O}_{5}$ (Table 4) after homogenization were heated in the following temperature stages: I $600{ }^{\circ} \mathrm{C} \quad(24 \mathrm{~h}) \rightarrow \mathrm{II}-625^{\circ} \mathrm{C} \quad(24 \mathrm{~h}) \rightarrow \mathrm{III}-635^{\circ} \mathrm{C}$ $(24 \mathrm{~h}) \rightarrow \mathrm{IV}-1200^{\circ} \mathrm{C}(24 \mathrm{~h}) \rightarrow \mathrm{V}-1400^{\circ} \mathrm{C}(24 \mathrm{~h}) \rightarrow$ VI- $1450{ }^{\circ} \mathrm{C}(24 \mathrm{~h})$.

According to the XRD results, all the samples studied changed their phase composition already after the first stage of heating. The diffractograms of samples $1-7$ already showed the XRD lines characteristic of $\mathrm{YbVO}_{4}$. After the next stage of heating of samples 6 and 7 at $625^{\circ} \mathrm{C}$, the oxides $\mathrm{Yb}_{2} \mathrm{O}_{3}$ and $\mathrm{V}_{2} \mathrm{O}_{5}$

were present in them in small amounts. The diffractogram of sample 6 after the third stage of its heating revealed only the set of XRD lines characteristic of $\mathrm{YbVO}_{4}$ (PDF card no. 00-017-0338) (Fig. 6d). After the same stage of heating, the diffractogram of sample 7 proved that this sample was biphasic and besides $\mathrm{YbVO}_{4}$ contained also small amounts of $\mathrm{V}_{2} \mathrm{O}_{5}$. Analysis of the phase composition of samples $1-5$, representing the other concentration range of the system components, i.e., the concentrations over $50.00 \mathrm{~mol} \%$ $\mathrm{Yb}_{2} \mathrm{O}_{3}$, proved that after stage IV of their heating (at $1200^{\circ} \mathrm{C}$ ) the samples contained the oxide $\mathrm{Yb}_{2} \mathrm{O}_{3}$ besides $\mathrm{YbVO}_{4}$ (Fig. 6c). After the next stage of heating at $1400{ }^{\circ} \mathrm{C}$, the phase composition of samples $1-3$ changed significantly. Their diffractograms no longer showed the XRD lines characteristic of $\mathrm{YbVO}_{4}$. After this stage of heating, these samples were biphasic and besides $\mathrm{Yb}_{2} \mathrm{O}_{3}$ contained a known compound $\mathrm{Yb}_{8} \mathrm{~V}_{2} \mathrm{O}_{17}$ (Fig. 6a) [15, 16]. After the last stage of heating at $1450{ }^{\circ} \mathrm{C}$, sample 3 was monophasic and contained only $\mathrm{Yb}_{8} \mathrm{~V}_{2} \mathrm{O}_{17}$ (Fig. 6b) [16]. According to the above results of the high-temperature reaction study, besides the known compounds forming in the binary system $\mathrm{V}_{2} \mathrm{O}_{5}-\mathrm{Yb}_{2} \mathrm{O}_{3}$ [7-16], i.e., $\mathrm{YbVO}_{4}$ and $\mathrm{Yb}_{8} \mathrm{~V}_{2} \mathrm{O}_{17}$, no other phase was obtained. It means that the solid solution showing the structure of $\mathrm{Yb}_{2} \mathrm{O}_{3}$ forms only as a result of highenergy ball milling of a mixture of oxides $\mathrm{V}_{2} \mathrm{O}_{5}$ and $\mathrm{Yb}_{2} \mathrm{O}_{3}$, whereas pure $\mathrm{YbVO}_{4}$ can be obtained by the two methods. On the other hand, the compound $\mathrm{Yb}_{8} \mathrm{~V}_{2} \mathrm{O}_{17}$ was obtained only as a result of the hightemperature reaction (Fig. 6b). Figure 6 presents a fragment of XRD diffractogram of the (a) $\mathrm{Yb}_{2} \mathrm{O}_{3}$ $+\mathrm{Yb}_{8} \mathrm{~V}_{2} \mathrm{O}_{17}$, (b) $\mathrm{Yb}_{8} \mathrm{~V}_{2} \mathrm{O}_{17}$, (c) $\mathrm{Yb}_{2} \mathrm{O}_{3}+\mathrm{YbVO}_{4}$ and (d) $\mathrm{YbVO}_{4}$.

## Conclusions

- The substitutional limited solid solution of the formula $\mathrm{Yb}_{2-5 x} \square_{2 x} \mathrm{~V}_{3 x} \mathrm{O}_{3}$ and $0.00<x<0.1667$ is formed in the system $\mathrm{Yb}_{2} \mathrm{O}_{3}-\mathrm{V}_{2} \mathrm{O}_{5}$.
- The solid solution has been obtained in air only by high-energy ball milling of the oxides: $\mathrm{Yb}_{2} \mathrm{O}_{3}$ and $\mathrm{V}_{2} \mathrm{O}_{5}$.
- The solid solution $\mathrm{Yb}_{2-5 x} \square_{2 x} \mathrm{~V}_{3 x} \mathrm{O}_{3}$ crystallizes in the cubic system.
- With an increasing $x$ in $\mathrm{Yb}_{2-5 x} \square_{2 x} \mathrm{~V}_{3 x} \mathrm{O}_{3}$, the crystal lattice of solid solution expands.
- The solid solution $\mathrm{Yb}_{2-5 x} \square_{2 x} \mathrm{~V}_{3 x} \mathrm{O}_{3}$ is stable in air atmosphere up to $\sim 800^{\circ} \mathrm{C}$.
- $\mathrm{Yb}_{2-5 x} \square_{2 x} \mathrm{~V}_{3 x} \mathrm{O}_{3}$ belongs to the group of semiconductors with the band gap energies $\sim 2.5 \pm 0.2 \mathrm{eV}$.
