

Abstracts from the 38th Annual Meeting of the Society of General Internal Medicine

SCIENTIFIC ABSTRACTS

“WE ALL HAVE DIFFERENT STORIES”: VETERANS’ EXPERIENCES AND PREFERENCES FOR PROACTIVE IN-BETWEEN VISIT CARE

Ashley E. Jensen^{1, 2}; Nicole Skursky¹; Erica Sedlander¹; Katherine Barboza¹; Katelyn Bennett^{1, 2}; Scott Sherman^{2, 1}; Mark D. Schwartz^{2, 1}. ¹NYU School of Medicine, New York, NY; ²VHA New York Harbor Healthcare System, New York, NY. (Tracking ID #2198048)

BACKGROUND: Medical home models, like VA’s Patient Aligned Care Team (PACT) seek to engage patients via proactive outreach for prevention and chronic disease management (panel management). We know little about patients’ perspectives, experiences and preferences in receiving this type of non-face-to-face care. To address this gap and inform future implementation efforts, we conducted a qualitative study of veterans at two VA campuses.

METHODS: We conducted a qualitative study of veterans with hypertension or current smoking, who had participated in a cluster-randomized trial of panel management support in which Panel Management Assistants provided outreach and coaching to veterans. We recruited eligible patients by mail and phone, who were invited to participate in focus groups stratified by hospital, gender (six male and four female groups), and age (under or over age 60). Participants completed brief questionnaires to ascertain their health status and supplemental demographic information. Discussion questions focused on facilitators and barriers to healthy behavior change, experience with proactive outreach, and preferences for receiving care in-between visits. Each focus group was audio recorded and transcribed, and supplemental field notes were taken. A subset of transcripts was reviewed independently by four researchers, who then created an initial consensus codebook. Two researchers independently coded each transcript, modified the codebook as new themes emerged, and met to reconcile coding. Nvivo software was used for analysis.

RESULTS: A total of 1179 patients were invited, 127 were scheduled to attend, and 77 participated. Participants had a mean age of 59 years, were predominantly African American (64 %), and completed at least some college (57 %) with 29 % reporting that they worked outside the home. Most participants had hypertension (78 %), and smoked at least 100 cigarettes in their lifetime (77 %). Participants generally appreciated existing efforts to provide care in between visits including post-discharge phone calls and reminder letters. As one veteran put it, “I don’t mind somebody calling and checking up on me because that’s letting me know that you care...” Participants were receptive to additional outreach for referral, reminders and motivational support in between visits. However, they felt that these outreach efforts should be tailored to their needs and preferences in terms of frequency, content and mode of contact and some had concerns about privacy. Although many participants were open to non-clinicians contacting them as long as they had strong communication skills, empathy, connection to PC teams and training, many felt that the individual should be a veteran or at least able to relate to their military experience. Avoiding medications was a consistent motivator for making lifestyle changes and female

veterans in particular wanted access to more holistic health options either at the VA or within their communities.

CONCLUSIONS: Our findings indicate that veterans are receptive to proactive outreach for prevention and management of chronic conditions, especially when this outreach is personalized and flexible. This study has important limitations as it was restricted only to veterans and those agreeing to attend a focus group. However, the information gathered from this study will be useful to inform the design of future panel management efforts.

“I JUST WANT MY DOCTOR’S UNDIVIDED ATTENTION”: PATIENT PERCEPTIONS OF THE IMPACT OF EMR USE ON COMMUNICATION

Obiama Ukabiala³; Wei Wei Lee¹; Lollita Alkureishi¹; Laura Ruth Venable²; Samantha Ngoor²; Jeanne M. Farnan¹; Vineet M. Arora¹. ¹University of Chicago, Chicago, IL; ²University of Chicago Medical Center, Chicago, IL; ³Pritzker School of Medicine, Chicago, IL. (Tracking ID #2196181)

BACKGROUND: The use of the Electronic Medical Record (EMR) in exam rooms can impede the doctor-patient relationship. Little research to date has explored patient perceptions of provider EMR use and the impact on communication. Despite widespread EMR use, few curricula teach providers how to use the EMR to enhance communication with patients. The aims of our study are to identify patients’ perceptions of EMR use and elicit their suggestions to inform development of a patient-centered EMR use curriculum.

METHODS: Patients seen by internal medicine attendings and residents at the University of Chicago’s primary care clinic were randomly selected for our study. One year after EMR implementation, trained research assistants conducted structured telephone interviews with patients using critical incident technique and appreciative inquiry to elicit their positive and negative perceptions of EMR use by physicians. Using constant comparative analysis, three investigators independently coded 10 % of the transcripts to develop the coding library. An additional 10 % of the transcripts were coded to establish inter-rater reliability. The coding library was applied to the remainder of the transcripts for analysis using ATLAS.ti software.

RESULTS: Of the 384 patients selected, 12 were excluded due to disability, language barriers, or death. Of the 372 eligible patients, 113 telephone interviews were completed. The interviews revealed two overarching themes: (1) Clinical Functions of EMR (2) Communication functions of EMR. Six subthemes were identified: (1) Documentation functions of the EMR (2) Clinical Workflow functions of EMR (3) EMR as educational resource (4) Information access, (5) Facilitate Engagement and (6) Physical focus. To date we have analyzed 58 % (56/113) of the transcripts. Overall, 84 % (576/687) of total codes reflected positive perceptions of EMR. The majority of the positive perceptions fell under the “Clinical Workflow Functions of EMR” subtheme (i.e. ‘increases clinical efficiency’ and ‘promotes teamwork and communication between doctors’). For example one patient said ‘they can see all the other doctors’ notes... they really work together as a team. I love it!’ Only 16 % (111/687) of the codes represented negative perceptions. Interestingly, 45 % (50/111) of negative codes fell under the “Physical Focus” subtheme (i.e. ‘poor eye contact’ and ‘unbalanced focus’). For example one patient stated ‘how can you focus on the patient if you’re looking somewhere else... it gets in the way.’

CONCLUSIONS: Patients have both positive and negative perceptions of EMR use. Positive perceptions centered on improving clinical efficiency by promoting efficient note writing and teamwork between providers. Negative perceptions focused on communication skills related to EMR use. Patients with negative perceptions cited poor attentiveness (i.e. poor eye contact, unbalanced focus, etc.). Interestingly, many patients who identified the EMR as a barrier to communication also acknowledged that it was useful in increasing clinical efficiency. By interviewing patients, we gained unique insights into their perceptions of EMR use. We will use our findings to inform a patient-centered EMR use curriculum to teach providers how to use the EMR to enhance communication with patients.

“IT ENCOURAGES THEM TO COMPLAIN”: POTENTIAL UNINTENDED CONSEQUENCES OF ROUTINE PAIN SCREENING AND IMPLICATIONS FOR IMPROVEMENT Sangeeta Ahluwalia³; Risa Cromer⁴; Karleen Giannitrapani⁵; Hannah Schreiber-Baum²; Steven Dobscha²; Erin E. Krebs¹; Karl Lorenz². ¹Minneapolis VA Health Care System, Minneapolis, MN; ²Portland VAMC, Portland, OR; ³RAND Corporation, Encino, CA; ⁴Veterans Health Administration, Portland, OR; ⁵Veterans Health Administration, Los Angeles, CA. (Tracking ID #2192233)

BACKGROUND: The Veterans Health Administration (VHA) implemented the “Pain as the 5th Vital Sign” (P5VS) initiative in 1999, requiring a pain intensity rating on a 0–10 scale at all clinical encounters. We sought to better understand the perceived impact of implementing a routine pain screening program on primary care clinicians and clinical processes in order to identify opportunities for improving pain screening and management.

METHODS: We conducted multidisciplinary focus groups with VHA primary care team members including physicians, nurses, social workers, pharmacists, and other clinical and administrative staff involved in pain screening and management at multiple VHA sites. We explored current screening practices and multidisciplinary roles in pain screening; perceptions of the value of pain screening; preferred approaches to pain screening; and critical information needs for improved screening and management. We audiotaped, transcribed, and qualitatively analyzed the focus groups and characterized themes using constant comparison.

RESULTS: Primary care team members participated in nine multidisciplinary focus groups, each comprised of six to nine respondents. We identified five themes and several subthemes characterizing potential unintended consequences of routine pain screening in primary care: (1) Screening for pain encourages an affirmative response, because a) it prompts patient recall of old and chronic pain (“They say, ‘oh yeah, last year I had this and that’, and just go on and on”); or because b) answering “0” on the 0–10 scale is perceived as non-response (“they’ll eventually think of something and say ‘well now that I think of it, I’ll put something down’”). (2) Screening highlights the presence of a problem rather than directing the patient towards a solution for their pain, hindering self-management efforts (“If we’re asking about pain every visit then over time [the patient] will just assume, ‘it’s a limiting factor for me, I can’t do these things’”). (3) Screening for pain sets an expectation of intervention (“We have to treat the number”); and (4) worsens reliance on drug treatment because visit brevity and limited access to non-pharmacologic approaches preclude exploration of other interventions (“I have a lot of things to do on this short visit, and then there’s this pain. I give him [drug], and I’m done, boom.”) (5) Screening can unnecessarily change the focus of the clinic encounter because a) addressing pain consumes extra time (“They can be there for something else but it seems like then the whole visit will turn to the pain issue. It’s time consuming”); and b) it re-directs the patient from other medical issues (“all [screening] does is refocuses them on the pain and it’s not productive when I need to discuss whether their blood pressure medication is effective”).

CONCLUSIONS: Systematic efforts to address undertreatment of pain through routine screening may heighten expectations for treatment and interfere with other primary care priorities. To maximize the benefits of pain screening, clinicians may need more agency in determining the appropriateness of screening for each patient and the approach to intervening, and both clinicians and patients require greater access to non-pharmacologic and self-management resources.

“THEY ARE INTERRELATED, ONE FEEDS OFF THE OTHER”: A TAXONOMY OF DISEASE INTERACTIONS DERIVED FROM PATIENTS WITH MULTIPLE CHRONIC CONDITIONS Donna M. Zulman^{1, 2}; Cindie A. Slightam²; Jonathan G. Shaw^{1, 2}; Kirsten Brandt³; Eleanor T. Lewis²; Steven Asch^{1, 2}. ¹Stanford University, Stanford, CA; ²VA Palo Alto, Menlo Park, CA; ³Stanford University School of Medicine, Stanford, CA. (Tracking ID #2198546)

BACKGROUND: There is growing awareness that multiple chronic conditions (MCCs) generate challenges that exceed the sum of their parts. Little is known, however, about patients’ perceptions of, and experiences with, condition interactions, and the impact of these interactions on self-management and treatment.

METHODS: We analyzed qualitative data from a study of patients with MCCs to understand patients’ perceptions about how their conditions interact. The study included a survey (administered by mail, e-mail, and in clinic) of patients from an academic medical center and a Veterans Affairs facility. We analyzed survey responses from 383 individuals who had two or more conditions and responded to multiple choice and open-ended questions about how their conditions interact. Patients were asked to indicate their health conditions, circle the condition that bothers them the most, and then respond to the question: “How do your other health problems affect your ability to take care of the health problem that you circled above?” Standard content analysis methods were used to code textual data, with the goal of identifying: 1) patients’ perceptions about the extent to which their conditions interact, and 2) the nature of those interactions. Four investigators iteratively reviewed textual data to develop a taxonomy of mutually exclusive codes capturing types of condition interactions, and cross-cutting themes about the quality of interactions. After refining codes and themes with all collaborators, three investigators independently coded all responses and collectively chose representative quotes. Themes and representative quotes were validated through an online survey with a sample of study participants.

RESULTS: Among survey respondents, the mean (SD) number of chronic conditions was 4(2) with the most common including hypertension (60 %), chronic pain (49 %), arthritis (41 %), depression (32 %), diabetes (29 %), and PTSD (26 %). Patients described interrelated relationships among their MCCs and treatments. For example, patients described condition-condition interactions (“The constant worry about prostate cancer recurrence aggravates my anxiety and depression”), condition-treatment interactions (“My back pain keeps me from getting enough exercise which makes it difficult to manage my weight which ultimately is bad for my already damaged heart”), treatment-condition interactions (“The epidurals I had [for chronic pain] caused extremely high blood sugar levels causing anxiety”), and treatment-treatment interactions (“Cancer treatments have caused fatigue and interrupted spine care”). Some patients expressed uncertainty about, or denied the presence of, condition interactions, while others described cyclic/multi-dimensional interactions (“Chronic pain causes loss of sleep and restless leg syndrome, which keeps me awake, exacerbating my depression and anxiety”). Cross-cutting themes included the presence of positive interactions (“What I do for diabetes has a beneficial effect on my other conditions”) as well as negative interactions (above), discussions about causal relationships (“It is the cancer and its required medications that causes the other health problems”), and frequent comments describing interactions among physical and mental health conditions.

CONCLUSIONS: This qualitative study revealed a novel taxonomy of condition interactions from the perspective of patients with MCCs. In order to support self-management and strengthen shared decision-making, it is important to address patients’ perceived interrelated symptoms and condition-treatment interactions.

“WE FOLLOW-UP”: IMPROVING FOLLOW-UP, COMMUNICATION AND DOCUMENTATION OF OUTPATIENT TEST RESULTS BY DUKE RESIDENTS Aparna C. Swaminathan; Joel C. Boggan; Samantha Thomas; Jonathan Bae. Duke University Health System, Durham, NC. (Tracking ID #2191330)

BACKGROUND: Following up on outpatient test results is a time-consuming process that has important patient safety implications. Failure to inform patients of test results and document communication may lead to diagnostic and therapeutic delays and are common sources of malpractice claims. We sought to compare the rates of follow up, communication, and documentation of outpatient test results by Duke residents before and after an educational quality improvement effort.

METHODS: All three resident clinics—a community-based clinic (Clinic 1), a Veterans Affairs clinic (Clinic 2) and a private practice model (Clinic 3)—were included in this study. A follow-up standard was developed to include definitions of ‘significant’ test results and appropriate times to follow-up. A predetermined subset of test results with significant results were to be communicated to patients within 72 h, while other, ‘non-significant’ results were to be communicated with 14 days. An online interactive experience to guide the project was developed utilizing Microsoft Sharepoint™. Residents were required to participate in this mandatory residency-wide project as part of their regularly scheduled ambulatory blocks during each half of the academic year 2013–14. We examined follow-up rates both before and after an intervention that provided resident physicians with education, feedback, and real-time comparison to their peers.

RESULTS: Seventy-six residents completed the online module prior to the intervention (reviewing 1713 patient charts), and 73 residents completed the online module subsequent to the intervention (reviewing 1509 patient charts). At baseline 78 % of test results were communicated to patients within 14 days (Table 1). After our educational intervention, this rate of communication significantly improved to 85 % ($p < 0.001$). This observation held true across all clinic sites (Clinic 1: 69.5 vs. 79 %, Clinic 2: 85 vs. 89 %, Clinic 3: 86 vs. 94 %, $p < 0.02$ for all). Of the test results reviewed, 32 % were significant. The rate of communication of significant test results within 72 h also improved, from 70 % before the

intervention to 81.5 % afterwards ($p < 0.01$). Prior to the intervention, 50 % of all results were communicated through patient letters and 23 % via phone calls. Letters were used more commonly for non-significant results (56 vs. 39 %) while phone calls were used more often for significant results (43 vs. 13 %, $p < 0.001$). Following the intervention the use of patient letters increased from 50 to 56 % ($p < 0.001$), while ratios of other types of communication remained stable. There was no change in the types of test followed up on before or after the intervention.

CONCLUSIONS: This study demonstrates that lack of follow-up of outpatient test results is a common problem, and that our simple educational interventions and feedback resulted in significant improvement across a large internal medicine residency program. Such interventions should be routinely integrated into residency education and patient care. With the prevalence of the electronic medical record it has become even easier to communicate results through letters or online portals. However it remains imperative that communication of time sensitive results occur in a reliable fashion.

“WORLD VAPE DAY” 2014: LESSONS FROM THE TWITTERSPHERE Jason Colditz²; Kevin Pang²; Alton Everette James²; Christine Stanley²; Ellen Beckjord³; Judith Brook¹; Brian A. Primack². ¹New York University School of Medicine, New York, NY; ²University of Pittsburgh, Pittsburgh, PA; ³University of Pittsburgh Cancer Institute, Pittsburgh, PA. (Tracking ID #2198803)

BACKGROUND: “Vaping” with electronic nicotine delivery systems (ENDS) has been increasing since these products entered the US consumer market about a decade ago. ENDS devices, more commonly referred to as e-cigarettes, hookah pens, or vapor pens, present dilemmas for public health advocates and regulatory agencies. For example, while ENDS may be valuable for cigarette smoking cessation among established adult smokers, thousands of non-cigarette smoking individuals are now experimenting with ENDS, which may lead to subsequent sensitization to nicotine and transition to cigarette smoking. ENDS are available in flavorings and packaging which may be attractive to youth. Furthermore, there are limited data on the toxicant load associated with use of these devices. Assessing public sentiment surrounding these products may help guide interventions by discovering information such as apparent misconceptions. Open-ended qualitative assessment of publicly available discussion such as that on social media may help focus researchers on rich data to which millions of people are exposed. Therefore, the purpose of this study was to qualitatively analyze publicly available information on Twitter related to ENDS.

METHODS: We selected Twitter not only because of its extreme popularity (about 400 million “Tweets” consisting of no more than 140 characters each are exchanged each day) but also because of ease of data collection via a programming interface. We focused data collection on one particular day—Thursday, September 18, 2014—which was promoted as “World Vape Day” by multiple businesses, organizations, and individuals. By focusing on this particular day, we hoped to access a valuable perspective on public discourse and perceptions surrounding ENDS use. We retrieved all Tweets and meta-data from the Twitter live-stream using customized software that filtered by relevant keywords, including “e-cig,” “e-hookah,” “vape,” “vapes,” and “vaping.” Two independent coders coded a random sample of 1000 Tweets related to ENDS and developed a comprehensive codebook through an iterative process based on grounded theory. This approach allowed us to (1) better understand public discourse surrounding ENDS use and the nature of World Vape Day specifically, (2) develop a structured content analysis framework (i.e., codebook) that future research projects may utilize or adapt, and (3) provide an open source software tool for other researchers to more-easily utilize live Twitter data for similar projects.

RESULTS: The filtered Twitter stream resulted in 5205 tweets over a strategically selected 12 h span. Five random subsamples of 200 tweets were double-coded and discussed in order to develop and refine the coding framework. This resulted in broad coding categories including positive and negative sentiment, health- and policy-related, cigarette-related, and marketing. The coders then independently coded a randomized subsample of 1000 different ENDS-related tweets. Inter-rater agreement for each coded variable was good-to-perfect (Cohen’s kappa ranged from 0.56 to 1.00 depending on the variable). Marketing-related messages were highly prevalent (41 %), while only 8 % of Tweets were related to health and only 3 % were related to policy or law. Of non-marketing tweets, coders detected more positive than negative sentiment (24 vs. 13 %). Open-ended content analysis yielded additional nuance to each of the broad coding categories and revealed valuable insights into contextual associations with ENDS in public discourse. For example, marketing messages focused on diversity of ENDS devices and associated parts/accessories for modifying and refilling them (e.g., high-power batteries, unique shapes and colors, novel flavors of “vape juice” or “e-liquid”). Users frequently referred to flavorings, social settings and social approval, and modifications (i.e., “mods” such as building, modifying, or personalizing ENDS devices). Young adults and teenage users seemed to focus on general social approval (e.g., “coolness”) and use at school.

CONCLUSIONS: Examination of Tweets exchanged on “World Vape Day” provided a valuable window into discourse from ENDS marketers and end-users. After an appropriate iterative codebook development process, double-coding was internally consistent. Available data suggest that ENDS represents a highly active area ripe with technical innovation by marketers and consequent excitement and invigoration among users. While the medical and public health community are actively interested in potential health implications and legal loopholes potentially created by this phenomenon, these themes were not commonly manifested in our sample of Tweets. These are trends of which researchers and practitioners should be aware when engaging in dialogue related to ENDS usage. Continued research and effective translational approaches are needed to inform the medical community of these emerging trends in ENDS use, which is a growing medical and public health concern.

INAPPROPRIATE NONFORMULARY REQUESTS: FORMULARY COMPLIANCE THROUGH CLINICAL DECISION SUPPORT IN AN ACADEMIC MEDICAL CENTER Qoua L. Her^{1,2}; Mary Amato^{1,2}; Diane L. Seger^{1,3}; James F. Gilmore¹; John Fanikos¹; Julie Fiskio³; David W. Bates^{1,3}. ¹Brigham and Women’s Hospital, Boston, MA; ²Massachusetts College of Pharmacy and Health Services University, Boston, MA; ³Partners Healthcare, Wellesley, MA. (Tracking ID #2195247)

BACKGROUND: Formularies are widely accepted as a cost containment tool, and can also help enhance medication safety, quality of care, and improve care efficiency.(1) Medicare and The Joint Commission require a formulary for reimbursement and hospital accreditation, respectively. The Joint Commission expanded their requirement mandating hospitals to at least review their formulary annually base on emerging safety and efficacy information, standardizing and limiting available drug concentrations, and implementing a process to select, approve, and procure nonformulary medications (NFM).(2) Such mandate expansion has the potential to increase hospital cost beyond the cost-savings of formularies in the form of physician and pharmacist time complying with formulary policies.(1) Appropriate clinical decision support (CDS) for formulary management can help realize these cost-savings. We evaluated a NFM system at a large academic medical center, quantified the proportion of inappropriate NFM requests, and used the results to develop best practice guidance on the design of automated formulary management systems.

METHODS: All approved NFM requests from Brigham and Women’s Hospital from 2009 to 2012, were extracted and quantified according to the American Hospital Formulary System (AHFS) Classification. A random sample of 2000 approved NFM requests were selected for preliminary ‘reason of NFM request’ analysis. Reasons were categorized and presented to an interdisciplinary panel of physicians, nurses, and pharmacists, where NFM appropriateness criteria were developed. A random sample of 206 requests from 2012 of the 11 most expensive and most frequently approved NFMs were further reviewed for appropriateness using the interdisciplinary appropriateness criteria by two pharmacists. Agreement between the reviewers was assessed using a Cohen’s kappa. Best practice guidance for automated formulary management systems were developed from these findings.

RESULTS: A total of 223,266 original NFM requests were approved between 2009 and 2012. The top 50 % of these approvals were classified into six AHFS Tier 2 Classes. Psychotherapeutic agents accounted for one-fifth of all NFM approvals, where quetiapine and olanzapine accounted for 62.6 % of all psychotherapeutic agents approved. We found that 46.9 % of the reasons for NFM requests provided no or marginal value for nonformulary appropriateness evaluation and could be considered inappropriate at the point-of-care. Approximately one-third of all approved NFM requests were for chronic or pre-admission medications. Other reasons listed includes disease/conditions, specialist or pharmacist recommendation, failure or intolerant of formulary alternatives, allergy or contraindication, end-of-life care, and medication interactions. The interdisciplinary panel simplified the complex NFM request reasons into four NFM appropriateness criteria. The review of 206 inpatient charts estimated that approximately 18 % of all approved NFM request were truly inappropriate. We recommend the following features for any automated formulary management system; 1) require prescribers to provide a ‘valid’ reason for NFM request to enhance retrospective medication utilization review (MUE) and trending; 2) provide pharmacists with a ‘comment option’ at the point of computer order verification to address inappropriate requests or reasons that provide no or marginal value for retrospective MUE; 3) utilize drop-down menus for standard and common NFM request reasons to facilitate deployment of more complex CDS, such as automated interchange for specific indications; and 4) begin annual clinical decision support and formulary reviews with the most expensive and commonly requested NFM (psychotherapeutic agents).

CONCLUSIONS: We found that nearly one-fifth of all NFM requests at our institution were inappropriate. Optimization of the NFM computer system could decrease the proportion of inappropriate NFM requested and improve cost-savings. NFM request systems with better tracking and trending features will guide better CDS development for automated formulary management. This study was funded by grant #U19HS021094 from the Agency for Healthcare Research and Quality (AHRQ). 1. Helmons PJ, Kosterink

SIMILARITIES AND DIFFERENCES IN COMMUNITY, ACADEMIC, AND HEALTHCARE STAKEHOLDERS' PERSPECTIVES OF IMPORTANT CONTRIBUTORS TO TRUST IN RESEARCH PARTNERSHIPS Leah Frerichs¹; Crystal W. Cene²; Gaurav Dave²; Mimi Kim²; Tiffany L. Young²; Anne Cheney³; Jessica Burke⁴; Jennifer Jones⁴; Arlene Brown⁵; Linda Cottler⁶; Giselle M. Corbie-Smith^{1, 1}. ¹University of North Carolina, Chapel Hill, NC; ²University of North Carolina at Chapel Hill, Chapel Hill, NC; ³University of Arkansas, Fayetteville, AR; ⁴University of Pittsburgh, Pittsburgh, PA; ⁵University of California, Los Angeles, Los Angeles, CA; ⁶University of Florida, Gainesville, FL. (Tracking ID #2194545)

BACKGROUND: Community engagement is recognized as critical to furthering translation of evidence to practice and improving quality of care. Research partnerships among community, academic, and healthcare institutions have become a common avenue for community engagement, a recommended strategy to address health disparities. These partnerships have found that trust between the diverse stakeholders is foundational to their success; yet, there has been limited empirical research on determinants of trust. The objective of this study was to determine the similarities and differences among community member, academic researcher, and healthcare provider stakeholders' perspectives on important contributors to creating and maintaining trust within research partnerships.

METHODS: Across four institutions (University of Arkansas, University of California Los Angeles, University of Florida, and University of North Carolina) with Clinical and Translational Science Awards, we conducted concept mapping sessions with participants from three stakeholder groups. A fifth site, University of Pittsburgh, served as the data coordinating center. Each site conducted brainstorming sessions with each stakeholder group to generate lists of statements viewed as contributing to trust in community-academic research partnerships. All participants rated each statement by level of importance for creating and maintaining trust using a 5-point Likert scale (1=not important, 5=

very important). Data were analyzed using Concept Systems Global Max©. Multi-dimensional scaling and hierarchical cluster analysis were used to determine statements that clustered together based on sorting and rating data, and clusters were collaboratively labeled by each stakeholder group. We compared and contrasted average ratings of statement clusters and assessed correlation of all statement ratings across stakeholder groups.

RESULTS: Participants ($n=65$ community members, $n=74$ academic researchers, and $n=47$ healthcare providers) generated 125 unique statements that clustered into the following five themes: mutually respectful relationships, authentic communication, committed partnerships, sustainability, and communication and methodology to anticipate changes. Community members overall average rating of statements was higher (4.20) than academic researchers (4.10) and healthcare providers (4.02). Ratings of importance for creating and maintaining trust were highly correlated ($r=0.96$ and $r=0.93$) between academic researchers and healthcare providers, and less correlated between healthcare provider and community members ($r=0.36$ and $r=0.58$) and academic research and community members ($r=0.31$ and $r=0.81$). Figures 1 and 2 provide ladder graphs of average importance ratings of statement clusters by stakeholder group. The ranked order of average importance (i.e., lowest to highest) of the five clusters differed for community members compared to academic researchers and healthcare providers.

CONCLUSIONS: While there were similarities, we also found important differences between the ratings of the three stakeholder groups. Healthcare providers and academic researchers often have overlapping roles and similar work cultures that likely contribute to greater correlation in their importance ratings. Without proper attention, there is a risk that these similarities will mutually reinforce perspectives that differ from community members and create power imbalances that undermine trust between community members and researchers; thereby, potentially reducing efficiency (e.g., recruitment of underserved research participants) and quality (e.g., completeness of self-reported data) of research. Our findings identified specific areas of convergence and divergence of perspectives, which may be leveraged to improve trust. For example, partnership sessions could use role-playing exercises to help stakeholders build upon common perspectives as well as understand differences. More research is merited to explore the mechanisms that create differences in stakeholders' perspectives of trust.

Figure 1. Average Rating of Importance of Clustered Statement Themes in Creating Trust by Stakeholder Group

COMMUNITY HEALTH WORKERS ARE ASSOCIATED WITH PATIENT REPORTED ACCESS TO CARE WITHOUT AFFECT ON SERVICE UTILIZATION AMONG LATINOS WITH POORLY CONTROLLED DIABETES Aileen Chang¹; Victor Cueto¹; Hua Li¹; Bhavana Singh³; Sonjia Kenya²; Yisel Alonzo¹; Olveen Carrasquillo¹. ¹University of Miami, Miami, FL; ²University of Miami Miller School of Medicine, Miami, FL; ³Duke University, Durham, NC. (Tracking ID #2190676)

BACKGROUND: Community health workers (CHWs) are one promising approach to improve diabetes care among vulnerable populations. However, few rigorous randomized

studies have evaluated the impact of CHWs on service utilization. The Miami Health Heart Initiative (MHII) was a clinical trial testing the impact of a CHW intervention on physiologic outcomes among low-income Hispanics with poorly controlled diabetes versus usual care (USC). Preliminary data from MHII suggests that as compared to the USC group patients randomized to the CHW group had improvements in blood pressure and hemoglobin A1C. In this abstract we report the impact of the CHW intervention on access to care and service utilization.

METHODS: We analyzed data from 215 Hispanics with poorly controlled diabetes recruited via physician referral and electronic medical record (EMR) from Miami's public hospital system. Self-reported access to care measures were similar to those used in the Medical Expenditure Panel Survey (MEPS) and included the ability to access care when needed, obtain needed medications, ability to contact physicians and communicate in language of choice. Self reported utilization measures were also collected using MEPS questions and included number of care encounters and percent with inpatient stay. We also abstracted utilization data on outpatient visits, emergency room (ER) visits and hospitalizations from the EMR at the public hospital. Statistical significance of continuous outcomes were examined using the *t*-test if normally distributed or the Kruskal-Wallis test when not normally distributed. Categorical variables were examined using chi-square comparisons or generalized estimating equation (GEE) modeling when needed. We also performed logistic regression adjusted for age, gender, education, depression, and comorbidities on access to needed health care and medications.

RESULTS: This was a vulnerable population with 42 % having less than 12 years of education and 72 % were depressed. At 1 year, we found statistically significant differences in 2 of 4 self-reported access to care measures. For example, 30 % of the participants in the CHW group reported inability to access care in the last year compared to 43 % in the USC group ($p=0.04$). Additionally, 28 % of the participants in the CHW group reported inability to access medications in the last year compared to 41 % in the USC group ($p=0.03$). The differences in access to needed care and needed medications persisted after adjustment for age, gender, education, depression, and comorbidities with (OR=0.52, 95 % CI=0.29, 0.93) and (OR=0.45, 95 % CI=0.24, 0.82) respectively. Self-reported measures of utilization were similar in both groups with a median of seven care encounters in the past year and about a third reporting an inpatient stay in the last year. Similarly, EMR review found similar rates of outpatient visits, ER utilization and percentage having as hospital stay in the last year between the CHW and USC groups.

CONCLUSIONS: Among patients with diabetes, a greater percentage of those having a CHW intervention reported access to care but we found no significant changes in service utilization.

A COMPARISON OF IHI OPEN SCHOOL TO A FACULTY-LED QUALITY IMPROVEMENT AND PATIENT SAFETY CURRICULUM FOR UNDERGRADUATE MEDICAL EDUCATION Jason Fish¹; Michael Burton¹; Tammy Chung²; Deepa Bhat²; Meredith Mayo². ¹UT Southwestern, Dallas, TX; ²UT Southwestern Medical Center, Dallas, TX. (Tracking ID #2198367)

BACKGROUND: Education in the principles and practice of quality improvement (QI) and patient safety is now required in undergraduate medical education. Most QI curriculum studies involving medical students have utilized didactics and web-based learning, with the majority providing less than 10 h of contact hours. Student knowledge, attitudes, and beliefs have been the mainstay of assessments, with no literature found focusing on assessment of QI skills or self-efficacy. In addition, the lack of resources and faculty expertise in QI have led to many institutions turning to online curricula. While requiring less faculty participation, the relative effectiveness and acceptance of online learning modules in QI has not been determined. This study evaluates the comparative effectiveness of a well-established online QI curriculum (online) with a Faculty-led face-to-face curriculum (pilot) for undergraduate medical education.

METHODS: Third-year medical students rotating through the University of Texas Southwestern Medical School Internal Medicine and Family Medicine services from July 2012 to June 2013 were included in this study. Students were randomly assigned to either a series of four weekly live didactic sessions with an applied, simulation project or to complete a predetermined subset of the Institute for Healthcare Improvement's Open School online modules. The objectives for both curricula included 1) understanding basic concepts of QI/PS, 2) developing specific aim statements and identifying key stakeholders; 3) understanding fundamental concepts of measurement; 4) learning QI tools; and 5) recognizing human factors associated with change. All participants were asked to complete a modified Quality Improvement Knowledge Assessment Tool (QIKAT) at the beginning and conclusion of the study period. The QIKAT assesses attitudes and beliefs as well as QI skills through the use of clinical scenarios to identify improvement strategies.

At the end of each 4 week period, students were asked to complete an online survey on student satisfaction, perceived effectiveness, and self-efficacy on being able to participate in, teach, and lead QI projects.

RESULTS: One hundred seventy-four students participated in the study—86 in the pilot and 88 in the online. Completion rates for the monthly surveys were 64 % (pilot) and 75 % (online). Using a Likert scale 1 to 5 (1 being least satisfied/comfortable and 5 being most satisfied/comfortable) for the monthly survey, the mean scores for the pilot and online groups were as follows: effectiveness of course 3.47, 2.91 ($p<0.001$); satisfaction with course delivery 3.48, 2.88 ($p<0.001$); confidence in participating in QI project 3.10, 2.61 ($p<0.01$); confidence in teaching QI principles 2.62, 2.38 ($p=0.08$); and confidence with leading a QI project 2.50, 2.28 ($p=0.13$). The modified QIKAT clinical scenario section was assessed with a 10 point score. The pilot group had 97 and 93 % completion rates for the pre- and post-surveys respectively; the online group had 83 and 82 % completion rates for the surveys respectively. The pre- and post-test average QIKAT scores for the pilot group were 2.77 and 3.12; the scores for the online group were 2.70 and 2.54. There was no difference between the pilot and online groups for the pre-test or post-test mean scores ($p=0.72$; $p=0.08$), nor between the paired pre- and post-test means (pilot $p=0.27$; online $p=0.95$). The components of the QIKAT score included assessment of skills involving specific aim statements, stakeholders, current knowledge and processes, measurement and intervention design, and continuous process improvement strategies. The pilot group had statistically significant higher scores on specific aim statements ($p<0.01$) and trended towards significance on identifying processes and stakeholders ($p=0.07$). There were no statistical significant differences in the other skills.

CONCLUSIONS: Our research indicates students in the face-to-face pilot program reported the course as more effective and more satisfying than those students in the online program. Students in the pilot also reported greater self-efficacy for future participation in QI projects than the on-line group. Although the study did not demonstrate a difference in overall effectiveness by objective measures, our study did indicate that the combination of didactics with an applied, simulation project improved some QI skills. More research is needed to identify important strategies to achieving sustainable and significant gains in applying QI/PS knowledge and demonstrating skills.

A QUALITATIVE EXAMINATION OF ATTITUDES TOWARD SMOKE-FREE POLICIES AMONG HOMELESS ADULTS Maya Vijayaraghavan^{1, 2}; Samantha Hurs²; John Pierce^{1, 2}. ¹University of California, San Diego, San Diego, CA; ²Division of Health Policy, San Diego, CA. (Tracking ID #2192801)

BACKGROUND: Smoke-free policies in indoor and some outdoor public spaces and the workplace has become normative in many states across the United States. These policies are an integral component of current population-wide tobacco control efforts. While there is widespread support for these policies among the general public, attitudes toward these policies among populations where the majority are smokers, such as the homeless population (70–80 % smoking prevalence), is unknown. In this study, we examined attitudes toward smoke-free policies among sheltered homeless adults.

METHODS: Quantitative and qualitative data were collected from 65 current and former smokers residing in seven transitional, or long-term homeless shelters in San Diego County. All of the participating shelters had indoor smoking restrictions, and four facilities also had outdoor bans on smoking. We administered a questionnaire to participants on smoking behaviors and perceived norms around smoking, and conducted eight focus groups to discuss attitudes toward smoke-free policies. We examined the association of smoke-free policies and perceived norms around smoking. We used a directed qualitative content analysis approach to analyze the focus group transcripts.

RESULTS: The sample included 62 current smokers and 3 former smokers. The mean age was 43.1 years (SD 11.5), 44.6 % were male, and 49.2 % were white. Average daily cigarette consumption for current smokers was 8.9 cigarettes per day. Approximately half the current smokers reported making a quit attempt in the past year. Fewer than one-fourth reported using nicotine replacement therapy or medications in a prior quit attempt. The majority of participants who lived in facilities that had fewer restrictions on smoking reported that staff smoked with them during breaks compared to those living in facilities with more restrictions ($p<0.001$). In focus group interviews six major themes emerged: attitudes toward smoke-free policies, support for smoke-free housing, the use of electronic cigarettes, addictive potential of cigarettes, vulnerability to tobacco industry marketing, and interest in smoking cessation. The majority of current smokers and all former smokers were supportive of smoke-free policies because they limited secondhand smoke exposure to non-smokers and children. However, some current smokers who felt that the policies thwarted their autonomy to smoke felt marginalized by neighborhood-wide and countywide smoke-free policies. All current smokers were supportive of and did not express concerns about transitioning to low-income smoke-free housing. Cigarette smokers had tried electronic cigarettes because of the perception that they were safe and

could be smoked in areas where smoking was prohibited, and/or used as a cessation aid. Some of the current smokers described their vulnerability to tobacco industry marketing, and felt targeted in part due to their addiction to nicotine and challenges with smoking cessation. The majority of current smokers described interest in smoking cessation and highlighted potential strategies to aid in smoking cessation attempts.

CONCLUSIONS: The general acceptance of smoke-free policies may highlight a shift in social norms around smoking in the homeless population; such policies may present an important strategy to reduce social inequalities and health disparities related to tobacco use among vulnerable populations. Findings highlight potential opportunities to increase acceptance of such policies and to educate about the potential risks of electronic cigarettes among the homeless population.

A SILVER-LINING IN THE CLOUDS? A QUALITATIVE ANALYSIS OF PATIENT'S SENTIMENTS ON HOSPITALIST SERVICE CHANGES Charlie M. Wray¹; Jeanne M. Farnan¹; Vineet M. Arora²; David Meltzer¹. ¹University of Chicago, Chicago, IL; ²University of Chicago Medical Center, Chicago, IL. (Tracking ID #2196253)

BACKGROUND: Inpatient service handoffs are a frequent source of discontinuity in inpatient care. Despite the large amount of research on handoffs, none has described the patient perspective when cared for by a hospitalist physician. We sought to qualitatively describe hospitalized patient's experiences regarding service changes and develop a conceptual framework from which to understand the patient perspective for future research.

METHODS: We approached hospitalized patients on the non-teaching hospitalist service at an academic tertiary care medical center whose hospitalizations spanned a weekly service change. Consenting patients were administered a semi-structured interview developed to elicit their perspective regarding physician service change. Questions were informed by expert opinion and existing literature review. All responses were digitally recorded, deidentified and transcribed. Grounded theory was utilized, with an inductive approach with no a priori hypotheses. The constant comparative method was used to generate emerging and reoccurring themes. Units of analysis were sentences and phrases. MAXQDA 11 was used to ease analysis.

RESULTS: The overall response rate was 96 % (22/23). Respondents had a mean age of 53.6 years (± 15.6), with 60 % being female, and 56 % African American. At the time of interview, respondents had a mean LOS of 6.8 days (± 4.0) and averaged 2.3 (± 0.6) hospitalists/patient. The analysis yielded 192 discrete mentions that were mapped into 20 themes representing patients' thoughts on hospitalist changeovers. Predominant themes were: importance of communication (82 %, 18/22), a lack of concern about the transition (63 %, 14/22), a lack of awareness that the transition had occurred (50 %, 11/22), new opportunities with a fresh doctor (36 %, 8/22) (ie. "I really liked her... she looked at my ears, when the first doctor never did."), bedside manner (36 %, 8/22) (ie. "...he sat down with me and spent the time to talk to me. I liked that."), and trust (32 %, 7/22). Like themes were assembled into larger domains of construct, which included: communication, doctor-patient relationship, and systems-based issues.

CONCLUSIONS: The cloudy nature of service changes is evident from the findings that although almost all patients mentioned the importance of communication, only half were aware that a transition had occurred. Interestingly, some viewed service changes as a positive opportunity to address their care needs with a new doctor, appreciated good bedside manner, and trusted their new physician. These silver linings could represent an opportunity for hospitalists to rapidly form effective doctor-patient relationships with their patients. Better education of patients as to the occurrence and potential positive and negative effects of inpatient service changes is needed to both understand and improve care transitions from a patient-centered perspective.

APPROPRIATENESS OF ECHOCARDIOGRAPHY ORDERING IN AN AMBULATORY INTERNAL MEDICINE RESIDENT CLINIC. Abdulaziz R. Algethami¹; Rajan S. Bhatia¹; Brian Wong²; Tina Borschel¹. ¹Women's College Hospital, Toronto, ON, Canada; ²Sunnybrook Health Science Centre, Toronto, ON, Canada. (Tracking ID #2194950)

BACKGROUND: The American college of echocardiography had published criteria for appropriate use of echocardiography (AUC) to ensure echocardiography services are utilized in ways that will most impact patient care. Previous studies have suggested increased rates of inappropriate ordering of echocardiography in the ambulatory environment, but to date there is little data about echocardiography appropriateness in a medical resident run clinic.

METHODS: We conducted a retrospective chart review to examine outpatient transthoracic echocardiogram ordering by internal medicine residents over a 12 month period. We classified echocardiograms ordered into three categories: Appropriate (A), Inappropriate (I) and Uncertain (U) as per the 2011 AUC criteria for transthoracic echocardiography.

RESULTS: A total of 61 echocardiograms were reviewed. The median patient age was 62 ± 18 years (65.5 % female). The proportion of studies classified as appropriate was 82 %. The proportion of inappropriate studies was 8 % and the proportion of uncertain studies was 10 %. The proportional percentage of appropriate studies between males and females was similar. Common inappropriate indications were LV assessment with a recent normal LV assessment (5 %), presyncope without symptoms or signs of cardiac disease (2 %) and for initial diagnosis of pulmonary embolism (2 %).

CONCLUSIONS: Overall, the proportion of inappropriate echocardiograms ordered in this resident run clinic was lower than has been previously reported in outpatient studies. It is possible that education and initiatives such as the Choosing Wisely campaign have improved appropriate ordering.

ASSOCIATION BETWEEN THYROID DYSFUNCTION AND ANEMIA: A LARGE POPULATION-BASED STUDY Khadija M'Rabet-Bensalah¹; Christine Baumgartner¹; Michael Coslovsky⁵; Tinh-Hai Collet⁴; Wendy P. den Elzen³; Robert N. Luben²; Anne Angelillo-Scherer¹; Drahomir Aujesky¹; Kay-Tee Khaw²; Nicolas Rodondi¹. ¹Inselspital, Bern University Hospital, Bern, Switzerland; ²University of Cambridge, Cambridge, United Kingdom; ³Leiden University Medical Center, Leiden, Netherlands; ⁴University Hospital of Lausanne, Lausanne, Switzerland; ⁵University of Bern, Bern, Switzerland. (Tracking ID #2191357)

BACKGROUND: Anemia and abnormal thyroid function are common disorders that often co-occur in the elderly. Most textbooks and guidelines mention that thyroid-stimulating hormone (TSH) should be measured in the work-up of anemia. However, data on the association between thyroid dysfunction and anemia are scarce.

METHODS: In the population-based European Prospective Investigation of Cancer (EPIC)-Norfolk cohort, we examined 12,972 men and women aged 39–79 years with measured thyroid function and hematological parameters. Thyroid dysfunction was defined as hypothyroidism when TSH was >4.49 mIU/L, either subclinical (SHypo) with normal free thyroxine (FT4) or overt (OHypo) with low FT4, and as hyperthyroidism when TSH was <0.45 mIU/L, either subclinical (SHyper) with normal FT4 or overt (OHyper) with elevated FT4. Anemia was defined as hemoglobin (Hb) <13 g/dL for men and <12 g/dL for women based on the WHO definition. We examined the association between thyroid function and anemia, as well as Hb levels, using linear regression models first with adjustment for age and gender, then for other potential confounding factors. After excluding common causes of anemia, we also compared the prevalence of anemia according to different thyroid functionality groups.

RESULTS: Among 12,972 participants, 55 % were women and the mean age was 58.9 ± 9.5 years. Prevalence of thyroid dysfunction was 1.7 % OHypo, 5.6 % SHypo, 0.6 % OHyper, and 2.8 % SHyper. Anemia was observed in 1058 participants (8.2 %) and was more prevalent among those with thyroid dysfunction (10.3 %) compared to those in euthyroid state (7.9 %). The risk of anemia was increased for OHypo with an age and gender adjusted risk ratio (RR) of 1.55 [95 % confidence interval (CI) 1.10, 2.18] and OHyper with RR 1.86 [CI 1.12, 3.10], but not for SHypo (RR 1.06 [CI 0.84, 1.35]) and SHyper (RR 1.07 [CI 0.77, 1.49]). Hb concentration was decreased in participants with both higher and lower TSH levels (p for quadratic pattern <0.001) in age and sex adjusted analyses, but this association was only significant for participants with OHypo (Hb 0.19 g/dL lower [CI -0.34 , -0.04]) and remained significant after additional adjustment for BMI, smoking, and diabetes. After excluding participants with common causes of anemia, such as iron deficiency, inflammatory disease, and kidney disease, 8.8 % of participants with OHypo ($p=0.048$), 16.3 % with OHyper ($p=0.005$), 5.6 % with SHypo ($p=0.49$) and 3.78 % with SHyper ($p=0.60$) had anemia compared to 4.9 % of the euthyroid participants.

CONCLUSIONS: Overt hypothyroidism and overt hyperthyroidism, but not subclinical thyroid dysfunction, are associated with a higher prevalence of anemia. Given these data from the largest population-based study on this issue, TSH measurement is likely indicated only after excluding other common causes of anaemia.

ASSOCIATIONS BETWEEN TEACHING EFFECTIVENESS SCORES AND CHARACTERISTICS OF PRESENTATIONS IN HOSPITAL MEDICINE CONTINUING EDUCATION John T. Ratelle; Christopher M. Wittich; Roger Yu; James Newman; Sarah Jenkins; Thomas J. Beckman. Mayo Clinic, Rochester, MN. (Tracking ID #2193724)

BACKGROUND: Hospital medicine (HM) is the fastest growing medical specialty in the United States. As HM evolves, the need for successful continuing medical education (CME) will be increasingly important. The Society for Hospital Medicine (SHM) recently developed core competencies for CME. However, there is little research regarding characteristics of effective CME presentations in HM. Our objectives were to describe the traits of participants at a national HM CME course, and to identify associations

between validated CME teaching effectiveness scores and characteristics of CME presentations in the field of HM.

METHODS: This was a cross-sectional study of 368 participants, and 30 presenters delivering 32 didactic presentations, at a Mayo Clinic HM CME course in 2014. Participants provided CME teaching effectiveness (CMETE) ratings, which were obtained from an instrument with known content, internal structure, and criterion validity evidence (Wittich et al. JGIM. 2011). The instrument has the following 8 items: 1) clear and organized, 2) relevant, 3) case-based, 4) effective slides, 5) audience interactivity, 6) supporting literature, 7) appropriate length and 8) summary slide. For statistical analysis, overall CMETE scores (5-point scale: 1=strongly disagree; 5=strongly agree) were averaged across items and participants for all presenters. We estimated that this study of >200 participants would provide >90 % power to detect a medium Cohen's effect size of 0.25 for associations between CMETE scores and variables related to characteristics of presentations. Associations between the CMETE overall scores and presentation characteristics were determined using the Wilcoxon rank sum or Kruskal-Wallis test, as appropriate. The threshold for statistical significance was set at $p < 0.05$.

RESULTS: A total of 277 out of 368 participants (75.3 %) returned evaluations, yielding 7947 ratings for statistical analysis. Overall, course participants (number, %), described themselves as hospitalists (181, 70.4 %), ABIM certified with HM focus (48, 18.8 %), physicians with MD or MBBS degrees (181, 70.4 %), nurse practitioners or physician assistants (52; 20.2 %), and in practice >20 years (73, 28 %). The majority of participants (148, 53.4 %) worked in private practice, while only 63 (24.8 %) worked in academic settings. CMETE scores (mean [SD]) were significantly associated with the use of audience response (4.64 [0.16]) versus no audience response (4.49 [0.16]; $p = 0.01$), longer presentations (>30 min: 4.67 [0.13] versus <30 min: 4.51 [0.18]; $p = 0.02$), and larger number of slides (>50: 4.66 [0.16] versus <50: 4.55 [0.17]; $p = 0.04$). There were no significant associations between CMETE scores and use of clinical cases, defined goals, or summary slides.

CONCLUSIONS: To our knowledge, this is the first study regarding associations between validated teaching effectiveness scores and characteristics of effective CME presentations in HM. Course participants were diverse in terms of types of providers and practice settings. Our findings, which support previous research in other fields, indicate that CME presentations may be improved by increasing interactivity through the use of audience response systems, in addition to allowing longer presentations. Future research should determine whether course content that reflects the SHM core competencies improves the quality of CME presentations.

BASELINE OPIOID USE AS A PREDICTOR OF TELECARE COLLABORATIVE PAIN MANAGEMENT OUTCOMES Erin E. Krebs^{2, 3}; Kurt Kroenke^{4, 1}; Jingwei Wu¹; Matthew J. Bair^{4, 1}; Zhangsheng Yu¹. ¹Indiana University, Indianapolis, IN; ²Minneapolis VA Health Care System, Minneapolis, MN; ³University of Minnesota, Minneapolis, MN; ⁴Roudebush VAMC, Indianapolis, IN. (Tracking ID #2192185)

BACKGROUND: Use of opioids for chronic pain is controversial. Among patients with chronic pain, receipt of opioid therapy is associated with worse pain, disability, and mental health. Furthermore, longitudinal observational studies have reported that patients treated with opioids have poorer functional outcomes than those not treated with opioids. These observations have led to concerns that patients receiving opioid therapy may be resistant to pain management or that opioids may interfere with treatment response. We conducted a secondary analysis of data from the Stepped Care to Optimize Pain Care Effectiveness (SCOPE) randomized trial, which compared a telephone-based collaborative analgesic optimization intervention to usual care over 12 months. Our objectives were to 1) characterize factors associated with baseline opioid use among SCOPE participants and 2) determine whether baseline opioid use predicted pain outcomes. We hypothesized that participants with baseline opioid use would have worse pain, disability, and mental health comorbidity at baseline and that baseline opioid use would predict worse pain outcomes over 12 months.

METHODS: SCOPE participants were 250 VA primary care patients with chronic musculoskeletal pain of at least moderate severity. Participants were randomized to either intervention or usual care. Those assigned to the intervention group received 12 months of automated symptom monitoring, telephone-based nurse care management, and algorithm-guided analgesic optimization. Analgesic optimization focused primarily on active adjustment of non-opioid medications. The intensity of opioid therapy remained stable over the course of the trial. The primary trial outcome was the total score (0 to 10) on the Brief Pain Inventory (BPI), which assesses pain intensity and functional interference. For this analysis, we used chi-square and t-tests to conduct unadjusted comparisons between opioid users and non-users at baseline. We used multivariable logistic regression to examine cross-sectional associations with baseline opioid use; the model included variables that were theoretically related to opioid use or associated at the $p \leq 0.2$ level in unadjusted comparisons. Finally, we used mixed-effect models for repeated measures

(MMRM) to examine baseline opioid use as a predictor of the primary pain outcome (i.e., BPI score).

RESULTS: At baseline, 84 (33.6 %) trial participants reported use of prescribed opioid analgesics. In unadjusted comparisons, opioid users had worse baseline BPI total scores (6.2 vs. 4.7), more painful sites (5.5 vs. 4.6), and more medical comorbidities (2.3 vs. 1.9) than non-users. They were also less likely to be employed (52.4 vs. 69.9 %), more likely to have depression (42.9 vs. 14.5 %), more likely to smoke (35.7 vs. 19.9 %), and more likely to have high disability days in the past month (53.6 vs. 21.1 %). In the multivariable model examining baseline associations, only baseline pain ($p = 0.006$) and disability days ($p = 0.036$) were independently associated with baseline opioid use. In the model examining predictors of outcomes over 12 months, which included baseline BPI, treatment group assignment, disability days, depression, and smoking, there was no statistically significant effect of baseline opioid use ($p = 0.98$) on BPI score. In contrast, treatment group assignment, baseline BPI, and time were all significant predictors of BPI over 12 months. A test for interaction between baseline opioid use and treatment group assignment was not statistically significant ($p = 0.95$).

CONCLUSIONS: In this analysis of data from a randomized controlled trial of telecare collaborative pain management, we found that baseline opioid use did not predict the primary pain outcome and did not modify the intervention's beneficial effect on pain. Results of our cross-sectional analyses were consistent with prior studies, showing that patients receiving opioid therapy at baseline had worse baseline pain, disability, and mental health than patients not receiving opioid therapy; in the adjusted model, pain and disability were independently associated with opioid use. We are encouraged by our finding that response to the collaborative pain management intervention was not significantly affected by pre-existing opioid therapy. Although patients on opioids were more distressed at baseline, they benefited from a relatively low-intensity telephone-based intervention involving symptom monitoring and optimization of primarily non-opioid analgesics. Given growing concerns about harms of long-term and high-dose opioid therapy, future research should examine whether a modified collaborative management protocol could be an effective strategy to achieve dual goals of improving pain outcomes and reducing intensity of opioid therapy.

BRIEF COMMUNICATION CURRICULUM IMPROVES DISCHARGE SUMMARY QUALITY Valerie Perel¹; Adam Carrington²; Michael Janjigian⁴; Verity Schaye²; Rachel Shur²; Jessica Taft³; Ellen Wagner²; David Wei²; Meng Yang⁵; Lisa Altschuler². ¹NYU Department of Internal Medicine, New York, NY; ²NYU School of Medicine, New York, NY; ³New York University, New York, NY; ⁴New York University School of Medicine, New York, NY; ⁵Columbia University Mailman School of Public Health, New York, NY. (Tracking ID #2198189)

BACKGROUND: Good written communication is essential to maintaining continuity of care across transitions and minimizing adverse outcomes. Written discharge summaries (DCS) are the main mechanism for communication between hospital providers and those caring for the patient after discharge. Short-cuts such as "cut and paste" that are often used to save time when writing notes can lead to poor quality documentation. Improvements in DCS have been shown to reduce patient medication errors and other adverse events. To improve the quality of written communication at our institution, we provide interns and residents on a specialized inpatient ward rotation (Bedside Skills Team (BST)) a session on both written and verbal communication skills. This study examined the impact of this rotation on the quality of DCS.

METHODS: This study assessed DCS written by 48 Internal Medicine interns at an urban safety-net hospital who were rotating on the BST or a general ward team when they wrote the DCS (21 intervention, 27 control). Four to five DCS per intern written during the rotation were selected for review (102 intervention, 111 control). The intervention group received a one-hour session on note writing reviewing standardized note formats and previous notes they had written. The interns continued to receive feedback on their notes throughout the 2 week rotation by their attending and resident. A rating scale to assess the quality of summaries was developed based on Joint Commission standards and expert consensus. The initial scale consisted of 15 items but was reduced to 11 in order to achieve suitable internal consistency. Four items were rated as present or not present and seven quality items were scored on a three-point Likert scale for a total possible summary score ranging from 4 to 24. Each item had specific descriptors for each anchor point. Coding was done by four experienced physicians blinded to group status. Inter-rater reliability was established by having the four raters rate two DCS that another rater had also rated (kappa .77). 20 % of charts were scored by all four raters and reviewed as a group to standardize rating system and establish consensus. Two sample t-tests were computed on the summary score as well as on individual items to assess impact of the rotation.

RESULTS: Mean DCS score for the intervention group was 20.8 (SD 4.2) and for the control group was 17.5 (SD 4.2) with a significant mean difference of 3.3 ($p = 0.0002$), with a Cohen's d of 0.78 (large effect size). Interns in the intervention group were less likely than control interns to inappropriately copy and paste information (39 vs 74 %

respectively, $p < 0.001$). Intervention interns were more likely than control interns to chronologically document the History of Present Illness and to clearly list consults and procedures from the hospitalization.

CONCLUSIONS: Interns who engaged in a 2-week rotation with a focus on written and oral communication skills wrote higher quality DCSs compared to trainees who had not received the rotation. In particular, interns in the intervention group produced a more

organized, concise and chronological history of present illness, and better described the consultations and procedures completed during the hospital stay. The control group was twice as likely to show evidence of inappropriate copying and pasting of information. Both groups had room for improvement in important patient safety areas (e.g., deficits in medication reconciliation) that need continued focus during resident training. Futures studies should focus on durability of communication skills following a brief intervention.

CARDIAC VALVE DISEASE IN ADULTS WITH DOWN SYNDROME Kristin M. Jensen¹; Laura A. Seewald¹; Molly Levitt¹; Edward R. McCabe²; Francis J. Hickey³; Jeremy R. Nicolarsen^{3, 4}; Joseph Kay^{4, 3}; Amber Khanna^{4, 3}. ¹University of Colorado School of Medicine, Aurora, CO; ²March of Dimes Foundation, White Plains, NY; ³Children's Hospital Colorado, Aurora, CO; ⁴University of Colorado Hospital, Aurora, CO. (Tracking ID #2192787)

BACKGROUND: The care of adults with Down syndrome (DS) is an emerging field, due to the fact that few persons with DS survived past adolescence until the 1980s. As such, evidence to guide providers of the adult DS population has lagged behind the pediatric population. Children with DS have high rates of congenital heart disease (CHD) with prevalence estimates of 40–60 %. However, case reports in the 1980s–1990s suggest additional risk for acquired valve disease in adults with DS, regardless of their congenital heart disease status. To date, routine echocardiographic screening of adults with DS has not been adopted by the field of Cardiology, likely due to the small size and lack of controls in those early reports. In this study, we sought to systematically evaluate the prevalence of valve disease in adults with DS compared to non-DS adults undergoing echocardiogram for purposes other than known valve disease.

METHODS: We conducted a retrospective chart review from 2006 to 2012 of all persons ages 16–65 years with DS who underwent an echocardiogram at our institution. Controls were randomly identified at ratios of 2.5 controls: 1 case from all persons ages 18–65 years old who underwent an echocardiogram for complaints of syncope or palpitations. Stress and pregnancy echocardiograms were excluded from our analysis. We defined valve disease as the presence of moderate or severe valve disease on echocardiogram. Comparisons were made using t-tests and Pearson's chi-squared tests as appropriate.

RESULTS: From 2006 to 2012, 81 adults with DS underwent echocardiography at our institution. Compared to non-DS controls ($n = 225$), adults with DS were younger at the time of their echocardiogram (median age at echocardiogram: DS 30.0y, nonDS 46.0y, $p < 0.001$) with higher rates of congenital heart disease (DS 73 %, nonDS 19 %, $p < 0.001$). Twenty-eight percent of adults with DS had echocardiographic findings of moderate to severe valve disease vs. 14 % of the non-DS population ($p = 0.003$). In subgroup analysis, we observed valve disease in 14 % of persons with DS and 11 % of persons without DS who did not also have a history of CHD and thus would qualify as truly acquired valve disease ($p = 0.452$). No differences were found in rates or pathology of valve disease among persons with CHD history regardless of DS status. There were no differences in rates of congestive heart failure, oxygen use, or valve repair between our cohorts. Eisenmenger's syndrome was seen exclusively in the DS cohort (DS 2.5 %, nonDS 0 %, $p = 0.018$).

CONCLUSIONS: In this single center retrospective cohort study, we observed valve disease in DS patients both with and without a history of CHD. This indicates that the cardiac history of persons with DS continues to evolve beyond their initial CHD status and suggests the need to adapt recommendations for adults with DS to include screening for acquired valve disease in addition to following for sequelae of their CHD.

CHANGES IN HOSPITALIZED ANEMIC PATIENTS' FATIGUE WITH RED BLOOD CELL TRANSFUSIONS Micah T. Prochaska; Richard Newcomb; Andrea Flores; Tamar Polonsky; Andrew Artz; Caitlin Phillips; Sarah Follman; David Meltzer. University of Chicago, Chicago, IL. (Tracking ID #2199099)

BACKGROUND: The current AABB guidelines recommend transfusing red blood cells in hospitalized patients at "restrictive" hemoglobin (Hb) concentrations and for symptoms of anemia. However, studies incorporating objective patient symptoms into transfusion

decisions are lacking. Therefore, we sought to measure how anemia related fatigue changes from hospitalization to 30 days post-discharge and whether baseline (in-hospital) Hb and receipt of red blood cell transfusions are associated with changes in fatigue.

METHODS: From May-December 2014, all hospitalized general medicine patients at a single urban academic medical center with Hb<9 g/dL, were approached for an in-person interview while in the hospital and a 30-day post-discharge phone interview. The Functional Assessment of Cancer Therapy Fatigue Subscale (FACIT) was used to measure fatigue at both times. FACIT scores range from 0 to 52, with lower scores reflecting greater symptoms of fatigue, and score differences of 3 reflect the minimum for a clinically important difference. A "change in fatigue" score was calculated by subtracting responses on the FACIT while hospitalized from responses on the FACIT at the interview 30-days post discharge. Positive change in fatigue scores represented decreased (or improved) fatigue from hospital to 30 days post-discharge. Patients with baseline FACIT scores <31 were considered to have "high" baseline fatigue. Patients' Hb level and number of transfusions received while in the hospital were assessed by chart review. Linear regression was used to test associations between "change in fatigue" score, baseline Hb concentration, and receipt of a transfusion.

RESULTS: Two hundred seventy-four patients completed the inpatient and follow up interview. The median age of participants was 58, with 61 % female, and 69 % African American. There were no significant differences in these demographics between those who were transfused versus those who were not transfused [(median age 58 vs. 55; $p=0.33$), (percent female 60 vs. 61 %; $p=0.84$), (African American 69 vs. 69 %; $p=0.54$). There were also no significant differences in comorbidities between those who were transfused versus those who were not transfused [(cancer 18 vs. 14 %; $p=0.69$), (diabetes 28 vs. 39 %; $p=0.21$), (heart failure 28 vs. 25 %; $p=0.87$), (chronic kidney disease 22 vs. 35 %; $p=0.08$)]. Baseline FACIT score was 27 in those transfused and was 27 in those not transfused ($p=0.87$). Among patients with baseline high levels of fatigue and a Hb<8 g/dL, those receiving a transfusion had a clinically significant improvement in fatigue compared to non-transfused patients (median change in fatigue, transfused 16 vs. non-transfused group 6.75; $p=0.007$) (Fig 1). Among patients with high levels of fatigue and a Hb>8 g/dL, those receiving a transfusion also had improved fatigue compared to patients not transfused, although the difference was not statistically significant (median change in fatigue, transfused 10.8 vs. non-transfused group 9.45; $p=0.66$). Among patients with low levels of fatigue (FACIT score >31) irrespective of Hb level, no significant difference in change in fatigue was found between those transfused and those not transfused.

CONCLUSIONS: These findings are consistent with the hypothesis that blood transfusions may improve fatigue in hospitalized anemic patients, specifically those with high levels of pre-transfusion fatigue. This suggests that inpatient providers may be able to combine self-reported fatigue in patients and their Hb concentration to better target those most likely to benefit symptomatically from a transfusion, while avoiding transfusions and attendant complications in other patients. Prospective studies are warranted to identify the effects of a symptom-guided transfusion strategy on other symptoms of anemia, such as functional capacity, as well as to evaluate other outcomes of hospitalized patients with anemia.

CHANGING THE CULTURE OF BEDSIDE TEACHING: MASTER CLINICIAN AND JUNIOR FACULTY PARTNERSHIP Lisa Altshuler², Douglas Bails¹, Adam Carrington², Patrick M. Cocks³, Danise Schiliro⁴, Verity Schaye², Ellen Wagner², Sondra Zabar², Michael Janjigian². ¹Bellevue Hospital Center, New York, NY; ²NYU School of Medicine, New York, NY; ³NYU School of medicine, New York, NY; ⁴Yale-Waterbury Internal Medicine Residency Program, Waterbury, CT. (Tracking ID #2197740)

BACKGROUND: We developed a 2-week ward rotation at an urban safety net teaching hospital with a focus on bedside teaching to improve physical examination, communication, and clinical reasoning skills in both house staff and faculty. Highly regarded clinical teachers, deemed "master clinicians" by their peers, lead morning sessions with a focus on clinical reasoning and afternoon sessions on physical diagnosis skills at the bedside. The ward attending physician supervises patient care and participates in all educational activities. While bedside teaching is a powerful teaching strategy, barriers to implementation include time constraints, concerns about patient comfort, and lack of confidence on part of faculty. This qualitative study evaluates how attending faculty perceive the benefit of such a teaching service, and the impact of clinical reasoning and physical exam sessions on their own methods of teaching.

METHODS: We conducted focus groups or structured interviews with 12 of the 18 faculty who served as attendings on this rotation from July 2012-June 2013, including seven females and one male. One attending had 20 years experience, with the remainder ranging from 2 to 10 years experience. Faculty were asked about their perceptions of the rotation and how it differed from other inpatient ward rotations, their participation in the teaching sessions, and the impact of the rotation on their own teaching. The interview was transcribed and imported into qualitative analysis software (dedoose) for analysis. A

grounded theory analysis was used to develop and link thematic cues describing the responses. All data was read and coded by three independent readers.

RESULTS: The focus group highlighted the value of bedside rounds as an effective teaching method. Bedside teaching reinforced key concepts in physical examination and clinical reasoning and provided opportunities for evaluation of trainee performance. With respect to their own professional development, faculty found it "very helpful" to observe master clinicians demonstrating physical exam techniques and explaining their clinical reasoning because as junior faculty they "don't ever really get to do that". Many faculty reported teaching the physical exam skills that they learned during these bedside sessions and increasing the frequency of bedside teaching. One attending reported "...only if I'm going to the bedside with some expert teachers did I realize how much value there is in going to the bedside." Another noted, "it let me focus on the skills that I had deficits in. And then I would get to learn those deficits and then re teach what I learned back to the residents and the interns." Faculty reported integrating teaching skills modeled from the master clinician sessions, including how to effectively engage learners in clinical reasoning and physical exam sessions and how to assess their clinical reasoning. They valued observing different teaching styles from "expert teachers". As one faculty member noted, "I definitely learned... how to think on your feet and how to approach a case presentation. How to lead a team through a case."

CONCLUSIONS: This 2-week inpatient rotation is an effective way to partner junior faculty and master clinicians in order to teach clinical reasoning and physical exam skills. This partnership has been effective in overcoming barriers to bedside teaching by improving confidence in physical exam skills and providing a framework for effective teaching. The range of master clinician teaching styles enables junior faculty to adopt teaching strategies that play to their strengths. We have created an effective faculty development program by enhancing a mandatory ward rotation with teaching of clinical reasoning and physical exam skills by master clinicians.

CONTINUITY OF CARE BETWEEN MENTAL HEALTH AND PRIMARY CARE PROVIDERS AFTER A MENTAL HEALTH CONSULTATION. Ben Colaiaco³, Carol Roth⁴, David Ganz^{1, 5}, Mark Hanson³, Patty Smith³, Neil Wenger^{2, 3}. ¹RAND Corporation, Santa Monica, CA; ²University of California, Los Angeles, Los Angeles, CA; ³RAND Health, Santa Monica, CA; ⁴RAND, Santa Monica, CA; ⁵GLAVA, Los Angeles, CA. (Tracking ID #2198037)

BACKGROUND: Continuity between mental health providers (MHPs) and primary care providers (PCPs) is important to coordinate care for persons with mental illness. Lack of continuity can lead to therapeutic failure and dangerous drug interactions. Efforts have been undertaken to enhance communication, but the level of continuity in community practice has not been rigorously studied. We evaluated communication between MHPs seeing a patient for a new consult and PCPs, and compared continuity among providers sharing a mutual access electronic health record (EHR), and continuity among providers not sharing an EHR.

METHODS: Medicare Advantage enrollees with a new outpatient mental health consultation in 2012 were randomly selected within six geographically diverse health plans. Patients had no mental health visits in 2011 and an outpatient mental health consult, as well as at least 1 PCP visit, in 2012. Plans endeavored to retrieve medical records from MHPs and PCPs. Among patients for whom MHP and PCP records were obtained, charts were abstracted for information about the mental health consultation in the PCP record, evidence of documented continuity with the PCP about mental health hospital admissions and emergency department visits, and acknowledgement in the PCP record of psychotropic medications noted in the mental health record. These measures were compared between patients whose providers used and did not use a mutual access EHR.

RESULTS: For 141 (65 %) of 216 patients, plans were able to retrieve both MHP and PCP records. Records could not be retrieved from MHPs for 45 patients, from PCPs for 13 patients, and from neither MHPs nor PCPs for 17 patients. The 141 patients had a mean of 4.2 mental health visits (range 1-30) and a mean of 5.5 primary care visits (range 1-20) in 2012. Thirty (21 %) patients had PCP medical record documentation of communication from the MHP within 3 months of the consultation. Among these 30 patients, for 8 patients there was evidence of a telephone call, e-mail or other correspondence between MHP and PCP, for 4 there was an indication of a plan for, or attempt at, a telephone call, for 11 there was a mental health consultation note or report in the primary care record, and for 10 patients in systems with a mutual access EHR, the PCP reviewed the mental health note within the record. The PCP medical record revealed evidence of timely communication about 11 of 26 (42 %) mental health admissions and emergency department visits. Seventy-eight of the 141 patients were receiving 152 psychotropic medications according to the MHP record during the study interval. For 103 (68 %) of those medications, there was acknowledgement in the PCP record of the medication (or for cases with a mutual access EHR, the medication list that included psychotropic medications was accessed by the PCP at the follow up visit). Evaluating only the 126 medications of the 54 patients whose physicians did not use a mutual access EHR, half of the psychotropic medications

were antidepressants, 27 % were benzodiazepines and hypnotics, and 10 % were antipsychotics. Information discontinuity between the MHP and PCP records was found for 7 of 15 antipsychotic medications and 13 of 34 hypnotic/benzodiazepine medications. PCPs who shared a mutual access EHR with MHPs more often had access to mental health consult information (46 % v 11 %, $p<0.001$) and information about psychotropic medication use (100 % v 56 %, $p<0.001$).

CONCLUSIONS: This small, but detailed, study of patients receiving new outpatient mental health consults shows poor care continuity between MHPs and PCPs. Furthermore, evaluation of continuity between MHPs and PCPs is difficult for Medicare Advantage plans because of lack of mental health record accessibility. A mutual access EHR might mitigate discontinuity between mental health and primary care.

COST-EFFECTIVENESS OF HERPES ZOSTER (SHINGLES) VACCINE FOR PEOPLE AGED 50 YEARS Phuc H. Le; Michael B. Rothberg. Cleveland Clinic, Cleveland, OH. (Tracking ID #2192780)

BACKGROUND: Herpes zoster (HZ) affects approximately 30 % of the general population over their lifetime. Both the incidence and severity of HZ increase with age. The zoster vaccine can prevent HZ and postherpetic neuralgia (PHN), and is licensed for use among people aged ≥ 50 years. However, the Advisory Committee on Immunization Practices recommends the vaccine for people aged ≥ 60 years only. To inform the decision making process, this study aimed to analyze the cost-effectiveness of HZ vaccine versus no vaccine for immunocompetent adults aged 50 years.

METHODS: We employed a previously published Markov decision model and updated the inputs relevant for people aged 50–59 years. The entire cohort entered the model in the ‘Healthy’ state at age 50; then moved between health states with transition probabilities for a life-long time horizon. The model considered cases of HZ, PHN, and other complications of HZ including ophthalmic and otic complications, hospitalization and death. Compared to the unvaccinated group, the vaccinated group had reduced disease incidence and complications proportional to vaccine efficacy. Model inputs were derived primarily from US-based studies to reflect the epidemiology, utilities, and quality-adjusted life years (QALYs) of a general US population. Vaccine efficacy was based on the Zostavax Efficacy and Safety Trial, and duration of efficacy on the Long-Term Persistence Substudy, which reported 11 years of follow up from the Shingles Prevention Study. Costs were drawn from the medical literature. They included both direct medical costs and indirect costs due to lost productivity, expressed in 2014 US dollars (\$) adjusted for inflation. Outcomes included costs and effectiveness (the number of HZ cases, PHN cases, and QALYs) for each strategy. Results were presented as incremental cost-effectiveness ratio (ICER) per QALY saved. The study was conducted from the societal perspective, with both costs and QALYs discounted at 3 % per year. In addition to deterministic sensitivity analysis, probabilistic sensitivity analysis was also conducted, in which all variables were varied simultaneously; 10,000 Monte Carlo iterations were performed.

RESULTS: In the base case, for every 1000 persons vaccinated, 25 HZ cases and one PHN case would be prevented, equivalent to 0.4 QALYs saved at a cost of \$134,000 (\$318,071/QALY saved). Because HZ incidences were higher in women, the ICER was half as much for women as for men. In deterministic sensitivity analysis, only changes in vaccine cost resulted in an ICER of $< \$100,000/\text{QALY}$ (at \$82/dose) (Figure 1). In probabilistic sensitivity analysis, the mean ICER was \$422,112/QALY (95 % CI \$17,814–\$1,438,991/QALY). At a willingness-to-pay threshold of \$100,000/QALY, the vaccine was cost-effective in 11 % of iterations.

CONCLUSIONS: Although HZ vaccine is efficacious in protecting people aged 50–59 years, it does not appear to represent good value for this group.

Figure 1: Incremental costs per quality-adjusted life year (QALY) saved of the herpes zoster vaccination program as a function of vaccine cost.

DEPRESSION CARE MANAGEMENT AMONG U.S. MEDICAL GROUPS Tara F. Bishop²; Patricia Ramsay³; Lawrence P. Casalino²; Shortell Stephen¹. ¹UC Berkeley, Berkeley, CA; ²Weill Cornell Medical College, New York, NY; ³University of California Berkeley, Berkeley, CA. (Tracking ID #2197973)

BACKGROUND: The Centers for Disease Control and Prevention (CDC) estimates that 6.8 to 8.7 % of the U.S. adult population suffers from depression at any given time. Primary care physicians play an important role in the diagnosis and management of depression. It is unclear whether primary care practices are well-equipped to manage depression as a chronic illness. To assess whether primary care practices are well-equipped to manage depression as a chronic illness, we analyzed data from the largest national survey of physician practice to answer three research questions: 1) what care management processes (CMPs) do practices use for patients with depression, 2) are the rates of use of CMPs for depression lower than for other chronic illnesses and 3) what practice characteristics correlate with high depression CMP use.

METHODS: We used data from the largest national survey of physician practices in the U.S.—the National Survey of Physician Organizations 3. The survey was a 40-min telephone survey with medical directors, presidents, or chief executive officers of the medical groups in the U.S. and focused on the use of care management processes particularly for patients with depression, asthma, diabetes, and congestive heart failure. For this study, we selected practices that were all primary care (general internists, family practitioners, and general practitioners) or multi-specialty which we defined as practices with between 33 and 99 % primary care physicians yielding. Data were collected in 2012 and 2013. The primary outcome was a CMP index for depression, asthma, diabetes, and congestive heart failure which ranged from 0 to 5 based on a practice's response to the individual components. We calculated the percentage of practices that used each CMP for patients with depression, asthma, diabetes, and congestive heart failure and the mean CMP score for each of these conditions. We used multivariable logistic regression to explore associations between practice characteristics and high depression CMP scores (≥ 3).

RESULTS: A total of 1070 practices were included in the analysis. The mean practice size was 21 physicians and 81 % of the practices were all primary care physicians. Practices had been in existence a mean of 21 years. The mean CMP scores for depression (0.82, SE 0.02) were lower than the mean CMP scores for asthma (1.13, SE 0.07), congestive heart failure (1.13, SE 0.07), and diabetes (1.74, SE 0.13). In the multivariable model, practices with high depression CMP scores were more likely to be larger (adjusted odds ratio [aOR] 0.98, $p=0.008$), in the South (aOR 4.15 compared with the Northeast, $p<0.001$), have higher pay-for-performance indices (aOR 1.71, $p=0.02$), have higher public reporting indices (aOR 1.36, $p=0.02$), have higher use of CMPs for other conditions (aOR 2.45, $p=0.0002$), and have higher health information technology indices (aOR 1.06, $p=0.01$). Practices that were owned by hospitals were less likely to have high depression CMP scores (aOR 0.46, $p=0.06$ compared with physician-owned practices) as were practices in the West (aOR 0.18, $p<0.001$ compared with the Northeast) and the Midwest (aOR 0.53, $p=0.08$).

CONCLUSIONS: In this national survey of physician groups, the use of CMPs for depression in primary care practices was less than the use of CMPs for other chronic medical conditions. Our analysis also revealed regional variation in the use of CMPs for depression. Practices that had more incentives in place to improve quality and used CMPs for other conditions were more likely to have higher depression CMP scores. Our findings highlight the underuse of evidence-based CMPs for depression in U.S. primary care practices which may limit both access to and quality of depression care in the U.S.

EDUCATIONAL LEVEL, ANTICOAGULATION QUALITY, AND CLINICAL OUTCOMES IN PATIENTS WITH ACUTE VENOUS THROMBOEMBOLISM

Eveline Hofmann²; Andreas Limacher¹; Marie Méan^{2, 3}; Tobias Tritschler²; Nicolas Rodondi²; Drahomir Aujesky². ¹University of Bern, Bern, Switzerland; ²Bern University Hospital, Bern, Switzerland; ³Lausanne University Hospital, Lausanne, Switzerland. (Tracking ID #2197822)

BACKGROUND: Previous studies have demonstrated an association between a lower educational level and an increased risk for venous thromboembolism (VTE). However, whether the educational level is associated with anticoagulation quality and clinical outcomes in patients with acute VTE is unknown.

METHODS: We studied 817 patients aged ≥ 65 years with acute VTE from a Swiss prospective multicenter cohort study between September 2009 and December 2013. We defined three educational levels: 1) less than high school (≤ 9 years of education), 2) high school, or 3) post-secondary (diploma from a university or an equivalent institution). The primary outcome was the quality of anticoagulation, expressed as the percentage of time in therapeutic INR range (2.0–3.0). Secondary outcomes were the time to a first fatal or non-fatal recurrent VTE, and the time to a first fatal or non-fatal major bleeding. We examined the association between educational level and outcomes using linear and competing risk regression, adjusting for patient baseline characteristics and treatments, including periods of anticoagulation as a time-varying covariate.

RESULTS: Overall, 56 % of patients had a less than high school, 25 % a high school, and 19 % a post-secondary educational level. The median time spent in the therapeutic INR range was 64 % for patients with less than high school, 68 % for patients with high school, and 65 % for patients with a post-secondary educational level ($P=0.27$). After adjustment, we found no association between educational level and time in the therapeutic INR range. Furthermore, there was no association between educational level and recurrent VTE or major bleeding (Table).

CONCLUSIONS: In our prospective multicenter cohort, we did not find an association between educational level and anticoagulation quality or medical outcomes in patients with acute VTE.

Association between educational level and medical outcomes

Educational level	Adjusted sub-hazard ratio (95 % confidence interval)
Recurrent venous thromboembolism	
Less than high school	—
High school	0.97 (0.58–1.65)
Post-secondary	1.16 (0.69–1.96)
Major bleeding	
Less than high school	—
High school	1.13 (0.70–1.82)
Post-secondary	1.40 (0.82–2.38)

EFFECT OF A PHARMACIST COUNSELING INTERVENTION ON HEALTHCARE UTILIZATION AFTER HOSPITAL DISCHARGE: A RANDOMIZED CONTROLLED TRIAL Susan P. Bell³; Jeffrey L. Schnipper¹; Kathryn Goggins³; Aihua Bian³; Ayumi Shintani³; Christianne Roumie³; anuj dalal¹; terry jacobson³; Kim Rask⁴; Viola Vaccarino⁴; tejah gandhi¹; Stephanie Labonville¹; Daniel Johnson²; Erin Neal²; Sunil Kripalani³. ¹Brigham and Women, Boston, MA; ²Vanderbilt University Medical Center, Nashville, TN; ³Vanderbilt University, Nashville, TN; ⁴Emory, Atlanta, GA. (Tracking ID #2201028)

BACKGROUND: Reduction in 30 day readmission rates following hospitalization for acute coronary syndrome (ACS) and acute decompensated heart failure (ADHF) is a national goal. We sought to determine the effect of a tailored, pharmacist-delivered, health literacy intervention on time to first hospital readmission or Emergency Department (ED) visit following discharge.

METHODS: The Pharmacist Intervention for Low Literacy in Cardiovascular Disease (PILLCVD) study enrolled adults at two tertiary care academic centers between May 2008 and September 2009 with a diagnosis of ACS and/or ADHF. Participants were randomized to intervention or standard of care in a 1:1 ratio by concealed allocation, and outcomes were assessed by blinded researchers. The intervention group received pharmacist-assisted medication reconciliation, inpatient pharmacist counseling, and low literacy adherence aids while hospitalized, and individualized telephone followup calls after discharge. A Cox proportional hazard model was constructed to assess the effect of the intervention on time to first ED visit or unplanned rehospitalization during the 30 days after discharge. The multivariable analysis controlled for age, sex, race, marital status, health literacy, cognition, prior hospitalizations, and length of stay. Prespecified secondary analyses were performed to assess the differential effects of the intervention by site, health literacy, and cognition.

RESULTS: Among the 851 participants enrolled at Vanderbilt University Hospital (VUH) and Brigham and Women's Hospital (BWH), 10 % of patients had inadequate health literacy, and 12 % had impaired cognition. Overall, the intervention and control groups did not differ significantly in their 30 day rate of ED visits (21.8 vs. 20.2 %, respectively) or unplanned readmissions (15.0 vs. 15.8 %). In the primary, adjusted analysis, the intervention did not show a significant effect overall on time to first unplanned hospital readmission or ED visit (HR=1.04, 95 % CI 0.78, 1.39). Stratified analysis by site demonstrated a more beneficial effect at VUH as compared to BWH ($P=0.039$). Among patients with inadequate health literacy, the intervention significantly improved the primary outcome, with a longer time to first unplanned hospital readmission or ED visit compared to usual care (HR=0.41, 95 % CI 0.17, 1.00). There was no differential effect of the intervention by cognition.

CONCLUSIONS: A tailored, pharmacist-delivered medication safety intervention did not demonstrate an overall beneficial effect on time to first unplanned health care utilization after hospital discharge. Individuals with inadequate health literacy, however, did appear to benefit, suggesting targeted practice of pharmacist intervention in this population may reduce 30 day unplanned health care utilization.

EFFECT OF FAMILY HISTORY AND GENETIC RISK COUNSELLING FOR TYPE 2 DIABETES ON PERCEPTIONS OF RISK AND CONTROL: SECONDARY ANALYSIS OF A RANDOMIZED CONTROLLED TRIAL R. R. Wu^{2, 1}; Tiffany Himmel²; Rachel A. Myers²; Elizabeth Hauser²; Allison Vorderstrasse²; Geoffrey Ginsburg²; Lori A. Orlando². ¹VA Health System, Durham, NC; ²Duke University, Durham, NC. (Tracking ID #2198114)

BACKGROUND: Family health history (FHH) based risk assessment has been shown to increase perceived risk of disease and affect behavior change. Incorporating genetic testing as part of a risk assessment (either alone or in combination with FHH) has the potential to further refine patient and provider understanding of individual risk and improve collaborative efforts to manage that risk. To understand the additive impact of genetic risk assessment, we performed a secondary analysis to determine the effect of personalized risk counselling for Type 2 Diabetes (T2D), with incorporation of FHH and genetic risk counselling, on risk perception and perception of control, two cognitive precursors of behavior change.

METHODS: A convenience sample of non-diabetic patients from two primary care clinics was recruited while awaiting bloodwork. Subjects were randomized to receive traditional risk counselling including FHH with or without the incorporation of genetic test results of SNP-based testing of four genes (i.e. eight alleles) known to be associated with T2D. FHH risk was categorized based on published algorithms and explained to subjects as average, moderate, or high. Genetic results were provided as total positive alleles out of the maximum of 8. Surveys were completed at baseline and post-counselling at 3 and 12 months to assess perceptions of overall disease risk and genetic risk for T2D using questions derived from the Common Sense Model and control over disease development using questions from the Illness Perception Questionnaire. Primary outcomes have already been reported.

RESULTS: Participants who completed the study (invited=1416, enrolled=409, completed=321) were 69 % female (64 % Caucasian, 24 % black, and 12 % other). The mean age was 52. There was a reasonable distribution of participants in each of the FHH risk categories (average=143, moderate=84, high=94), and the mean number of high risk alleles for the study population was 4.99 (SD 1.22, range 2–7.) FHH risk category and number of high risk alleles were correlated. Subjects with average FHH had a mean of 4.76 alleles, moderate FHH had a mean of 4.79 alleles, and high FHH subjects had a mean of 5.18 alleles (p -value=0.03). Higher FHH risk level was associated with higher perceptions of overall risk of disease development across all time points (all p -values<0.001) and did not change over time as a result of risk counselling. In addition perception of genetic risk for disease was correlated with FHH risk category (all p -values<0.001) across all time points and was not affected by the counselling session. In regards to genetic testing, number of positive alleles did not influence perception of overall disease development risk at any time point. However having an increased number of alleles did lead to a change in perception of genetic risk from pre- to post-counselling (more risk: 5.21 alleles, same risk: 5.06 alleles, less risk: 4.44 alleles, ANOVA p -value=0.007). When stratified by FHH risk category, this effect was most strongly seen in those with FHH risk that was average (p -value=0.04) or moderate (p -value=0.005) with no effect in the high FHH risk category (p -value=0.46). (Table) Perception of control over risk of disease development was high overall (mean 24.08, SD 3.43, possible range 0–25) and not affected by FHH or genetic risk.

CONCLUSIONS: Patients have a strong sense of personal control over diabetes development. There was a strong understanding of the relationship of FHH to their overall risk of disease and perceptions of their genetic risk. A higher number of genetic risk alleles did not correlate with perception of overall disease risk but did have an effect on perceptions of genetic risk. Strongest effects were seen among those with an average or moderate FHH risk level. As genetic testing for risk prediction becomes more main stream, further work should be done to understand who most benefits from testing and optimal methods for delivery of that information to optimize behavior change and risk reduction.

Mean genetic allele number stratified by FHH risk category effect on change in perception of genetic risk over time

	Increased Risk		Same Risk		Decreased Risk		Overall	
	Mean (SD)	N (%)	Mean (SD)	N (%)	Mean (SD)	N (%)	Mean (SD)	N (%)
Average FHH*	5.08 (1.18)	36 (55)	4.90 (1.37)	20 (31)	3.89 (1.17)	9 (14)	4.86 (1.29)	65 (100)

ELECTRONIC MEDICAL RECORD BASED INTERVENTION TO REDUCE LENGTH OF STAY FOR VETERANS HOSPITALIZED WITH PNEUMONIA

Eric Mortensen^{1, 2}; Mary Bollinger³; Michael Fine⁴. ¹VANTHCS, Dallas, TX; ²UT Southwestern Medical Center, Dallas, TX; ³STVHCS, San Antonio, TX; ⁴VA Pittsburgh Health Care System, Pittsburgh, PA. (Tracking ID #2194967)

BACKGROUND: There are more than 1.2 million hospitalizations for pneumonia each year in the United States. Although there has been considerable focus on improving pneumonia-related process of care measures, such as use of guideline concordant antibiotics, there has been much less attention paid to reducing length of hospital stay. Therefore we conducted a pre-post intervention trial of a electronic medical record (EMR) based clinical reminder to identify when patients with pneumonia were clinically stable and ready for conversion from IV to oral antibiotics.

METHODS: We conducted this study at a single Department of Veterans Affairs hospital. We developed an EMR-based inpatient clinical reminder to assist physicians with appropriate conversion from IV to oral antibiotics and that encouraged discharge on the same day unless there were other social problems or unstable comorbid conditions. We implemented this reminder with academic detailing on February 1, 2011. We then compared patients hospitalized in April/May 2010 (pre) to patients hospitalized in April/May 2011 (post).

RESULTS: There were 66 patients in the pre-intervention period and 63 patients in the post-intervention period. There were no statistically significant differences in characteristics between the pre- and post-intervention groups. Overall, mean age was 69.7 years, 96 % were male, and 29 % were in the ICU during part of their stay. Regarding pneumonia severity index, 28 % were classes I–III, 46 % were class IV, and 26 % were class V. Mortality within 30-days was 3.0 % in the pre-intervention and 3.2 % in the post-intervention groups ($p=0.96$). Length of hospital stay pre-implementation was 7.3 days and post-implementation was 5.4 days ($p=0.05$).

CONCLUSIONS: Implementing an EMR-based reminder was associated with a significantly reduced length of hospital stay without significantly increasing mortality at a single VA medical center. Appropriately reducing length of hospital stay for pneumonia has been previously demonstrated to be associated with reduced costs, and may potentially be associated with improved patient safety. Additional research is needed to determine if this reminder can be successfully implemented in other hospitals.

ELECTRONIC PHARMACOVIGILANCE OF PATIENTS NEWLY STARTED ON MEDICATIONS FOR HYPERTENSION, DIABETES, INSOMNIA, OR DEPRESSION

Elissa V. Klinger³; Alejandra Salazar³; Jeffrey Medoff³; Patricia C. Dykes³; Jennifer Haas¹; Japneet Kwatra³; Endel J. Orav⁴; Lucas Marinacci³; Shimon Shaykevich²; David W. Bates²; Gordon D. Schiff³. ¹BWH, Boston, MA; ²Brigham and Women, Boston, MA; ³Brigham and Women's Hospital, Boston, MA; ⁴Northwestern University, Boston, MA. (Tracking ID #2200262)

BACKGROUND: The safe and effective use of prescription drugs in the outpatient setting requires monitoring of patients to track outcomes and ensure potential adverse effects are identified and addressed in a timely fashion. Automated approaches offer the promise that such monitoring could be performed easily, reliably, and efficiently. We developed a patient-centered, EHR-integrated interactive voice response system (IVRS) to actively monitor the safety and effectiveness of treatment for patients taking FDA-approved medications for one of four common chronic conditions (diabetes, hypertension, insomnia, depression), with integrated management support by a clinical pharmacist. We report on preliminary findings of Calling for Earlier Detection of Adverse Reactions (CEDAR), a cluster-randomized, controlled trial.

METHODS: Eighteen primary care clinics using an integrated EHR were identified and matched based on geographic and patient-population characteristics and then randomized to either an intervention or control arm. We developed an algorithm to identify any adult primary care patient at any of the clinics who had been newly started on a medication for one of these four conditions. Eligible patients in the intervention clinics were sent a letter with study information and an opportunity to decline participation. Using automated IVRS phone calls, patients were called 4–6 weeks and again at 6–8 months following their medication start date and prompted to confirm that they were taking the drug and it was prescribed for the condition of interest. The IVRS then asked a series of targeted questions querying both adherence and symptoms commonly associated with ADRs. Any patient with a positive symptom was transferred to a clinical pharmacist in real-time at the conclusion of call; these IVRS-collected data sent a real-time secure email message to the pharmacist, containing relevant clinical information captured during the call, including reported possible drug-related symptoms. Patients reporting no symptoms on the IVRS call could also opt to transfer to the pharmacist. All patients counseled by the pharmacist had a note filed in the EHR, with more urgent clinical concerns triaged accordingly. Eligible patients from control clinics were identified via the EHR using the same eligibility criteria but did not receive any component of the intervention. A manual chart review at

1 year from time of the target prescription was performed for the intervention group and for a set of controls generated by propensity score matching. This outcome chart review compared target drug discontinuation, action taken by clinician following patient-reported symptoms consistent with ADRs, and other clinically relevant information.

RESULTS: Between June 2013–September 2014, 11,945 eligible patients from nine intervention and nine control clinic sites were identified who were classified as a new start on one of 103 target medications. Of these, 4847 eligible intervention patients were called and 609 (12.6 %) participated in the IVRS interviews, 496 (10.2 %) actively declined participation, and the remaining patients (77.2 %) either answered but did not complete the call or did not answer any call attempt. Of the 609 participating patients, 306 (6.3 % of all patients called, 50.2 % of those completing the calls) reported symptoms consistent with ADRs. A total of 430 (8.9 % of all patients called) were transferred to the pharmacist (for reported symptoms or request to speak to pharmacist) and had notes filed in their charts and their PCPs alerted accordingly. Outcome chart reviews are on-going as the cohort of participants reaches 1 year of follow-up to compare the percent of patients with identified adverse effects, drug discontinuation, and physician awareness and action in the intervention vs. control cohorts.

CONCLUSIONS: We demonstrate that an EHR-integrated IVRS that leverages real-time data capture and live transfer to a pharmacist can be an effective tool to reach out in a proactive manner to patients starting new medications. Consistent with prior studies screening for ADRs, 1 in 3 participating patients reported a potential ADR, many of which had not been reported or documented previously by the PCP. Our specially designed system allows real time transfer of IVRS calls to a pharmacist who can simultaneously access patient-reported data and the patient's chart, and thereby troubleshoot symptoms that may be consistent with ADRs that may necessitate a change in dosage or a drug discontinuation. For patients not experiencing symptoms, the platform also provides a service to individuals who have questions or concerns about their medications.

ENGAGING RESIDENTS IN VENOUS THROMBOEMBOLISM PREVENTION AND STROKE QUALITY MEASURES THROUGH AN INTERACTIVE CHECKLIST AND INCENTIVE PROGRAM

Syed A. Hussain¹; Wilhelmine Wiese-Rometsch¹; Corinne Hamstra¹; Camelia Arsene²; Suzanne White¹. ¹Detroit Medical Center/Wayne State University, Troy, MI; ²Sinai-Grace Hospital/Detroit Medical Center, Detroit, MI. (Tracking ID #2154842)

BACKGROUND: Venous thromboembolism (VTE) is the most common preventable cause of hospital death. Stroke is the third leading cause of death in the United States. Given that checklists have been demonstrated to improve patient safety, we developed a novel, interactive Electronic Medical Record (EMR) checklist to monitor real-time gaps in VTE prevention and stroke process measures. We hypothesized that the use of this platform, coupled with a pay-for-performance plan, would globally engage residents in quality improvement and optimize the clinical learning environment as specified in the Accreditation Council for Graduate Medical Education "CLER Pathways to Excellence".

METHODS: The real-time, interactive checklist was launched 1/1/14 for all adult patients at four hospitals within a major academic center. Twenty resident quality directors from various residency programs across the system led daily monitoring of performance and provided feedback on care gaps to physicians, midlevel providers, and 800 resident colleagues. Data on VTE prevention and stroke process measures were sampled and abstracted as per The Joint Commission and CMS guidelines.

RESULTS: Compliance with VTE prevention measures in the 6 months prior to implementation of the checklist and resident engagement program was 88.46 % and in the 6 months post-intervention was 94.15 %, with analysis done using the Mann–Whitney U test with $p<0.006$. Similarly, compliance with stroke process measures 6 months prior to intervention was 88 % compared to 96.56 % post-intervention ($p<0.024$). Over 800 residents received their second incentive payment in November 2014.

CONCLUSIONS: Implementing a real-time, interactive decision support checklist and pay-for-performance program for residents improved compliance with VTE prevention and stroke process measures. Empowering residents through leadership roles has been an important step toward integrating them into the quality infrastructure of the health system. Our project is unique in complexity, magnitude and goals in engaging trainees from training programs across the spectrum for one unified vision and purpose—increasing compliance for evidence based quality measures.

FALLING THROUGH THE CRACKS: CAN A MEDICAL HOME IMPROVE ACCESS AND CARE COORDINATION FOR PEOPLE WITH MENTAL HEALTH ISSUES?

Chloe Anderson¹; Rose Kleiman¹; Dominique Hall¹; Susan L. Hayes¹. The Commonwealth Fund, New York, NY. (Tracking ID #2198275)

BACKGROUND: About a quarter of U.S. adults live with a diagnosable mental illness. These individuals are at higher risk for comorbid chronic conditions, and without accessible and coordinated care, they may not receive appropriate treatment. This analysis provides an overview of the access and coordination problems faced by insured people with mental health issues, as compared to the general insured population, and explores whether having a medical home may mitigate these disparities in care experiences.

METHODS: Data come from the 2013 Commonwealth Fund International Health Policy Survey, a nationally representative telephone survey of adults conducted from February through June 2013. The full sample consisted of 1350 adults ages 18–64 in the United States, 453 of whom reported a mental health issue (defined as emotional distress in the past 2 years or a mental health problem diagnosed by a doctor). In this analysis, we assessed access to care and care coordination among adults who reported mental health problems, and examined the role of a medical home in improving care experiences, using bivariate analysis and logistic regression.

RESULTS: More than one-third of adults reported a mental health issue, including nearly half of all lower income adults; 41 % also reported a chronic condition. Even with insurance, adults with mental health problems had significantly ($p<0.05$) higher rates of ER use (55 vs. 40 %), access problems because of cost (54 vs. 37 %), gaps in care coordination (63 vs. 44 %), and medical or medication errors (31 vs. 20 %), compared to the full sample. Insured adults with a chronic condition in addition to a mental health problem had significantly higher hospital and ER utilization rates than those with a mental health problem and no chronic condition. Medical homes make a difference for adults with mental health issues. Among adults with a mental health issue, the odds of having access problems, care coordination problems, or experiencing a medical or medication mistake were reduced by more than 50 % ($p<0.05$) for adults with a medical home, even after controlling for insurance and other demographic characteristics.

CONCLUSIONS: Consistent with previous studies, our analysis found that having mental health issues may not only lead to high utilization, but also may leave individuals vulnerable to inadequate care coordination and cost-related access issues. Our research shows that the medical home is associated with improved access and care coordination. Mental health is often addressed outside of the health care delivery system despite its impact on physical health. Primary care providers are often unequipped to adequately address patients' behavioral health needs. The Affordable Care Act aims to expand requirements for health insurers to cover mental health benefits. However, in order for this expansion to have an impact on care outcomes, delivery systems need to better integrate physical and behavioral health care. States and payers, likewise, will need to incorporate financing and payment models that support this level of integration. Care coordination, particularly in the form of a medical home, may be one such way to improve outcomes for those experiencing both mental health issues and chronic conditions.

FIFTY YEARS OF HEALTH SPENDING BY LOW, MIDDLE, AND HIGH-INCOME AMERICANS, 1963–2012 Samuel L. Dickman⁴; Steffie Woolhandler³; Jacob Bor⁶; Danny McCormick⁵; David Bor²; David Himmelstein¹. ¹CUNY School of Public Health, New York, NY; ²Cambridge Health Alliance, Cambridge, MA; ³City University of New York School of Public Health, New York, NY; ⁴Harvard Medical

School, Boston, MA; ⁵Harvard Medical School / Cambridge Health Alliance, Cambridge, MA; ⁶Boston University School of Public Health, Boston, MA. (Tracking ID #2196643)

BACKGROUND: Growth in U.S. medical spending has slowed since 2004. Increased patient cost-sharing, a likely contributor to the slowdown, would be expected to have the greatest impact on lower income households, which have seen little income growth during this period. Whether the health spending slowdown has affected all income groups uniformly is unknown.

METHODS: Data on annual health expenditures were compiled from 22 nationally representative surveys carried out since 1963: the 1963 and 1970 Surveys of Health Services Utilization and Expenditures ($N=7759$ and $11,619$, respectively); the 1977 and 1980 National Medical Care Utilization and Expenditure Surveys ($N=38,815$ and $17,123$, respectively); the 1987 National Medical Expenditure Survey ($N=23,652$); and the 1996–2012 Medical Expenditure Panel Surveys ($N=21,571$ – $37,418$ per year). These expenditures data include all spending on health care services, including out-of-pocket and insurance payments. We assessed average expenditure trends for each income quintile according to payer (private insurers, out-of-pocket, Medicare, and Medicaid), type of service (inpatient, outpatient, prescription medications, and dental), and self-reported health status in linear regression models. We also examined trends in the distribution of health expenditures by income group using quantile regression.

RESULTS: Per capita inflation-adjusted health expenditures grew from \$785 in 1963 to \$4309 in 2012. In 1963, prior to the introduction of Medicare and Medicaid, respondents in the lowest income quintile had the lowest health expenditures, despite having the worst health status. By 1977 their expenditures were the highest of any quintile, exceeding those for other Americans by 23 %; this pattern persisted until 2004. Since 2004, expenditures have fallen 3 % for the poorest quintile, increased 9 % for the middle three quintiles and increased 15 % for the wealthiest quintile, which now has the highest expenditures (Figure 1). Since 2004, increases in both per-visit costs and the number of visits drove the rapid rise in health spending among respondents in the highest income quintile. Adjusting for age and health status, 2012 per capita expenditures for the wealthiest Americans exceeded those for the poorest quintile by \$1743, or 43 %. The divergence in health spending by income group since 2004 was limited to the under-65 population, with spending growth among the elderly flat across all income groups. These divergent trends were not driven by a very small number of very high cost patients, but by the larger number of respondents who incurred moderate-to-high health expenditures in any given year.

CONCLUSIONS: The post-2004 slowdown in the growth of U.S. health expenditures was concentrated among lower income Americans, indicative of a reallocation of health care resources nationally towards persons with the highest incomes. The wealthy, who report to be the healthiest segment of the population, now make the most healthcare visits and have the highest healthcare expenditures, a pattern not observed since prior to the introduction of Medicare and Medicaid in the 1960s.

Figure 1: Medical spending by income group, adjusted for inflation, 1996–2012

FINANCIAL BARRIERS TO ADULT VACCINE DELIVERY Laura P. Hurley⁴; Megan C. Lindley²; Mandy Allison⁸; Lori A. Crane³; Michaela Brtmikova³; Brenda Beatty⁹; Megan Snow⁶; Carolyn Bridges¹; Allison Kempe⁷. ¹CDC, Atlanta, GA; ²Centers for Disease Control and Prevention, Atlanta, GA; ³Children's Outcomes Research Program, Aurora, CO; ⁴Denver Health, Denver, CO; ⁵University of Colorado Anschutz Medical Campus, Aurora, CO; ⁶University of Colorado Denver, Aurora, CO; ⁷University of Colorado and Children's Hospital Colorado, Aurora, CO; ⁸University of Colorado, Anschutz Medical Campus, Aurora, CO; ⁹University of Colorado, Aurora, CO. (*Tracking ID #2192476*)

BACKGROUND: A prior national survey found many physicians were not knowledgeable about adult vaccine financing in their practice; little is known about specific financial barriers to adult vaccination. The Affordable Care Act (ACA) increased reimbursement for vaccine administration for Medicaid patients to Medicare levels (~\$25) for 2013 and 2014 and mandated that non-grandfathered health plans and plans for the newly eligible beneficiaries of the Medicaid expansion cover Advisory Committee on Immunization Practices recommended vaccines at no cost to patients while encouraging this practice for traditionally-eligible Medicaid beneficiaries. Our objectives were to assess attitudes about adequacy of reimbursement for adult vaccine purchase and administration, frequency of vaccine claim denial, estimated vaccination profit margin under different payers, and whether practices had considered stopping purchasing vaccines due to financial concerns.

METHODS: We administered a telephone survey 12/2013 to 4/2014 to staff that had been identified as knowledgeable about adult vaccine financing on a prior physician survey. Questions were developed jointly with the CDC and modified based on input from advisory committees and pilot testing. Respondents' practices were stratified by size and financial decision-making capacity and quota sampling was conducted to make sure all practice types were represented. Multiple contacts to set up telephone interviews via mail or email were attempted to encourage non-responders to respond.

RESULTS: The response rate was 39 % (104/266). Most respondents were office managers/health administrators (52 %) or billing personnel (25 %). Respondents reported their practices included patients with the following types of insurance: Medicare Part B (100 %), Preferred Provider Organization (99 %), Private Fee for Service insurance (91 %), Managed Care (83 %), Medicare Part D (76 %), and Medicaid (72 %). Respondents reported perceived reimbursement. Medicaid was most often reported to reimburse less than purchase price for vaccines (58 %), followed by Medicare Part B (39 %). Fifty-four percent of respondents reported Medicaid pays less than \$11 for vaccine administration and 79 % reported Medicaid pays less than \$24 for vaccine administration. Sixty-four percent reported Medicare Part B and 48 % reported Medicare Part D pays less than \$24 for vaccine administration. Thirty-seven percent reported Medicaid and Medicare Part B 'frequently' or 'sometimes' deny vaccine claims. Respondents most often reported losing money delivering vaccines to Medicaid patients (55 %). Regarding profit margin for vaccine delivery in recent years, 40 % reported it had stayed the same, 31 % reported it had decreased, 18 % reported it had increased and 11 % reported not knowing how profit margin had changed. Eight percent had stopped and 3 % had seriously considered stopping purchase of one or more vaccines for adults due to financial concerns. The top reasons for stopping or seriously considering stopping were the upfront cost of purchasing vaccines and the inconsistent coverage across insurance plans.

CONCLUSIONS: Practices may benefit from guidance about how to bill for vaccines including how to distinguish Medicare Part B from Medicare Part D vaccines and how to avoid errors that result in vaccine claim denials. Changes in vaccination reimbursement due to ACA may not yet be fully realized in practices, and may be contributing to a continuing financial burden to stock and administer adult vaccines.

GENDER REPRESENTATION IN THE JOHNS HOPKINS UNIVERSITY SCHOOL OF MEDICINE (JHUSOM) LEARNING ENVIRONMENT Madeleine Manka²; Megan S. Orlando²; David M. Levine¹; April S. Fitzgerald¹. ¹Johns Hopkins University, Baltimore, MD; ²Johns Hopkins University School of Medicine, Baltimore, MD. (*Tracking ID #2198808*)

BACKGROUND: At JHUSOM, 50 % of students and over 35 % of faculty are female, yet study data found female student comfort negotiating for oneself, following on a team, and giving negative feedback decreased from matriculation to the end of the preclinical years, while male student comfort with the same skills increased. It is unclear if aspects of the learning environment contribute to this finding. We hypothesized that exposure to female vs. male leaders differs in the preclinical years and might lead to a disparity in gender-concordant role-modeling.

METHODS: We looked at exposure to academic leaders during the preclinical curriculum and examined the AY 2012–2013 1st and 2nd year courses for gender representation among both core and intercession course directors and lecturers. We used t-tests to

evaluate the proportion of female faculty included as lecturers by female vs. male course directors.

RESULTS: Ten percent (3/31) of academic department heads, 0 % (0/4) of heads of learning colleges, 33 % (8/24) of salary-supported advisors, and 25 % (1/4) of deans in the Office of Student Affairs at JHUSOM are women. In core courses, 26 % (9/35) of course directors, 30 % (121/396) of course lecturers, and 23 % (184/789) of course hours were provided by female faculty. Intersections had 55 % (6/11) female directors, 56 % (30/54) female lecturers, and 54 % (41/75) female lecture hours. Female course directors included higher proportions of female lecturers in their courses than did male course directors (48 % vs. 26 %; $p < 0.0001$).

CONCLUSIONS: Female faculty representation among preclinical leaders has not reached parity with the percentage of females on faculty. Interestingly, female course directors included a higher proportion of female lecturers in their courses. Medical students were not directly studied with regard to faculty gender role-modeling, and further investigation is needed to determine if increased exposure to female leader role-models affects female student comfort with leadership skills.

GUIDELINE-CONCORDANT TREATMENT OF HYPERTENSION AT COMMUNITY HEALTH CENTERS COMPARED TO PRIVATE PHYSICIANS' OFFICES IN THE UNITED STATES Vally Fontil^{2, 4}; Kirsten Bibbins-Domingo^{2, 4}; Oanh K. Nguyen³; David Guzman¹; Lauren Goldman². ¹UCSF, San Francisco, CA; ²University of California San Francisco, San Francisco, CA; ³University of Texas Southwestern Medical Center, Dallas, TX; ⁴University of California, San Francisco, CA. (*Tracking ID #2191557*)

BACKGROUND: Hypertension is the most important treatable risk factor for cardiovascular death, yet it is inadequately treated in nearly half of at-risk adults in the U.S. Community health centers (CHCs) provide care to a disproportionate share of vulnerable populations who are at highest risk for uncontrolled hypertension. Though guidelines recommend escalation of pharmacotherapy for those with uncontrolled hypertension and use of fixed-dose combination medications, thiazides, and aldosterone antagonists in resistant hypertension, it is unknown how hypertension treatment at CHCs reflects guideline-concordant therapy compared to private practice.

METHODS: This study is a cross-sectional analysis of all non-pregnant adults with hypertension receiving care at CHCs and private physicians' offices in 2006–2010 National Ambulatory Medical Care Surveys, a probability sample of outpatient visits in the U.S. Our primary outcomes were prescription of new medication for uncontrolled hypertension (blood pressure above 140/90 mmHg); prescription of fixed-dose combination drugs for those on multiple antihypertensive medications; use of thiazide diuretics among patients with uncontrolled resistant hypertension; and use of aldosterone antagonist for resistant hypertension. Analyses were weighted to reflect national estimates. Odds ratios were estimated from logistic regression models adjusted for patient, visit, and practice characteristics. We also tested for interactions between clinic setting and payer in predicting use of fixed-dose combination drugs and prescribing of new medication for uncontrolled hypertension, hypothesizing that individuals with Medicaid would be less likely to receive either of these interventions due to concerns around affordability.

RESULTS: We identified an estimated 496 million patient visits for hypertension to primary care physicians in private practice and 25.4 million visits to CHCs. Patients at CHCs had higher odds of receiving a new medication for uncontrolled hypertension as compared to private physicians' offices (AOR 1.5, 95 % CI 0.9–2.4). Among patients at CHCs, individuals with Medicaid were as likely as privately insured individuals to receive a new medication for uncontrolled hypertension (AOR 1.0, 95 % CI 0.6–1.9). However among patients at private physicians' offices, those with Medicaid were less likely to receive a new medication compared to those with private insurance (AOR 0.4, 95 % CI 0.1–0.7). Patients at CHCs were less likely to be on fixed-dose combination drugs compared to those at private offices (AOR 0.6, 95 % CI 0.4–0.9). There was no difference in thiazide use (adjusted OR 0.7, 95 % CI 0.4–1.5). Aldosterone antagonist use in resistant hypertension was too low in both clinic settings (<3 %) to perform any reliable multivariable regression analysis.

CONCLUSIONS: Compared to private practices, CHCs are more likely to intensify hypertension treatment for patients with Medicaid but less likely to use fixed-dose combination drugs for patients taking multiple medications. Increasing physician use of fixed-dose combination drugs may be helpful in improving hypertension control, particularly in CHCs where there are higher rates of uncontrolled hypertension.

HIV TESTING AMONG PATIENTS WITH CANCER BEFORE INITIATION OF CHEMOTHERAPY Jessica P. Hwang¹; Bruno Granwehr¹; Harrys Torres¹; Maria Suarez-Almazor¹; Thomas Giordano²; Andrea Gabriela Barbo¹; Heather Lin¹; Michael Fisch¹; Elizabeth Chiao². ¹MD Anderson Cancer Center, Houston, TX; ²Baylor College of Medicine, Houston, TX. (*Tracking ID #2198882*)

BACKGROUND: The Centers for Disease Control and Prevention (CDC) and the US Preventive Services Task Force recommend routine opt-out HIV testing for persons aged 13 to 65 years. In patients with cancer, routine HIV testing is warranted because it has the potential to improve patient outcomes; however, the rates of HIV testing and infection among patients with cancer at the initiation of systemic chemotherapy are unknown.

METHODS: Retrospective cohort study of adult patients with cancer who registered at a comprehensive cancer center from January 1, 2004, through April 30, 2011, and received systemic chemotherapy. We identified rates of HIV-1/2 and/or Western blot testing and HIV positivity at the initiation of cancer therapy. Multivariable logistic regression was used to determine the predictors of HIV testing among patients with AIDS-defining (non-Hodgkin lymphoma [NHL], cervical cancer) and non-AIDS-defining cancers.

RESULTS: A total of 18,874 patients with cancer received chemotherapy during the study period. Of these, 3514 patients (18.6 %) were tested for HIV at the initiation of chemotherapy. The rate of HIV testing was similar among patients 65 years of age or younger (19.5 %) and patients older than 65 years (15.8 %). The prevalence of positive HIV test results among tested patients was 1.2 % (41/3514). The rate of HIV testing was lower in Black patients than in White patients (13.7 vs 19.2 %), but the prevalence of positive HIV test results was higher in Black patients (4.5 %) than in any other racial/ethnic group. Among patients with AIDS-defining cancers, history of NHL, history of sexually transmitted disease, and registration after publication of the 2006 CDC recommendations were significant predictors of HIV testing. Among patients with non-AIDS-defining cancers, the latter 2 factors also predicted HIV testing as did younger age, male sex, history of illicit drug use, and having a hematologic malignancy while Black patients had 30 % lower odds of HIV testing than White patients.

CONCLUSIONS: The prevalence of HIV infection was high among patients with cancer. Our study supports HIV testing in patients with cancer before initiation of chemotherapy. For patients with HIV and cancer, co-management of care by internists and oncologists would allow personalized HIV and cancer care planning and potentially improve clinical outcomes.

IDENTIFYING THE TRAINING AND SUPPORT NEEDS OF VOLUNTEER LAY HEALTH ADVOCATES: A FOCUS GROUP STUDY *Rebeca Rios¹; Margaret Haroth²; Joan Kub³. ¹Johns Hopkins School of Medicine, Baltimore, MD; ²Johns Hopkins Medicine, Baltimore, MD; ³Johns Hopkins School of Nursing, Baltimore, MD. (Tracking ID #2199139)*

BACKGROUND: The use of peer support has emerged as a promising strategy to improve disparities in chronic disease outcomes among racial minority and economically disadvantaged groups. These models train lay individuals (as lay health advisors, community health workers, etc.) to provide self-management support and linkage to community resources, and have demonstrated improvements in reducing health risks and improving chronic disease outcomes. Within faith institutions and other community institutions, individuals trained as lay health leaders are often volunteers. Given the efficacy and proliferation of peer support models, surprisingly little research has addressed the training and support needs of lay health leaders. As a valuable source of human capital and important partner to address community health needs, it is important to develop effective training and support models to meet the needs of lay health leaders. Using focus groups, this study sought to identify the perceived successes, challenges and training and support needs of trained, congregation-based lay health advocates.

METHODS: The LHA program is a 6-week training that covers learn principles and skills to provide self-management support to individuals with chronic diseases. Skills include guidance to effectively engage in health care, support for health behavior change and adherence to medical recommendations, and linkage to community resources. We recruited key stakeholders involved with our Lay Health Advocate (LHA) program, a training program offered through a medical-religious partnership with local faith institutions. We invited individuals to participate who were members of faith community partner organizations and who had trained as LHAs, or who were identified as key stakeholders involved with health advocacy activities within the partnering congregations. We recruited 18 individuals who participated in one of 3 focus groups, each lasting 1 h, 45 min. Mean age of participants was 54 years, and 78 % ($n=14$) were female. The majority (78 %; $n=14$) of participants had taken the LHA training and were African American ($n=10$; 56 %); 8 were White (44 %). 8 (44 %) represented Protestant churches, 8 (44 %) represented Catholic churches, and 2 (11 %) represented other religious traditions. Participants represented 9 churches, the majority of which (67 %) were located in geographic areas designated as medically underserved. Trained study team members moderated the discussions and digitally audio-recorded the groups. Recordings were transcribed verbatim and independently coded by two investigators to identify and group comments into categories with discrete themes. A third investigator adjudicated discrepancies in theme assignments. In order to add confidence to the validity of the findings, we used a process for member checking by inviting commentary from participants on the accuracy of a draft of the thematic codes generated in the analysis.

RESULTS: Consistent themes related to perceived benefits of lay health advocate activities were (1a) the ability to address spiritual and physical health holistically, (1b) provision of social support, (1c) facilitating self-efficacy for health, and (1d) enhancing existing health ministries. Challenges were categorized as (2a) navigating relational and role boundaries, (2b) challenging church policies, and (2c) social stigma. Essential sources of support were categorized into (3a) church leadership support, and (3b), ongoing peer support.

CONCLUSIONS: LHAs have the strong potential to extend needed health information and self-management support to racial and ethnic minority and low income communities. Partnerships with faith institutions to train lay health leaders offer a promising strategy, yet adequate infrastructure and ongoing support for volunteer leaders should be given careful attention. Such support should include ongoing peer support and strategies to promote clergy leadership support for health advocacy. We will use results of this study to develop models for training and support of volunteer lay health leaders.

IMPACT OF CASE MANAGEMENT ON FREQUENT USERS' QUALITY OF LIFE: A RANDOMIZED CONTROLLED TRIAL *Katia Iglesias^{6, 2}; Karine Moschetti^{1, 7}; Stéphanie Baggio³; Venetia - Sofia Velonaki²; Ornella Ruggeri⁵; Olivier Hugli⁴; Bernard Bumand²; Jean-Blaise Wasserfallen²; Jean-Bernard Daeppen²; Patrick Bodenmann². ¹University of Lausanne, Lausanne, Switzerland; ²Lausanne University Hospital, Lausanne, Switzerland; ³Lausanne University, Lausanne, Switzerland; ⁴Lausanne university hospital, Lausanne, Switzerland; ⁵University Hospital of Lausanne (CHUV), Lausanne, Switzerland; ⁶University of Neuchâtel, Neuchâtel, Switzerland; ⁷Lausanne University Hospital, Lausanne, Switzerland. (Tracking ID #2197194)*

BACKGROUND: Frequent emergency department users represent a small number of patients but account for a large number of emergency department visits. They should be a focus because they are often vulnerable patients with many risk factors affecting their quality of life (QoL). Case management interventions have resulted in a significant decrease in emergency department visits, but association with QoL has not been assessed. One aim of our study was to examine to what extent an interdisciplinary case management intervention, compared to standard emergency care, improved frequent emergency department users' QoL.

METHODS: Data are part of a randomized, controlled trial designed to improve frequent emergency department users' QoL and use of health-care resources at the Lausanne University Hospital, Switzerland. In total, 250 frequent emergency department users (≥ 5 attendances during the previous 12 months; ≥ 18 years of age) were interviewed between May 2012 and July 2013. Following an assessment focused on social characteristics; social, mental, and somatic determinants of health; risk behaviors; health care use; and QoL, participants were randomly assigned to the control or the intervention group ($n=125$ in each group). The final sample included 194 participants (20 deaths, 36 dropouts, $n=96$ in the intervention group, $n=99$ in the control group). Participants in the intervention group received a case management intervention by an interdisciplinary, mobile team in addition to standard emergency care. The case management intervention involved four nurses and a physician who provided counseling and assistance concerning social determinants of health, substance-use disorders, and access to the health-care system. The participants' QoL was evaluated by a study nurse using the WHOQOL-BREF five times during the study (at baseline, and at 2, 5.5, 9, and 12 months). Four of the six WHOQOL dimensions of QoL were retained here: physical health, psychological health, social relationship, and environment, with scores ranging from 0 (low QoL) to 100 (high QoL). A linear, mixed-effects model with participants as a random effect was run to analyze the change in QoL over time. The effects of time, participants' group, and the interaction between time and group were tested. These effects were controlled for socio-demographic characteristics and health-related variables (i.e., age, gender, education, citizenship, marital status, type of financial resources, proficiency in French, somatic and mental health problems, and behaviors at risk).

RESULTS: Participants were 45.5 (SD=17.9) years old on average; 56 % were men; 50 % Swiss, 18 % European, and 32 % non-European; 43 % were beneficiaries of social welfare; 69 % suffered from somatic health problems and 50 % from mental health problems; and 32 % had at-risk behaviors. Levels of QoL were on average 54.1 (SD=15.0) for physical health, 54.1 (SD=17.3) for psychological health, 58.2 (SD=24.8) for social relationship, and 58.9 (SD=20.8) for environment (with no significant differences between control and intervention groups at baseline). Multivariate models showed an improvement in QoL for the 4 dimensions (physical health: $b=8.1$, $p<0.001$; psychological health: $b=9.5$, $p<0.001$; social relationship: $b=13.9$, $p<0.001$; environment: $b=10.1$, $p<0.001$) on both groups. Moreover, this improvement was significantly greater for the intervention group concerning the environment element ($b=6.2$, $p=0.016$). No other interactions were significant.

CONCLUSIONS: The case management intervention was accompanied by some improvement in frequent emergency department users' QoL, with a significant positive effect on environment—a dimension composed of items such as physical safety and security,

financial resources, and access to health-care. This result shows the success of case management in this context as the approach essentially aims to improve these aspects by providing assistance in obtaining income entitlements, health insurance coverage, stable housing, and schooling for children, and in preventing potential domestic violence and finding general practitioners or specialists. However, overall, QoL improved over time even without the intervention of the mobile team. One possible explanation could be that being a frequent emergency department user is a transient state associated with vulnerability and with a decrease in QoL, and that adaptation to this condition tends to return QoL to its initial level. A second, more plausible, explanation is that although the control group did not receive a "real" intervention per se, a study nurse contacted participants regularly to ask them about their QoL, which could have created social bonds and generally increased QoL. In terms of policy implications, this study shows that case management may improve environment QoL, and suggests that this dimension is most suitable for short-term interventions.

IMPACT OF HYPONATREMIA CORRECTION ON THE RISK OF 30-DAY READMISSION AND DEATH IN PATIENTS WITH CONGESTIVE HEART FAILURE Jacques Donze^{2,1}, Patrick E. Beeler^{1,4}, David W. Bates^{1,3}. ¹Brigham and Women, Boston, MA; ²Bern University Hospital, Bern, Switzerland; ³Harvard Medical School, Boston, MA; ⁴University Hospital Zurich, Zurich, Switzerland. (Tracking ID #2190632)

BACKGROUND: Hyponatremia has been shown to be associated with worse outcomes in patients with heart failure. There are however conflicting findings regarding its prognostic value for readmission in patients with heart failure, and in particular whether or not correction of a low sodium level at admission affects the risk of readmission and death. We assessed whether correction of a low sodium level during a hospital stay impacted on the risk of 30-day unplanned readmission and death in patients with congestive heart failure, as compared to patients who did not have their sodium level corrected before discharge.

METHODS: We performed a retrospective study on adult patients admitted with a diagnosis of congestive heart failure between July 2003 and October 2009 at a tertiary-care hospital in Boston, MA. We restricted the analysis to those presenting with hyponatremia at admission. We captured the sodium level at admission and discharge to measure the difference between both. The exposure was categorized in 2 groups: 1) hyponatremia at admission without correction during the hospitalization, defined as a sodium level of less than 135 mmol/l both at admission and discharge; 2) hyponatremia at admission with correction during the hospitalization, defined as a sodium level at admission of less than 135 mmol/l, but 135 mmol/l or more at time of discharge. The primary outcome of interest was a composite of 30-day unplanned readmission or death. The secondary outcome was any 30-day unplanned readmission without death. We performed a multivariable logistic regression to evaluate the effect of hyponatremia correction on the outcome.

RESULTS: Among the 4295 eligible patients with hyponatremia at admission, 1799 (41.9%) did not have their hyponatremia corrected before discharge, over a median length of stay of 6 (IQR 3–9). Overall, 1269 (29.6%) patients had a 30-day unplanned readmission or died. In a multivariable logistic regression analysis, the absence of hyponatremia correction was associated with a 46% increase in the odds of having a 30-day unplanned readmission or death (odds ratio 1.46 [95%CI 1.27–1.67]; Table). The odds ratio for specifically any 30-day unplanned readmission was 1.35 (95%CI 1.17–1.57).

CONCLUSIONS: The absence of correction of hyponatremia over the course of hospitalization is frequent and associated with an increase of nearly 50% in the odds of having a 30-day unplanned readmission or death. This may or may not be causal as there is almost certainly confounding by severity of illness, but absence of correction is strongly correlated with a worse outcome.

Comparison of 30-day unplanned readmission and death between patients with and without hyponatremia correction

Variable	Odds ratio	95 % Confidence Interval
Persistent hyponatremia	1.46	1.27–1.67
Age, per additional year	1.00	1.00–1.01
Female vs. male	1.13	0.98–1.30
Race		
White	reference	
Black	1.31	1.06–1.61
Hispanic	1.32	1.00–1.73
Other	1.24	0.79–1.94
Number of admissions in the last 6 months, per additional admission	1.30	1.24–1.36
Unplanned vs. elective index admission	1.86	1.44–2.39

(continued)

Length of stay, per additional day	1.01	1.00–1.01
Atrial fibrillation	1.07	0.92–1.24
Ischemic heart disease	0.86	0.74–0.99
Cancer	1.85	1.56–2.20
COPD	1.02	0.85–1.22
Diabetes	1.12	0.96–1.30
Chronic kidney disease	1.03	0.87–1.24

IMPACT OF THE 2008 USPSTF RECOMMENDATIONS ON CLINICIANS' PRACTICE FOLLOWING AN ELEVATED PSA TEST IN ELDERLY MEN

Sami Ibrahim⁵, Fadi Alkhatib⁵, Shin Yin Lee⁴, Jennifer Friderici¹, Michael B. Rothberg³, Janice Fitzgerald², Mihaela S. Stefan⁵. ¹Baystate Health System, Springfield, MA; ²Baystate Medical Center, Springfield, MA; ³Cleveland Clinic, Cleveland, OH; ⁴Boston University, Boston, MA; ⁵Baystate Medical Center/Tufts Univ. School of Medicine, Springfield, MA. (Tracking ID #2195183)

BACKGROUND: Prostate specific antigen (PSA) for prostate cancer screening remains controversial. In 2008, the United States Preventive Services Task Force (USPSTF) published a statement recommending against screening for prostate cancer in men aged 75 years or older. Since then, 2 studies have shown a decrease in PSA testing frequency in this age group. It is unknown however, whether the 2008 recommendations had any impact on clinicians' approach following an elevated PSA level in elderly men.

METHODS: We performed a retrospective cohort study and structured data abstraction of patients 65 years or older with an elevated PSA test (≥ 4 ng/ μ l), seen at one of 15 community-affiliated primary care practices in Western MA between 1/1/06 and 12/31/10. Patients with an abnormal PSA result in the prior year or with a prior diagnosis of prostate cancer were excluded. A stratified random sample was selected to yield the following study groups of equal sizes ($n=75$ each or 300 total): age $\geq 75+$ and 65 to 75, and into 2 time periods: before and after the USPSTF 2008 recommendations. The primary outcome was PSA retesting frequency within a 12 month follow up period after the first abnormal PSA. Secondary outcomes included (yes vs. no) prostate biopsy, urology referral, prostatectomy and other modalities of therapy including radiation therapy, chemotherapy and hormone treatment. Each outcome was analyzed using multiple logistic regression with an age-group by study period interaction term (criterion p -value for stratification ≤ 0.20). Two-sided p -values of 0.05 were used to determine statistical significance for remaining comparisons. All analyses were performed in Stata 13.1 (© 2014 StataCorp LP, Union Station, TX)

RESULTS: Three-hundred records were abstracted. The average age was 74.7 years (SD 7.0); most patients (82%) were White; (7%) were Black and (5%) were Hispanic. Patient characteristics were similar between pre- and post study periods. The proportion of patients who underwent confirmatory testing decreased slightly in men aged ≥ 75 after the guidelines (53% pre vs. 47% post, $p=0.34$), but increased slightly among men aged <75 (68% vs. 76%, $p=0.28$). The difference in the intervention effect on this outcome achieved borderline significance (difference of 15 percentage points, $p<0.10$). Among those with a confirmatory test, the proportion of patients referred to urologist increased dramatically in both age groups (age ≥ 75 : 35% pre vs. 74% post, $p=0.001$; age 65 to 75: 51% pre vs. 86% post, $p<0.001$); this increase was similar between both groups (difference of 4 percentage points, $p=0.79$). Similar large increase in biopsy rates were noted in both age groups (age $75+$: 8% pre vs. 42% post, $p=0.005$; age <75 : 23% pre vs. 42% post, $p=0.002$). (Difference of 8 percentage points, $p=0.53$). The number of patients receiving prostatectomy, chemotherapy or radiation therapy was small.

CONCLUSIONS: Among patients with an elevated PSA test, the guidelines had no impact on the frequency of repeat PSA testing to confirm result. More patients were referred to urology and underwent biopsy in both age groups after the guidelines.

IN-HOSPITAL COMMUNICATION PREFERENCES AMONG INTERNAL MEDICINE RESIDENTS: EASE OF USE VS. PRIVACY? Micah T. Prochaska², Amber Bird², Amar R. Chadaga³, Vineet M. Arora¹. ¹University of Chicago, Chicago, IL, IL; ²University of Chicago, Chicago, IL; ³Advocate Christ Medical Center, Chicago, IL. (Tracking ID #2199026)

BACKGROUND: Mobile technology (smartphones and tablets) has been shown to improve physician efficiency and providers perceive it to improve inpatient communication. Short message service text messaging (texting) is one form of communication using mobile technology that is easy to use, accessible, and allows for the rapid and direct transfer of clinical information between providers. Therefore, texting has become pervasive in healthcare and is preferred for in-hospital communication between providers,

compared to a traditional in-hospital paging system. Yet, texting is discouraged by the Joint Commission for security reasons, and there are concerns about its HIPAA compliance and ability to protect confidential patient health information when used on personal mobile devices. Currently, it is unclear if inpatient providers share these security concerns and how they may affect providers' preferred method of communicating with other inpatient providers. Therefore, our study aimed to compare internal medicine residents' preferences for texting versus other available in-hospital communication modalities when considering efficiency, ease of use, and security. Additionally, we sought to determine residents' experiences and perceptions of receiving confidential patient information through texting.

METHODS: A cross-sectional survey of internal medicine residents at two academic medical centers during the 2013–2014 academic year. Residents at both institutions were provided iPads through their training programs, and were instructed to use only approved secured applications on the iPad for patient care activities. At both institutions the standard mode of communication between providers was the hospital paging system with a telephone call back. Residents were asked to rank on a four-point Likert scale their preferred form of communication when considering efficiency, the ease of use, and the security of the communication modality. Responses were dichotomized to represent either “preferred” or “not preferred”. Communication options included telephone, email, alphanumeric text (hospital) paging system, and texting. Respondents were also asked to report whether they had received confidential patient identifiers (name, patient initials, or medical record numbers) through any of the above modalities. Descriptive statistics were used to summarize the results.

RESULTS: The overall response rate was 76 % (132/173). For overall efficiency 72 % (94/131) of respondents preferred texting, while 80 % (103/129) of respondents reported texting to be their preferred communication modality with respect to ease of use when communicating with other providers (Fig 1). In comparison, 36 % (46/129) of respondents preferred the current hospital paging system for ease of use when communicating with other providers. However, 83 % (104/126) of respondents rated the hospital paging system their preferred form of communication for security, while only 21 % (26/126) of respondents preferred texting for secure communication. Despite the security concerns of texting, 71 % (93/131) of respondents reported having received protected patient identifiers including a patient's first and/or last name through text messages. Many [82 % (107/131)] reported receiving patient initials through text messages, and half [50 % (66/131)] reported receiving a patient's medical record number through text messages. Responses did not vary by site.

CONCLUSIONS: Our data demonstrates that texting is preferred for in-hospital communication when considering efficiency and ease of use, but that providers are also aware of and concerned about its security. Interestingly, despite concerns about security, a large majority of residents reported receiving confidential patient information through text messaging. One possible explanation is that for providers the benefits of improved in-hospital communication with texting, and any presumed improvements in the coordination and delivery of care for patients, outweigh security concerns they may have. However, inpatient providers, patients, and even health systems may differ on what is an acceptable standard for texting or any new inpatient technology that improves communication or care, at some potential cost to security. As a two-institution study our results may not be generalizable, but they do highlight that there is an important role for the education and training of providers on how HIPAA applies to new mobile technology. Additionally, our findings suggest a tension providers face when communicating, in that texting is ubiquitous, efficient, and may improve care, but at some potential cost to securing patient data appropriately. In the future solutions should be sought that ensure the security and HIPAA compliance of mobile technology, without compromising efficiency and ease of use.

INCIDENCE OF CONVERSION TO ACTIVE WAITLIST STATUS AMONG TEMPORARILY INACTIVE TRANSPLANT CANDIDATES FROM LINGUISTICALLY ISOLATED COMMUNITIES Efrain Talamantes¹; Keith Norris; Carol Mangione; Amy Wateman; John D. Peipert; Suphamai Bunnapradist; Edmund Huang. University of California, Los Angeles, CA. (Tracking ID #2199541)

BACKGROUND: One of the barriers to kidney transplantation occurs at the level of the waitlist, where temporarily inactive candidates cannot receive deceased donor organ offers. We hypothesized that candidates living in linguistically-isolated communities would be less likely to achieve active status.

METHODS: Using Organ Procurement and Transplantation Network/United Network for Organ Sharing data merged with five-digit zip code socioeconomic data from the 2000 U.S. Census, competing risks methods were performed to determine the cumulative incidence of conversion to active status (activation), death, and delisting before conversion among 84,783 adult kidney candidates designated temporarily inactive on the transplant waiting list from 2004 to 2012. Multivariate logistic regression and Fine and Gray competing risks regression were performed to characterize the association between linguistic isolation, incomplete transplantation evaluation, and conversion to active status. The U.S. Census defines a linguistically isolated household as one in which all members 14 years of age and over speak a non-English language and also speak English less than “very well.”

RESULTS: At 8 years, the cumulative incidence of activation was 74.3 %, of death before conversion was 9.7 %, and of delisting was 13.4 %. The most commonly recorded initial reason for inactive status was “candidate work-up incomplete” (54.5 %). Compared to zip codes with <1 % linguistically-isolated households, candidates in zip codes with higher percentages had significantly higher odds of incomplete evaluation: 1 to 5 %, adjusted odds ratio [AOR]=1.07, 95 % CI 1.00–1.14; 5 to 10 %, AOR=1.16, 95 % CI 1.09–1.24; 10 to 20 %, AOR=1.29, 95 % CI 1.20–1.39; ≥20 % AOR=1.38; 95 % CI 1.27–1.50). After adjusting for demographic characteristics, co-morbid conditions, and socioeconomic variables candidates living in zip codes with increasing percentages of linguistically isolated households were strongly associated with decreasing subhazards of activation: 1 to 5 %, sHR 0.89 (0.87–0.92), 5 to 10 %, sHR: 0.84; 0.81–0.87, 10 to 20 %, sHR: 0.77; 0.74–0.79, ≥20 %, sHR: 0.73; 0.70–0.76, versus <1 % linguistically isolated households.

CONCLUSIONS: Our findings indicate that linguistic isolation is strongly associated with failure to complete candidate evaluations and negatively associated with achievement of active waitlist status. This study suggests that candidates living in linguistically-isolated communities may require improved levels of communication from providers to facilitate conversion to active waitlist status.

INCIDENCE OF GENITAL MYCOTIC INFECTIONS DECREASES OVER TIME IN OLDER PATIENTS WITH TYPE 2 DIABETES MELLITUS TREATED WITH CANAGLIFLOZIN Michael Davies¹; Pamela Kushner²; Ujjwala Vijapurkar³; Gary Meisinger³. ¹Janssen Scientific Affairs, LLC, Raritan, NJ; ²University of California, Irvine, CA; ³Janssen Research & Development LLC, Raritan, NJ. (Tracking ID #2197721)

BACKGROUND: Patients with type 2 diabetes mellitus (T2DM) are at increased risk of genital mycotic infections (GMIs), and those with poorly controlled diabetes have higher risks. Sodium glucose co-transporter 2 inhibitors, such as canagliflozin (CANA), improve glycemic control by inhibiting renal glucose reabsorption and increasing urinary glucose excretion, a mechanism of action associated with an increased incidence of GMIs. This analysis evaluated the incidence of GMIs over time in older patients with T2DM treated with CANA.

METHODS: In a double-blind, Phase 3 clinical study, patients aged ≥55 to ≤80 years and inadequately controlled with their current treatment regimen ($N=714$) were randomized to receive CANA 100 mg or 300 mg, or placebo (PBO). The incidence of GMIs was monitored over 2 years, and evaluated overall and at 3-monthly intervals in women and men.

RESULTS: The cumulative incidence of GMIs was higher with CANA 100 mg and 300 mg versus PBO in women (23.9 % and 18.7 % vs 4.3 %) and men (5.6 % and 10.9 % vs 1.4 %). The largest number of events occurred within 6 months of treatment initiation and declined with time (Figure). Between Months 0–3, the incidence of GMIs with CANA 100 mg and 300 mg was 12.8 and 9.3 %, respectively, in women; and 3.2 and 3.9 %, respectively, in men. Between Months >12–15, the incidence of GMIs decreased to 3.0 and 2.4 % with CANA 100 mg and 300 mg, respectively, in women; and 0.9 and 0 %, respectively, in men. GMIs were characterized by investigators as generally mild to moderate in intensity and responded to standard treatment. The most commonly reported female and male GMIs were vulvovaginal mycotic infection and balanoposthitis, respectively. Of the CANA-treated patients, 1.2 % of men and 1.3 % of women discontinued treatment for a GMI versus 0 % on PBO.

CONCLUSIONS: The results of this analysis indicate that, in older patients with T2DM treated with CANA, the risk of GMIs with CANA use is increased mostly early after

treatment initiation. Most GMIs were mild to moderate in intensity and responded to standard treatment.

Incidence of GMIs in older female and male patients with T2DM treated with CANA 100 mg and 300 mg over 2 years

INCORPORATION OF GUIDELINE DATA INTO ORDERING SYSTEMS REDUCES TRANSTHORACIC ECHOCARDIOGRAPHY ORDER FREQUENCY

Joel C. Boggan^{1, 2}; Ryan D. Schulte^{1, 2}; Mark Donahue¹; David L. Simel^{1, 2}. ¹Durham Veterans Affairs Medical Center, Durham, NC; ²Duke University Health System, Durham, NC. (Tracking ID #2191290)

BACKGROUND: Guidance for appropriate utilization of transthoracic echocardiograms (TTEs) is available from several sources. At Durham Veterans Affairs Medical Center, approximately 50 % of ordered TTEs are ordered for the indications of dyspnea, edema, and/or valvular disease. We hypothesized that increasing the information available for these indications at the point of order would lead to a reduction in TTEs ordered.

METHODS: We incorporated data from the 2011 Appropriate Use Criteria for Echocardiography, the 2010 National Institute for Clinical Excellence Guideline on Chronic Heart Failure, and the American College of Cardiology Choosing Wisely® list on TTE use for dyspnea, edema, and valvular disease into our electronic ordering system as a quality improvement intervention beginning in September 2013. The primary outcome was the number of TTE orders per month from both the inpatient and outpatient settings modeled using Poisson regression. Secondary outcomes included rates of outpatient TTE ordering per 100 visits and frequency of brain natriuretic peptide (BNP) level ordering in the 30 days prior to TTE ordering. Outcomes were measured for 20 months before and 12 months after the intervention. Ordering rates for TTEs and BNP tests were obtained using the electronic health record.

RESULTS: The number of TTEs ordered across the medical center decreased significantly by 5.3 % after the intervention (338 ± 32 TTEs/month prior vs. 320 ± 33 afterward, $p < 0.01$). Rates of TTE ordering in the outpatient setting also decreased significantly post-intervention (2.28 per 100 primary care or cardiology visits prior vs. 1.99 afterward, $p < 0.01$). Over the same period, outpatient primary care and cardiology clinic visits at DVAMC increased by 10.7 % from fiscal year 2012 to fiscal year 2014. Thus, in fiscal year 2014, the reduced rate means that >300 TTEs were avoided. The intervention significantly interacted with the time from the intervention ($p < 0.01$ for both TTE orders and outpatient TTE orders/visit), as the effect of the intervention partially waned over time. BNP measurement prior to ordering TTEs increased modestly after the intervention (21.8 % prior to intervention vs. 26.1 % after, $p < 0.01$). This was true for TTEs ordered from both the inpatient and outpatient settings (36.5 % prior vs. 42.2 % after in the inpatient setting, $p = 0.01$; 10.8 % prior vs. 14.5 % after in the outpatient setting, $p < 0.01$).

CONCLUSIONS: Incorporation of evidence-based guideline information into ordering prompts for TTEs throughout a VA hospital and its associated clinics led to improved adherence to guidelines with reduced ordering frequency and a significant increase in the frequency of TTEs linked to a prior BNP test. As the immediate effect of the intervention decayed with time, long-term educational strategies may be necessary to optimize utilization of TTEs.

UCL = Upper Control Limit, equal to +3 standard deviations from the mean

CL = Center Line, or mean

LCL = Lower Control Limit, equal to -3 standard deviations from the mean

*Fiscal Year 2012 corresponds to October 2011 through September 2012, Fiscal Year 2013 corresponds to October 2012 through September 2013, and Fiscal Year 2014 corresponds to October 2013 through September 2014. The separating space in the graph indicates the time of the intervention.

INTEREST IN SMOKING CESSATION RELATED TO A SMOKE-FREE POLICY AMONG HOMELESS ADULTS

Maya Vijayaraghavan^{1, 2}; John Pierce^{1, 2}. ¹University of California, San Diego, San Diego, CA; ²Division of Health Policy, San Diego, CA. (Tracking ID #2192798)

BACKGROUND: The prevalence of smoking in the homeless population is 70 %, almost 5 times the general population. The high rates of tobacco use and its associated morbidity and mortality highlight an urgent need for specific tobacco control interventions in the homeless population. Smoke-free policies are an effective population-based strategy to reduce exposure to secondhand smoke among non-smokers and reduce smoking behaviors among smokers. Few studies have explored the potential of smoke-free policies as facilitators of smoking cessation or harm reduction among sheltered homeless adults.

METHODS: We focused on clients of a homeless shelter in San Diego, California. The facility prohibited smoking indoors and outdoors within 5 blocks of the building, and permitted smoking during 4 daily smoking breaks in designated smoking zones away from the building. Staff were not permitted to smoke with clients. Shortly after policy implementation, we interviewed current and former smokers on their smoking behaviors, perceived norms around smoking, and attitudes to smoke-free policies in the facility. Participants reported their level of agreement or disagreement to statements that described the facility's norms around smoking and smoke-free policies.

RESULTS: Of the 170 ever smokers, 75.3 % were current smokers. The average daily cigarette consumption was 6.6 cigarettes per day (SD 4.3). More than half (57.8 %) attempted to quit smoking in the past year, with the average length of quit attempt being 45 days. One-third (33.6 %) of the current smokers reported having used nicotine replacement therapy and 12.5 % used medications in a prior quit attempt. Of the 128 current smokers, less than 15 % agreed that staff offered them cigarettes or smoked with them during smoking breaks. Two-thirds of the current smokers reported never smoking in an area where smoking was prohibited in the past month. Of the current smokers, three-fourths agreed that the facility policies were associated with their reduced consumption, and about half agreed that the policies were associated with either making a quit attempt or getting ready to quit completely. Less than 10 % reported that they would be unhappy to stay in the facility because of the policies. Sixty percent agreed that further restrictions on smoking, beyond the current policies, would be associated with increased interest in quitting smoking completely. Of the 42 former smokers, 30.9 % reported quitting after entering the facility, and of these, about half reported that the facility policies were part or

the main reason for quitting smoking. Almost all current smokers (88.3 %) and former smokers (97.6 %) agreed that smoke-free policies were important because they offered a clean and safe living environment.

CONCLUSIONS: Findings suggest that smoke-free policies may not influence occupancy rates in shelters serving clientele with high rates of cigarette smoking. The facility's policies on smoking were associated with reduced consumption and increased interest in smoking cessation among homeless adults. Thus, establishing a tobacco control program that includes smoke-free policies and resources for cessation may facilitate successful cessation among sheltered homeless adults.

INTERNATIONAL MULTICENTER VALIDATION OF THE "HOSPITAL" SCORE TO PREDICT 30-DAY POTENTIALLY AVOIDABLE READMISSIONS IN MEDICAL PATIENTS Jacques Donze^{6, 1}; Mark Williams⁷; Edmondo Robinson²; Eyal Zimlichman⁸; Drahomir Aujesky⁶; Eduard E. Vasilevskis⁵; Sunil Kripalani⁵; Joshua Metlay³; Tamara Wallington⁹; Grant Fletcher¹⁰; Andrew D. Auerbach⁴; Jeffrey L. Schnipper¹. ¹Brigham and Women's Hospital, Boston, MA; ²Christiana Care Health System, Wilmington, DE; ³Massachusetts General Hospital, Boston, MA; ⁴UCSF Division of Hospital Medicine, San Francisco, CA; ⁵Vanderbilt University, Nashville, TN; ⁶Bern University Hospital, Bern, Switzerland; ⁷University of Kentucky, Lexington, KY; ⁸Sheba Medical Centre, Tel HaShomer, Israel; ⁹William Osler Health System, Brampton, ON, Canada; ¹⁰Harborview Medical Center, Seattle, WA. (Tracking ID #2191115)

BACKGROUND: Efficiently improving transitions in care requires hospitals to target discharge interventions at those patients at high risk of potentially avoidable readmission. We previously derived the "HOSPITAL" score, an easy to use prediction model for medical patients (Table 1). This score had good discrimination for determining potentially avoidable readmissions in the hospital in which it was derived (C-statistic of 0.71). To assess its generalizability, we aimed to externally validate the "HOSPITAL" score in an international multicenter study.

METHODS: We applied the score to 124,212 adult patients consecutively discharged alive from the medical departments of 6 medical centers in the US, 1 in Israel, 1 in Canada, and 1 in Switzerland, between January and December, 2011. The outcome was any 30-day readmission that was classified as potentially avoidable using the previously validated SQLape algorithm. By comparing mainly ICD-9 codes from the two hospitalizations,

SQLape excludes elective readmissions, foreseen readmissions such as chemotherapy, and readmissions for new diseases unknown during the preceding hospital stay unless a known complication of previously received treatment. The performance of the score was evaluated according to its discrimination (C-statistic, representing the area under the ROC curve) and its calibration (based on the Pearson goodness-of-fit statistic).

RESULTS: Among all patients in the cohort, the potentially avoidable readmission rate was 9.5 % (overall 30-day readmission rate was 14.5 %). The discriminatory power of the "HOSPITAL" score to predict potentially avoidable readmission was good with a C-statistic of 0.72 (95 % CI 0.71–0.72). As in the derivation study, patients were classified into 3 risk categories: low (63 %), intermediate (23 %), and high risk (14 %). The estimated proportions of potentially avoidable readmission for each risk category matched exactly the observed proportion, with a consequent excellent calibration ($p=0.97$, with high p values indicating better fit; Table 2).

CONCLUSIONS: The "HOSPITAL" score identified patients at high risk of 30-day potentially avoidable readmission with high discrimination when applied to a large international multicenter cohort of medical patients. The "HOSPITAL" score is the first score to focus on potentially avoidable (as opposed to all-cause) readmissions, using readily available predictors at the time of discharge, and that is externally validated in a large cohort in 4 different countries. This score has the potential to easily identify patients in need of more intensive transitional care interventions to prevent avoidable hospital readmissions.

Table 1. 'HOSPITAL' Score for 30-day Potentially Avoidable Readmissions

Attribute	Points
Low Hemoglobin level at discharge (<12 g/dL)	1
Discharge from an Oncology service	2
Low Sodium level at discharge (<135 mmol/L)	1
Procedure during hospital stay (any ICD-9 coded procedure)	1
Index admission Type: non-elective	1
Number of hospital Admission(s) during the previous year	
≤ 1	0
2–5	2
>5	5
Length of stay ≥5 days	2

Maximum=13 points

Table 2. Observed vs. Predicted 30-day Potentially Avoidable Readmissions (PAR)

Points	Risk category	Patients in each category, n (%)	Observed proportion of PAR in the derivation study, %	Observed proportion of PAR in the validation study, %	Estimated risk of PAR in the validation study, %
0–4	Low	77,896 (63 %)	5.4	5.8	5.8
5–6	Intermediate	29,239 (23 %)	9.0	11.8	11.8
≥7	High	17,077 (14 %)	18.7	22.4	22.4

PAR: potentially avoidable readmission

LOW RATES OF HIV PRE-EXPOSURE PROPHYLAXIS (PREP) AND NON-OCUPATIONAL POST-EXPOSURE PROPHYLAXIS (NPEP) IN A LARGE URBAN HEALTH CARE SYSTEM: IMPLICATIONS FOR IMPLEMENTING PREP AND NPEP Monica Mercon²; Uriel R. Felsen²; Viraj V. Patel¹. ¹Albert Einstein College of Medicine, Bronx, NY; ²Montefiore Medical Center, Rye Brook, NY. (Tracking ID #2199596)

BACKGROUND: The Bronx is an ongoing epicenter of the HIV epidemic in New York City with overall prevalence of 1.7 %, some Bronx neighborhoods the rate is as high as 2.6 %, while the general prevalence estimate for the United States is 0.4–0.9 %. The health care system studied provides health care service to more than 2 million people in the Bronx and Westchester, being one of most important health care system in that area. New tools are now available to help prevent HIV acquisition. Several recent trials have shown efficacy of daily oral antiretroviral for pre-exposure prophylaxis for HIV (PrEP) in reducing risk of HIV infection. Post-sexual exposure to HIV is also recommended by using 28 days course of daily highly active anti-retroviral therapy (nPEP). Both PrEP and nPEP have been FDA approved and have been covered by NY Medicaid and most other commercial insurers. Little is known about to what extent these new tools are being used and who is accessing PrEP and nPEP. This study aims to describe socio-demographic characteristics and risk exposure among individuals prescribed nPEP or PrEP in a large urban health care system.

METHODS: We used a previously validated algorithm to identify all HIV negative individuals in the electronic medical records who attended outpatient

visits and had also been prescribed one or more antiretrovirals from January 2011 through March 2014. A standardized chart abstraction tool was used to verify that the antiretrovirals had been prescribed for PrEP and nPEP and to collect sociodemographic and risk behavior data. We conducted descriptive statistics using SPSS 21 statistical software to calculate proportions and means as appropriate.

RESULTS: During the studied period, 51 individuals received nPEP and 10 individuals received PrEP. Socio-demographic characteristics were similar between two groups. Individuals that received nPEP were mostly heterosexual women (33; 64.7 %), or men who have sex with men-MSM (15; 29.4 %), non-white (46; 90.1 %), age range 13–52 years old. The most frequent indication for nPEP was non-consensual sex (24; 47.1 %), and was frequently prescribed at the Emergency Department (30; 58.8 %). Poor adherence to follow up after nPEP was noted; 14 (27 %) among individuals who received PEP had documented 28 days of use of antiretroviral medication. PrEP was prescribed exclusively for heterosexual women (5; 50 %) and MSM (5; 50 %); 9 (90 %) individuals were non-white, and age range was 19–48 years old. PrEP was mostly prescribed by primary care providers (6; 60 %), and almost exclusively for individuals in stable serodiscordant relationship (9; 90 %). There was no record of seroconversion.

CONCLUSIONS: In a large urban health care system with a high burden of HIV, located in a community with a high HIV prevalence, use of antiretroviral medications for nPEP and PrEP was extremely low. Better understanding of barriers to and facilitators of PrEP and nPEP are needed to inform implementation and increase uptake and improve the health of those at risk for HIV.

MEDICATION ADVISING AMONG LIMITED-ENGLISH PROFICIENT PATIENTS Eva Chang¹; Elizabeth Lin¹; Gerardo Moreno²; Ron L. Johnson¹; Heidi Berthoud¹; Leo Morales³. ¹Group Health Cooperative, Seattle, WA; ²UCLA, Los Angeles, CA; ³University of Washington, Seattle, WA. (Tracking ID #2198621)

BACKGROUND: Receipt of verbal and written medication advising for newly prescribed medication is key for medication safety, but little is known about how much information are given to patients with limited-English proficiency. This study described whether medication advising is associated with English language proficiency and immigration-related factors among insured patients with chronic conditions (hypertension, high cholesterol, and/or diabetes).

METHODS: We conducted a cross-sectional telephone survey of limited-English proficiency (LEP; $n=328$) and English proficient (EP; $n=181$) patients in an integrated healthcare system. The survey was administered in 6 languages/dialects (English, Spanish, Korean, Vietnamese, Chinese-Mandarin, and Chinese-Cantonese). Medication advising outcomes for the most recent prescription were verbal (explanation of medication purpose, medication directions, and possible side effects) and written (receipt of medication label in native language, receipt of medication information from pharmacy in native language). Univariate and bivariate analyses were conducted.

RESULTS: Among all patients, 98 % reported being told about the purpose of the medication, 97 % about how to take it, and 87 % about side effects; 85 % received all 3 pieces of verbal information. LEP patients reported similar percentages of receiving all verbal information as EP patients. Only 12 % of all LEP patients reported receiving a medication bottle in their native language and 63 % reported receiving medication information written in their native language. Ten percent of all LEP patients reported receiving both pieces of written information.

CONCLUSIONS: While the majority of patients received verbal medication advising, 10 % of LEP patients received all forms of written medication advising. The results suggest that the health care system can improve health care services to LEP patients. Requiring translated medication labels is an important next step to ensuring that LEP patients take their medications properly and avoid costly medication errors.

OPTIMIZING ACCESS TO OUTPATIENT SPECIALTY CARE IN THE SAFETY NET: A NATIONWIDE SURVEY Chelsea Bowman⁴; Kevin Duan¹; Nathan R. Handley²; Lena K. Makaroun³; Daniel Wheeler⁴; Alice Chen^{4, 5}; Edgar Pierluissi^{4, 5}. ¹UCSF, San Francisco, CA; ²University of California - San Francisco, San Francisco, CA; ³University of California San Francisco, San Francisco, CA; ⁴University of California, San Francisco, San Francisco, CA; ⁵San Francisco General Hospital, San Francisco, CA. (Tracking ID #2190207)

BACKGROUND: Safety-net health care systems struggle to provide timely access to specialty care for uninsured, underinsured and Medicaid populations.

While these challenges are longstanding, little is known about how safety-net health systems monitor specialty care access. We surveyed how specialty care is provided, assessed, and prospectively planned for in a national sample of safety-net health care systems. Based on our analysis, we propose a conceptual framework for how safety-net institutions can assess and plan for the provision of specialty care.

METHODS: We conducted a descriptive study of safety-net hospitals using a semi-structured interview with health systems' leadership to address how systems planned for and measured specialty care access. Our sample included a member from each county in the California Association of Public Hospitals (CAPH) ($N=15$) as well as members of America's Essential Hospitals (AEH) in the 20 largest metropolitan areas according to the US 2010 census data ($N=16$). Thirty-one health care systems were contacted between December 2013 and March 2014. Four authors independently reviewed the interviews and reached consensus on 5 major themes including 1) provider models for specialty care, 2) challenges in access to specialty care, 3) metrics for access, 4) metrics for productivity, and 5) strategies for improving access. The University of California, San Francisco committee on Human Research approved this study.

RESULTS: Eighteen of 31 (58 %) health care systems completed the interview. Of these, 10 were safety-net health care systems in California. A variety of models were used to provide specialty care including: academic affiliation with a School of Medicine, contracting with individual specialists, directly hiring specialists and a combination of these. The most commonly cited challenge to providing specialty care was the lack of available specialists. This was attributed to lower salaries compared to non-safety-net institutions, difficulty obtaining clinical space and inadequate funding for appropriate levels of support staff. The primary metric for measuring specialty care access was appointment wait times, although definition for this metric varied. Additional measures included the ratio of referrals to available clinic slots and patient satisfaction. Many systems collected subjective feedback from specialty leaders and had external consultation groups provide evaluation of specialty care access. Clinic productivity was measured using work relative value units, new to follow up visit ratios and full time equivalent providers to number of patients served. Strategies to improve access were categorized into three main approaches: 1) increasing specialist capacity, 2) expanding the role of the PCP, and 3) enhancing communication and coordination. (Table 1) No system employed a comprehensive framework to help guide provision and assessment of specialty care services.

CONCLUSIONS: Our study confirms that safety-net institutions face significant challenges in providing access to specialty care. Using the themes and metrics identified in our survey, we developed a conceptual framework to evaluate and plan for access to specialty care. (Figure 1) The framework may help health systems optimize existing services and plan for future provision of care.

Strategies for increasing specialty care access

Increasing Specialist Capacity

Employ physician extenders (NPs,PAs) to help decrease specialist physician workload

Place specialists physically within primary care clinic space to improve ease of access and consultation
Use tele-dermatology as means of remote access to dermatology consultative services
Identify appropriate discharges from clinic to increase number of new patient appointments
Increase number of total clinic half-days per week

Adjust clinic schedule to include early morning and evening appointment time slots
Use digital retinal photography to improve access to ophthalmologic care
Reverse the model of primary and specialty care; bring PCPs into specialty care clinics for management of select patients

Expanding Role of PCP

Create "mini-fellowships" for prolonged PCP immersion into specialty clinic, providing PCP with skills to bring back to primary care
Develop system in which specialists develop management plans that are communicated to and carried out by PCPs
Allow some Family Medicine physicians to accept referrals for basic dermatologic procedures
Create "mini-specialty" clinics (e.g. A1c, HTN, CHF, women's health), all staffed by primary care providers
Place physician extenders and primary care physicians in specialty clinic for basic procedures

Enhancing Communication and Coordination

Create electronic referral system with screening template to ensure necessary labs and studies are completed before appointment with specialist
Embed physician support tools and templates within electronic referral to improve specialty referral quality
Utilize a central referral office to coordinate all specialty referrals

Implement an electronic consult ("E-consult") program to allow remote consultation for patients not requiring in-office visits
Organize social events (e.g. informal dinners) to foster education and fraternization between specialists and PCPs
Protocolize initial steps of treating certain medical conditions before initiating referral
Encourage "curbside" consults by disseminating provider contact information
Standardize scheduling for all specialty clinics to improve efficiency of scheduling process and support staff

Utilize electronic health record messaging tools to increase patient-provider communication
Offer telephone visits as alternative to in-person specialty clinic appointments

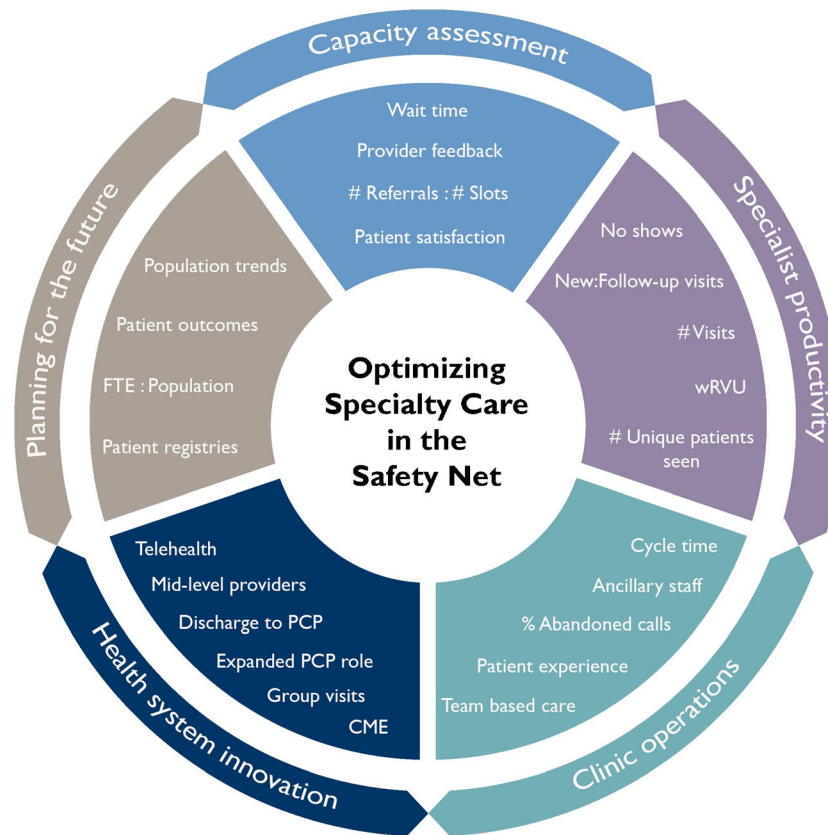

Figure 1: Conceptual framework to evaluate and plan for specialty care.

PERCEPTIONS OF ONLINE PORTAL USE AMONG PATIENTS WITH CHRONIC DISEASE IN A SAFETY NET HEALTHCARE SYSTEM Lina Tieu²; Umimala Sarkar³; Dean Schillinger^{3, 2}; James Ralston⁴; Neda Ratanawongsa^{1, 2}; Courtney R. Lyles². ¹UCSF, San Francisco, CA; ²University of California San Francisco, San Francisco, CA; ³University of California, San Francisco, San Francisco, CA; ⁴Group Health Research Institute, Seattle, WA. (Tracking ID #2192276)

BACKGROUND: Online portals, which provide patients access to electronic health record information, are becoming ubiquitous in the US, especially with the support of Meaningful Use financial incentives. While portals will be the first health technology to reach many diverse patient populations across the country, little is known about barriers to accessing these systems among vulnerable patients, especially among those with chronic illness for whom ongoing self-management is particularly important. This study examined patient and caregiver perspectives to the use of a patient portal before its implementation at San Francisco General Hospital (SFGH) in December 2014.

METHODS: We conducted 16 in-depth interviews with chronic disease patients receiving primary care at SFGH and caregivers providing instrumental chronic disease self-management support, from December 2013 to August 2014. We defined a caregiver as anyone giving formal or informal support in managing the health of a patient. Discussions focused on experiences with the healthcare system, technology use in everyday life, and interest in using an online portal to manage healthcare tasks. All participants were English-speaking (as the portal will only be initially available in English) and reported at least some interest in using a website to manage their healthcare (as we focused on those with existing Internet/computer access). We also assessed participant age, gender, years with diabetes, frequency of Internet use, and health literacy status. We used both deductive and inductive (open) coding to categorize barriers and facilitators to portal use. In an exploratory analysis, we also examined specific barriers among those categorized as having limited health literacy.

RESULTS: The sample included 11 patients and 5 caregivers. The mean age was 55 years, 69 % of the sample had diabetes or cared for someone with diabetes >5 years, and 10 (63 %) had limited health literacy. Overall, 8 respondents (50 %) were African American, 3 were Latino (19 %), 3 were Asian/Pacific Islander (19 %), and 2 were white (13 %); 10 were male (63 %). Ninety-four percent of participants had computer access at home, and approximately 70 % of participants reported using the Internet daily. At the conclusion of the interview, 88 % of participants reported that they would use a portal for future healthcare management. Participants reported completing a range of Internet tasks, such as using search engines, reading news, emailing and using social media, and paying bills. The major barriers to portal use were: concerns about security of information online, lack of technical skills/interest, and preferences for in-person visits/communication. However, participants with limited health literacy more often discussed fundamental barriers to using an online portal, including: challenges with reading, writing, and typing ("I think that's the reason why I don't really use the computer a lot because it's a lot of reading. Like I said, I'm not really a heavily educated guy."); personal experiences with online

security breaches/viruses; and a distrust of potential portal security measures ("Regardless of what a person says that this site is secured and all that, I just don't believe it."). Overall, participants were satisfied with the current healthcare system, but saw the value of a patient portal to increase the convenience of care coordination ("Instead of bugging the front desk...and they have to look everywhere for you...it's convenient I think just looking at the calendar yourself."); improve health monitoring; and support patient-driven communication ("I just hope that it's just useful when you're not at the doctor and you just want to know different information or contact your doctor:").

CONCLUSIONS: Patients in a safety net system reported major barriers to using an online portal. Overall, there was a high level of concern about reading and understanding medical information and preserving existing in-person relationships with providers. However, participants were enthusiastic about using a portal to improve their ability to manage their chronic conditions. Patient portals have the potential to be a convenient and effective way for patients and caregivers receiving care from safety net settings to improve self-management, quality of care, and improvements in health. Our findings suggest a strong need for training and support to assist vulnerable patients with portal registration and use, perhaps most so for those with limited health literacy.

PHYSICIAN ATTITUDES AND PRACTICES REGARDING ADULT VACCINES AND OTHER PREVENTION PRACTICES IN A SHIFTING PRACTICE ENVIRONMENT Laura P. Hurley^{3, 10}; Carolyn Bridges¹; Mandy Allison⁸; Lori A. Crane⁴; Michaela Brtnikova²; Sean O'Leary⁶; Brenda Beaty⁹; Megan Snow⁵; Rafael Harpaz¹; Allison Kempe⁷. ¹CDC, Atlanta, GA; ²Children's Outcomes Research Program, Aurora, CO; ³Denver Health, Denver, CO; ⁴University of Colorado Anschutz Medical Campus, Aurora, CO; ⁵University of Colorado Denver, Aurora, CO; ⁶University of Colorado School of Medicine, Aurora, CO; ⁷University of Colorado and Children's Hospital Colorado, Aurora, CO; ⁸University of Colorado, Anschutz Medical Campus, Aurora, CO; ⁹University of Colorado, Aurora, CO; ¹⁰The Children's Hospital Colorado, Aurora, CO. (Tracking ID #2181305)

BACKGROUND: United States Preventive Services Task Force (USPSTF) and Advisory Committee on Immunization Practices (ACIP) recommendations are widely used to guide delivery of non-immunization and immunization related clinical preventive services, respectively. Rates of all recommended preventive services remain below national goals and vaccination rates often trail rates for other preventive services. The Affordable Care Act (ACA) promotes delivery of preventive services by requiring that USPSTF Grade A and B and ACIP recommendations be provided without cost to several groups of patients and by creating the 'Annual Wellness' visit for Medicare beneficiaries. The short amount of time allotted for primary care visits makes it challenging to deliver all recommended preventive services to adult patients. Little is known about how physicians prioritize vaccination versus other preventive services for adults. Our objectives were to describe among U.S.

primary care physicians: the perceived importance of vaccines relative to other USPSTF or ACIP recommended preventive services and awareness and use of 'Annual Wellness' visits.

METHODS: We administered an Internet and mail survey from March to June 2012 to national networks of 443 general internal medicine (GIM) and 409 family medicine (FM) physicians representative of the American College of Physicians and American Academy of Family Physicians memberships, respectively. Questions were developed jointly with the CDC and modified based on input from advisory committees and pilot testing among primary care physicians. GIM and FM results were combined where similar with differences noted.

RESULTS: Response rates were 79 % (352/443) for GIM and 62 % (255/409) for FM. Physician perceived importance of ACIP recommended vaccines relative to each other and Grade A or B USPSTF recommended preventive services for hypothetical, gender neutral, non-smoking, healthy 67 and 30 year-old patients are presented in the figure. Eighty-five percent of physicians were aware of

'Annual Wellness' visits, but 30 % of the aware physicians reported having conducted none of these visits in the prior month and 36 % reported having conducted less than ten. Physicians with ≥ 25 % Medicare patients compared to those with <25 % Medicare were more aware of these types of visits ($p=0.03$), but did not report conducting more of these visits ($p=0.38$). Sixty-nine percent of respondents reported it would be feasible, 28 % reported it would not be feasible and 3 % reported not knowing the feasibility of conducting 'Annual Wellness' visits for the majority of their Medicare patients.

CONCLUSIONS: Despite uniform recommendations by ACIP, physicians are prioritizing some vaccines over others, and, sometimes, are ranking them below other clinical preventive services. Whether these attitudes result in missed opportunities for vaccination is uncertain and should be explored. Promotion of use of the 'Annual Wellness' visit might improve delivery of preventive services including vaccine-based prevention for seniors.

Figure 1: % of Physicians Who Reported Vaccine, Assessment, or Screening Measure Was 'Very Important'

USPSTF = U.S. Preventive Services Task Force

Tdap/Td = tetanus, diphtheria, acellular pertussis/tetanus, diphtheria

MMR = measles, mumps, rubella

* Higher proportion of FM than GIM viewed Tdap/Td vaccine as 'very important' (69% vs. 57%, $p<0.01$).

** Higher proportion of FM than GIM viewed Seasonal Influenza vaccine as 'very important' (50% vs. 39%, $p<0.01$).

PHYSICIAN ATTITUDES REGARDING ADVANCE CARE PLANNING FOR PATIENTS UNDERGOING CANCER TREATMENT Ali John Zarrabi¹; Alexandra Rosenberg¹; Julia P. Brockway²; Matthew J. Press³; Orit Saigh²; Jenny J. Lin¹. ¹Icahn School of Medicine at Mount Sinai, New York, NY; ²Mount Sinai Beth Israel, New York, NY; ³Weill Cornell Medical College, New York, NY. (Tracking ID #2195648)

BACKGROUND: Palliative care can help manage physical and emotional symptoms and improve quality of life during active cancer treatment. Yet many physicians still view palliative care only for terminal cases. We undertook this study to assess perceived roles and responsibilities of medical oncologists and primary care physicians (PCPs) regarding advance care planning for patients receiving active cancer treatment.

METHODS: PCPs and medical oncologists practicing at three academic hospitals in New York City were administered an anonymous survey that included a vignette of a 55 year-old woman with early-stage breast cancer who had comorbid hypertension, hyperlipidemia, and

diabetes. Physicians were asked about their attitudes regarding cancer-related symptom management, goals of care discussions, and palliative care involvement. Descriptive and univariate analyses were used to assess differences between PCPs vs. oncologists.

RESULTS: Of a total of 203 surveys returned out of 232 distributed (response rate 87.5 %), 127 (62.5 %) were from PCPs and 32 (15.8 %) were from oncologists. One hundred fifteen (56.7 %) were attending-level physicians, and 75 (36.9 %) were male. Oncologists were far more likely than PCPs to believe that they had received adequate training in symptom management related to cancer treatment (91 % vs 24 %, $p<0.01$), and more oncologists reported feeling comfortable managing treatment-related physical symptoms (97 % vs 40 %, $p<0.01$). Both PCPs and oncologists felt equally comfortable managing emotional symptoms (80 % vs. 90 %, $p=0.19$) but PCPs were more comfortable than oncologists managing patients' practical needs (49 % vs. 25 %, $p=0.02$). Compared to PCPs, oncologists were less likely to address goals of care with the vignette patient with early-stage cancer (91 % vs. 66 %, $p<0.01$) or to involve specialty palliative care in patients with advanced cancer (92 % vs. 69 %, $p<0.01$). While the majority of PCPs and oncologists felt that all cancer patients should have their goals of care

addressed while undergoing active cancer treatment (89 and 71 %, respectively, $p=0.02$) and reported feeling comfortable addressing goals of care (84 and 97 %, respectively, $p=0.08$), PCPs were more likely to agree with the statement that all cancer patients undergoing active cancer treatment should have a palliative care consultation (62 % vs 13 %, $p<0.01$).

CONCLUSIONS: While the majority of PCPs and oncologists believed that all patients undergoing active cancer treatment should have goals of care addressed, PCPs were more likely to request specialty palliative care for all their active cancer patients, and oncologists were less likely to address goals of care in patients with non-advanced disease. PCPs were half as likely as oncologists to feel comfortable managing symptoms related to cancer treatment. Further efforts should target improving PCPs' confidence in managing cancer-related symptoms and increasing multi-disciplinary collaboration for advanced care planning in cancer patients.

PHYSICIAN VIEWS ON COMMUNICATION AND COORDINATION OF CARE DURING ACTIVE TREATMENT OF PATIENTS WITH CANCER AND COMORBIDITIES Julia P. Brockway¹; Alexandra Rosenberg²; Ali John Zamabi²; Matthew J. Press³; Orit Saigh¹; Jenny J. Lin². ¹Mount Sinai Beth Israel, New York, NY; ²Icahn School of Medicine at Mount Sinai, New York, NY; ³Weill Cornell Medical College, New York, NY. (Tracking ID #2193526)

BACKGROUND: Poorly controlled comorbidities, such as diabetes mellitus, may be associated with poor outcomes during and after cancer therapy. However, the management of chronic medical conditions may be overlooked in patients undergoing active cancer treatment. Part of the challenge lies in identifying the roles of primary care providers and medical oncologists in coordinating care. Few studies have explored medical providers' perceptions and expectations regarding care practices for patients actively undergoing cancer treatment. Our study aims to identify providers' knowledge, practices, and beliefs regarding coordination of care for these patients.

METHODS: We developed a questionnaire centered on a vignette about a 55-year-old woman with early stage breast cancer who had comorbid diabetes, hypertension, and hyperlipidemia.

Primary care providers (PCPs) and medical oncologists practicing at three academic hospitals in New York City were surveyed anonymously about their knowledge, attitudes, and practices regarding care coordination during active cancer treatment. Descriptive and univariate analyses were used to assess differences in the responses between the PCPs and oncologists.

RESULTS: To date, a total of 203 surveys have been completed, with a response rate of 87.5 %. Of these, 127 (62 %) were PCPs, 32 (16 %) were medical oncologists, 11 (5 %) were palliative care physicians, and the remainder were nurse practitioners or physician assistants. More than half (57 %) were attending physicians, and 126 (62 %) worked primarily in a hospital-based setting. Compared to PCPs, oncologists were twice as likely to feel uncertain about which physician should be providing cancer patients' general preventive care (16.5 % vs. 34.4 %, $p=0.02$). Yet PCPs were more likely to feel concerned about duplicated care (23 % vs. 6 %, $p=0.03$). Medical oncologists were more likely to agree with the statement that they can readily access medical specialists for consultation about treatment plans (91 % vs 61 %, $p<0.01$) and most (66 %) felt they had adequate resources and technical support to facilitate communication with other providers, whereas only 44 % of PCPs reported they had adequate resources to facilitate communication ($p=<0.01$). Regarding management of diabetes during active cancer treatment, almost all PCPs and oncologists (99 % vs. 100 %) agreed that diabetes should be actively managed while undergoing cancer treatment. However, more PCPs agreed with the statement "it's okay for diabetes control to be less strict during cancer treatment" (57 % vs. 38 %, $p=0.05$). PCPs were also more likely to agree that patients would miss some diabetes-related visits while undergoing cancer treatment (81 % vs. 57 %, $p=0.01$) and twice as many PCPs (60 % vs 29 %, $p=<0.01$) were able to identify the correct hemoglobin A1c goal of 6.5–7.5 % for the patient in the vignette case.

CONCLUSIONS: Primary care providers and medical oncologists differ in their knowledge, attitudes, and practices regarding the management of comorbid conditions in patients actively undergoing cancer treatment. There is a communication gap and uncertainty about physician roles in providing coordinated care. Further efforts should help providers clearly define their roles to enhance multi-disciplinary collaboration for optimal cancer care delivery.

Table 1: Physician Beliefs Regarding Patient Care during Active Cancer Treatment

Statement, n (%)	PCP (N=127)	Med-Onc (N=32)	p Value
I am often uncertain about which physician is providing patients' general preventative care	21 (16.5)	11 (34.4)	0.02*
I am often uncertain about which physician is providing care for patients' other co-morbid conditions	13 (10.2)	7 (21.9)	0.13
I am often concerned about duplicated care	29 (22.8)	2 (6.3)	0.03*
I am often concerned about missed care	48 (37.8)	8 (25.0)	0.18
This patient's diabetes should be actively managed while she is undergoing active cancer treatment	123 (99.2)	32 (100.0)	1.0
This patient will likely miss some diabetes-related appointments with her PCP while getting cancer treatment	100 (80.6)	18 (56.3)	<0.01*
It's okay for this patient's diabetes control to be less strict while getting cancer treatment	71 (56.8)	12 (37.5)	0.05*
This patient's diabetes would currently best be managed by her PCP	112 (91.1)	26 (86.7)	0.50
It is my responsibility to communicate with other providers regarding my treatment plan for this patient	115 (92.0)	31 (96.9)	0.46
I have adequate resources and technical support to facilitate communication with other providers	55 (44.0)	21 (65.6)	0.03*
I can readily access medical subspecialists for consultation about treatment plans	76 (60.8)	29 (90.6)	<0.01*
Patients of mine typically see providers within my health system	112 (90.3)	22 (71.0)	0.02*

PHYSICIANS', NURSES', PHYSICAL THERAPISTS' AND MIDWIVES' ATTITUDES TOWARDS COMPLEMENTARY MEDICINES: A SURVEY AT AN ACADEMIC HOSPITAL Eléonore Aveni¹; Brent Bauer²; Ramelet Anne-Sylvie¹; Decoster Isabelle¹; Pierluigi Ballabeni¹; Pierre-Yves Rodondi¹. ¹Unil/CHUV, Epalinges, Switzerland; ²Mayo Clinic, Rochester, MN. (Tracking ID #2193889)

BACKGROUND: The use of complementary medicines (CM) has increased in Europe and in the United States during the last decades, although CM are not integrated in most healthcare systems and are not part of the academic's tradition. Few data are available about academic healthcare professionals' attitude towards CM. The objective of this study was to assess the attitude of physicians, nurses, physical therapists and midwives in an academic hospital towards CM.

METHODS: The cross-sectional survey took place from October to December 2013. An email sent to 4925 healthcare professionals (1969 physicians, 2372 nurses, 145 physical therapists, and 111 midwives) working at the University Hospital of Lausanne, Switzerland, invited them to answer a web-based questionnaire. The questionnaire was built according to other surveys among healthcare professionals.

RESULTS: One thousand two hundred forty-seven health professionals answered the questionnaire (response rate: 25.3 %). More female doctors than men answered the questionnaire according to the whole sample ($p=0.044$), but the representativity of the sample was good for other professions (nurses: $p=0.57$; physical therapists: $p=0.49$; midwives: $p=0.39$). A quarter (24.1 %) of healthcare professionals never spoke with patients about the possible benefits of using CM and 43.6 % never spoke about the risks of CM. Although 80.4 % of respondents thought they should inform patients about CM, 44.2 % found it difficult or very difficult to find reliable information about CM at the academic hospital. Respondents admitted that they initiated discussion about CM less frequently (35 %) than patients, with women and professionals trained in practicing CM (16 % of the respondents) having a tendency to initiate more frequently the discussion ($p=0.011$ and $p=0.004$, respectively). The majority of respondents (82.5 %) thought they lacked knowledge about CM with nurses (86 %) and physicians (81.7 %) thinking they lacked more information compared to physical therapists (75 %) ($p<0.001$ and $p=0.003$, respectively). When asked about the impact of several factors on their opinion towards CM, personal experience with CM had a higher impact for nurses (77.6 %) and midwives (85.3 %) than for physicians (51.8 %) ($p<0.001$). Prospective randomized controlled clinical trials published in medical journals had a higher impact on physicians' opinion (75.9 %) compared to nurses (52.1 %) ($p<0.001$). Published case reports had the lowest impact for all professions.

CONCLUSIONS: Our results showed that a quarter never spoke about the potential benefits of CM and 44 % never spoke about potential risks. With the documented reluctance of patients to disclose their use of CM and the risk of herb-drug interactions, healthcare professionals must take a more active role in initiating discussions about CM and be able to inform patients about their use. There is a difference between the professions as to which factor impacts the most on their opinion towards CM: physicians are more influenced by published controlled trials compared to nurses and midwives, who are more affected by personal experience. This could have an impact on the recommendations about CM given to patients. With the need to develop more interprofessional education, CM could be a good example for the introduction of interprofessional training. To our knowledge, it is the largest study about professionals' attitude towards CM at an academic hospital.

PREDICTING LOW TESTOSTERONE IN THE AGING MALE: A SYSTEMATIC REVIEW Adam C. Millar¹; Adrian Lau²; George A. Tomlinson²; Alan P. Kraguljac³; David Simel⁴; Allan S. Detsky¹; Lorraine Lipscombe⁵. ¹University of Toronto, Mount Sinai Hospital, Toronto, ON, Canada; ²University Health Network, Toronto, ON, Canada; ³Mount Sinai Hospital, Toronto, ON, Canada; ⁴Durham VAMC and Duke University, Durham, NC; ⁵University of Toronto, Women's College Hospital, Toronto, ON, Canada. (Tracking ID #2191601)

BACKGROUND: Physicians diagnose and treat suspected hypogonadism in aging men based on low testosterone levels and/or symptoms, extrapolating from the defined clinical entity of hypogonadism found in younger men. The objective of this study is to systematically review the literature to estimate the accuracy of clinical symptoms and signs for predicting low testosterone among men over the age of 40 years.

METHODS: The MEDLINE and EMBASE databases (January 1966 to July 2014) were searched for English-language articles on patient history or physical examination characteristics for identifying low testosterone in males over the age of 40. Original studies on the association between signs or symptoms and low testosterone in men over the age of 40 years were included. Three authors independently reviewed 6053 articles for inclusion and quality review, as well as extracted data from each of the selected 37 papers. The definition of the reference standard (both the method of measuring testosterone and lower limit of normal) varied considerably across studies.

RESULTS: In high quality studies, prevalence rates of low testosterone varied between 14 and 67 %, with a median of 33 %. Threshold testosterone levels used for reference standards also varied substantially. The individual symptoms most commonly evaluated were decreased libido and erectile dysfunction. The summary likelihood ratio (LR) for low testosterone associated with decreased libido was 1.6 (95 % CI: 1.3–1.9), and the LR for absence of this finding was 0.72 (95 % CI: 0.58–0.85). Similarly, the LR associated with the presence of erectile dysfunction was 1.7 (95 % CI: 1.3–2.1) and LR in the absence of erectile dysfunction was 0.76 (95 % CI: 0.61–0.89). In terms of multiple item instruments, the Androtest appears to have both the most favorable LR+ (range 1.9–2.2) and LR- (range 0.37–0.49), but head-to-head comparisons between instruments have not been done.

CONCLUSIONS: Few of the individual signs or symptoms used to identify or exclude low testosterone in men over the age of 40 years had a LR+ ≥ 2.0 , while only one symptom (normal vigor) had a LR- ≤ 0.5 . This poor overall correlation between signs, symptoms and testosterone levels coupled with uncertainty about what threshold testosterone levels should be considered low for older men and the wide variation in estimated prevalence of the condition, makes it difficult to extrapolate the method of diagnosing hypogonadism in younger men to clinical decisions for aging males.

PREFERENCES FOR FAMILY INVOLVEMENT IN END-OF-LIFE DECISION-MAKING Alyssa Harlow¹; Michael Green³; Benjamin Levi²; Jane Schubart⁵; Renee R. Stewart³; Jorge A. Dorantes²; Lisa S. Lehmann^{2, 4}. ¹Brigham and Women's Hospital, Cambridge, MA; ²Brigham and Women's Hospital, Boston, MA; ³Penn State College of Medicine, Hershey, PA; ⁴Harvard Medical School, Boston, MA; ⁵Penn State Hershey Medical Center, Hershey, PA. (Tracking ID #2199218)

BACKGROUND: Of the nearly 2.5 million people who die each year in the United States, 70 % lack decision-making capacity at the end of life. In most cases, family members serve as surrogate decision makers for end-of-life decisions. Family surrogates are often unsure of loved one's preferences for end-of-life decisions, resulting in stress and angst. Furthermore, patients' preferences for level of involvement of family members' in end-of-life decision-making are variable. Addressing these complexities, this study of patients with advanced illnesses aimed to determine their preferences for family involvement in end-of-life decision-making. We also sought to assess whether patients' decision preferences differ by demographic characteristics such as age, gender, race, religion, education, or disease category.

METHODS: We recruited a convenience sample of 92 severely ill patients from Brigham and Women's Hospital and Penn State Hershey Medical Center. Patients were included if they were likely to lose decisional capacity within 2 years and had one or more of the following diagnoses: advanced cancer, severe congestive heart failure (New York Heart Association Class III or Class IV), severe lung disease (Stage III or Stage IV COPD by modified GOLD Spirometric Classification), or End Stage Renal Disease. We measured patients' preferences for family involvement in medical decision-making using the Decision Control Preferences scale. Patients were asked to articulate their preferences for family involvement under two scenarios: 1) when they are awake with decision-making capacity, and 2) when they lack the ability to participate in decision-making. Response options ranged from family-centered (family member wishes take priority) to shared roles (equally weigh family member wishes with their own) to patient-centered (patient wishes take priority). Patients were also asked to weigh family members' versus doctor's input on decision-making. Socio-demographic information was collected for all participants. Descriptive and multivariate analyses were conducted to assess patient control preferences, and predictors of patient control preferences.

RESULTS: The mean age of participants was 63 years (SD ± 14). Fifty-one percent (44) of participants had cancer, 24 % (21) had COPD, 21 % (18) had CHF, and 4 % (3) had ESRD. Seventy-four percent (66) of participants were white, 18 % (16) were black, and 8 % (7) identified as a race other than black or white. Sixty-eight percent (16) did not have a college degree, 71 % (65) reported having strong religious faith, and 29 % (27) reported having weak or no religious faith. Fifty-four percent (50) preferred a shared role in decision-making when awake with decision-making capacity, 38 % (70) preferred patient centered roles, and 8 % (14) preferred family centered roles. When lacking decision-making capacity, less than half preferred a shared role [46 % (42)], opting for either patient-centered [30 % (28)] or family-centered roles [24 % (22)]. Most patients preferred the input of family members and doctors to be weighed equally in both clinical situations (69 % $n=63$ and 63 % $n=56$, respectively). There was no significant association between disease category, age, gender, religion, race and patients' decision control preferences. College education was significantly associated with preferring a patient-centered role in decision-making (OR 2.8, [95%CI 1.2,6.9] $p=0.02$), and with weighing a doctor's input more heavily than family members' (OR 2.8, [95 % CI 1.1,7.4] $p=0.04$). Strong religious faith was significantly associated with preferring a family-centered role in decision-making (OR 0.3, [95 % CI 0.150,0.710] $p=0.005$).

CONCLUSIONS: Only half of severely ill patients prefer a shared role with family members when the time comes to make a significant end-of-life medical decision. When

patients lose decision-making capacity, a significant percentage state a preference for family members' wishes taking priority over their own prior stated wishes. Individuals with a strong religious faith prefer greater family involvement in decision-making. Our findings challenge the commonly held understanding of health care agents being the voice of the patient. In some cases, patients want family members' preferences to trump their own preferences. Patient preferences for family involvement in end-of-life decision making may be highly variable. Therefore, health care providers will need to encourage early communication between patients and family members in order for family surrogates to better understand how their loved ones want end-of-life decisions to be made.

PROGNOSTIC PERFORMANCE OF ECHOCARDIOGRAPHY IN HEMODYNAMICALLY STABLE ELDERLY PATIENTS WITH ACUTE PULMONARY EMBOLISM Eveline Hofmann³; Andreas Limacher⁵; Marie Méan^{3, 1}; Nils Kucher³; Marc Righini⁴; Beat Frauchiger¹⁰; Juerg-Hans Beer⁶; Joseph J. Osterwalder¹¹; Markus Aschwanden²; Christian M. (Tracking ID #2195765)

BACKGROUND: Evidence suggests that several echocardiographic signs of right ventricular (RV) dysfunction are associated with an increased short-term mortality in hemodynamically stable patients with acute pulmonary embolism (PE). Cardiology guidelines recommend performing transthoracic echocardiography to risk-stratify such patients. Although elderly patients with PE have a higher complication rate than younger patients, the prognostic performance of transthoracic echocardiography to predict adverse outcomes has not been specifically examined in the elderly.

METHODS: We studied 400 hemodynamically stable patients aged ≥ 65 years with acute PE in a Swiss prospective multicenter cohort study between September 2009 and June 2012. Transthoracic echocardiography was performed by blinded cardiologists within three days of PE diagnosis. We defined RV dysfunction as a RV/left ventricular ratio >0.9 or RV hypokinesis (primary definition) or the presence of either ≥ 1 or ≥ 2 of 6 predefined echocardiographic signs of RV dysfunction (secondary definitions). Outcomes were overall mortality, the combination of mortality/non-fatal recurrent venous thromboembolism (VTE) and health-related quality of life at 90 days, and length of hospital stay. We examined the association between RV dysfunction and outcomes, adjusting for patient baseline characteristics.

RESULTS: Overall, 36 % of patients had RV dysfunction based on our primary definition, and 81 and 53 % based on our secondary definitions, respectively. Using our primary definition, there was no association between RV dysfunction and mortality (adjusted HR 0.81, 95%CI 0.35–1.88), mortality/non-fatal VTE (adjusted HR 0.96, 95%CI 0.45–2.08), or quality of life. RV dysfunction was associated with an increased length of stay (adjusted time ratio 1.18, 95%CI 1.03–1.36). Using our secondary definitions, we found no association between RV dysfunction and clinical outcomes. However, RV dysfunction was associated with a poorer quality of life and a longer hospital stay.

CONCLUSIONS: The prevalence of echocardiographic RV dysfunction varied widely based on the criteria used to define RV dysfunction in elderly, hemodynamically stable patients with acute PE. We did not find an association between RV dysfunction and clinical outcomes but patients with RV dysfunction had a poorer health-related quality of life and a longer hospital stay. The assessment of echocardiographic RV dysfunction as a stand-alone risk stratification tool appears to be of uncertain usefulness in elderly, hemodynamically stable patients with acute PE.

READMISSION-FREE SURVIVAL: ACCOUNTING FOR THE EFFECT OF MORTALITY RATES ON CHF READMISSION RATES John Hughes¹; Richard Averill²; James Vertrees²; Norbert Goldfield²; Jean Xiang²; Elizabeth McCullough². ¹Yale University School of Medicine, New Haven, CT; ²3 M Health Information Systems, Wallingford, CT. (Tracking ID #2198922)

BACKGROUND: The sickest among hospitalized patients are the most likely to be readmitted, but are also the most likely to die either in hospital or shortly after discharge. Patients who die cannot be readmitted, and therefore hospitals with excessive mortality rates may have lower readmission rates as a consequence. Support for this possibility comes from several reports of an inverse relationship between hospital mortality rates and readmission rates for Congestive Heart Failure (CHF).

METHODS: We examined the relationship between CHF readmission and mortality rates using CMS data from 2010 to 2012 for 2352 hospitals with more than 100 CHF discharges in 2010. We ranked hospitals by their risk-adjusted mortality rates from the time of admission until 30 days post discharge, using the All-Patient Refined Diagnosis Related Groups (APR DRG) Risk of Mortality method. We used the published Excess Readmission Ratios (ERR) for CHF for each hospital, drawn from Medicare data from 2009 to 2012, as a measure of readmission rates at 30 days after discharge. Medicare uses ERR as part of its formula to determine which hospitals will be subject to payment penalties. Individual hospital ERRs ranged from 0.746 to 1.333, with scores greater than 1.0 indicating higher than expected readmission rates.

RESULTS: While hospitals that score high on one outcome measure might be expected to score high on others, we found a modest inverse correlation between risk-adjusted mortality rates and ERR overall (Pearson = -0.2259) for CHF. We sorted hospitals into quartiles based on the ERR, and calculated severity-adjusted 30-day post discharge mortality rates for each quartile. Average ERR ranged from 0.893 for quartile 1 (Q1) up to 1.116 for quartile 4 (Q4). By contrast, risk adjusted mortality was highest for Q1 (9.0 %), where the ERR was lowest, and conversely was lowest for Q4 (6.8 %), where ERR was highest. These findings are consistent with an inverse relation for mortality and readmission rates. We then calculated a Readmission-Free Survival Rate (RFSR), a measure of positive performance based on the number of patients admitted for CHF who had survived hospitalization and had neither died nor been readmitted by 30 days after discharge. By including both readmissions and mortality, this calculation minimizes any censoring effect of excessive mortality rates. RFSR overall was 73.9 %, ranging from 75.8 % in Q1 to 72.2 % in Q4. We then examined the relationship between the CMS ERR and the RFSR with a cross-tabulation of quartiles to see how assessments of hospital performance would differ between the two measures. There were substantial differences within ERR Q4 (worst performing), containing the hospitals with the highest ERR scores. Twenty-five percent of hospital in EER Q4 would have ranked in the top two quartiles of RFSR (best performing), and over half (52 %) would have ranked in the top 3 RFSR quartiles.

CONCLUSIONS: These results confirm that lower readmission rates can be associated with higher mortality rates for CHF. Some hospitals could therefore be subject to financial penalties for excess readmissions under current Medicare rules, even though they had better overall survival outcomes. These findings can be explained in two ways: either because high-readmission hospitals kept their patients alive longer, who therefore had more opportunity to be readmitted, or perhaps because more frequent hospitalizations actually helped to keep their CHF patients alive longer. The Readmission-Free Survival Rate is a useful measure to assess the impact of CHF mortality rates on hospital readmission performance.

RED CELL DISTRIBUTION WIDTH (RDW) AS A PREDICTOR OF CLINICAL OUTCOMES IN PATIENTS WITH HYPERTENSIVE CRISIS Sagger Mawri²; Suraj Raheja¹; Alexander Michaels¹; Joseph Gibbs¹; Niraj M. Patel¹; Bharat Rao¹; Ruchir Patel¹; James McCord¹. ¹Henry Ford Health System, Detroit, MI; ²Henry Ford Hospital, Detroit, MI. (Tracking ID #2196441)

BACKGROUND: Red cell distribution width (RDW) is a measure of the variability in size of erythrocytes. A high RDW value indicates greater variation in size between individual erythrocytes and has been shown to be an independent predictor of mortality in patients with coronary artery disease, heart failure and in patients undergoing percutaneous coronary intervention (PCI). The aim of this study was to evaluate the prognostic value of RDW in predicting clinical outcomes in patients with hypertensive crisis.

METHODS: We performed a retrospective study of 465 consecutive patients from January 2007 to March 2010 who presented with hypertensive crisis. Hypertensive crisis was defined as systolic BP >180 and/or diastolic BP >110 mmHg with impending or progressive end organ dysfunction requiring inpatient hospitalization. The study sample consisted of 465 patients (38.9 % men; mean age 59.6 ± 15.9). Baseline levels of RDW were measured at time of admission and analyzed as continuous and categorical variables (elevated RDW was defined as >14.5 %). Multivariable regression analysis was performed for development of all-cause mortality, myocardial infarction, new-onset heart failure (defined as first time hospital admission for heart failure), stroke and MACE (MI, new-onset heart failure and stroke) at 2 years.

RESULTS: RDW >14.5 % was a strong independent predictor of all-cause mortality at 2 years (OR: 1.90, 95 % CI: 1.1–3.3, $p < 0.05$). Elevated RDW was also found to be an independent predictor of new-onset heart failure at 2 years (OR: 1.97, 95 % CI: 1.1–3.7, $p < 0.05$). Elevated RDW was not a predictor of MI, PCI or stroke at 2 years.

CONCLUSIONS: Elevated RDW level in patients with hypertensive crisis was an independent predictor of all-cause mortality and new-onset heart failure in patients with hypertensive crisis.

REFERRAL BY PRIMARY CARE PROVIDERS INTO THE POWER WEIGHT LOSS TRIAL WAS NOT ASSOCIATED WITH GREATER WEIGHT LOSS

Eva Tseng¹; Nae-Yuh Wang³; Jeanne M. Clark³; Lawrence J. Appel²; Wendy L. Bennett².
¹Johns Hopkins, Baltimore, MD; ²Johns Hopkins School of Medicine, Baltimore, MD;
³Johns Hopkins University, Baltimore, MD. (Tracking ID #2193342)

BACKGROUND: Primary care providers (PCPs) play an important role in identifying and counseling obese patients to lose weight. However, PCPs report many barriers to weight loss counseling and many prefer to refer patients into effective weight loss programs. The Hopkins POWER behavioral weight loss trial provided an opportunity to evaluate the method of recruitment into the trial and to determine if PCP referral is associated with greater weight loss and participation rates. We hypothesized that participants referred to the POWER trial by their PCP achieved greater weight loss and had higher participation rates and satisfaction level compared to other non-PCP recruitment methods.

METHODS: The Hopkins POWER trial was a 3-arm randomized controlled trial of 415 obese patients with at least one cardiovascular risk factor from six primary care practices in the Baltimore, MD area. Participants were randomized to a control group or one of two behavioral weight-loss interventions (remote or in-person coaching). A screening survey assessed participants' stated recruitment method, which was dichotomized into "PCP referral" or "non-PCP" recruitment (including brochures or posters in the practice, mailed letters) methods. Study participants assigned to the intervention arms had PCPs who reviewed their weight loss progress reports at routine office visits and encouraged their participation. The primary outcome was percent weight change from baseline to 24 months. The secondary outcomes were satisfaction with PCP-patient relationship and participation rates in the intervention, assessed as the percentage of recommended coach contacts and web logins. We conducted longitudinal mixed-effects model, adjusting for clinic, sex, age, and race or ethnic group.

RESULTS: Of the 415 participants, 171 (41 %) reported PCP referral compared to 244 (59 %) who reported other recruitment methods. Those referred by their PCP were younger (52.8 ± 0.8 vs. 54.9 ± 0.7 years, $p=0.04$), had a higher BMI (37.6 ± 0.4 vs. 35.9 ± 0.3 kg/m², $p=0.0006$), were more likely to be female (71.4 % vs. 58.2 %, $P=0.0006$), and African American (46.2 % vs. 37.3 %, $p=0.0006$). Participants in both "PCP referral" and "non-PCP" recruitment groups lost similar percentages of weight from baseline to 24 months (between-group difference: -0.6 %, 95%CI -2.3 – 1.1 %; $p=0.49$), after adjusting for age, race, gender, and clinic site. PCP referral was also not significantly associated with percentage of completed coach contacts and web logins. However, those referred by their PCP into the trial reported higher satisfaction with the relationship with their PCP at the end of trial ($p=0.003$).

CONCLUSIONS: Our study represents the first of its kind to examine the role of PCP recruitment of patients into a weight loss trial. Although the POWER trial was not designed to evaluate the effect of PCP recruitment on weight loss outcomes, our study does highlight the need for additional research to develop strategies for PCPs to identify eligible patients and recommend weight loss programs to ultimately impact patients' success.

REFORMING AMBULATORY RESIDENCY EDUCATION: LONG TERM IMPACTS ON LEARNING, SATISFACTION, AND CAREER DECISIONS

Lauren Block; Jennifer Verbsky; Nancy A. LaVine; Joseph Conigliaro; Saima Chaudhry. North Shore-LIJ Health System, Lake Success, NY. (Tracking ID #2196735)

BACKGROUND: Restructuring of ambulatory residency education has been promoted by professional groups. A major goal of reform is to increase the number of trainees entering primary care careers. Between 2010 and 2014 our health system sought to improve ambulatory education and increase the number of residents entering primary care through an iterative reform. Changes at the institutional level included electronic health record implementation and improving compensation for residency graduates entering primary care. Departmental initiatives were patient centered medical home (PCMH) transformation and a Hospital Medical Home Demonstration Grant to support care coordination within the resident practice. Residency program changes included establishing a 4+1 residency schedule and implementing a resident mentoring program, a team based learning curriculum, and a community primary care rotation. We sought to assess whether teaching, learning, and satisfaction with ambulatory training improved over the 4-year period, and whether more residents entered primary care careers subsequent to the reform.

METHODS: We employed a pre- and post-intervention survey to study second and third year internal medicine residents at a large residency program in New York. Residents are assigned to one of two ambulatory sites; a hospital-based clinic and a freestanding faculty and resident practice. All 2nd and 3rd year residents in the program were surveyed in 2011 regarding the prior academic year (2009–10, baseline) compared with the 2010–11

academic year (first round of reform) using a retrospective pre/post assessment methodology. All 2nd and 3rd year residents were surveyed in April 2014 (post-all reform efforts) using the same items. Residents reported career plans from the years 2010–2014. The Table displays key features of each redesign effort. The primary outcomes were self reported teaching and learning, satisfaction with ambulatory training, and number of trainees entering primary care careers. Secondary outcomes were measures of continuity and workload. All measures were validated and used in prior educational research.

RESULTS: The overall response rate was 93 %. A total of 46 % of residents were PGY2, 53 % were male, and 71 % practiced at the PCMH site. Mean scores on self reported learning and faculty teaching scales improved significantly over the study period (mean 3.6 baseline vs. 4.1 post-reform on a 1–5 Likert scale, $p<0.01$ and 3.3 baseline vs. 3.6 post-reform, $p=0.04$, respectively). Resident enjoyment of clinic improved during the study period as did satisfaction with the overall ambulatory experience (3.1 vs. 3.8 on a 1–5 Likert scale, 2.9 vs. 4, $p<0.01$ for each). Residents reported that the schedule supported continuity of care to a higher extent in 2014 than 2010 (2.3 vs. 3.6, $p<0.01$). The number of patients seen per half day declined (5.9 vs. 4.3, $p<0.01$). The number of residents entering careers in primary care was: 0 (2010), 2 (2011), 1 (2012), 1 (2013) and 8 (2014).

CONCLUSIONS: Four years after implementation of a large structural and educational reform effort, residents reported improvements in learning and teaching, continuity, and satisfaction with ambulatory training. This came at a cost of fewer patients seen per day. Our redesign efforts addressed several of the factors reported in the literature as important towards increasing the primary care workforce, and included institution, department, and program-level reforms. A greater number of residents planned to enter primary care careers in the final year of study. The strengths of this intervention included its comprehensive approach and buy-in at all levels of the health system. Strengths of the evaluation include using validated measures over four years and studying two ambulatory sites. Limitations of the evaluation include potential confounding by concurrent changes to residency education, and surveying different residents in 2010–11 and 2014. More follow-up data on resident career paths is needed.

Components of ambulatory reform

Level	Date	Component	Description
Institution	2010 and 2012	EHR conversion	Allscripts electronic health record implemented
	2010	Compensation enhancement	Included loan forgiveness, base salary increase, and incentive program for primary care clinicians
Department	Late 2009	PCMH certification	National Committee for Quality Assurance level 3 certification
	2010	Hospital Medical Home Demonstration grant	Grant funded hiring of a nurse practitioner, clinic secretary, and data analyst to improve continuity in resident clinic
Program	2010	4+1 schedule	Block schedule where residents do not assume simultaneous inpatient and outpatient responsibilities
	2010	Residency mentoring	One-on-one mentoring for residents in their clinical area of interest
	2012	Team-based learning curriculum	Approach to ambulatory curriculum based on individual preparation, team problem solving, and skill application
	2012	Community primary care rotation	Residents practice alongside seasoned primary care physicians

RESIDENT RESILIENCY - HOW RESILIENT ARE OUR MEDICAL TRAINEES AND HOW DOES IT RELATE TO STRESS AND BURNOUT?

Amber Bird; Amber Pincavage. University of Chicago, Chicago, IL. (Tracking ID #2192709)

BACKGROUND: Burnout amongst medical professionals is a growing concern. Many studies have shown that burnout is pervasive amongst medical trainees and is associated with increased rates of depression, suicide, and poor clinical performance. Data exists showing the correlation between physician burnout and depression. However, there remains little data on how physician burnout relates to resilience.

METHODS: Our objectives were to characterize levels of resilience amongst Internal Medicine residents and examine how levels of resilience impact self-reported measures of stress, burnout, and clinical performance, looking specifically at experience with medical errors and medical error reporting. Cross-sectional surveys were provided to a convenience sample of Internal Medicine residents attending the 2014 Northern Illinois Regional American College of Physicians meeting. Baseline resilience scores were assessed using the validated Connor-Davidson Resilience scale (CD-25). Responses were then divided into resilience categories of low (CD-25 of <70), intermediate (CD-25 70–79), and high (CD-25 80–100). Residents were also surveyed on their experience with burnout, resilience training, and involvement in medical errors.

RESULTS: A total of 77 residents from six institutions completed surveys. 26.0 % of residents had high resilience, 43.9 % intermediate, and 31.2 % low (range 40–100). The majority of residents believe burnout is an important issue during residency (92.2 %). Trainees with high resilience were more likely to report never having stress interfere with their relationships outside of work as compared to trainees with low resilience (high-40.0 %, low-0.0 %, $p<0.001$). High resilience residents were more likely to report having the skills to manage feelings of stress and burnout (high-80.0 %, low-45.8 %, $p=0.02$) and less likely to report feeling inferior to peers (high-20.0 %, low-70.8 %, $p<0.001$). There was a trend towards more trainees with high resilience reporting less burnout from work (rarely or never feeling burnout) compared to trainees with low resilience (high-40.0 %, intermediate-27 %, low-16.7 %, $p=0.08$). Medical errors and reporting were not associated with resilience level. The majority of respondents in all categories reported prior involvement in medical errors (high-70.0 %, intermediate-69.7 %, low-79.2 %), but most respondents stated they had never reported these errors (high-55.0 %, intermediate-60.6 %, low-83.3 %). Overall, only 50 % of residents report an outlet within their program to discuss feelings of stress and burnout.

CONCLUSIONS: There is a wide range of resilience scores amongst Internal Medicine residents with many residents without high levels of resilience. Low resilience is associated with more stress interfering with relationships, feeling inferior to peers and fewer skills to manage stress and burnout. Burnout from work is high among residents and there are not enough outlets in programs to discuss stress and burnout. In addition, although there was no association with resilience and medical errors, our results show that despite most respondents acknowledging direct involvement in medical errors, most residents never formally report these incidents. More curricula to increase resilience and address stress, burnout, and medical errors involving medical trainees are needed.

RESIDENTS' PERCEPTIONS OF THEIR HEALTH LITERACY SKILLS AND TRAINING NEEDS ACROSS SPECIALTIES Tamasy Nelson²; Lisa Altshuler¹; Colleen Gillespie¹; Mrudula Naidu¹; Alison Squires³; Shonna Yin¹; Sondra Zabar¹. ¹NYU School of Medicine, New York, NY; ²Vanderbilt University School of Medicine, Nashville, TN; ³NYU School of Nursing, New York, NY. (Tracking ID #2198469)

BACKGROUND: Low health literacy (HL) is common, particularly in underserved communities. HL deficits have been associated with patient safety issues and poor health outcomes. Provider use of HL-informed communication strategies, including plain language verbal and written communication, and use of "teach back" to confirm patient understanding, has been linked to improved patient outcomes, therefore, a "universal precautions" approach is recommended. A recent survey of medical schools found that 72 % of the 133 U.S. allopathic medical schools included HL in their curriculum, with a only a median time spent of 3 h in total (Coleman & Appy, 2012). As part of a needs assessment of residents at our institution, we surveyed residents across 7 programs to determine their previous training in HL, current practices, comfort level with HL skills and desire for further training. This allowed us to assess overall need and to identify differences by specialty.

METHODS: Data was collected from residents via an online survey (Qualtrics) during the 2013–2014 academic year. Residency programs surveyed included Emergency Medicine (EM), Internal Medicine (IM), Obstetrics/Gynecology (OB), Orthopedics (OR), Pediatrics (PED), Primary Care (PC), and Surgery (SUR). Completed responses were received from 269 residents (of 394 total), for a response rate of 68 % overall. This ranged from a 100 % response rate from OR down to 57 % from EM. HL questions for the survey were adapted from Schwartzberg et al. (2007) and Turner et al. (2009). The following domains were assessed: 1) prior HL training (1Q), 2) use of HL techniques (8Q), 3) perceived skill in key HL techniques (3Q), 4) desire for HL training (1Q). Prior HL training was assessed with a question about whether they had HL training, and if so, where they received it. Use of HL techniques was rated on a 5-point Likert scale from 1 (never) to 5 (always); techniques included teach-back, providing easy to read written materials, underlining key points on written materials. A Overall HL Use score was calculated by averaging responses (Cronbach's alpha=.88). Perceived skill in key HL techniques was, rated on a 4-point scale from 1 (not at all skilled) to 4 (very skilled); skills assessed included teach-back, choosing appropriate written materials, and converting medical terms into plain language. A HL Skills score was calculated by averaging responses

(Cronbach's alpha=.70). Finally, participants were asked to respond to open-ended questions re: what HL training they would like.

RESULTS: Sixty-five percent of residents reported prior training related to HL, with the majority of this being in medical school; educational formats used included didactics and OSCEs. Across specialties, 84 % of OR residents reported having had previous training, while IM was the lowest at 47 %. Statistically significant differences in reported Overall HL Use across programs was determined by one way ANOVA ($F(6, 268)=8.77$, $p=0.0001$). Post hoc Tukey test revealed that SUR Overall HL Use score was significantly higher than the other specialties, ($p=0.05$). No other significant differences were found. For the HL Skill score, one way ANOVA was significant ($F(6265)=3.48$, $p=0.002$). Tukey post-hoc analysis revealed that SUR was again the highest scorer, with scores significantly higher than both IM and OB ($p=0.05$). When asked what future training residents wanted, there were consistent themes across the specialties. Many residents wanted to know where to find easily accessible printed material suitable for low-literacy patients, ways to match health education literature to patients' HL levels, and pragmatic strategies for integrating HL approaches in a busy clinical setting with diverse patient populations.

CONCLUSIONS: Most residents across multiple specialties report at least some training in HL during medical school, although the extent of such training is not known. There are differences between specialties with respect to self-reported use of and comfort with HL approaches, with surgeons feeling the most prepared and internal medicine and obstetrics trainees less so. In spite of their reported skill level, all groups identified need for further HL training. Additionally, this study assessed self-report of HL skill and use. To better understand differences by specialty assessing actual HL skill and use from an observational study is planned.

RISK OF ATRIAL FIBRILLATION ACROSS THE FULL TSH RANGE: AN INDIVIDUAL PARTICIPANT POOLED ANALYSIS OF LARGE PROSPECTIVE INTERNATIONAL COHORT STUDIES Christine Baumgartner¹; Bruno R. da Costa²; Tinh-Hai Collet³; Anne R. Cappola⁴; Douglas Bauer⁴; Daniel Segna¹; Anette van Dorland¹; Carmen Floriani¹; Peter Jüni²; Graziano Ceresini²; Jacobijn Gussekloo⁶; Wendy P. den Elzen⁶; Robin P. (Tracking ID #2191361)

BACKGROUND: The lower and upper limits of the optimal reference range of thyroid stimulating hormone (TSH) and optimal TSH targets in clinical guidelines remain controversial, leading to variability in the clinical management of thyroid dysfunction. Some prospective studies have found subclinical hypothyroidism to be associated with a reduced risk of atrial fibrillation (AF), while others have found an increased AF risk within the lower normal TSH reference range. Identification of modifiable risk factors and potentially reversible causes of AF is important to optimize prevention and treatment, given its significant public health burden. We aimed to assess the risk of AF across the full TSH range in prospective cohort studies participating in the International Thyroid Studies Collaboration.

METHODS: Individual participant data from seven large prospective cohort studies with measurement of thyroid function at baseline and assessment of incident AF outcomes were pooled to assess the risk of incident AF according to TSH levels. Euthyroidism was defined as TSH level from 0.45 to 4.49 mIU/l and subdivided into five categories (0.45–0.99 mIU/l, 1.00–1.49 mIU/l, 1.50–2.49 mIU/l, 2.50–3.49 mIU/l and 3.50–4.49 mIU/l). We compared the incidence of AF of all TSH groups to the reference group 3.50–4.49 mIU/l. Subclinical hypothyroidism was defined as TSH level between 4.5 and 19.9 mIU/l and subclinical hyperthyroidism as TSH level <0.45 mIU/l, both with normal free thyroxine levels.

RESULTS: Among 11,387 adults, 1064 (9.3 %) had subclinical hyperthyroidism and 900 (7.9 %) had subclinical hypothyroidism. In total, 962 individuals developed AF during follow-up. In individuals with subclinical hyperthyroidism, the risk of AF increased with lower TSH levels: age- and sex-adjusted hazard ratio (HR) 1.64 (95 % confidence interval [CI] 1.07–2.53) for a TSH level of 0.10–0.44 mIU/l and 1.71 (95 % CI 0.69–4.26) for a

TSH level <0.10 mIU/L, *p* value for trend 0.024. The risk of AF events was not increased in TSH categories within the euthyroid range, with an HR of 1.16 (95 % CI 0.86–1.56) for a TSH level of 0.45–0.99 mIU/L, HR 0.97 (95 % CI 0.73–1.28) for a TSH level of 1.00–1.49 mIU/L, HR 1.14 (95 % CI 0.89–1.46) for a TSH level of 1.50–2.49 mIU/L, and HR 1.07 (95 % CI 0.82–1.39) for a TSH of 2.50–3.49 mIU/L compared to a TSH level of 3.50–4.49 mIU/L. Subclinical hypothyroidism was not significantly associated with a lower risk of incident AF (HR 1.15 [95%CI 0.86–1.55] for TSH 4.5–6.9 mIU/L, HR 0.80 [95 % CI 0.50–1.28] for TSH 7.0–9.9 mIU/L and HR 1.29 [95%CI 0.75–2.20] for TSH 10.0–19.9 mIU/L). Excluding patients with thyroid hormone medication at baseline yielded similar results.

CONCLUSIONS: Euthyroid individuals, even those with TSH levels within the low-normal range, are not at increased risk of developing AF, whereas the risk of AF increases with lower TSH levels in patients with subclinical hyperthyroidism. Subclinical hypothyroidism is not associated with a protective effect for AF. These data do not support changing the lower or upper limit of TSH based upon the risk of AF.

SHARED SYSTEMS, PERSONAL DECISIONS: VARIATION IN MAMMOGRAPHY UTILIZATION AMONG A DIVERSE GROUP OF WOMEN AGED 40–49 YEARS. Hana Akselrod; Kathleen Fairfield. Maine Medical Center, Portland, ME. (Tracking ID #2199345)

BACKGROUND: Since 2009, the US Preventive Services Task Force (USPSTF) has recommended that physicians engage in individualized decision-making regarding starting screening mammography in women before age 50, taking into account clinical factors as well as patient values and beliefs regarding specific benefits and harms. Prior research and clinical experience suggest that such individualized decision-making can prove challenging when there are barriers of language, culture, or trust between the patient and her provider. In recent years, our area has become home to a large population of refugees and secondary migrants hailing from areas as diverse as East Africa, the Middle East, Central Asia, and Latin America. Consequent to this demographic transition, our health system now serves a diverse population of patients, with cultural and socioeconomic barriers to optimal preventive care and shared decision making (SDM). At the same time, the integration of a system-wide electronic health record (EHR) affords an unprecedented opportunity to examine screening practices and SDM across populations. We therefore designed a study aiming (1) to describe patterns of mammography utilization in women aged 40–49 receiving primary care through in our network; and (2) to assess whether SDM took place with equal frequency among English-speaking versus non-speaking patients.

METHODS: After human subjects review, we queried the EHR to identify a retrospective cohort of women aged 40–49 who were seen for primary care visits in 2013. The primary outcome was incidence of screening mammography (performed or ordered during the study period). Covariates of interest included demographic variables including ethnicity, primary language, insurance type, zip code, and clinical site; and pertinent history affecting risk of breast cancer (medical, family, and social). Descriptive and analytical statistics were obtained using SAS software to evaluate relationships between covariate and outcome variables, and to identify disparities between demographic groups. Next, a systematic chart review will be conducted on a randomly selected subsample using a scoring system to assess documentation of SDM before the ordering of mammography.

RESULTS: Of a total of 3343 patients meeting inclusion criteria, 1265 (38 %) of the women had a mammogram in 2013. Compared to patients identified as White Non-Hispanic, who accounted for 87 % of the population, mammography rates were significantly higher among patients who self-identified as Asian (52 % vs. 38 %; *p*=0.006) and as Multiracial/Other (71 % vs. 38 %; *p*<0.001). Among English-speaking patients, mammography screening rate was lower compared to patients whose primary language was not English (38 % vs. 47 %; *p*=0.005). Never-smokers had lower screening rate (20 %) compared to either current (27 %) or former (45 %) smokers (*p*<0.001). Among women with public insurance (Medicare/Medicaid), rates were lower compared to those with self-pay or private insurance (30 % vs. 40 %, *p*<0.001). There was wide variation in mammography rates between the ten ambulatory sites, ranging from 29 to 50 %. Systematic chart reviews are being performed to determine whether SDM was documented.

CONCLUSIONS: Mammography screening continues to be performed quite commonly among women in their 40s in our patient population, at rates roughly comparable to the nationally reported figures (reported between 40 and 50 % in 2011 NHANES). On initial analysis, screening rates in our patients varied widely by racial/ethnic group, national origin, insurance type, smoking, and clinic location. We have found that specific racial/ethnic minority status and lack of English fluency in our patient population were associated with higher rates of mammography during the study period. Additional reviews are being conducted to explore the role of SDM in the clinical encounters preceding the screening, to assess whether the higher screening rates observed in some patient groups are

the outcomes of engaging in SDM, or on the contrary may indicate a disproportionate lack of engagement.

SKILLS FOR IDENTIFYING A STRUGGLING COLLEAGUE: I CANNOT TAKE THIS ANY MORE! Sondra Zabar¹; Russell Burman¹; Mark Hochberg¹; Donna Phillips¹; Amara Shaker-Brown¹; Kathleen Hanley¹; Adina Kalet²; Colleen Gillespie¹. ¹NYU School of Medicine, New York, NY; ²New York University School of Medicine, New York, NY. (Tracking ID #2198823)

BACKGROUND: House staff generally receive little training in recognizing a colleague at risk. Even if they do realize a colleague needs help, there is reluctance to recommend or seek care because of the stigma surrounding emotional distress and the fear of being labeled as “incompetent” or “weak”. Residency training has been documented to be a stressful time. There is a need to change the culture in training programs and make sure all residents have the skills to address these issues and understand resources that are available.

METHODS: We designed an OSCE station to assess a resident’s ability to recognize substance abuse and depression in a colleague, to assess the acuteness of the situation and to make a plan. Skills were assessed in a 10-min case by “Standardized Intern” as part of the annual multi-station OSCE for 2 surgical residency programs and one medicine program. The learner was tasked with “giving sign-out” to an intern (Standardized Healthcare Professional) coming on-service with a reputation for being disorganized and a loner. The SHP is scripted to make clear comments about how difficult residency is and admits to being stressed. Case background includes being new to the city, stressed about residency and meeting criteria for major depression and risky alcohol use. A checklist was created to assess general communication and case specific skills. Domains included: depression and substance use screen, current life situation assessment, and follow-up. Item response options were: not done, partly done, and well done, each with descriptive behavioral anchors to enhance rating reliability.

RESULTS: Sixty residents performed the case: 37 surgical and 24 medical. Almost all residents checked in with the intern about their emotional state (49/60; 82 %). Eleven percent (1 surgical and 6 medical residents) fully screened for depression with 2 question screen but a third asked generally about depression (21/60). Almost half did not ask about depression (28/60). Ten percent (6 medical residents) asked about suicidal ideations, 8 surgical residents asked if he thought about hurting himself and 46/60 did not ask about suicide. Over half of the surgical residents asked about alcohol use (20/37) compared to only less than a third of medical residents (7/23). A quarter (15/60) of the residents attempted to identify a person for the intern to talk to, either outside or inside the program. For follow up, 75 % (45/60) personally included themselves in the intern’s support system and 65 % (39/60) directed them toward specific resources (e.g. GME psychiatrist, program director, or outside resource).

CONCLUSIONS: We identified a wide range of performance across three programs but most importantly this case provided an opportunity for experiential learning and an open discussion of an important topic. This data will help us design a curriculum on resident wellness.

SOCIAL SUPPORT AND ITS RELATIONSHIP TO ADVANCE CARE PLANNING Phuong Luu¹; Lucy Meoni²; Marie Nolan³; Joseph J. Gallo². ¹Johns Hopkins University School of Medicine, Baltimore, MD; ²Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD; ³Johns Hopkins University School of Nursing, Baltimore, MD. (Tracking ID #2193025)

BACKGROUND: The Institute of Medicine’s recent report on “Dying in America” highlights the urgent need to focus on advance care planning to improve end-of-life care. Social support is an important component in understanding how patients approach advance care planning, however, limited studies have focused on this association. Thus our study’s aim was to assess whether older adults were more likely to complete an advance directive or have end-of-life discussions with their family and/or friends if they had strong social support.

METHODS: We conducted a cross-sectional study using the 2012 Precursors Study questionnaire. The Precursors Study is a cohort study of medical students beginning in the 1960’s. Social support was defined using the Medical Outcomes Study (MOS) Social Support Survey, which is further divided into four subscales of emotional, tangible, affective and positive social support. The overall social support score and each of the four subscales total scores were averaged and generated into binary variables. Respondents who had an average score of 5 within each subscale or across the overall social support scale, were assigned a 1 for that subscale or total score. All others were assigned a zero. The outcomes assessed were self-reported completion of advance directive or reporting having had an end-of-life discussion with family and/or friends. Five multivariate logistic models were done for the overall support scale and each of the subscales, respectively. Each model was adjusted for age, marital status, retirement status, personal preferences for

end-of-life care, and preferences regarding doctor's input and loved ones' input in end-of-life care.

RESULTS: Of those who answered the question regarding advance directive completion ($N=449$), 85 % reported having an advance directive. Of those who answered the question regarding end-of-life discussion ($N=452$), 94 % reported having had an end-of-life discussion with their family and/or friends. Tangible support (adjusted OR 2.00, 95 % CI 1.13–3.57) and positive social support (adjusted OR 2.49, 95 % CI 1.38–4.50) were significantly associated with advance directive completion. Affective support (adjusted OR 2.92, 95 % CI 1.18–7.22) was significantly associated with reported having had an end-of-life discussion with family and/or friends. Though the remainder of the associations were not statistically significant, they all showed trend towards greater social support, regardless of the type, being related to completing an advance directive or having an end-of-life discussion.

CONCLUSIONS: Our results indicate that specific types of social support are associated with advance care planning. Individuals reporting tangible, affective and positive social support had greater than two-fold odds of reporting advance care planning. To our knowledge, this is the first study to utilize the MOS social support survey to understand the role of social support in advance care planning. These findings indicate that approaches to advance care planning should incorporate discussions regarding the patient's social support.

THE 5 PHENOTYPES OF HIGH COST PATIENT Sang Been N. Hong², Noah Whitman¹, Nirav Vakharia¹, Michael B. Rothberg¹. ¹Cleveland Clinic, Cleveland, OH; ²Cleveland Clinic, Cleveland Heights, OH. (Tracking ID #2190027)

BACKGROUND: In order to design cost reduction strategies, it is important to understand the resource utilization patterns of those patients who drive the majority of healthcare costs. High cost patients may use resources in diverse ways. We used cluster analysis to identify profiles of utilization among the high cost population.

METHODS: We utilized a retrospective observational design. Using the Quality Resource and Use Report distributed by the Centers for Medicare and Medicaid Services, we identified all Medicare patients who were hospitalized exclusively at Cleveland Clinic Health System (CCHS) hospitals and received ≥ 90 % of their primary care services at a CCHS facility in 2012. We defined high-cost patients as the 10 % of the population with the highest sum of direct and indirect costs at a CCHS facility, based on CCHS internal cost accounting data. Total admissions, inpatient days, ICU days, inpatient surgeries, ED visits, and outpatient visits were obtained from the electronic medical record. We used the Agency for Healthcare Research and Quality Clinical Conditions Software to group ICD-9 diagnosis and procedures codes. Based on data review and clinical judgment, we used the k-medoids, a clustering algorithm that robustly organizes a heterogeneous dataset into a pre-determined number of distinct groups, to create five clusters. For each cluster, odds ratios of 24 high cost conditions were calculated in comparison to the high-cost population mean prevalence. Statistical significance was calculated by logistic regression.

RESULTS: Our high-cost sample included 1486 patients; 55 % were male, and median age was 68 (IQR 15). The "ambulatory" cluster contained patients with few admissions or ED visits (Table). They were most likely to have cancer and chemotherapy. "Surgical" patients generally had one expensive surgical admission. They had the highest odds of osteoarthritis and procedure/device complications; 61 % of these patients with osteoarthritis received arthroplasty. "Critically Ill" patients required intensive care; they had the highest inpatient as well as overall costs. They had higher odds of heart failure and cardiac arrhythmia and arrest. The "Frequent Care" cluster had frequent admissions, ED visits, and outpatient visits. Psychiatric disorders and COPD/asthma were most characteristic. "Mixed Utilization" patients had a mixture of admissions, ED visits, primary care visits, and specialist visits. They were not characterized by specific diagnoses, but complications of medical care and procedures were less common in this cluster.

CONCLUSIONS: Using cluster analysis, we identified subgroups of high cost patients exhibiting distinct utilization patterns. Efforts to reduce cost may benefit from a targeted approach that addresses the diversity of high cost utilization.

	Ambulatory Care	Surgical	Critically Ill	Frequent Care	Mixed Utilization

THE EFFECT OF A PAYER-MANDATED DECREASE IN BUPRENORPHINE DOSE ON RELAPSE RATES OF PATIENTS WITH OPIOID DEPENDENCE, A NATURAL EXPERIMENT. Anthony Accurso. Johns Hopkins Bayview Medical Center, Baltimore, MD. (Tracking ID #2197277)

BACKGROUND: Although office-based buprenorphine therapy is now a decade old, the optimal buprenorphine maintenance dose is still not known. Under-dosing may lead to

craving and use of illicit drugs, while providing higher than needed doses may contribute to pill-diversion. In January 2013, a major local Medicaid-insurance organization stopped covering buprenorphine doses greater than 16 mg/day without prior authorization. This policy led to a subset of patients on stable buprenorphine therapy of higher doses being forced to decrease their dose to 16 mg/day. This event created conditions for a natural experiment in which to study the effects of a mandated dose decrease. The objective of the study was to assess whether patients with prior stability on higher doses of buprenorphine had greater relapse rates after this payer-imposed dose decrease.

METHODS: This study was a retrospective cohort study of laboratory test results and charts from patients at an urban, primary-care clinic in Baltimore with academic affiliation. The study population was comprised of patients of adults with a diagnosis of opioid dependence who had been maintained on buprenorphine from September through December 2012. Urine drug testing results for the entire practice were obtained from the period of August 2012–April 2013. Charts were reviewed to determine each subject's insurer, buprenorphine dose, and other prescribed medications. Cohorts were then created with an experimental group comprised of patients who had experienced a dose decrease, and control groups based on insurer and buprenorphine dose, as described in Table 1. Urine drug testing was aggregated by test date and defined as “pass” or “fail” with “pass” defined as the presence of buprenorphine and absence of cocaine, opiates, methadone or nonprescribed benzodiazepines. Pass rates were calculated for each patient in the pre and post period of the study, which were then compared for each patient with the Wilcoxon Signed Rank Test.

RESULTS: We identified 410 patients in our practice who had been prescribed buprenorphine during the study period, of whom 310 met study criteria. Of those, 98 patients experienced a payer-mandated buprenorphine dose decrease, and were assigned to group 1. Overall pre-decrease urine pass rate by patient was 75 %, and post-decrease urine pass rate was 66 %, ($p=0.030$). This analysis was repeated among three other control groups, none of which showed a significant change in urine pass-rate.

CONCLUSIONS: Our study suggests that mandated limits on buprenorphine dose may lead to increases in other drug use, at least in the short term. This data can inform policy decisions about the proper maintenance dose of buprenorphine. Of note, while a mandated dose-decrease to 16 mg had a statistically significant negative effect on treatment success, the effect size was small. Many of the patients in the practice tolerated the switch and acclimated to the dose decrease. Further research is needed on the optimal dosing of buprenorphine.

Description of Group Attributes and Pre/Post-Period Urine Pass Rates

	High Dose to Low Dose Imposed by Insurer	Low Dose, Same Insurer	High Dose, Other Insurer	Low Dose, Other Insurer

Mandated Dose Decrease	Yes	No	No	No
Insurance	Priority Partners	Priority Partners	Other Insurance	Other Insurance
Initial Daily Buprenorphine Dosage	>16 mg	≤16 mg	>16 mg	≤16 mg
Pre-Period Pass Rate (%)	74.5	68.5	78.5	67.9
Post-Period Pass Rate (%)	65.9	63.3	80.1	65.1
<i>p</i> -value	0.030	0.203	0.659	0.307

THE IMPACT OF A HEART FAILURE PATHWAY IMPLEMENTATION: AN INSTITUTIONAL REVIEW Charles Allderice²; Neal Mehta, MD²; William Burkhardt²; Nicole Simmons, APN²; Laura Bullock, PharmD²; Eric Heidele, PhD²; Natalie Varner, PhD²; Mark Rasnake¹. ¹UT Medical Center Knoxville, Knoxville, TN; ²University of Tennessee Medical Center-Knoxville, Knoxville, TN. (Tracking ID #2195792)

BACKGROUND: Heart failure is a primary diagnosis on admission in over 1 million cases annually and its prevalence is expected to rise 46 % by 2030 as survival after diagnosis has increased. All-cause re-hospitalization can reach as high as 25 % within one month, with case fatality rates being as high as 10.4 %. Our facility created a multidisciplinary clinical pathway to facilitate the provision of evidenced based care for heart failure patients. To compare the efficacy of this pathway versus standard care, we examined the primary endpoints of length of stay, 30-day readmission rate, and all-cause mortality for patients admitted with a primary diagnosis of heart failure. Secondary endpoints include evidence based heart failure medications administered upon discharge.

METHODS: All adults admitted with a primary diagnosis of heart failure to our facility between January 1, 2014 and June 30, 2014 were eligible for the study. Subjects were identified using ICD-9-CM heart failure codes. Baseline characteristics according to admission history and physicals and echocardiogram reports were compared. Adverse events including acute kidney injury and hyperkalemia were reviewed. Those placed on hospice or admitted primarily for other interventions were excluded.

RESULTS: A total of 310 patients were admitted with heart failure between January and June 2014, with 308 being included in the study. 133 (43 %) patients were managed through use of a pathway versus 175 (57 %) who underwent standard care. Length of stay remained equivalent at 5.64 days for both sets of patients, with a p -value of 0.99. There was a trend toward lower 30-day readmission (26 versus 23) and all-cause mortality (12 versus 4) with use of a pathway, however, the results did not reach significance. (p -value 0.64 and 0.14 respectively). Adverse events during the hospitalization including acute kidney injury and hyperkalemia showed no statistical difference (p -value 0.65 and 0.81 respectively). Secondary outcomes regarding evidence based heart failure medications on discharge also showed no statistical difference.

CONCLUSIONS: Among patients admitted with a primary diagnosis of heart failure, 43 % were managed with use of a pathway. Baseline characteristics and adverse events were compared between both groups and showed no significant difference. Pathway implementation did not reduce 30-day readmission rate, all-cause mortality, and length of stay, with length of stay remaining unchanged between both groups. None of these findings reached significance among unadjusted comparisons. Secondary outcomes regarding medication use at discharge according to evidence based medication guidelines also showed no difference with use of a pathway versus standard care. Our institution's compliance with heart failure core measures was 96.6 % prior to pathway implementation, potentially limiting the amount of benefit achievable through pathway use. It is also unclear of the impact of this pathway after discharge. Such entities as nursing patient education and appropriate outpatient follow up were not taken into account. This use of the pathway may have direct positive results and will need further review in future studies.

THE RELATIONSHIP AMONG OPIOID USE, HIV, AND ACCIDENTAL DEATH: IS IT IN THE EYE OF THE BEHOLDER? William Becker²; Janet P. Tate⁶; Eva J. Edelman⁶; Julie Gaither³; Kathleen Akgun²; Declan Barry³; Stephen Crystal⁴; Adam Gordon¹; Jessica S. Merlin²; Robert D. Kerns²; Amy C. Justice⁶; David A. Fiellin⁶. ¹University of Pittsburgh and VA Pittsburgh Healthcare System, Pittsburgh, PA; ²VA Connecticut, West Haven, CT; ³Yale University, New Haven, CT; ⁴Rutgers University, New Brunswick, NJ; ⁵University of Alabama at Birmingham, Birmingham, AL; ⁶Internal Medicine, Yale University, New Haven, CT. (Tracking ID #2198782)

BACKGROUND: Opioid-related accidental deaths, including unintentional overdose, have increased markedly in the U.S. Several large observational studies have demonstrated increased risk of opioid-related accidental death among those with serious mental illness, substance use disorders and pain, conditions that are disproportionately prevalent among individuals with HIV. Furthermore, as individuals with HIV live longer, they may be more vulnerable to harm from opioid use. To understand the relationship among opioid use, HIV status and accidental death, exposures and outcomes need to be determined in an unbiased manner. Recognizing that assigning cause of death is challenging and may be subject to bias, we sought to examine whether the relationship between opioid use and accidental death, including unintentional overdose death, varied by HIV status.

METHODS: Our data source was the Veterans Aging Cohort Study (VACS), a cohort of HIV-infected and matched uninfected Veterans consented for prospective, recurrent surveys on alcohol and drug use (including heroin and non-medical use of prescription opioids), among other health behaviors, with survey data linked to the electronic medical record (e.g. pharmacy data). Our analytic sample consisted of VACS decedents from 2002–2009 who, prior to death, responded to at least one follow-up survey. We linked VACS records with the National Death Index cause of death file, which lists underlying and contributory causes of death as reported by the medical examiner or coroner. Based on ICD-10 codes, we categorized cause of death, either underlying or contributory, as accidental (e.g. motor vehicle crash), unintentional overdose, or other, and categorized decedents as having had opioid use or not based on VACS survey self-report. Stratified by decedent's HIV status, we calculated the ratio—with and without opioid use—of the proportion of decedents coded as accidental death and, separately, calculated the ratio—with and without opioid use—of the proportion of decedents with unintentional overdose death. For comparison, we examined different measures of opioid use (i.e. self-reported heroin use and pharmacy record of opioid receipt).

RESULTS: The sample consisted of 738 HIV-infected and 321 uninfected decedents. Accidental death and unintentional overdose death were 9.5 and 2.6 % of total deaths, respectively, with HIV-infected decedents less likely to be coded as having an accidental death (8.1 % vs. 12.8 %, $p<.001$) and equally likely to be coded as unintentional overdose death (2.5 % vs. 2.8 %, $p=.322$). Opioid use was equally likely in decedents with and without HIV (24 % vs 26 %; $p=.587$). As depicted in the Table, among HIV-infected decedents, the ratio of opioid use vs. non-use status was 1.0 ($p=.821$) for those coded as having an accidental death and 1.7 ($p=.269$) for unintentional overdose death. However, uninfected decedents with opioid use were 4 times as likely to be coded as having an accidental death than those without opioid use ($p<.001$) and were 6.4 times as

likely to be coded as having an unintentional overdose death than those without opioid use ($p=.003$). Patterns were similar regardless of measure of opioid use.

CONCLUSIONS: While opioid use was equally likely among decedents with and without HIV, the non-differential coding of accidental and unintentional overdose death among HIV-infected respondents with and without opioid use suggests a potential misclassification bias away from coding cause of death as opioid-related. Caution should be used in interpreting accidental and unintentional overdose death data among patients with life-limiting, chronic conditions. Future efforts to improve the validity of cause of death classification may be warranted to promote better understanding of harms of opioid treatment in vulnerable populations.

Self-Reported Opioid Use and Cause of Death by HIV status

	HIV (+) n=738			HIV (-) n=321		
	Opioid use	No opioid use	Ratio (p value)	Opioid use	No opioid use	Ratio (p value)

Unintentional overdose death; n, (proportion)	7 (3.7)	1 2 (2.2)	1 . 7 (.27)	6 (7.7)	3 (1.2)	6 . 4 (.003)

THE RELATIONSHIP BETWEEN PRIMARY CARE ORGANIZATIONAL PROCESSES AND PATIENT-REPORTED CARE EXPERIENCES Jaya Aysola¹; Rachel M. Werner². ¹University of Pennsylvania, Philadelphia, PA; ²University of Pennsylvania and Philadelphia VA, Philadelphia, PA. (Tracking ID #2199159)

BACKGROUND: There is increasing emphasis on the use of patient-reported experience data in the evaluations of outpatient primary care practice and provider performance. Yet there remains an insufficient understanding of what aspects of primary care organizational processes relate to patient primary care experiences. Therefore, we evaluated the relationships between organizational processes and patient-reported experiences in the network of University of Pennsylvania primary care practices.

METHODS: We analyzed visit data from patients ($n=8356$) collected between January 2012 through July 2014 at all University of Pennsylvania Health System affiliated adult primary care practices with three or more providers ($n=22$). We first surveyed practice managers at these 22 sites using a previously validated scale from 0 to 100 to quantify practice adoption of organizational processes across six domains: access and communication; patient tracking and registry; care management; test referral tracking; quality improvement; and external coordination. This practice-level data was then linked to data on patient experience and demographics. Experience was measured using visit-triggered survey data generating a patient experience score (0 to 100). To investigate the relationship between practice structural processes and patient experience, we used generalized estimating equations (GEE) with an exchangeable correlation structure to account for patient clustering by practice. In our multivariate models we accounted for practice location, practice patient panel size, number and type of providers, as well as patient demographics and clinical comorbidities (Charlson Comorbidity Index (CCI)). To determine if relationships between practice processes and patient experiences varied by the degree of patient comorbidity, we performed the above models stratified by categorical CCI (0, 1, 2, >2).

RESULTS: The mean scores (SD) across the 22 practices for the six domains of organizational processes were as follows: 74.8 (10.2) for access and communication; 67.5 (11.6) for patient tracking and registry; 53.8 (11.3) for care management; 37.2 (10.5) for test referral tracking; 48.8 (9.6) for quality improvement; and 74.5 (12.7) for external coordination. Of the 8356 patients in the study, 64 % were female, 24 % were Black, 5.3 % had Medicaid, 6.3 % had multiple chronic conditions ($CCI>2$) and the mean age (SD) was 57 (17.5). The patient experience mean score (SD) was 87.4 (13.6). Amongst the entire patient sample in multivariate models, there were no statistical significant associations between any practice adopted processes and patient experience. Amongst a subset of patients with comorbid conditions ($CCI>2$), there were statistically significant positive associations between specific practice processes and overall patient experience and key aspects of patient experience, even after adjusting for a robust set of patient, provider, and practice characteristics. For example, a 10-point higher practice score in patient tracking

and registry was associated with a 1.8 percentage point higher score in overall patient experience (95 % CI, 0.3, 2.0; $p=0.007$), as well as a 1.5 percentage point higher score in patient experiences with access (95 % CI, 0.2, 2.8; $p=0.02$). In addition, a 10-point higher score care management was associated with a 2.4 percentage point higher score in patient experiences with access (95 % CI, 1.6, 3.2; $p<0.001$).

CONCLUSIONS: Amongst all primary care patients in our sample, we found no significant associations between practice adoption of organizational processes and patient experience in multivariate models. Understanding what practice processes if any influence patient experiences of care is paramount to improving practice and provider performance in this area. Amongst the subset of patients with comorbidities ($CCI>2$), we found that organizational processes across several domains were positively associated with patient care experiences. These findings suggest that extensive practice efforts to adopt well-promoted organizational processes do appear to be associated with better care experiences in a subset of patients with multiple chronic conditions and that practices may benefit from targeting current efforts in practice redesign towards those patients.

THE ROLE OF CONTINUITY IN HOSPITAL CARE FOR READMITTED COLON CANCER PATIENTS Phuong Luu²; Tanvir Hussain²; Hsien-Yen Chang¹; Elizabeth Pföh²; Craig E. Pollack². ¹Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; ²Johns Hopkins University School of Medicine, Baltimore, MD. (Tracking ID #2193016)

BACKGROUND: Readmissions may reflect a failure to provide care and/or to coordinate care prior to discharge, resulting in increased cost and potentially poorer outcomes. Identifying how to best care for this high risk group during readmissions to contain further cost and prevent poor outcomes has received relatively little attention. Our study seeks to evaluate whether mortality and costs differ based on whether patients are readmitted to the hospital they were initially discharged from or to a different hospital. We chose colon cancer as an important example; colon cancer is a leading cause of cancer mortality, its treatment often requires patients to see multiple different types of specialists, and efforts have focused on improving continuity of care for patients with cancer.

METHODS: We conducted a retrospective analysis using SEER-Medicare linked data of patients with stage I-III colon cancer between 2000 and 2009 who had surgery within 3 months of diagnosis and were readmitted within 30-days of discharge from their surgical hospital. Our independent variable was whether a patient was readmitted to the same hospital as their initial discharge or a different hospital. Our primary outcome was all-cause mortality (censor date: 12/31/2011). Secondary outcomes included colon cancer specific mortality and costs of care in the 12-months following diagnosis. We used Cox proportional hazards to assess all-cause mortality and subhazards for colon cancer specific mortality; we employed hierarchical generalized linear models for 12-months costs. For each model, we used a propensity-score weighted doubly robust approach to adjust for patient, physician, and hospital characteristics.

RESULTS: Approximately 23 % ($N=769$) of the 3399 patients were readmitted to a different hospital than where they were initially discharged. Those readmitted to a different hospital tended to be older and have higher comorbidity burden compared to those readmitted to their initial discharge hospital. After adjustment, there was no difference in either all-cause or colon cancer specific mortality for patients readmitted to a different hospital compared to those readmitted to the same hospital (adjusted Hazard Ratio [HR] 1.09, 95 % Confidence Interval [CI] 0.97–1.24 for all-cause mortality; adjusted HR 0.98, 95 % CI 0.56–1.73 for colon cancer specific mortality). However, costs of care were significantly higher among patients readmitted to a different hospital (the adjusted costs difference was \$13,364, 95 % CI \$742–\$28,954) for 12-months after colon cancer diagnosis.

CONCLUSIONS: Almost a quarter of patients were readmitted to a hospital different from which they were discharged; this may pose a challenge to providing continuity in care as these patients are more likely to be older and have more comorbidities and may increase health care expenses. Creating continuity between episodes of hospital care may be a strategy for managing the complex care of cancer patients.

THE USE OF TABLET TECHNOLOGY BY ELDERLY IN HEALTH CARE SETTINGS—IS IT EFFECTIVE AND SATISFYING? A SYSTEMATIC REVIEW AND META ANALYSIS Chethan Ramprasad²; Leonardo Tamariz¹; Yanira Garcia-Barcena²; Ana Palacio². ¹University of Miami, Miami, FL; ²University of Miami Miller School of Medicine, Miami, FL. (Tracking ID #2198013)

BACKGROUND: Tablet technologies such as iPads have become ubiquitous in today's society. The use of these technologies by the elderly in clinical settings has the potential to increase clinical effectiveness as well as satisfaction. Appropriate use may reduce health care costs, especially for chronic conditions. The objective of the current study is to

systematically review, appraise, and summarize the evidence of the impact of tablet technology on clinical effectiveness and satisfaction in cross-sectional, pre/post, and randomized controlled trials.

METHODS: A comprehensive literature search was conducted of Pubmed, Scopus, CINAHL through July 2014 using keywords such as 'iPads', 'tablet technology', 'elderly' and 'health promotion.' We included randomized control trials, cross sectional, and pre/post studies. We defined satisfaction to include direct ratings of satisfaction as well as indirect ratings of satisfaction such as helpfulness, completion rates, and usability. We defined effectiveness as any improved health outcome including memory scores, blood pressure control, medication error reduction, number of steps per day, and gait speed. To calculate the pooled prevalent satisfaction we used the inverse variance method. To calculate effectiveness we used DeSirmonian and Laird method. This reported the standardized mean difference (SMD) for both intervention and control groups between two measurements before and after the intervention in randomized studies.

RESULTS: Our search strategy yielded 265 abstracts. We excluded 250 on abstract level and selected 25 for full-text review. We included a total of 9 studies (3

randomized controlled trials, 3 cross-sectional, 3 pre/post) with a median methodological quality of 26 out of 31 for cross-sectional and pre/post studies and 34 out of 37 for randomized control trials. There were a total of 517 subjects. The 9 studies included interventions of medication self-management, post-surgery education, memory retention, speech rehabilitation, and exercise promotion. The mean age was 70.07 (2.83). Common conditions among patients included diabetes, dementia, aphasia, and COPD. The 9 studies took place in the United States with the exception of one each in Spain, Switzerland, Australia, and South Korea. The pooled prevalence of satisfaction was 76 %; 95 % CI 21–100. The SMD for the intervention group was -0.22 ; 95 % CI -0.49 to 0.04 $p=0.09$ and the SMD for the control group was -0.014 ; 95 % CI -0.16 to 0.13 $p=0.85$.

CONCLUSIONS: The use of tablet technology by the elderly is associated with high satisfaction. There was a trend towards the improvement of health behaviors such as medicine self-management, memory retention, and exercise promotion. Given high satisfaction, there is strong potential for increased effectiveness for tablet technology use in patient education and rehabilitation as well. More studies should be conducted for further evaluation of such technology interventions.

TIOTROPIUM RESPIMAT®: CONTROL IN SYMPTOMATIC ASTHMA Kevin Murphy¹; William Berger²; Michael Engel³; Hendrik Schmidt⁴; Petra Moroni-Zentgraf⁵; Huib A. Kerstjens⁵. ¹BTNRH, Boys Town, NE; ²Southern California Research Center, Mission Viejo, CA; ³Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim am Rhein, Germany; ⁴Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach an der Riss, Germany; ⁵University of Groningen, Groningen, Netherlands. (Tracking ID #2194847)

BACKGROUND: The goal of asthma treatment is to achieve control and minimize future risk. Here we assess the efficacy of once-daily tiotropium Respimat® add-on to inhaled corticosteroid (ICS)±long-acting β_2 -agonist (LABA) maintenance therapy in patients with symptomatic asthma: lung function, asthma control, and asthma worsening data are presented.

METHODS: Data were evaluated from four Phase III, randomized, double-blind, placebo-controlled, parallel-group trials. PrimoTinA-asthma® (NCT00776984/NCT00772538): once-daily tiotropium Respimat® 5 µg or placebo Respimat® add-on to high-dose ICS (≥800 µg budesonide or equivalent) plus a LABA in adults over 48 weeks; MezzoTinA-asthma® (NCT01172808/NCT01172821): once-daily tiotropium Respimat® 5 µg or 2.5 µg, twice-daily salmeterol hydrofluoroalkane metered-dose inhaler 50 µg, or placebo (identical devices in a double-dummy protocol) add-on to medium-dose ICS (400–800 µg budesonide or equivalent) in adults over 24 weeks. Lung function was assessed at 24 weeks as peak forced expiratory volume in 1 s (FEV₁) within 3 h post-dose (peak FEV_{1(0-3h)}) and trough FEV₁. Asthma symptoms and control were assessed using the seven-question Asthma Control Questionnaire (ACQ-7) as responder rate (percentage

of patients with minimally important change of ≥0.5). Time to first episode of asthma worsening (defined as a progressive increase in symptoms, or a ≥30 % decrease in best morning peak expiratory flow from the patient's mean morning peak expiratory flow for ≥2 consecutive days) was also assessed.

RESULTS: Overall, 3012 patients were treated (PrimoTinA-asthma®, *n*=912; MezzoTinA-asthma®, *n*=2100). Tiotropium Respimat® provided statistically significant and sustained improvements in both peak FEV_{1(0-3h)} (all *p*<0.05) and trough FEV₁ (all *p*<0.01) responses compared with placebo. A higher proportion of patients achieved an ACQ-7 response with tiotropium Respimat® compared with placebo (Table). Risk of asthma worsening was reduced with tiotropium Respimat® compared with placebo: 31 % risk reduction [RR] with 5 µg (hazard ratio [HR] 0.69; 95 % confidence interval [CI] 0.58, 0.82; *p*<0.001) in PrimoTinA-asthma® over 48 weeks; 13 % RR with 5 µg (HR 0.87; 95 % CI 0.69, 1.08; *p*=0.211) and 34 % RR with 2.5 µg (HR 0.66; 95 % CI 0.52, 0.84; *p*<0.001) in MezzoTinA-asthma® over 24 weeks. The incidence of adverse events (AEs) was balanced between the treatment groups in all trials: PrimoTinA-asthma®, 73.5 and 80.3 % for tiotropium Respimat® 5 µg and placebo Respimat®, MezzoTinA-asthma®, 57.3 %, 58.2 %, and 59.1 % for tiotropium Respimat® 5 µg, tiotropium Respimat® 2.5 µg, and placebo, respectively. The incidence of serious AEs and drug-related AEs was low in all treatment groups. No fatal adverse events were reported.

CONCLUSIONS: Once-daily tiotropium Respimat® add-on to at least medium-dose ICS±LABA provided significant and sustained improvements in lung function, improved asthma control, and reduced risk of asthma worsening in adults with moderate or severe symptomatic asthma.

TOWARD NATIONAL ESTIMATES OF INPATIENT QUALITY OF CARE AMONG HISPANICS: THE CASE OF ACUTE MYOCARDIAL INFARCTION MORTALITY RATES Meng-Yun Lin^{1, 4}; Nancy R. Kressin^{2, 3}; Michael Paasche-Orlow²; Lenny Lopez⁵; Jennifer E. Rosen⁶; Amresh D. Hanchate^{2, 3}. ¹Boston Medical Center, Boston, MA; ²Boston University School of Medicine, Boston, MA; ³Dept of Veterans Affairs and Boston University, West Roxbury, MA; ⁴Boston University School of Public Health, Boston, MA; ⁵Harvard University, Boston, MA; ⁶MedStar Washington Hospital Center, Washington, DC. (Tracking ID #2195780)

BACKGROUND: Although Hispanics now form the largest US minority, national estimates of disparities in quality of inpatient care have largely focused on the differences between blacks and whites, partly due to data limitations, including misclassification of Hispanics. We pooled inpatient discharge data from 15 states that together contain over 85 % of the national Hispanic population, and with near-complete identification of Hispanic ethnicity. Applying the Agency for Healthcare Research & Quality (AHRQ) Inpatient Quality Indicators (IQI) protocol, we compared risk-adjusted inpatient mortality from acute myocardial infarction (AMI) among Hispanics, non-Hispanic blacks, and non-Hispanic whites.

METHODS: Using comprehensive inpatient discharge data from Arizona, California, Colorado, Florida, Massachusetts, Maryland, New Jersey, New Mexico, Nevada, New York, Oregon, Pennsylvania, Texas, Virginia, and Washington, we identified AMI discharges for patients 18 and older in 2010–2011. Following AHRQ IQI protocol, we excluded discharges relating to

patients transferred between acute hospitals. Our primary estimate of interest was racial/ethnic differences in inpatient mortality rates (odds ratio [OR]) after adjusting for compositional differences in age, sex and comorbidities (Elixhauser indicators) using a logistic regression model with state-level fixed effects. To delineate confounding with socioeconomic status (SES) we further adjusted for county-level differences in zip-code household median income, poverty, uninsurance and provider availability. We estimated inpatient mortality differences among Hispanics by national origin (Mexican, Cuban, Puerto Rican and Other), using census data at county level. We also examined mortality disparities for ST-elevation and non-ST-elevation AMI (STEMI & NSTEMI). Statistical significance was assessed at 5 % level.

RESULTS: We identified 444,431 AMI discharges by patient race/ethnicity: Hispanics (12 %), blacks (9 %), whites (70 %), others (6 %) and missing (3 %). Observed inpatient mortality was 6.4 % with lower rates among Hispanics (6.1 %) and blacks (5.5 %). Adjusted for age, sex, comorbidities, and state, and compared to whites, inpatient mortality was higher among Hispanics (OR=1.11, 95 % confidence interval (CI) [1.07, 1.16]) and similar among blacks (OR=1.01, 95 % CI [0.96, 1.05]) (Table 1). This trend persisted after additional adjustment for income, poverty, uninsurance, and provider availability. The distribution of the Hispanic population by national origin was: Mexican (62 %), Puerto Rico (9 %), Cuban (4 %), and Others (25 %). Compared to Mexican Hispanics, adjusted mortality was higher among Cuban Hispanics (OR=1.25, 95 % CI [1.12, 1.40]) and similar among Puerto Rican and Other Hispanics. For STEMI cases, adjusted mortality was higher among blacks (OR=1.21, 95 % CI [1.12, 1.30]) and Hispanics (OR=1.08, 95 % CI [1.01, 1.15]), and for NSTEMI cases, adjusted mortality was higher

among Hispanics (OR=1.18, 95 % CI [1.11, 1.27]) and similar among blacks (OR=0.99, 95 % CI [0.93, 1.05]).

CONCLUSIONS: Nationally, Hispanics experienced worse inpatient mortality following AMI compared to whites and blacks, among both types of AMI, and after accounting for SES indicators. Further research is needed to extend comparisons to other indicators of hospital quality outcomes, and to explore the underlying factors. **Keywords:** disparity, race, ethnicity, quality, acute myocardial infarction, inpatient mortality

Table 1 Racial/Ethnic Differences in AMI Inpatient Mortality Rates

Race/Ethnicity (ref=NH white)	Unadjusted OR [95 % CI]	Model 1 OR [95 % CI]	Model 2 OR [95 % CI]
Hispanics	0.94 [0.90, 0.97]	1.11 [1.07, 1.16]	1.08 [1.02, 1.14]
Black, NH	0.85 [0.81, 0.88]	1.01 [0.96, 1.05]	1.00 [0.94, 1.05]

TRANSITIONS OF CARE FROM OUTPATIENT TO INPATIENT: A SYSTEMATIC REVIEW [Phuong Luu](#)²; [Samantha I. Pitts](#)²; [Brent Petty](#)²; [Melinda Sawyer](#)¹; [Cheryl Himmelfarb-Dennison](#)¹; [Romsai T. Boonyasai](#)²; [Nisa Maruthur](#)². ¹Johns Hopkins University, Baltimore, MD; ²Johns Hopkins University School of Medicine, Baltimore, MD. (Tracking ID #2193027)

BACKGROUND: Optimizing delivery of care at times of transition has been a prominent focus of healthcare reform. However, most transitions of care research has focused on the transition from the acute care setting back to the outpatient setting. The transition from outpatient to acute care setting is also important, but little is known about the outpatient to acute care transition. We conducted a systematic review of the evidence on transitions of care from the outpatient to acute care setting, focusing on provider-to-provider communication and its impact on quality of care.

METHODS: We searched the MEDLINE, CINAHL, Scopus, EMBASE, and Cochrane electronic databases for English-language articles describing direct communication between an outpatient clinician (e.g., primary care provider, outpatient specialist, pharmacist, nursing home provider) and an acute care clinician (e.g., emergency department provider, hospitalist, pharmacist) around patients presenting to the emergency room or admitted to the hospital. Key questions were to describe communication and its impact on outcomes (e.g., 30-day readmission). Search terms were generated from database subject headings and keyword terms. We conducted double, independent review of titles, abstracts, and full text articles. All citations included by ≥1 reviewer were advanced to abstract review. Conflicts on abstract and full text article inclusions were resolved by consensus. Included articles were abstracted using standardized forms. Search results were maintained via Refworks (ProQuest, Bethesda, MD).

RESULTS: Of 4009 citations, twenty articles evaluated communication around the outpatient to acute care transition. Most studies were cross-sectional (12) with others being cohort studies (4), randomized controlled trials (3) and a pre-post study (1). Studies were conducted in the US (11), Australia (6) and the UK (3). Most transitions studied were from the outpatient clinic to admission to the hospital (12); others were clinic to the ED (4) and nursing home to ED (4). Modes of communication used were telephone (8), referral letters (5), fax (5), and in-person (2). None discussed communication via email. Primary care providers/general practitioners comprised the majority of outpatient providers (16), with the remainder being nursing home providers (4) and pharmacists (3). The majority of acute care providers were ED physicians (8), then hospitalists (4), pharmacists (2), residents (1), and unknown (3). Only 35 % of studies (7/20) evaluated outcomes related to provider-to-provider communication: Thirty-day readmissions (3 studies) and utilization of laboratory testing and imaging (2 studies) were lower when outpatient to acute care setting communication occurred. Patient satisfaction (1 study) and provider satisfaction (2 studies) were higher when communication was successful. There were no significant differences in length of hospital stay (2 studies) or mortality (2 studies) associated with provider-to-provider communication.

CONCLUSIONS: The literature on provider-to-provider communication at the transition from the outpatient to acute care setting is sparse and heterogeneous. The current evidence does suggest that successful communication at this transition can improve outcomes. Further research is needed on how to optimize communication to facilitate seamless transfer of information at this stage of care transitions.

TRENDS IN HOSPITAL-OWNERSHIP OF PHYSICIAN PRACTICES AND THE EFFECT ON PROCESSES TO IMPROVE QUALITY [Tara F. Bishop](#)^{1, 1}; [Shortell Stephen](#)²; [Patricia Ramsay](#)²; [Kennon Copeland](#)³; [Lawrence P. Casalino](#)¹. ¹Weill Cornell Medical College, New York, NY; ²University of California, Berkeley, CA; ³NORC at the University of Chicago, Bethesda, MD. (Tracking ID #2194686)

BACKGROUND: Recent reports suggest a trend for physician practices to change ownership from physicians to hospitals. It is unclear how a change to hospital-ownership affects quality of patient care. Given that hospitals generally have greater resources than physician practices, increased hospital ownership of practices may improve quality of care. The objective of this study was to report the change in prevalence of hospital ownership of physician practices owned and the effect on the use of care management processes (CMPs) and health information technology (HIT).

METHODS: We performed cross-sectional and trend analyses of the three largest national surveys of physician practices in the U.S. The sample consisted of a nationally-representative sample of leaders in primary care and select specialty practices in the U.S. treating patients with asthma, congestive heart failure, diabetes, and depression. Large practices (>19 physicians) were surveyed in 2005/2006 and 2012/2013. Small practices (≤19 physicians) were surveyed in 2008/2009 and 2012/2013. The main outcomes were the percentage of practices owned by hospitals in 2005/2006, 2008/2009, and 2012/2013 and the changes in CMP and HIT indices among practices that were acquired by hospitals.

RESULTS: There was a non-significant increase in the percentage of large practices that were owned by hospitals in 2005/2006 (26.6 %) and 2012/2013 (35.6 %, $p=0.37$) and small/medium practices that were owned by hospitals in 2008/2009 (8.3 %) and 2012/2013 (11.3 %, $p=0.47$). Large practices acquired by hospitals had larger increases in their CMP index than those that remained physician owned (11.0 point increase vs. 7.0 point decrease, adjusted p -value=0.03). Small/medium practices acquired by hospitals had smaller but significantly higher increases in their CMP score (3.8 points vs. 2.6 points, adjusted $p=0.04$) compared with practices that remained physician-owned. Among all practices, there were no significant differences in the change in the HIT index between practices that were acquired by hospitals versus those that remained physician-owned.

CONCLUSIONS: This survey of physician groups showed minimal increase in the percentage of practices that were owned by hospitals, which is contrary to some previous surveys and anecdotal reports that physician groups are rapidly being acquired by hospitals. It may be that practices are considering changes in ownership but have not made that change or that reports of this change are over-stating what is actually occurring. As the healthcare environment continues to change and evolve due to changes in public and private policies, it will be important to continue to monitor both the prevalence and the effects of hospital ownership of practices on patients and physicians.

USE OF INTERNET AND TELEPHONE REFILLS AMONG LINGUISTICALLY DIVERSE PATIENTS WITH LIMITED-ENGLISH PROFICIENCY AND CHRONIC CONDITIONS Gerardo Moreno²; Elizabeth Lin¹; Eva Chang¹; Do Peterson¹; Ron Johnson¹; Heidi Berthoud¹; Leo Morales³. ¹Group Health Research Institute, Seattle, WA; ²UCLA, Los Angeles, CA; ³University of Washington, Seattle, WA. (Tracking ID #2196338)

BACKGROUND: The availability of patient internet sites with shared medical records (SMR) may provide an effective system level approach to help mitigate language-based disparities in medication non-adherence. The use of online prescription medication refill systems is relatively new in many healthcare systems and its application has been limited and targeted mostly to populations receiving care in vertically integrated health systems. Research shows that blacks and Latinos are less likely to use an online SMR system that has options to request medication refills, and that low education, income, and internet access are associated with lower use of online SMR. Despite emerging research on internet SMR, more research is needed on the use of online medication refill systems among non-English speaking patients and different ethnic groups with limited-English proficiency. The objective of this study was to describe the use of internet and telephone medication refill systems among an ethnically diverse sample of limited-English proficient (LEP) and English proficient (EP) patients with chronic conditions in a population of insured patients.

METHODS: We conducted a cross-sectional telephone survey in 6 languages/dialects (English, Cantonese, Mandarin, Korean, Vietnamese, and Spanish). The telephone survey was conducted between September and December 2013. Participants were 509 adults in ambulatory care in an integrated group practice healthcare delivery system. The study inclusion criteria included: (1) 18 years of age or older, (2) enrolled in the health systems health plan, (3) Diagnosis of one of the following three chronic conditions hypertension, hyperlipidemia, and/or diabetes, (4) had at least one medical visit (not urgent care or emergency room) within the health system during the last 6 months, and (5) spoke English, Cantonese, Mandarin, Korean, Vietnamese, or Spanish. Primary outcomes were use of 1) internet refill system, 2) telephone refill system, and 3) either internet or telephone refill system. The primary predictor was LEP as measured by the use of an interpreter. Other measures included race-ethnicity, age, gender, education, income, years in the U.S., and health status. We performed bivariate and multiple logistic regression analyses. In all regression models we adjusted for age, gender, education, and self-reported health status.

RESULTS: We found that among all survey participants, both EP and LEP ($n=509$), 38.4 % used the telephone and 31.4 % used the internet to refill medication. Patients that used a remote refill system were more educated, had higher incomes, and were younger compared to those didn't use a refill system. Among LEP patients ($n=328$), 21.2 % used the internet and 34.7 % used the telephone refill systems, compared to 50.8 and 37.6 % for English speaking patients ($n=181$). Half (49.5 %) of LEP patients used either the telephone or internet refill systems compared to 82.3 % for English speaking patients. LEP status was independently associated with not using the internet refill system (adjusted odds ratio [AOR]=0.30; 95 % Confidence Intervals [CI] 0.18, 0.49; $p < .001$) compared to English proficient patients. In adjusted analysis, LEP status was not significantly associated with use of the telephone refill system. The proportion of patients within each language group that used the internet refill system was: English (50.8 %), Cantonese/Mandarin (27.9 %), Vietnamese (24.7 %), Korean (17.4 %), and Spanish (12.0 %). The proportion of patients within each language group that used the telephone refill system was: English (37.6 %), Cantonese/Mandarin (19.5 %), Vietnamese (27.2 %), Korean (56.2 %), and Spanish (38.0 %).

CONCLUSIONS: In this study we found substantial variation in the use of remote medication refill systems among a linguistically diverse group of LEP adults with chronic conditions. We found that 50 % LEP patients do not use either internet or telephone remote medication refill systems compared to 20 % among EP patients. To reach all populations within a health system that may potentially benefit from this system level change, efforts will need to be made to open access to persons with limited English proficiency. The results may be of interest to health systems that serve a linguistically diverse patient population at high risk for medication non-adherence.

USING PHOTOVOICE TO PROMOTE DIABETES SELF-MANAGEMENT FOR LATINO ADULTS Arshiya A. Baig¹; Matthew Stutz⁴; Patricia Fernandez¹; Amanda Benitez²; Cara A. Locklin³; Yue Gao³; Sang Mee Lee¹; Michael T. Quinn¹; Marla C. Solomon²; Lisa Sanchez-Johnsen³; Deborah L. Bumet¹; Marshall Chin¹. ¹University of Chicago, Chicago, IL; ²University of Illinois, Chicago, IL; ³University of Illinois at Chicago, Chicago, IL; ⁴University of California, Los Angeles, Los Angeles, CA. (Tracking ID #2198802)

BACKGROUND: No studies have assessed the feasibility and acceptability of using photovoice to promote diabetes self-management. We assessed the themes that emerged

from a photovoice exercise that was part of a diabetes self-management program for Latino adults and measured patient satisfaction.

METHODS: Fifty adults with self-reported diabetes were enrolled in an 8-week church-based, culturally tailored intervention that consisted of weekly diabetes self-management classes led by lay leaders trained in motivational interviewing. Intervention participants were given disposable cameras and asked to take photographs of their lives with diabetes. In the weekly classes, participants discussed their photos with the group and shared their challenges and successes in diabetes self-care. The class leaders guided the group photo discussions and took notes on why the photo was important to the person who took it and what others in the class discussed regarding the photo. Using a codebook derived from prevalent themes, two researchers coded the photos and the discussion notes. Participants evaluated the photovoice activities at 6-month follow-up. The evaluation questions were analyzed using descriptive statistics.

RESULTS: Participants' mean age was 54 ± 12 years, 81 % were female, 98 % were Latino, 71 % only spoke Spanish at home, 82 % had a household income below \$30,000, and 51 % were uninsured. Of the 50 participants enrolled in the intervention, 37 attended at least one class, 26 participants took photos and 23 participants shared their photos in class. Participants' photos spurred group discussion around diabetes self-management. Participants gave advice, were empathetic, and motivated the participants who presented their photos to make or sustain healthy behaviors. For example, one participant showed the group a photo of a statue holding a pack of cigarettes. He stated the picture captured the moment he decided to quit smoking while at work. The group encouraged him to try to stop smoking and understood the challenges in trying to quit. Of all the photographs taken, 79 % were of family, friends, or social gatherings, 47 % were of nutrition and exercise, 39 % were of the local neighborhood, 33 % depicted diabetes medications and supplies, 25 % depicted the patient's home, and 8 % were of religious images. At 6-month follow-up, 86 % of participants who attended the intervention learned about better managing their diabetes from others' photos, 82 % said they gained more confidence in managing their diabetes from talking about the photos, 82 % noted the photo discussions helped them better manage their diabetes, and 93 % noted that sharing photos made them feel more connected to the people in the group.

CONCLUSIONS: In a diabetes self-management intervention for Latinos, participants were highly satisfied with the photovoice exercise and had high rates of participation. Photovoice provided an effective vehicle to receive and provide social support and promote behavior change. Future studies should consider using photovoice as a way to encourage healthy behavior change and facilitate social support in a group setting.

VALIDATION OF A BRIEF CLINICIAN SURVEY TO REDUCE CLINICIAN BURNOUT. Scott Shimotsu; Sara Poplau; Mark Linzer. Hennepin County Medical Center, Minneapolis, MN. (Tracking ID #2191173)

BACKGROUND: Clinician stress and burnout rates are high and rising in the US. We validated a brief (10 question) survey to determine areas for work life improvement within all clinical departments at an upper Midwestern safety net hospital. The survey was administered by a provider wellness committee charged with improving clinician wellness. A valid and reliable tool that captures the dimensions of clinician work life may be effective in improving the longevity of providers in health care systems. This paper evaluates the psychometric properties of the brief instrument.

METHODS: We developed a brief self-administered questionnaire that was distributed electronically via Survey Monkey to clinicians. The instrument was modified from prior work life measures of the MEMO study (Minimizing Error Maximizing Outcome), and is called the Mini Z (for Zero Burnout Program). It included 10 quantitative questions concerning stress, burnout and their predictors. The survey was sent to a total of 603 clinicians including dentists, psychologists, physicians and advanced practice providers (NPs and PAs). The survey used 5 point likert scales to query job satisfaction, stress, burnout, workload, time for documentation, work environment (chaotic, busy, calm), values alignment with leadership, teamwork, time spent at home using the electronic medical record (EMR), and EMR proficiency. Main global measures included satisfaction ($n=3$ items), stress and burnout ($n=4$ items) and EMR-related stress ($n=3$ items). Returned surveys ($n=402$) resulted in 366 usable responses, which were randomly separated into developmental ($n=178$) and cross validation samples ($n=178$). All analyses were conducted using PC SAS 9.2 (Cary, North Carolina). First, we conducted confirmatory factor analyses (CFA) to evaluate a priori global scales. Based on Nunnally's convention, we used the Kaiser's eigenvalue rule and scree plots to identify total number of factors. An oblique rotation was applied to the CFA. We computed Cronbach alpha coefficients to assess reliability of each global scale. Second, pearson correlations were used to evaluate convergent and discriminant validity. Further, we used latent class analyses to determine characteristics of satisfied and dissatisfied clinicians. The same analyses were performed on both the developmental and cross-validation samples.

RESULTS: Of the 603 providers, 402 (67 %) clicked on the survey and 366 (61 %) completed it. Factor analysis revealed two factors: 1) teamwork/values, and 2) EMR use and stress. Overall alpha for the 10 items was 0.80; individual factor alphas were 0.74 and 0.72 for the teamwork/values factor and EMR use/stress factors, respectively. Correlations demonstrated convergent validity across survey items, with modest to moderate r values (0.39–0.57, $p < 0.0001$) between burnout and most mini Z items (satisfaction, values, teamwork, stress, work control, chaos and documentation time). Latent class analysis confirmed two classes of clinicians: a high satisfaction group (with teamwork and aligned values), and a high stress group (with high burnout and low work control). All analyses were similar in the cross-validation sample.

CONCLUSIONS: Clinician burnout and work life can be feasibly and reliably captured using the Mini Z survey tool. Our a priori sub-scales were partly supported as we hypothesized a satisfaction factor as well as a stress factor. The brief instrument may allow health care systems to feasibly assess stress, burnout and satisfaction among clinician workforces. By addressing root causes of stress and burnout in clinicians, health care systems can better recruit and retain their talent. Future work includes validation of the instrument on a nationwide sample of clinicians.

VULNERABILITY FOR HEALTHCARE COMMUNICATION GAPS FOR USERS OF VA PURCHASED CARE: IMPLICATIONS FOR THE VETERANS CHOICE ACT Donna L. Washington^{1,2}; Alison B. Hamilton^{1,2}; Kristina M. Cordasco^{1,2}. ¹VA Greater Los Angeles Healthcare System, Los Angeles, CA; ²UCLA School of Medicine, Los Angeles, CA. (Tracking ID #2198688)

BACKGROUND: The recent Veterans Choice Act is designed to expand timely access to health care for Veterans Health Administration (VA) users through purchasing services from non-VA community providers. These care arrangements will potentially create coordination and communication gaps between patients' VA and non-VA providers, and between patients and their providers. Some Veteran populations may be particularly vulnerable for experiencing these communication gaps, increasing their risk for poor health outcomes. Our objective was to identify patient characteristics associated with communication gaps among Veterans using VA-purchased care delivered by non-VA providers.

METHODS: We conducted a secondary data analysis of the National Survey of Women Veterans (NSWV), a 2008–09 population-based telephone survey of women Veterans (response rate 86 %). Our analytic sample was comprised of 604 NSWV participants who used any VA-purchased non-VA provider care in the 12 months prior to the survey. Health care coordination and communication was measured with five questions that each assessed patient perceptions of communication (table). All measures used five-point Likert response options (all of the time; most of the time; some of the time; rarely; never). Responses of never, rarely, or some of the time were classified as indicative of a communication gap. We assessed prevalences of having any communication gap, and gaps by measure, followed by chi square and logistic regression analyses for the association of patient characteristics with each of the five measures. All analyses applied weights to account for the study design and response rate.

RESULTS: Nearly half (46 %) of the respondents perceived a communication gap in one or more of the measures. In unadjusted analyses, characteristics associated with a greater likelihood of a perceived communication gap were age 18–44 years (65 %), being a college graduate (54 %), being a newer Veteran (military service during the first Gulf War, the following peacetime, or during Operations Enduring Freedom/Iraqi Freedom/New Dawn [OEF/OIF/OND]) (59 %), having a military service-connected disability (53 %), and screening positive for a mood disorder (depression, anxiety, or post-traumatic stress disorder) (54 %). The table shows prevalence of communication gaps by measure. For each measure, age 18–44 years (versus older) was associated with a greater likelihood of experiencing a communication gap. In each of the first four measures, newer Veterans were more likely than those who served in the post-Vietnam Era or earlier to experience a communication gap. For example, a communication gap was perceived for these measures by 28 %, 42 %, 40 %, and 28 %, respectively, of OEF/OIF/OND Veterans. Being a college graduate was associated with perceived communication gaps for measures 1 (26 %), 3 (29 %), and 5 (27 %). Employed Veterans, Veterans with a military service-connected disability, and those screening positive for a mood disorder were more likely than others to report a gap in being able to get a convenient appointment (all 26 %). Communication gaps did not appear to vary by respondents' race/ethnicity, income, insurance, or having three or more diagnosed medical conditions. In adjusted analysis, only younger age remained independently associated with having a perceived communication gap in one or more of the measures.

CONCLUSIONS: A sizable proportion of women Veterans using VA purchased care reported communication gaps in their care. Several patient characteristics identified Veterans at increased risk. The finding that younger Veterans are more likely to experience communication gaps is especially salient given that this is a growing demographic within VA-users. VA has recently implemented a new infrastructure to coordinate purchased care,

though its effect on patient experiences of care is unknown. As the national Veterans Choice Act is implemented, expanding use of VA-purchased non-VA provider care, the VA should continue to make efforts to ensure that care provided from multiple sources is coordinated and that communication between VA and non-VA providers is seamless.

Care Coordination and Communication Measures: Percent Reporting a Communication Gap (response: some of the time, rarely, or never)

1. How often do your medical providers at the VA know about test results or tests you have had at a contract facility?	1 9 %
2. How often do you know how to get the results of your tests or medical procedures that were done at a VA contract facility?	2 0 %
3. How often does there seem to be good communication about your healthcare between your providers at the VA and providers at the contract facility?	2 3 %
4. When you have problems with your health, how often do you know who to call among your VA and non-VA medical providers?	1 4 %
5. How often can you get an appointment at a time that is convenient for you for contract services?	2 1 %

WHAT CAN HOSPITALISTS TEACH THE TEACHING SERVICE? COMPARING PATIENT EXPERIENCES ON HOSPITALIST AND HOUSESTAFF SERVICES Charlie M. Wray¹; Micah Prochaska¹; David Meltzer²; Vineet M. Arora². ¹University of Chicago, Chicago, IL; ²University of Chicago Medical Center, Chicago, IL. (Tracking ID #2196296)

BACKGROUND: It is recommended that hospitalized patients understand and know who is in charge of their care. Yet the complex system of physician teams in academic teaching hospitals may interfere with current recommendations that patients know and understand who is responsible for their care at all times. Given the inherent differences between housestaff and hospitalist services, we aimed to compare patient's ability to identify and understand the roles of their physician(s) between these two services.

METHODS: We performed a retrospective cohort analysis using data from internal medicine teaching and non-teaching services from July 2007 to June 2013 at an academic medical center. Patients were allocated first to teaching services staffed by an attending, resident, and two interns until the team capped, and subsequently to the hospitalist service which includes a nurse practitioner. Self-reported responses to a 30-day follow-up questionnaire were used to assess patients' ability to 1) identify their physician(s) 2) understand the role of their physician(s) 3) rate the coordination of care, and 4) overall care. Responses were dichotomized to reflect the top 2 categories ("Excellent & Very Good") and chi-square analyses were used to assess any differences. A multivariate logistic regression which controlled for baseline differences in patient characteristics (age, gender, length of stay, Charlson Comorbidity Index, academic year, and prior hospitalizations) was performed to ascertain the association between service type and patient-reported outcomes.

RESULTS: Data from 5753 housestaff and 2252 hospitalist service patients demonstrated that those on the hospitalist service were more likely to report being able to identify their physician (49 % vs. 45 % $p < 0.05$), understand the role of their physician (55 % vs. 50 %, $p < 0.05$), report greater satisfaction with coordination and teamwork (68 vs. 65 %, $p < 0.05$), and with overall care (72 % vs. 67 %, $p < 0.05$). In multivariate logistic regression, patients on the hospitalist service were 13 % more likely to report being able to understand the role of their physician (OR 1.13; 95 % CI, 1.01–1.27) and rated their overall care higher (OR 1.15; 95 % CI, 1.02–1.30) than patients on the teaching service.

CONCLUSIONS: Compared with housestaff services, patients under the care of a hospitalist service report being better able to understand the role of their physician and rated their overall care better. These findings may reflect inherent structural differences between the two services such as fewer providers or process differences such as greater attention to team introductions. Understanding these mechanisms may provide insight into how best to enhance the patient experience on both teaching and hospitalist services in academic medical centers.

WHO WANTS TO KNOW? DESIRE FOR PREDICTIVE TESTING FOR ALZHEIMER'S DISEASE AND IMPACT ON ADVANCE CARE PLANNING Meera Sheffrin; Irena Stijacic Cenzer; Michael A. Steinman. UCSF/ San Francisco VA Medical Center, San Francisco, CA. (Tracking ID #2171144)

BACKGROUND: Currently, much research is devoted to developing a test that would predict future Alzheimer's disease. However, it is unknown who in the United States would want such as test, and how it would change subsequent behavior. Using a large national sample, we explored who would take a free and definitive test predictive of Alzheimer's disease, and examined how use of such a test may impact advance care planning.

METHODS: In this cross-sectional study, we identified 874 adults age 65 or older in the Health and Retirement Study in 2012 who were asked the question: "If you could receive a test from your doctor, free of charge, that would definitely determine whether or not you would develop Alzheimer's disease sometime in the future would you want to be tested?" Subjects were then told to imagine they knew they would develop Alzheimer's disease in the future, and with this knowledge to rate the chance of completing advance care planning activities on a scale of 0–100. We classified >50 as being likely to complete that activity. We evaluated characteristics associated with willingness to take a test for Alzheimer's disease, and how such a test would impact completing an advanced directive and discussing health plans with loved ones.

RESULTS: Among the 874 individuals, 861 (99 %) answered the question. Mean age was 74 years and 56 % were female. Overall, 75 % ($N=648$) would take a free and definitive test predictive of Alzheimer's disease. Older adults willing to take the test had similar race and educational levels as those that would not, but were more likely to be ≤ 75 years old (63 % vs 52 %, $p<0.01$). There were no differences in willingness to take the test by level of self-perceived health or memory problems, self-perceived risk of Alzheimer's disease, or number of comorbidities. After subjects were asked to assume they knew they would develop Alzheimer's disease, 87 % reported they would be likely to discuss health plans with loved ones. Most (81 %) reported they would be likely to complete an advanced directive, though only 15 % reported having done so already.

CONCLUSIONS: In this nationally representative sample, 75 % of older adults would take a free and definitive test predictive of future Alzheimer's disease. Many expressed intent to increase activities of advance care planning with this knowledge. The potential for high demand, widespread use, and the opportunity to engage patients in advance care planning should be considered as tests predictive of Alzheimer's disease become available.

AN EVALUATION OF DRUG-ALLERGY INTERACTION ALERT OVERRIDES IN INPATIENTS Sarah P. Slight^{1,3}; Patrick E. Beeler¹; Diane L. Seger⁴; Olivia Dalleur¹; Mary Amato²; Tewodros Eguale¹; Karen C. Nanji¹; Patricia C. Dykes¹; Michael Swerdlow⁶; Julie Fiskio⁴; David W. Bates¹. ¹Brigham and Women's Hospital, Boston, MA; ²Brigham and Women's Hospital/MCPHS, Boston, MA; ³Durham University, Stockton on Tees, United Kingdom; ⁴Partners Healthcare System, Wellesley, MA; ⁵Partners Healthcare Systems Inc., Wellesley, MA. (Tracking ID #2198426)

BACKGROUND: Clinical Decision Support (CDS) systems are designed to provide real-time guidance and support to providers at the point of prescribing. Drug allergy interaction alerts (DAIs) are generated when a known adverse sensitivity inducing substance is prescribed. High DAI override rates have been reported in the outpatient setting.⁽¹⁾ We evaluated the DAI override rates in the inpatient setting and the reasons why providers chose to override these alerts.

METHODS: After obtaining IRB approval, all Level 2 DAI alerts from Jan 2009 to Dec 2011 were obtained from the Brigham and Women's Hospital, Boston, MA. A total of 2783 prescribers received allergy alerts at this site. Level 2 alerts suggest an undesirable interaction likely to cause serious injury, and give the provider the option of 'cancelling' the order or 'overriding' the alert. The downloaded file included the coded reasons given by physicians at the time of overriding the alert.

RESULTS: Overall 83.9 % (110,414 / 131,615) of the DAI alerts generated were overridden. Drug classes, which were more frequently associated with allergies, triggered 31,843 DAI alerts (24.2 %) and were broken down as follows: cephalosporins (13.7 %, $n=17,978$), aspirin and NSAIDs (6.6 %, $n=8,730$), penicillins (1.8 %, $n=2,379$), sulfonamides (1.4 %, $n=1,819$), ACE inhibitors and angiotensin receptor blockers (0.55 %, $n=724$), contrast media (0.12 %, $n=161$), and monoclonal antibodies (0.04 %, $n=52$). Opioids triggered more than half of the alerts (50.9 %, $n=66,949$), although these drugs are usually associated with sensitivities rather than true allergies. Providers overrode 72.5 % (1721/2373) of alerts that indicated that the patient was at risk of developing anaphylaxis, and were more likely to override these alerts when prescribing penicillin (62.5 %, 50/80) than contrast media (15.4 %, 2/13). The most common coded reasons for overriding DAI alerts were 'Patient has taken previously without allergic reaction/patient has tolerated previously' (56.0 %, 61,858/110,414), 'Physician aware' (16.8 %, $n=18,583$) and 'Low risk cross sensitivity, will monitor' (12.0 %, $n=13,202$).

CONCLUSIONS: This study offers important insights into providers' behavior and the specific DAI alerts that were commonly overridden. The override rate of DAI alerts in inpatients was found to be very high. The inclusion of inaccurate or incomplete allergy information in the patient's electronic health record can lead to the production of clinically inappropriate alerts. Suppressing

alerts that have been previously overridden for an individual patient may help to reduce the numbers of inappropriate DAI alerts. Further research is needed to ascertain how best to record drug-allergy information and present the user with useful drug-allergy alerts. **References:** Nanji KC, Slight SP, Seger DL, Cho I, Fiskio JM, Redden LM, et al. Overrides of medication-related clinical decision support alerts in outpatients. *J Am Med Inform Assoc.* 2014;21(3):487–91.

CAN'T WE JUST HAVE SOME SAZ6N? EVALUATION OF A NEW SCHOOL FOOD PROGRAM IN DORCHESTER, MA Avik Chatterjee²; Genevieve Daftary³; Meg Campbell⁴; Lenward Gatison⁴; Liam Day⁴; Kibret Ramsey²; Roberta E. Goldman⁵; Matthew W. Gillman¹. ¹HMS-HPHCI, Boston, MA; ²Harvard Pilgrim Health Care Institute/Department of Population Medicine at Harvard Medical School, Cambridge, MA; ³Codman Square Health Center, Boston, MA; ⁴Codman Academy Charter Public School, Boston, MA; ⁵Warren Alpert Medical School, Brown University, Providence, RI. (Tracking ID #2192631)

BACKGROUND: Child and adolescent obesity is a growing problem in the United States and leads to obesity and chronic disease in adulthood. Certain dietary patterns, such as eating fruits, vegetables and whole grains and avoiding red meat, are linked to healthier weight and lower incidence of chronic disease. With 31 million children receiving food through the National School Lunch Program, schools provide a unique opportunity to promote healthy eating in children. In September 2013, a Dorchester high school in a low-income neighborhood launched a pilot nutrition program, with school food meeting new 2013 United States Department of Agriculture (USDA) requirements. The program included additional nutrition education and a junk food free policy. Our objective was to understand the attitudes of students, parents and staff to the new school food program that aimed to improve eating behaviors.

METHODS: Investigators employed community-based participatory research methods to complete a qualitative evaluation of the new food program at the school. School staff, student and community investigators from a neighboring health center were full partners in study design, implementation, and analysis. The study site was a public charter high school in the Dorchester neighborhood of Boston, MA, with approximately 140 students, where 98 % of students are people of color and 86 % qualify for free or reduced lunch. All students, parents, and faculty/staff were eligible, but due to resource constraints, we excluded parents who could not speak English. We conducted 4 student focus groups (1 per grades 9–12, $n=32$ participants), 2 parent focus groups ($n=10$), 1 faculty/staff focus group ($n=14$), and interviews with school leadership ($n=3$). We used the immersion/crystallization technique to find themes from transcripts of recordings of focus groups and interviews.

RESULTS: Ten themes emerged from the focus groups and interviews, in three major categories—impressions of the food itself (insufficient portion size, dislike of the taste, appreciation of the freshness, and overall dissatisfaction leading to fast food consumption outside of school), impact on student learning (students now knowing what's healthy, pride in the innovative nature of the program, the tension between external control vs. freedom to choose), and concerns about stakeholder engagement (need for more student and family engagement, and a lack of cultural appropriateness of the food). A representative statement from a parent was: "You need something to hold them from 9 to 5, because if they are hungry, McDonald's is right there" (Table 1).

CONCLUSIONS: Students, parents, and school staff appreciated the educational value of the new school food program based on USDA guidelines, but dissatisfaction with taste, portion size, student/family engagement, cultural appropriateness and unhealthy eating behaviors outside of school pose important challenges. School leadership were particularly sensitive to the fact that overall dissatisfaction with the new school food program may paradoxically be leading to increased consumption of unhealthy foods, such as fast food, outside of school. School leadership is committed to changing the school food program in order to improve student satisfaction with school food, while continuing to adhere to USDA guidelines. Near-term action steps could include creating a sodium-free seasoning bar for students, educating students and families about the new USDA guidelines and working with families to incorporate culturally appropriate recipes to the school's menu. Longer-term changes include finding resources to add an additional meal at the end of the school day, and working with local restaurants to promote healthy offerings for young people—a strategy that has been employed in another nearby community with success. Changing eating behaviors in children and adolescents will be vitally important to prevent obesity and chronic disease in adults. New USDA guidelines and other school-based solutions are important tools, but our study reveals some important challenges for schools that adopt the new guidelines. Schools and communities will need to address such challenges in order for school-based healthy eating interventions to be successful.

Table 1: Sample quotations from student, parent, and school staff focus group participants about a new school food program at a Dorchester, MA, high school

	Theme	Quote
Category 1: The Food Itself	Taste	"Can't we just have some sazón?"
	Portion size	"When I leave here, I leave hungry."
	Undesirable eating behaviors	"You need something to hold them from 9 to 5, because if they are hungry, McDonald's is right there."
Category 2: Student Learning	Freshness	"Healthy food is fresh food."
	Impact on student education	"Our students [now] know what is healthy and what isn't healthy."
	Control vs. choice	"At the end of the day, you can't really force anyone to eat [healthy foods]"
Category 3: Stakeholder Engagement	Innovation	"[The new school food program] helped me to think critically...kudos to the school."
	Student engagement	"I loved Saturday cooking class. I want to do more."
	Family engagement	"There's school breakfast?"
	Cultural representation	"All the vegetables together with meat, [we Haitians] call it 'legume,' and she loves that. That is a good food for them."

IT'S SO COMPLICATED: A NEEDS ASSESSMENT TO INFORM CONTINUING MEDICAL EDUCATION FOR PRIMARY CARE PROVIDERS ON PROSTATE CANCER AND AFRICAN AMERICAN MEN Nynikka R. Palmer¹; Justin Morgan²; Michael B. Potter¹; Eunice Neeley³; Matthew R. Cooperberg¹; June M. Chan^{1, 1}; Peter R. Carroll¹; Rena Pasick^{1, 1}. ¹University of California San Francisco, San Francisco, CA; ²John Hale Medical Society and John Hale Foundation, San Francisco, CA; ³Kaiser Permanente, Oakland, CA. (Tracking ID #2198141)

BACKGROUND: Advances in medical science can exacerbate existing disparities in prostate cancer (PCa) care if they are only adopted in settings that serve those who are affluent, insured, and/or highly educated. African American patients, bearing the greatest burden of PCa, are overrepresented in safety net settings, and the gap between best and actual practice in PCa care is wider for African American men than for other low-income patients. Primary care providers (PCPs) can play an important role across the PCa spectrum. While urologists are typically the first clinicians to discuss treatment options with newly diagnosed patients, screening and evaluation of symptoms usually takes place in primary care. PCPs often have established relationships with patients and are at times involved in PCa treatment decision-making. PCPs are also being called upon to assume more responsibility for cancer survivors' post-treatment follow-up. One step toward reduction of African American PCa disparities could be better integration of PCPs in the PCa management team. However, awareness and adoption of the most advanced treatment usually requires intensive promotion and education. We sought to explore the gaps between actual and optimal practice, and to elucidate the needs, preferences, and priorities around PCa care among PCPs who serve the African American community. These data were collected to inform the development of a continuing medical education (CME) curriculum for PCPs on state-of-the-science PCa care for African American men.

METHODS: We conducted a qualitative study which included three focus groups to explore the perceptions and practices regarding PCa care among clinicians serving African American men. Both PCPs and urologists from a range of settings were invited to participate through a partnership between the UCSF Clinical and Translational Science Institute's Clinical Research Network and the John Hale Medical Society. Each group included 6–9 participants, lasted approximately 90 min, and was led by PCP research team members (Drs. Morgan and Potter). Clinicians received a \$100 incentive payment for their time and participation. Focus groups were audio recorded, transcribed verbatim, and analyzed by two researchers (Drs. Palmer and Pasick) using thematic content analysis.

RESULTS: Twenty-three health care providers participated in focus groups in November 2012 (n=8), January 2013 (n=9), and February 2013 (n=6). The majority were PCPs (n=21), 12 were female, and there was one nurse practitioner and one urologist. Providers were Caucasian (n=13), African American (n=8), Latino (n=1) and Asian (n=1). Three main topics were discussed: PCa screening and shared decision-making, PCP's involvement in PCa care, and ideal components of a CME curriculum. *PCa Screening and Shared Decision-Making:* PCPs consistently expressed uncertainty about best screening practices in light of current controversies and shifting guidelines regarding efficacy of the prostate-

specific antigen test and the lack of data specific to those at high risk, particularly African Americans. PCa screening practices varied by provider and certain patient characteristics (e.g., high risk, requested test, or symptomatic). PCPs clearly recognized the importance of discussing the risks and benefits of PCa screening and engaging patients in shared decision-making, but admitted that this conversation is complicated and severely limited by time constraints. *PCP's Involvement in PCa care:* PCPs expressed the desire to participate in the treatment decision-making process; several noted that patients have sought their input and they want to remain part of the process. However, providers felt they lacked sufficient knowledge about PCa care, treatment options, side effects, and post-treatment care, to help their patients understand their options and receive the best care. Providers also mentioned the need for better communication between PCPs and urologists. *Developing A CME Curriculum:* Providers were amenable to attending a CME on PCa care, noting key topics: synthesis of the controversy in PCa screening and clarification of guidelines, treatment options, side effects, and any differences specific to African American men. They discussed the need to include both PCPs and urologists as presenters and participants. Providers preferred in-person CME that was interactive and focused on communication skill-building for a brief yet effective discussion with patients.

CONCLUSIONS: Many PCPs desire to play a more integral role in caring for their patients facing PCa. However, they are uncertain about best practices across the PCa continuum. Providers are amenable to a CME course addressing state-of-the-science PCa care from screening through survivorship.

WALKING IN FAITH: EXAMINING THE FEASIBILITY OF IMPLEMENTING A FAITH-BASED NUTRITION EDUCATION AND WALKING PROGRAM. Milele L. Bynum¹; Giselle M. Corbie-Smith². ¹University of North Carolina, Durham, NC; ²University of North Carolina, Chapel Hill, NC. (Tracking ID #2198779)

BACKGROUND: African Americans continue to be disproportionately affected by obesity and obesity-related health problems. Innovative methods that tap into the strengths and resources of the African American community are needed. The purpose of this study was to describe the feasibility of using a community-based participatory research (CBPR) approach to implement the Faithful Families: Eating Smart and Moving More curriculum coupled with a walking program in an African American church. The primary objectives of the study were to equip lay leaders to serve as program co-facilitators, increase physical activity, and improve knowledge and skills related to nutrition and healthy eating behaviors.

METHODS: Working with the partnering church, a 10-week nutrition education and walking program was piloted. Church lay leaders were trained to facilitate the Faithful Families curriculum. At baseline and 10-weeks, we collected quantitative outcome data on physical activity; fruit/vegetable intake; changes in blood pressure [BP], and weight) and post intervention process data through semi-structured interviews with participants and facilitators to assess acceptability, implementation fidelity, and limited efficacy testing.

RESULTS: Eight lay leaders were recruited and completed a two-day training. By the conclusion of the program, seven lay leaders each co-facilitated at least four nutrition education sessions, attended at least one walking session weekly and assisted with the collection of data from participants. Thirty-five church members attended an orientation session to hear about the program, with 31 consenting to participate in the study. Twenty-two of them completed the study and provided follow-up data. At baseline, the mean fruit and vegetable intake was 3.56 servings/day. Participants averaged 121.88 min/week of physical activity, with 23.81 % of the participants meeting physical activity recommendations of at least 150 min/week. At 10 weeks, participants realized a statistically insignificant reduction in BMI from 30.72 to 30.68; systolic and diastolic blood pressure decreased by 8.31 and 6.05 points respectively; mean fruit and vegetable intake increased by 0.58 servings/day to 4.14 servings/day; and physical activity mean improved by 50.82 min/week to 172.70 min/week with 61.90 % of the participants meeting physical activity recommendations of 150 min/week. Participants and facilitators endorsed the content and structure of the intervention as acceptable. Participants expressed satisfaction with the program, stating that it helped them to change habits, exercise more, and become conscious of what they were eating and drinking. However, they did voice a desire to have more support through accountability partners, more information on physical activity and an expanded faith component.

CONCLUSIONS: This study demonstrated that it is feasible to use a CBPR approach to implement a faith-based nutrition education and physical activity program using trained lay leaders recruited from the partnering church. By utilizing individuals from within the church to develop and implement the program, *Walking in Faith* was able to engage members of the faith community, while promoting improved health outcomes and program sustainability.

¹⁸F-FDG PET OR PET/CT AND ⁶⁷Ga-CITRATE SCINTIGRAPHY IN THE DIAGNOSIS OF CLASSIC FEVER OF UNKNOWN ORIGIN: A SYSTEMATIC REVIEW AND META-ANALYSIS OF TEST PERFORMANCE AND DIAGNOSTIC YIELD Motoki Takeuchi¹; Takashi Nishashi²; Issa Dahabreh³; Teruhiko Terasawa¹. ¹Fujita Health University, Nagoya, Japan; ²Nagoya University Graduate School of Medicine, Nagoya, Japan; ³Brown University, Providence, RI. (Tracking ID #2189730)

BACKGROUND: Fever of unknown origin (FUO) is a common clinical dilemma encountered in general medical practice. Although advances in anatomical imaging tests such as ultrasound, contrast-enhanced CT (CECT), and MRI, and improved culture techniques have continuously modified the spectrum of FUO-causing diseases, identifying the cause of FUO still remains a challenge. ¹⁸F-FDG PET or PET/CT (FDG-PET or -PET/CT) and ⁶⁷Ga-citrate scintigraphy (Ga-scintigraphy) are expensive but established functional imaging tests in the clinical management of malignant diseases, and are promising imaging modalities that may assist detecting the cause of FUO when conventional modalities are not helpful. Although several studies on the use of these functional imaging tests for diagnosing FUO have been published, their clinical role and impact remain unclear. We therefore performed systematic review and meta-analysis to quantitatively synthesize the current evidence. In this presentation, we focus on their test performance (i.e., sensitivity and specificity), and impact on diagnosis (i.e., diagnostic yield: how often these functional imaging tests can contribute to diagnosis) and diagnostic or therapeutic management.

METHODS: We searched PubMed and Scopus (from inception until June 30, 2014) and no language restrictions were applied. We included studies of FDG-PET or -PET/CT, or Ga-scintigraphy that were performed for evaluating the cause of FUO in adult patients with classic FUO. Two independent reviewers screened abstracts, perused full-text publications for eligibility, and performed data extraction. Sensitivity and specificity were calculated from a 2 by 2 contingency table data according to whether patients were a functional imaging test positive or negative, and whether the cause of FUO was identified by any add-on tests performed after the imaging test and/or clinical follow-up as the reference standard. Study validity was assessed using the QUADAS-2. Meta-analysis was performed when 4 or more studies were available for each imaging test.

RESULTS: Of 4458 citations retrieved, 74 were selected for full-text review, 30 of which (11 for FDG-PET; 15 for FDG-PET/CT; 6 for Ga-scintigraphy) including 1436 patients with classic FUO were eligible. Only two studies assessed both Ga-scintigraphy and FDG-PET or FDG-PET/CT to compare these modalities. Most (23 studies, 77 %) had a retrospective design based on data derived from clinical practice, and reported non-uniform work-up strategies before undertaking functional imaging tests. Few adopted standardized work-up algorithms for classic FUO including CECT of the chest and abdomen in all patients. More invasive and accurate tests such as biopsy or surgery were preferentially performed as add-on tests for patients with a positive scan result, while clinical follow-up was typically performed for those with a negative result, suggesting a possibility of differential verification bias. Also, treating physicians often employed functional imaging test results as the reference standard to make a clinical diagnosis when the uptake pattern was suggestive of a non-infectious inflammatory disease (NIID) such as large vessel vasculitis, which could overestimate both test performance and diagnostic yield. Overall, a cause of FUO was identified in approximately two-thirds of patients. The summary sensitivity and specificity were respectively 0.84 (95 % confidence interval [CI], 0.78–0.89) and 0.64 (CI, 0.44–0.79) for FDG-PET/CT; 0.76 (CI, 0.65–0.84) and 0.60 (CI, 0.39–0.77) for FDG-PET; and 0.60 (CI, 0.45–0.73) and 0.63 (CI, 0.37–0.84) for Ga-scintigraphy. The summary diagnostic yield was 56 % (CI, 49 %–65 %) for FDG-PET / CT, 47 % (CI, 34 %–64 %) for FDG-PET, and 35 % (CI, 23 %–53 %) for Ga-scintigraphy. Only 3 studies reported how often the scan results altered diagnostic or therapeutic management, which precluded in-depth analysis. Comparative evidence regarding FDG-PET or -PET/CT versus Ga-scintigraphy was limited.

CONCLUSIONS: FDG-PET, FDG-PET /CT and Ga-scintigraphy can contribute to identifying the cause of classic FUO. However, their clinical role particularly in contrast to alternative imaging modalities in contemporary diagnostic pathways is uncertain and the calculated naïve test performance based on the imperfect reference standards may be overestimated. Regarding FDG-PET and FDG-PET/CT, despite their moderately high sensitivity, management decisions based solely on the scan results may lead to unnecessary interventions given the low specificity. Prospective studies in settings where work-up algorithms are standardized are needed to better clarify the clinical role and impact of these functional imaging tests in contemporary diagnostic strategies.

24-HOUR EFFICACY OF TIOTROPIUM RESPIMAT® IN ASTHMA Thomas B. Casale¹; David M. Halpin²; Michael Engel³; Petra Moroni-Zentgraf²; Achim Muller⁴; Kai-Michael Beeh⁵. ¹University of South Florida, Tampa, FL; ²Royal Devon & Exeter Hospital, Exeter, United Kingdom; ³Boehringer Ingelheim Pharma GmbH & Co. KG,

Ingelheim am Rhein, Germany; ⁴Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach an der Riss, Germany; ⁵insaf Respiratory Research Institute GmbH, Wiesbaden, Germany. (Tracking ID #2194778)

BACKGROUND: The once-daily long-acting anticholinergic bronchodilator tiotropium Respimat® has demonstrated efficacy as add-on to at least inhaled corticosteroid (ICS) maintenance therapy across severities of symptomatic asthma. We assessed the efficacy of tiotropium Respimat® add-on therapy over 24 h in adult patients with moderate or severe symptomatic asthma.

METHODS: Four Phase III, randomized, double-blind, placebo-controlled, parallel-group trials. PrimoTinA-asthma® (NCT00772538/NCT00776984): once-daily (morning dosing) tiotropium Respimat® 5 µg or placebo Respimat® add-on to high-dose ICS (≥800 µg budesonide or equivalent) plus a long-acting β₂-agonist in adults over 48 weeks; MezzoTinA-asthma® (NCT01172808/NCT01172821): once-daily (evening dosing) tiotropium Respimat® 5 µg or 2.5 µg, twice-daily (morning and evening dosing) salmeterol hydrofluoroalkane metered-dose inhaler 50 µg, or placebo (identical devices in a double-dummy protocol) add-on to medium-dose ICS (400–800 µg budesonide or equivalent) in adults over 24 weeks. We report 24-h lung function measurements, performed in a subset of patients.

RESULTS: Patients included in the 24-h full analysis set: PrimoTinA-asthma®, n=349 (tiotropium Respimat® 5 µg, n=172; placebo Respimat®, n=177); MezzoTinA-asthma®, n=583 (tiotropium Respimat® 5 µg, n=141; tiotropium Respimat® 2.5 µg, n=144; salmeterol, n=150; placebo, n=148). Tiotropium Respimat® significantly improved lung function over 24 h, compared with placebo, after 24 weeks, with significant improvements observed in peak forced expiratory volume in 1 s (FEV₁) within 0–3 h, trough FEV₁, and all measures (0–12, 12–24, and 0–24 h) of FEV₁ area under the curve with the 5 µg dose in PrimoTinA-asthma® and both the 5 µg and 2.5 µg doses in MezzoTinA-asthma® (Table).

CONCLUSIONS: Once-daily tiotropium Respimat® add-on to at least ICS maintenance therapy improves lung function and provides sustained bronchodilation over 24 h in adults with moderate or severe symptomatic asthma.

30-DAY POTENTIALLY AVOIDABLE READMISSIONS DUE TO ADVERSE DRUG EVENTS IN MEDICAL PATIENTS Olivia Dalleur^{1, 4}; Patrick E. Beeler^{1, 3}; Jeffrey L. Schnipper¹; Jacques Donze^{2, 1}. ¹Brigham and Women, Boston, MA; ²Bern University Hospital, Bern, Switzerland; ³Zurich University Hospital, Zurich, Switzerland; ⁴Université Catholique de Louvain, Brussels, Belgium. (Tracking ID #2194243)

BACKGROUND: Adverse drug events occurring after hospital discharge are an important reason for readmissions within 30 days. However, these events need to be better characterized in order to find the most appropriate risk reduction interventions. The objective of this study was to describe instances of potentially avoidable readmissions due to adverse drug events in a medical population.

METHODS: In this nested case control study, we analyzed a random sample of 534 potentially avoidable 30-day readmissions from 10,275 consecutive discharges from the medical department of an academic medical center between July 1, 2009 and June 30, 2010. Potentially avoidable readmissions were determined using the previously validated SQLape algorithm. Medical records were independently reviewed by 9 trained physicians to identify those readmissions due to adverse drug events. Instances of over-prescribing (use of a drug without a valid indication), mis-prescribing (valid indication, but inappropriate duration, dose, choice of active agent, costs, interactions, or route of administration), under-prescribing (lack of a required drug given the previously known conditions of the patient), and other potential causes of adverse drug events were identified.

RESULTS: Among 534 cases of 30-day potentially avoidable readmissions reviewed, 80 (15 %) were partially or predominantly due to an adverse drug event. The drug classes that were the most frequently involved were: antineoplastic agents ($n=14$, 18 %), loop diuretics ($n=13$, 16 %), analgesics ($n=11$, 14 %), antibacterials for systemic use ($n=8$, 10 %) and antithrombotic agents ($n=7$, 9 %). Over-prescribing of drugs occurred in 9 % ($n=7$) of cases, mainly due to altered mental status on analgesics ($n=3$) and dehydration on diuretics ($n=2$). Mis-prescribing was identified in 24 % ($n=19$) of cases, mainly due to hypotension and acute renal failure on diuretics and antihypertensives ($n=8$), bleeding on overdosed or poorly monitored antithrombotics ($n=3$) and hypoglycemia on insulin ($n=3$). Under-prescribing involved 10 % ($n=8$) of the cases, most notably readmissions due to uncontrolled pain (analgesics, $n=3$) and volume overload and heart failure (lacking sufficient dosing of diuretics, $n=2$). The other 45 % ($n=36$) were cases where the adverse drug event was related to other factors, such as compliance issues ($n=6$).

CONCLUSIONS: Common drugs, such as analgesics and diuretics, were frequently involved in over-, mis- or under-prescribing, leading to adverse drug events that contributed to readmissions. Those drugs could be targets for interventions to prevent readmissions.

A DIAGNOSTIC SCORE FOR INSULIN RESISTANCE IN NON-DIABETIC PATIENTS WITH ISCHEMIC STROKE OR TRANSIENT ISCHEMIC ATTACK

Jin Xu; Catherine Viscoli; Walter N. Kernan. Yale School of Medicine, New Haven, CT. (Tracking ID #2184927)

BACKGROUND: Insulin resistance is associated with increased risk of progression from prediabetes to diabetes, cardiovascular disease, and ischemic stroke. Despite the known public health impact of insulin resistance, identification of non-diabetic patients with this condition remains challenging. Currently available methods are expensive, time consuming, or rely on fasting insulin measurements, which are not standardized across laboratory platforms. We sought to develop a simple, reliable instrument, not relying on fasting insulin, to screen for insulin resistance in patients with a recent ischemic stroke or transient ischemic attack (TIA).

METHODS: Subjects were non-diabetic men and women with ischemic strokes or TIA within the past six months, over age 40 years of age, and enrolled in the Insulin Resistance Intervention after Stroke (IRIS) trial. The 7262 subjects were randomly divided (60–40 %) into development and validation cohorts. In the development cohort, clinical features were analyzed in bivariate analysis for their association with insulin resistance as measured by the homeostasis model assessment for insulin resistance (HOMA-IR). Abdominal obesity was defined as waist circumference >88 cm in women and >102 cm in men. Body mass index ($\text{BMI}=\text{kg}/\text{m}^2$) was classified as <25 , 25–29, 30–35, and >35 . Elevated waist-hip (WTH) ratio was classified as >0.9 in men and >0.85 in women. Elevated systolic blood pressure (SBP) was defined as >130 mm Hg. Features that were significantly associated with HOMA-IR ($p<0.05$) were entered into a multivariable analysis. We used the magnitude of regression coefficients from the multivariable model to assign point values for a diagnostic scoring instrument. The performance of the instrument was then tested in the validation set using receiver operator characteristic (ROC) analysis.

RESULTS: Four features were retained in the multivariable regression analysis: BMI (25–29 kg/m^2 , 1 point; 30–35 kg/m^2 , 2 points; >35 kg/m^2 , 4 points), abdominal obesity (1 point), fasting glucose >100 mg/dL (4 points), and triglyceride-HDL ratio (1.6–2.3, 1 point; 2.4–3.5, 2 points; >3.6 , 4 points). Points for each feature were summed to yield a total score between 0 and 13, with increasing score predicting increasing degrees of insulin resistance. The area under the curve (aROC) for prediction of HOMA-IR >3 (our criterion for insulin resistance) was 0.77 in the development cohort and 0.78 in the validation cohort. A score of three had sensitivity and specificity of 85 and 50 %, respectively, in the

development cohort, and 86 and 53 %, respectively, in the validation cohort, for the prediction of HOMA-IR >3 . A score of seven had 91 % specificity but 44 % sensitivity for predicting HOMA-IR >3 in the development cohort, with similar performance in the validation cohort.

CONCLUSIONS: We have developed a simple, easy-to-use instrument for diagnosing insulin resistance in patients with a recent ischemic stroke or TIA. A score of three provided high sensitivity and moderate specificity. Use of a higher score as cutoff for insulin resistance would reduce unnecessary confirmatory testing but with lower sensitivity. Our instrument may assist clinicians in rapidly identifying candidates for further metabolic testing or direct referral for lifestyle counseling to prevent future adverse events including diabetes, coronary disease, and ischemic stroke.

A Health Literacy Assessment of Hospitalized Adult Patients and Written Discharge

Instructions Marina Arvanitis⁵; Alex Gertner²; Mona Xiao²; Eric Allman⁵; John Stephens¹; Edmund A. Liles⁴; Arlene E. Chung⁶; Daniel Jonas³; Darren A. DeWalt². ¹UNC Hospitals, Chapel Hill, NC; ²University of North Carolina, Chapel Hill, NC; ³University of North Carolina Chapel Hill, Chapel Hill, NC; ⁴University of North Carolina School of Medicine, Chapel Hill, NC; ⁵University of North Carolina at Chapel Hill, Chapel Hill, NC; ⁶University of North Carolina at Chapel Hill School of Medicine, Durham, NC. (Tracking ID #2200361)

BACKGROUND: One in five Medicare recipients is readmitted to the hospital within 30-days of discharge and excess hospital readmissions also occur to varying degrees in patients of all ages, especially those with certain high-risk diagnoses or health disparities, such as low health literacy. Written discharge instructions (DCI) are documents that patients must receive at the time of hospital discharge, ideally to summarize, clarify, and reinforce the important health information that patients need to maintain their health and avoid readmission. DCI are typically standard templates from electronic health record companies, which are often missing key instructions and not in lay-language. Attempts to standardize DCI content have shown inconsistent effects on patient comprehension, health outcomes, and readmission rates. As an initial step to improving the DCI we utilize at UNC Hospital, we aimed to assess the health literacy and associated characteristics of patients admitted to our General Internal Medicine services, as well as the readability, understandability and use of the DCI they receive.

METHODS: In this cross-sectional study at University of North Carolina Memorial Hospital, we recruited patients who were discharged from General Internal Medicine hospital services between June 23 and August 15, 2014. All adult patients who were being discharged to home after an unplanned admission, were acting as their own medical decision maker, had adequate vision to complete paper questionnaires, and were willing to receive a telephone call from a researcher after discharge were eligible to participate. We approached patients in their hospital room within 24 h of discharge, at which time the patient completed questionnaires of basic demographic information, a Short-Test of Functional Health Literacy (S-TOFHLA), a clock-draw test, and questionnaires of patient-reported physical and mental health, instrumental support, subjective socioeconomic status, and self-efficacy. We then made three attempts to contact the patient by telephone 5 to 14 days after discharge to assess their use and understanding of DCI. Two independent reviewers then systematically assessed the DCI reading level by Flesch-Kincaid and SMOG formulas and understandability by the Patient Education Materials Assessment Tool for Printable Materials (PEMAT-P). We used descriptive statistics and bivariate comparisons to assess patient and DCI characteristics.

RESULTS: Of 122 eligible patients, 55 participated in the study. The average participating patient age was 54, 48 % were female, 51 % reported their race as Caucasian and 40 % African-American. Nineteen percent of participants reported their highest level of educational completion as grade school, 28 % high school and 53 % some or more college. One-third of patients were Medicare recipients and 74 % reported having a primary care provider. Fifty one percent of patients reported having been admitted to a hospital on at least one other occasion within the last year, with a mean of 1.8 admissions and a range from one to 12. According to a health literacy assessment with the S-TOFHLA within 24 h of discharge, 61 % of patients had adequate, 11 % marginal and 28 % inadequate health literacy. According to a clock-draw test, which patients completed at the same time as the S-TOFHLA, 38 % of patients who were acting as their own medical decision maker, and therefore receiving their own discharge instructions, were cognitively impaired. Health literacy was correlated with cognition ($p=0.002$) and education ($p=0.05$), but not with patient-reported subjective socioeconomic status, self-efficacy, physical health, mental health or number of hospitalizations within the last year. The mean DCI length was 11 printed pages, with a range from 5 to 22. All DCI were found to be at a high school reading level with a mean grade level of 14 by Flesch-Kincaid and 15 by SMOG, with a range from approximately 10 to 17 by both formulas. Two independent reviewers systematically assessed DCI and found them all to be poorly understandable, with PEMAT-P understandability scores ranging from 0 to 46 % (scores less than 70 % suggest the written

document is poorly understandable). Of the 55 participating patients, we were able to reach 29 (53 %) by telephone 5 to 14 days after discharge. Of those, only 7 patients reported having their DCI available to reference at the time of the phone call, and only 6 patients reported reading their DCI after discharge.

CONCLUSIONS: The written DCI we provide to patients upon hospital discharge are long, written at a very high reading level, likely to be poorly understood, and are referenced by only a small percentage of patients after discharge. We should aim to create DCI templates that are better suited to the health literacy and cognitive status of patients at time of hospital discharge, and future research should focus on whether this will impact patient outcomes, including hospital readmission.

A HIGH NUMBER OF DAYS IN PAIN IS ASSOCIATED WITH MORE MISSED CLINIC VISITS AMONG HIV-POSITIVE WOMEN Stella Safo^{3, 2}; Chinazo Cunningham^{2, 3}; Arthur E. Blank^{1, 3}; E. Byrd Quinlivan⁶; Thomas Lincoln⁵; Oni J. Blackstock^{4, 3}. ¹Albert Einstein College of Medicine, Bronx, NY; ²Albert Einstein College of Medicine & Montefiore Medical Center, Bronx, NY; ³Montefiore Medical Center, Bronx, NY; ⁴Montefiore Medical Center/AECOM, New York, NY; ⁵Baystate Medical Center and Tufts University School of Medicine, Springfield, MA; ⁶University of North Carolina at Chapel Hill, Chapel Hill, NC. (Tracking ID #2199321)

BACKGROUND: Pain is highly prevalent among HIV-positive persons due to HIV infection itself and to other co-morbid conditions. Missed clinic visits is a widely used measure of retention in HIV medical care; poor retention care is associated with a lower likelihood of receiving antiretrovirals, a higher rate of antiretroviral failure, and worse survival. However, little is known about the relationship between pain and missed clinic visits, particularly among women. Therefore, using a multi-site cohort of HIV-positive women, we examined the relationship between pain and missed clinic visits.

METHODS: HRSA's Enhancing Access and Quality in HIV care for Women of Color Initiative was a longitudinal study of 921 HIV-positive women with varying levels of engagement in HIV medical care that took place at 9 community-based organizations and clinics in high HIV prevalence areas throughout the U.S. From 2010 to 2013, study staff conducted baseline interviews, which collected data on socio-demographic, risk behavior and clinical characteristics. Participants were followed for at least 12 months after the baseline interview. Pain was our independent variable of interest and was measured using the CDC's Healthy Days Symptoms Module; the module asks about the number of days in pain ("pain days") in the previous month. We categorized pain as: no pain days vs. low number of pain days (1–13 pain days) vs. high number of pain days (14–30 pain days), with 14 pain days being the median for those reporting ≥ 1 pain day. Our outcome variable was missed clinic visits during the 1-year period after the baseline interview. We assessed missed clinic visits by chart abstraction, and dichotomized our outcome as 0 or 1 missed visit vs. 2 or more missed visits. To examine the association between pain and missed clinic visits, we used multivariate logistic regression, adjusting for race, age, substance use, frequency of depressive symptoms, high-risk sexual behavior, insurance coverage, housing status, and antiretroviral use.

RESULTS: At baseline, median age was 42 years; 25.7 % were Hispanic and 68.6 % non-Hispanic black; 35.8 % reported high-risk sexual behavior and 13.1 % current high-risk substance use; 35.2 % reported frequent depressive symptoms; and 48.3 % reported taking antiretrovirals. In the previous month, 52 % of women reported no pain days, 23.7 % a low number of pain days, and 24.1 % a high number of pain days. Compared to women with no pain days, those with a high number of pain days were more likely to miss 2 or more clinic visits during the year (AOR=1.57, 95 % CI: 1.05–2.35). There was no significant difference in missed visits between those with no pain days and those with a low number of pain days (AOR=0.82, 95 % CI: 0.56–1.21).

CONCLUSIONS: Compared to HIV-positive women with no days in pain in the previous month, those with a high number of days in pain at baseline were more likely to miss visits during 1-year of follow-up. Women who experience more days of pain may represent an especially vulnerable group at risk for poor clinical outcomes. A better understanding of how pain may impact retention in care could guide efforts to improve retention in care of HIV-positive women.

A LONGITUDINAL ASSESSMENT OF DEPRESSIVE SYMPTOMS DURING INTERNAL MEDICINE RESIDENCY Mariah A. Quinn¹; Lingling Li²; Holly G. Prigerson³; Steven R. Simon². ¹University of Wisconsin, Middleton, WI; ²VA Boston Healthcare System, Boston, MA; ³Weill Cornell Medical College, New York City, NY; ⁴Harvard Pilgrim HealthCare Institute, Boston, MA. (Tracking ID #2196024)

BACKGROUND: Physicians experience considerable stress during residency training. Depressive symptoms, which are correlated with burnout and errors, occur frequently among housestaff. Relatively little is known about the frequency of depression among housestaff since the implementation of work-hour restrictions; there is a paucity of longitudinal data regarding mood disturbance during residency. We undertook this study

to assess the period prevalence of probable depression among a single cohort of Internal Medicine residents at a large training program.

METHODS: In 2006, we invited all Internal Medicine interns ($N=73$) at Brigham and Women's Hospital, Massachusetts, to complete an anonymous questionnaire assessing symptoms of depression, help-seeking, and use of time off work. We administered follow-up surveys throughout the subsequent 2 years of their training ($N=55$, after preliminary interns left the program prior to the second post-graduate year). The main outcome measure was the proportion of residents experiencing probable Major Depressive Disorder (MDD) during each year of training. Because of missing data, estimates of the cumulative incidence of probable depression were made based on complete cases, a conservative approach in which missing data was assumed to be a non-depressed, and Multiple Imputation.

RESULTS: Fifty-three individuals completed the survey during internship (response rate=74 %), of whom 38 completed at least one survey during the second or third year of residency (response rate over 2 years=69 %). Missing data did not vary by sex, age, prevalent depression, prior mental health care, or anti-depressant use at baseline (all $p>0.05$): a history of mental health care was associated with response to all surveys ($p=0.008$). Estimates of the period prevalence of probable MDD during *internship* were 35 % (95 % confidence interval [CI] [23, 49]) using a complete cases approach, 12 % (95 % CI [3, 20]) using a conservative estimation, and 21 % (95 % CI [0, 84]) using multiple imputation. When 3 years of longitudinal data were considered, the proportion of residents with at least one episode of probable MDD was 63 % (95 % CI [48, 79]) using the complete case approach, 36 % (95 % CI [22, 52]) by the conservative estimation approach, and 60 % (95 % CI [44, 73]) by multiple imputation. Prior receipt of mental health services and past history of personal diagnoses predicted being depressed at baseline, but not later in residency. Sadness was commonly reported, declining from 64 % during internship to 55 % during the third year, while anhedonia was prevalent but less so, declining from 38 % of respondents at the first time point to 19 % at the final time point. Active suicidal thinking was reported rarely (1 respondent); while passive suicidal thinking was reported at all time points except one (range 4–11 %). Over the course of the 3 years of residency, a total of 28 % of respondents reported that they utilized mental health services, while 8 % reported taking time off work for emotional issues.

CONCLUSIONS: Probable depression is common during internal medicine residency. More than 25 % of housestaff sought help for mental health symptoms. Rates of depression among housestaff remain high since the initiation of work hour's limitations. Given the possible consequences of depression among house officers, program directors and policy makers need to explore how programs for mental health screening and treatment can be effectively incorporated in residency training programs.

A LOOK INSIDE COMMUNITY HEALTH WORKERS' VISITS: A QUALITATIVE STUDY Julie B. Silverman²; Jim Krieger³; Karin M. Nelson¹. ¹University of Washington, VA Puget Sound, Seattle, WA; ²VA Puget Sound, Seattle, WA; ³Action for Healthy Food, Seattle, WA. (Tracking ID #2198635)

BACKGROUND: Utilization of community health workers (CHWs) shows promise in improving health outcomes and reducing disparities. However, incorporation of CHWs into the U.S. health care system has not been widely adopted. The reluctance to integrate CHWs into the health care team may be due in part to unfamiliarity with CHWs and their role within the medical team. While there is extensive literature on CHWs, these studies typically focus on the effectiveness of interventions and do not consider the skills and services of CHWs. CHWs are broadly described as educators, navigators, and promoters of healthy behaviors. However, the specifics of what they do remain unclear to the larger health care community. The purpose of this qualitative study is to describe the issues that CHWs confront and the actions they perform to help their clients.

METHODS: We performed a retrospective qualitative analysis of the open-text responses on encounter forms completed by CHWs in the Peer Support for Achieving Independence in Diabetes (Peer AID) study. This randomized controlled trial tested the effectiveness of a home-visit diabetes self-management support program for low-income individuals with poorly controlled diabetes. Participants were randomized to home visits by CHWs or to usual care. The CHWs were paid employees of Public Health - Seattle King County. After each home visit, the CHW filled out an encounter form documenting the health goal of the visit, the self-management strategies discussed and any participant concerns. Using ATLAS.ti, we performed inductive content analysis of the CHW encounter notes.

RESULTS: One hundred forty-five participants were randomized to the CHW intervention, resulting in a total of 634 encounter reports. CHW notes revealed large gaps in patient understanding of diabetes and diabetes self-management, including how to check sugar levels, what constitutes a healthy diet and the importance of taking medications as prescribed. To address these gaps, the CHWs taught participants how to read food labels, cooked and shared recipes, fixed glucose meters, explained the purpose and mechanism of each medication, and more. The encounter forms further revealed that despite appropriate

education and the desire to manage their diabetes more effectively, participants faced significant obstacles—such as the unaffordability of test strips or receipt of unhealthy foods from the food bank—to achieving optimal glycemic control. CHWs connected participants to community gardens, accompanied them to the grocery store to teach them how to find affordable and healthy foods, and helped fill out applications for discounted prescriptions. Visits with participants often uncovered frustration with and/or miscommunication between participants and their primary care providers (PCPs). The CHWs helped clarify the misunderstandings and coached participants on effective communications skills. In addition to these services, CHWs frequently called participants to check in regarding progress on their goals and to address any new questions or concerns.

CONCLUSIONS: CHWs may be able to provide services that are generally outside the scope of a primary care practice, such as connecting them to food banks and conducting grocery store tours. They also have the time to provide more thorough education that may not be possible in a 15-min PCP visit. CHWs may provide a valuable link between low-income patients and their providers.

A MULTICENTER RANDOMIZED TRIAL OF PHYSICIAN, PATIENT, AND PHYSICIAN/PATIENT INCENTIVES TO IMPROVE LIPID MANAGEMENT

(Tracking ID #2200183)

BACKGROUND: Pay for Performance programs that provide financial incentives to physicians for improved patient outcomes are widespread and increasing, though their prospective evaluation has been limited. Programs that provide financial incentives to patients for improved patient outcomes are similarly increasing, and their prospective evaluation has also been limited. At the same time, a growing literature suggests that traditional financial incentives might be made more effective if insights from behavioral economics were incorporated. In this large multicenter trial, we tested behavioral economic designs for physician and patient pay for performance in the management of hyperlipidemia.

METHODS: We enrolled 1503 patients nested within 238 primary care physicians (PCPs) in a multicenter, cluster-randomized trial comparing four alternative approaches to reduce LDL cholesterol among patients with high cardiovascular risk or established cardiovascular disease. PCPs were randomly assigned to one of four study arms: physician incentives (PHYS), patient incentives (PAT), shared physician-patient incentives (SHARE), or control (CNTRL). PCPs in PHYS accrued quarterly payments of \$256 for each enrolled patient meeting a quarterly LDL goal of a 10 point reduction from the prior quarter or being at guideline (maximum 12-month payment=\$1024 per enrolled patient). Patients in PAT could accrue up to the same amount for meeting quarterly LDL goals, distributed through a daily 'regret lottery.' The lottery encouraged medication adherence but payouts were conditioned on reaching quarterly LDL goals as described. PCPs and patients in SHARE shared those possible financial incentives—each eligible for up to half of the yearly maximum of \$1024. PCPs and patients in CNTRL received no financial incentives, but did receive the same electronic pill bottles as the other arms used for monitoring adherence. The primary outcome was mean change in LDL at 12 months.

RESULTS: Patients in SHARE achieved the largest reductions in LDL (36.8 mg/dL), followed by patients in PHYS (30.0), CNTRL (26.6), and PAT (26.4). The rankings of these arms persisted at each quarterly measurement, including 3 months following the cessation of the intervention. Only patients in SHARE achieved a reduction in LDL statistically different from those in CNTRL (9.8; 95% CI: 4.3–15.3, $P<0.001$). Patients in SHARE also achieved LDL reductions significantly different from PAT (10.1, CI: 4.7–15.5, $P<0.001$) and PHYS (6.7, CI: 1.6–11.8, $P=0.010$). No other pairwise comparisons were statistically significant. At 12 months, 49% of patients in SHARE had achieved their LDL goal compared to 40% in PHYS, 40% in PAT, and 36% in C ($P=0.027$). At 15 months, 3 months after all incentives had stopped, reassessment of LDL values showed essentially no change from 12 months.

CONCLUSIONS: This study simultaneously represents one of the largest prospective trials of pay for performance for physicians and for patients, and the only trial to have tested a shared incentive between patients and physicians. While the control condition in this study itself reflected an enhancement over usual care, we found that neither substantial payments to physicians nor substantial payments to patients offer incremental benefits in LDL reduction compared to this control when used alone. However, the study demonstrates superior results when such payments are shared between physicians and patients.

A MULTIVARIABLE STATISTICAL MODEL OF RISK FACTORS FOR HYPOGLYCEMIA IN DIABETES MELLITUS Michael Weiner^{1,2}; Zuoyi Zhang²; Larry Radican³; Jon Duke^{2,1}; Xiaochun Li¹; Jarod Baker²; Kimberly Brodovicz³; Karen Kurtyka³; Jeff Stroup²; Ramachandra G. Naik³; Jeremy Leventhal²; Amaub Chatterjee³; Samuel Engel³; Swapnil Rajpathak³; Paige DeChant²; Shengsheng Yu³. ¹Indiana University, Indianapolis, IN; ²Regenstrief Institute, Inc., Indianapolis, IN; ³Merck & Co., Inc., Kenilworth, NJ. (Tracking ID #2199146)

BACKGROUND: Approximately 346 million people globally have diabetes mellitus. Although treatment improves outcomes, hypoglycemia (HG) from treatment or patient-related factors is dangerous and occurs in more than a third of patients with diabetes. Although risk factors for HG have been identified, no recent reports identified relative risks of multiple factors in comprehensive models. Our objective was to test multiple established risk factors in a multivariable statistical model, to determine the magnitude of independent association between the factors and HG. We hypothesized that older age, non-long-acting insulin, and sulfonylurea (SU) drugs would pose significant risk.

METHODS: We reviewed medical literature to identify studies that reported risk factors for HG in diabetes. We studied an urban population in a tax-supported medical institution on an academic medical campus. The study period was 2004 to 2013. Eligible patients were at least 21 years of age on 01 January 2004 and were prescribed or dispensed a drug for diabetes mellitus during the study period. An index date was defined as the first HG event for a patient during the study period. For patients who did not experience a HG event, their index date was a randomly selected visit date during the study period. The baseline period was defined as the 2 years prior to the index date. We excluded patients with a diagnosis of abnormal glucose tolerance complicating pregnancy or childbirth, and patients with fewer than two clinical encounters on separate dates during the baseline period. From a health information exchange in which the target institution participates, we extracted data about risk factors and demographics, from medical records of patients seen at the institution during the study period. Using this retrospective cohort, we conducted multivariable logistic regression analysis, with HG as the primary outcome. HG was defined as an outpatient plasma glucose value of less than 70 mg/dL (3.9 mmol/L), identified through laboratory reports, previously validated International Classification of Diseases diagnosis codes, or narrative text that underwent natural language processing (NLP). Significance was defined by a p -value of less than or equal to 0.05.

RESULTS: The cohort had 38,780 patients with the following characteristics: mean age of 56 years, 56% female, 33% white, 34% African-American, 19% with Medicaid, and 39% uninsured. HG was identified in 7589 (20%) of them. Of these, NLP identified HG in 5488, with 1566 identified only by NLP. In logistic regression, positive risk factors included the following: eating disorder (OR 30.5; 95% CI 1.6, 582.9), infection within 30 days (2.5; 2.2, 2.8), insulin other than long-acting insulin (without SU drug, 2.3; 2.1, 2.6; with SU within 90 days, 1.6; 1.3, 1.9; vs. non-insulin and non-SU), previous hypoglycemia within 12 months (2.2; 1.8, 2.7), African-American (1.8; 1.6, 1.9; vs. white), diabetic neuropathy (1.6; 1.4, 1.8), Medicaid (1.5; 1.4, 1.6), alcohol (1.4; 1.2, 1.7), chronic heart failure (1.4; 1.2, 1.6), without antibiotics (1.3; 1.1, 1.5), antibiotics with SU (1.3; 1.0, 1.8), dementia or falls (1.3; 1.2, 1.5), and A1C 6.5 or less (1.1; 1.0, 1.3; vs. greater than 6.5 to less than 7.0). Negative risk factors included serum calcium mg/dL (OR 0.5; 95% CI 0.5, 0.5), age 85 years or more (0.6; 0.5, 0.8; vs. 45 to 64), long-acting insulin plus a SU within 90 days (0.6; 0.5, 0.8), Hispanic (0.6; 0.5, 0.8), and age 75 to 84 years (0.9; 0.8, 1.0).

CONCLUSIONS: HG was common in this population. NLP was a useful tool, uniquely identifying 21% (1566/7589) of the HG group. Many risk factors for HG were identified, including modifiable factors such as eating disorders, infections, and drugs. Insulin other than long-acting insulin, and SU drugs, were confirmed as important risks. Surprisingly, the oldest ages (age 75 years or more) posed less risk; this may reflect diminished awareness of hypoglycemia, greater attention to medical management, or other unmeasured factors in this population. Results suggest that tight diabetes control (A1C of 6.5 or less) poses greater risk of HG. These results can be used to develop decision support tools for primary care clinicians at the point of care.

A NARRATIVE REVIEW OF MEDICATION-RELATED CLINICAL DECISION SUPPORT Clare L. Brown¹; Sarah P. Slight²; Andrew K. Husband²; Neil W. Watson⁴; David W. Bates³. ¹University of Durham, Sunderland, United Kingdom; ²Durham University, Stockton on Tees, United Kingdom; ³Brigham and Women, Boston, MA; ⁴Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, United Kingdom. (Tracking ID #2193237)

BACKGROUND: Medication errors cause substantial patient harm and can occur at any stage of the medication use process. Health information technology, such as Computerized Physician Order Entry (CPOE) and Clinical Decision Support (CDS), may be used to reduce the likelihood of these errors. Medication-related CDS provides automated guidance and support to clinicians at the point of prescribing. CDS can provide drug-drug interaction (DDI) checks, drug allergy checks, dosing guidance, duplicate therapy checks and formulary decision support. CDS has been associated with a range of benefits such as improved patient safety, improved standards of care and reduction in healthcare costs. We

reviewed the recent literature around medication-related CDS functionality and reflected upon the issues pertinent to its future development.

METHODS: We searched for papers in Medline Ovid and Embase Ovid, using MeSH terms and key words including 'clinical decision support', 'decision support systems' and 'computerized physician order entry' with a date range of 2007 to 2014. Specific MeSH terms and keywords relevant to five basic CDS functionalities were also used. We included all publication types, all types of CPOE systems and all clinical settings. Only English language papers were selected for further review. Reference lists, papers from world leading experts and the 'other citing articles' function were also used to identify additional articles. Titles and abstracts were initially screened to identify relevant papers, followed by the full text by one reviewer. A total of 896 articles were identified across each of the five areas, of which 184 were included.

RESULTS: The success of CDS very much depends on users finding alerts valuable and acting on the information received. CDS functionality is continually evolving in response to users' needs. Assigning a severity level to DDI alerts has been shown to improve alert acceptance. Additionally, improving alert specificity and severity was found to be an important factor for realising the benefits of DDI alerts. Maintenance of accurate records and ability to carry out cross-sensitivity checks are key to the production of appropriate drug-allergy checks. Patient specific parameters should be incorporated into the decision-making algorithms to improve the accuracy and appropriateness of drug-dosage alerts; furthermore, suggested doses should be appropriately rounded to facilitate administration and include order sentences sequenced to reflect those most commonly used. How the CDS system is configured is important for drug-duplication checks and to avoid potentially exposing the patient to toxic drug levels. The knowledge base(s) for drug-formulary alerts must be accurate and reviewed regularly in order to produce relevant alerts and encourage formulary adherence. Finally, consideration of human factors principles during the design and implementation of CDS is critical and has been shown to improve system effectiveness.

CONCLUSIONS: CDS is still undergoing development. The implementation of automation in healthcare has surged in recent years and this is likely to continue. Moving forward, integration of patient specific parameters into CDS decision-making checks and consideration of human-factors design principles will be central to obtaining the potential benefits of CDS. Such advancements in CDS should enable it to have a much greater impact for improving patient care.

A PALLIATIVE NURSE PRACTITIONER INTERVENTION TO IMPROVE ADVANCE CARE PLANNING AND SUPPORTIVE CARE IN PATIENTS WITH ADVANCED CANCER Anne Walling²; Sarah F. D'Ambruso²; Sara Hurvitz²; Robin

Clarke¹; Andrew Hackbarth¹; Christopher Pietras²; Neil Wenger³. ¹UCLA, Los Angeles, CA; ²UCLA, Studio City, CA; ³University of California, Los Angeles, Los Angeles, CA. (Tracking ID #2199225)

BACKGROUND: The simultaneous care model for palliative care provides high quality care for patients with serious illness. Unfortunately, the U.S. healthcare system falls short of this goal, even in patients with advanced cancer. As the first phase of a system-wide advance care planning program, we used implementation science methods to test if a nurse practitioner (NP) with structured palliative care training using evidence-based principles of communication and a model that cultivates prognostic awareness with palliative care physician oversight can improve the quality of advance care planning and supportive care provided to patients with advanced cancer in an academic health system.

METHODS: Patients with advanced cancer were identified from the electronic health record (EHR) based on oncology visits and treatments and using free text analysis of oncology notes and imaging. An NP was integrated into the clinic of two oncologists who treated primarily breast cancer with the goal of seeing patients with incurable disease soon after presentation and then following patients in continuity. The oncologist documented prognosis and provided a warm handoff in referring the patient to the NP. Based on standardized assessments administered by the NP, patients were linked into resources for psychosocial support and symptoms were addressed. The NP focused on goals of care and valued future health states in advance care planning, which was documented in a Goals of care note in the EHR. The intervention was evaluated using EHR data to compare rates of advance care planning documented in Goals of care notes and hospice referral among decedents for patients with advanced cancer seen by the two target oncologists compared to all other advanced cancer patients in clinics without the NP intervention.

RESULTS: Of 10,228 patients with active cancer, 2535 patients had advanced cancer and were treated by 39 oncologists. Advance care planning as represented by EHR Goals of care notes increased for patients of the two intervention oncologists compared to patients of the other oncologists as seen in the run chart in the Figure. Hospice referral before death was not different between the two groups at baseline, but was significantly higher for patients of intervention oncologists compared to patients of control oncologists (50 % v. 19 %, $p=0.03$) over the 9 months of follow up.

CONCLUSIONS: This embedded NP-based model of advance care planning and palliative care delivery within an oncology clinic improves advance care planning and early results suggest better end of life care as evidenced by hospice enrollment.

A PATIENT-CENTERED APPROACH TO IMPROVING DISCHARGE INSTRUCTIONS David S. Pilkington³; Jessica R. Howard-Anderson³; Rachel Brook³; Ashley Busuttil¹; Nasim Afsarmanesh². ¹UCLA, Los Angeles, CA; ²UCLA Health, Pacific Palisades, CA; ³University of California, Los Angeles, Los Angeles, CA. (Tracking ID #2199487)

BACKGROUND: The transition from hospital to home is a crucial time in a patient's hospitalization as the inpatient team aims to create a seamless transfer to the ambulatory

providers. Patient comprehension of their post discharge care is critical for ensuring patient safety and wellness after a hospital discharge. With the advent of the electronic health record (EHR), more hospitals use templates and auto-populated discharge instructions. Studies have been done evaluating the EHR's affect on resident documentation - including their tendency to promote automaticity instead of creative clinical thinking. However, interestingly, patient satisfaction with and comprehension of EHR derived discharge instructions has not been robustly evaluated. The goal of our study was to use a patient-centered approach to evaluate patients' knowledge of and satisfaction with the new EHR generated discharge instructions.

METHODS: Over a 3-month period (07/02/2014–09/24/2014), we conducted structured phone interviews of all patients discharged within 3 weeks from the general internal medicine teams at a tertiary academic medical center. We excluded patients who were discharged to nursing facilities or hospice, or did not speak English. The interview script asked patients if they could clearly identify key pieces of information on their discharge paperwork including medications, follow-up appointments, expected symptoms, and contact phone numbers. Additionally patients were asked questions regarding comprehension of their medication regimen and details regarding follow-up appointments. Lastly, using a 1–10 numeric scale, patients were asked to rate their satisfaction with the discharge process.

RESULTS: Of the 235 eligible patients contacted, 47 patients were successfully interviewed (20 %); 135 patients (57 %) were unable to be reached, 46 patients refused (20 %) and 7 patients (3 %) did not read the discharge paperwork. Overall patients reported being able to identify their medication regimens, and understand changes in dosages and indications for specific treatments greater than 90 % of the time. One-hundred percent of patients reported that they could identify their scheduled follow-up appointments on the discharge paperwork. However only 76 % reported that they were aware of scheduled or to-be scheduled follow up appointments on discharge. Most notably, 13 % of patients could not identify warning symptoms to be aware of on discharge, and 33 % of patients were unaware of routine symptoms to expect after discharge. Lastly, 13 % of patients could not locate any emergency contact information for a physician on the discharge paperwork. Overall satisfaction with the discharge paperwork was 8.8 [SD 1.4] on a scale of 1–10.

CONCLUSIONS: While patient satisfaction was overall adequate with our discharge instructions, these interviews identified important gaps in our discharge practices that may hinder our patients' ability to fully understand their post-discharge care. For example, our institution has infrastructures in place to schedule 100 % of patients with follow-up appointments. However only 76 % of patients interviewed stated that they were scheduled for follow up appointments, or knew follow-up appointments would be scheduled for them. This discrepancy existed despite patients reporting being able to identify the post-discharge appointment section of the discharge paperwork. We think this discrepancy occurred because in our discharge instructions, follow up appointments needing to be scheduled (i.e. not secured prior to patient discharge) are located in a different place than the already scheduled appointments, thereby causing significant confusing. While this problem is specific to our institution, it provides a nice example of an area for intervention that we would have never known about had we not interviewed patients themselves. In addition, there was a significant percentage of patients who expressed confusion over both warning symptoms and expected symptoms post-discharge. Lastly, patients also described difficulty finding information on who to call if they had concerns when at home, after discharge. Both being aware of routine recovery symptoms, as well as knowing how to proceed if a question arises at home, can reduce patient anxiety on discharge and possibly prevent readmissions. Future steps will involve revising our institution's discharge instructions to more clearly elucidate when follow-up appointments are made, as well as clarifying expectations for post-discharge care and recovery. As the nation continues to strive to improve patient safety while adapting EHRs, it will be imperative that patient insights continue to be considered and implemented in the care delivery process.

A PILOT STUDY EXAMINING HEALTH LITERACY PROMOTION PRACTICES AMONG HEALTHCARE PROFESSIONALS Allison Squires¹; Shonna Yin²; Sherry A. Greenberg¹; Maryanne M. Giulianti¹; Margaret V. McDonald³; Lisa Altschuler²; Tara Cortes¹. ¹New York University, New York, NY; ²NYU School of Medicine, New York, NY; ³Visiting Nurse Service of New York, New York, NY. (Tracking ID #2198606)

BACKGROUND: As health services delivery becomes more interprofessional it is important to understand how different professionals address health literacy with their clients. Practice differences related to health literacy contribute to health disparities and patient outcomes. The purpose of this study was to pilot test a series of questions that assess health literacy promotion practices in a cohort of nurses, physicians, and social workers. It was hypothesized that health literacy-informed practices are an important way to promote interprofessional collaboration and avoid duplication of work and at the same time allow for reinforcement of important patient education content, enhancing patient self-management.

METHODS: The previously non-validated 17 questions were derived from Schwartzberg and Turner's (2007) list of practices promoting health literacy. We first completed an interprofessional content validation of the potential questions. Through the use of expert raters, as a pre-data collection step content validation evaluates questions for their relevance individually and as a group when measuring a phenomenon. Item and scale level scores result. Expert raters from medicine ($n=10$), nursing ($n=8$), and social work ($n=2$) participated in the content validation process. Social work and nurse raters were grouped to create an even comparison since more social workers were not available for the exercise. A cross-sectional pilot study was then conducted as part of a larger survey aimed

at evaluating perspectives on interprofessional practice. Participants rated the frequency with which they used the practices from 1=never to 5=always. Content validity scores of the questions were calculated using a modified kappa score. Trends in reported practices are described.

RESULTS: The scale content validity rating among physicians was 0.74 and among the nurse-social work cohort was 0.89. Each group of expert raters scored 3 items as fair or poor health literacy practice assessment measures, with only one low scoring item in common between the two groups. While data limitations around normalized distributions do not allow us to compare the means for significant differences, it appears that the relevance of certain practices around promoting health literacy in patients differ between groups. For the pilot test, 42 out of 53 eligible participants completed the health literacy assessment practices. Participants reported being most likely to use what they perceived as simple language to explain information to patients (4.05/5) and the use of models or drawing pictures as the least frequent strategy (2.73/5 and 2.9/5 respectively). All other responses ranged in the "sometimes" range between 3.02 and 3.93/5. While the sample is too small for comparison at this time, there do appear to be trends in practice differences between the professions in terms of which strategies they report using most.

CONCLUSIONS: Our data suggest that these questions designed to assess health professional's reported health literacy promotion practices have potential in the study of outcomes of interprofessional patient care. The content validation exercise revealed early differences in perceived relevance of different practices by experts. We plan to further examine these trends as we accumulate a larger dataset from these groups.

A PILOT STUDY OF A DIABETES PREVENTION PROGRAM IN AN URBAN RESIDENCY PRACTICE Rose Coady; Catherine D. Agricola; Robert J. Fortuna; Brett Robbins. University of Rochester, Rochester, NY. (Tracking ID #2193959)

BACKGROUND: There are an estimated 54 million Americans who have pre-diabetes, many of whom will progress to type 2 diabetes (T2D) without intervention or lifestyle modifications. The Diabetes Prevention Program (DPP) is an intensive 22 week intervention involving both group and individual sessions. It has been studied in controlled trials and proven to be clinically and cost effective, but the DPP model has not been studied in a real-world setting. We examined its effectiveness in an inner city, residency primary care clinic environment.

METHODS: We modeled the Rochester Diabetes Prevention Program (R-DPP) after national DPP standards and the core principles of self-determination theory. We included patients with pre-diabetes (HbA1c 5.7–6.4 %) and those with morbid obesity regardless of the HbA1c. The goal of the program was to reduce the progression and development of T2D. We measured body mass index (BMI), weight measured in pounds (lbs), low-density lipoprotein (LDL), hemoglobin A1c (HbA1c), and exercise activity time measured in minutes per week (min/wk) before and after the intervention.

RESULTS: To date, 22 participants have completed R-DPP. The mean age of the cohort was 48 years with 77 % female, 72 % African American, and 45 % with public health insurance, primarily Medicare or Medicaid. Participants experienced a mean weight loss of 7 lbs (232 lbs to 225 lbs, $p<0.0001$) and a decrease in BMI of 1.7 (38.8 to 37.1, $p=0.012$). Self-reported exercise time increased by 68.4 min/week (40.6 min/week to 109 min/week). Participants also experienced a decrease in HbA1c (7.4 to 7.0 %, $p=0.093$), total cholesterol (173 mg/dL to 165 mg/dL, $p=0.003$), and LDL (93 mg/dL to 88 mg/dL, $p=0.023$).

CONCLUSIONS: The R-DPP was an effectiveness pilot trial that reached an at-risk urban population in a resident clinic. It promoted positive behavior change leading to an increase in participants' weekly exercise with significant weight loss and improvements in HbA1c, total cholesterol and LDL.

Average Measures Before and After the R-DPP

BMI (kg/m ²)	Before R-DPP	After R-DPP	p value
Weight (lbs)	38.8	37.2	0.012
HbA1C (%)	232	226	<0.001
Total Cholesterol (mg/dL)	7.4	7.0	0.09
LDL (mg/dL)	173	166	<0.001
Exercise Time (min/week)	93	88	0.02

A RANDOMIZED COMPARATIVE EFFECTIVENESS TRIAL OF A PRIMARY CARE-COMMUNITY LINKAGE FOR PREVENTING TYPE 2 DIABETES Ronald T. Ackermann¹; David T. Liss¹; Emily Finch¹; Laura Hays²; David G. Marrero³; Chandan Saha⁴. ¹Northwestern University, Chicago, IL; ²Indiana University School of Nursing, Indianapolis, IN; ³Indiana University School of Medicine, Indianapolis, IN; ⁴Indiana University, Indianapolis, IN. (Tracking ID #2200110)

BACKGROUND: The U.S. Diabetes Prevention Program (DPP) showed that resource-intensive lifestyle interventions supporting daily physical activity and modest weight loss can cut the rate of developing type 2 diabetes in half. This randomized comparative effectiveness trial evaluated the weight loss effectiveness of a referral-based, 'YMCA Model' for offering the Diabetes Prevention Program (DPP) lifestyle intervention to adult primary care patients at high risk for developing type 2 diabetes.

METHODS: Five hundred nine overweight/obese, low-income, non-diabetic, adult primary care patients with elevated blood glucose were identified in 9 urban primary care settings and individually randomized to receive (1) standard care plus brief lifestyle counseling (SC); or (2) being offered a group-based adaption of the DPP delivered free-of-charge by the YMCA (YDPP). The primary outcome was mean difference in weight loss at 12 months. Intention-to-treat (ITT) analyses used longitudinal linear or logistic regression, with missing observations multiply imputed. Instrumental variables (IV) regression estimated weight loss effectiveness among participants completing ≥ 9 intervention lessons - a commonly cited threshold for high engagement in the DPP. Secondary outcomes included attendance in the referral-based intervention and changes in intermediate cardiometabolic risk factors across treatment arms.

RESULTS: At enrollment, participants had a mean age of 51, BMI 36.8 kg/m², and HbA1c 6.0 %; 57 % reported African American race and 61.3 % reported annual household incomes $< \$25,000$. In the YDPP arm, 161 (62.6 %) participants attended ≥ 1 lesson and 103 (40.0 %) completed ≥ 9 lessons. In ITT analysis, mean 12-month weight loss was 2.3 kg (95 % CI 1.1 to 3.4 kg) more for YDPP arm participants, compared to SC. In IV analyses, persons attending ≥ 9 lessons had a 5.3 kg (95 % CI, 2.8 to 7.9 kg) greater weight loss than without the intervention.

CONCLUSIONS: A 'YMCA model' for DPP delivery achieves meaningful weight losses at 12 months among low income adults. For every 5 high-risk primary care patients who were offered the intervention, about 1 additional person achieved and maintained ≥ 5 % weight loss after 12 months. This is the largest randomized intervention trial to date evaluating the uptake and weight loss effectiveness of community delivery of the DPP. It demonstrates that a primary care-community linkage is one promising approach for helping to slow the growing burden of type 2 diabetes in the U.S.

A RANDOMIZED CONTROL TRIAL OF OPT-IN VERSUS OPT-OUT ENROLLMENT INTO A DIABETES MANAGEMENT INTERVENTION

Jaya Aysola²; Andrea B. Troxel²; David A. Asch¹; Emin Tahirovic²; Kelsey Gangemi¹; Amanda T. Hodlofski¹; Jingsan Zhu¹; Kevin G. Volpp¹. ¹University of Pennsylvania, Philadelphia, PA; ²University of Pennsylvania, Philadelphia, PA. (Tracking ID #2199278)

BACKGROUND: Improving enrollment rates into research trials is central to ongoing efforts to maximize the external validity of research findings. This is particularly important for behavioral interventions, in which self selection in enrollment may be relevant in terms of intervention effectiveness. Opt-out defaults have been shown to influence decisions without restricting choice, but have primarily been tested in contexts that require a one-time decision such as retirement savings allocations or the release of childhood vaccination records. To examine the impact of an opt-out enrollment strategy for behavioral interventions, we conducted a randomized controlled trial comparing an opt-out recruitment strategy versus a conventional opt-in strategy on participation rates and adherence to a 6-month intervention for patients with poorly controlled diabetes.

METHODS: We recruited participants between November 2013 and March 2014 from two internal medicine primary care sites at the University of Pennsylvania Health System who met the following eligibility criteria: 1) age 18–80 years; 2) confirmed diagnosis of diabetes; and 3) a measured hemoglobin A1c greater than 8 % in the past 12 months. Eligible patients were randomized into opt-in and opt-out arms, using a 5:1 then 9:1 randomization ratio (opt-in versus opt-out). Participants in the opt-in arm received a letter inviting them to contact the study team if interested in enrolling in the study. Participants in the opt-out arm received a letter stating that they have been enrolled into a diabetes program being conducted at their practice and would be contacted within ten days to set up the initial appointment, at which point they could decline participation. Participants in both arms who agreed to participate received free wireless glucometers and blood pressure cuffs, automated messages regarding their glycemic control, ongoing support from nurse practitioners, and a lottery-based incentive tied to daily device use for the first 12 weeks of the study followed by a 12 week period of observation without incentives. Our primary outcomes were participation rate, defined as the proportion of enrollees invited to join the study via opt-in or opt-out who attended the baseline visit, and adherence to daily glycemic monitoring. We were powered to detect a difference of 20 % between arms in adherence to daily glycemic monitoring. As a secondary outcome we assessed attrition rates at 3 and 6 months.

RESULTS: Of the 569 eligible participants who received a recruitment letter, 496 were randomized to the opt-in arm and 73 to the opt-out arm. There were no differences in baseline characteristics between these groups. Participation rates were 13 % in the opt-in arm compared to 38 % in the opt-out arm (p value < 0.001). Of those who participated,

6 months attrition rates were 13 and 32 % in the opt-in and opt-out arms respectively (p value = 0.04). Amongst those who attended their 3-month visit, attrition rates at 6 months were similar (13 % opt in, 17 % opt out, p -value 0.72). There were significant but small differences between arms in the mean decline in adherence rates to glucometer usage during the first 12 weeks (opt-in vs. opt-out: -0.01 vs. -0.03 ; p -value = 0.02) and the last 12 weeks (opt-in vs. opt-out: -0.02 vs. -0.008 ; p -value = 0.02).

CONCLUSIONS: Participation rates were threefold higher amongst patients recruited through an opt out default compared to a conventional opt-in approach with no significant compromise in adherence to the intervention at 6 months. This suggests that opt-out defaults, where clinically appropriate, could be a useful approach for increasing the external validity of trials testing behavioral interventions in clinical settings.

A RANDOMIZED CONTROLLED TRIAL EVALUATING THE EFFECT OF COMPASS (COLLEAGUES MEETING TO PROMOTE AND SUSTAIN SATISFACTION) SMALL GROUP SESSIONS ON PHYSICIAN WELL-BEING, MEANING, AND JOB SATISFACTION

Colin P. West; Liselette Dyrbye; Daniel Satele; Tait Shanafelt. Mayo Clinic, Rochester, MN. (Tracking ID #2199380)

BACKGROUND: Burnout and low job satisfaction are all too common among physicians. However, studies evaluating interventions to address these issues have been limited. Application of validated instruments has been uncommon, and prior studies have been largely observational. A recent randomized study of facilitated physician meetings (West CP et al., JAMA Intern Med 2014;174(4):527-33) demonstrated improvement in meaning and reduced depersonalization in the intervention arm, but it is unknown whether less intensive and less structured forms of this intervention would also be beneficial for physician well-being.

METHODS: We conducted a randomized controlled trial of a 6-month intervention involving 12 biweekly one-hour meetings of self-formed groups of 6–8 academic internal medicine physicians, termed COMPASS Groups (Colleagues Meeting to Promote And Sustain Satisfaction). Each intervention session consisted of a brief 15-min group discussion of an assigned topic relevant to the physician experience and drawn from prior physician well-being literature, followed by 45 min for a shared lunch or other group activity as determined by each group itself. Each participant received \$20 per session for meal expenses. Control participants were wait-listed to complete their own small groups after the initial 6 months to ensure equity in study reimbursement opportunities. The small group topics included work-life balance, medical mistakes, meaning in work, and resiliency, among other topics relating to the physician experience. Participants completed surveys at baseline and then quarterly. Surveys included linear analog self assessment of overall quality of life (QOL), the Maslach Burnout Inventory, the 2-item PRIME-MD depression screen, the Empowerment at Work Scale assessing meaning from work, the Social Isolation PROMIS instrument, and the Physician Job Satisfaction Scale. The trial groups were compared using generalized estimating equations for repeated measures.

RESULTS: Of 125 study volunteers, 64 and 61 participants were randomized to the intervention and control arms of the study, respectively. At baseline, no statistically significant differences were observed between the study groups for any well-being variable. Results are shown in the Table ($p < 0.05$ designated with an asterisk in the Table for relevant outcome variables). Preliminary data also suggest sustained benefits up to 6 months after the end of the study intervention period for each outcome.

CONCLUSIONS: Study participants engaged in biweekly meetings with colleagues supported by modest study funds experienced statistically and clinically significant improvements in multiple domains of well-being and satisfaction, including overall QOL, the depersonalization and personal accomplishment domains of burnout, meaning from work, social isolation, and job satisfaction. These results suggest that a relatively non-intensive intervention involving self-selected physician small group meetings can be effective in promoting physician well-being, meaning from work, and job satisfaction.

Absolute Change in Outcomes from Baseline to 6 Months.

Outcome	Intervention (n=64)	Control (n=61)
Poor QOL*	-13.0 %	-6.2 %
Overall QOL Score (0–10)*	+0.72	+0.20
High Emotional Exhaustion	-10.0 %	-7.3 %
High Depersonalization*	-4.4 %	+2.4 %
Low Personal Accomplishment*	-10.2 %	+8.8 %
Overall Burnout	-6.1 %	-7.1 %
Positive depression screen	-7.5 %	-8.7 %
High Meaning from Work*	-0.8 %	-8.7 %
Social Isolation PROMIS Score (1–5)*	-0.15	+0.38
High Job Satisfaction*	+15.7 %	+7.8 %
Likelihood of Leaving in Next 2 Years*	+0.7 %	+5.8 %

A RANDOMIZED CONTROLLED TRIAL TO DECREASE JOB BURNOUT IN FIRST-YEAR INTERNAL MEDICINE RESIDENTS USING A FACILITATED DISCUSSION GROUP INTERVENTION Jonathan Ripp¹; Robert Fallar¹; Deborah R. Korenstein². ¹Icahn School of Medicine at Mount Sinai, New York, NY; ²Memorial Sloan-Kettering Cancer Center, New York, NY. (Tracking ID #2191957)

BACKGROUND: Job burnout is common in internal medicine (IM) trainees and has been associated with limited peer and professional support, depression, unprofessional behavior and sub-optimal patient care. Facilitated group discussion has reduced burnout among self-selected practicing clinicians. We hypothesized that a similar group discussion-based intervention would reduce the development of burnout among first-year IM resident physicians.

METHODS: We conducted a single-center randomized trial between June 2013 and May 2014 in an academic IM residency program. We selected participants from a convenience sample of 51 eligible incoming IM residents and randomly assigned groups of 3 participating residents to intervention or control. Intervention arm groups aimed to hold twice monthly discussion sessions (18 total). Expert group discussion facilitators led the sessions which were each organized around a theme (e.g. death and dying, difficult patients, coping mechanisms, etc.). Participants received lunch and one hour away from clinical duties. Due to residency program requirements, we were unable to hold the sessions in place of existing educational meetings. Residents in the control arm were provided lunch vouchers. We administered surveys at study onset and completion. The primary outcome was job burnout using the validated Maslach Burnout Inventory. Secondary outcomes included attitudinal items related to professional behavior and sub-optimal patient care, and fatigue as measured by the validated Epworth Sleep Scale. All metrics were dichotomized and changes in pre-post values were compared using chi-squared analyses or Fisher's Exact test when cell sizes were small ($n < 5$). When comparing changes in scores, the data were analyzed using analysis of variance techniques.

RESULTS: All 51 eligible residents consented to participate; 39 (76 %) completed both surveys. Neither burnout prevalence at the start of training (10/21 (48 %) v. 7/17 (41 %), $P = 0.69$) nor incident burnout (9/11 (82 %) v. 5/10 (50 %), $P = 0.18$) over the course of the year differed between intervention and control arms, though more intervention residents had high depersonalization scores at study end (18/21 (86 %) v. 9/17 (53 %), $P = 0.04$). (Table) Secondary outcomes did not differ between groups. During informal feedback, many intervention residents revealed that sessions did not effectively free them from their clinical responsibilities or eliminate other daily requirements.

CONCLUSIONS: A facilitated group discussion intervention was ineffective in decreasing job burnout in resident physicians. The failure of this approach highlights the difficulty of decreasing burnout in trainees. Failure of the intervention may be attributable to the unique challenges of residency training or to the fact that the intervention was performed in a convenience sample and not in a self-selected group. Future discussion-based interventions designed to mitigate the development of burnout in IM residents should consider a voluntary integrated format free from clinical duties.

Incidence and Prevalence of Job Burnout, Depersonalization and Emotional Exhaustion in a Cohort of Internal Medicine Resident Physicians Participating in a Randomized Controlled Study Examining the Impact of Facilitated Discussion

Residents' characteristic	No. (%) Intervention Arm (n=21)	No. (%) Control Arm (n=17)	P value
Overall Burnout			
Burnout Prevalence at the Start of Training	10/21 (48 %)	7/17 (41 %)	.70
Burnout prevalence at the end of PGY-1	18/21 (86 %)	12/17 (71 %)	.43
Burnout incidence	9/11 (82 %)	5/10 (50 %)	.18
Depersonalization			
High DP subscores at the start of training	6/21 (29 %)	4/17 (24 %)	1.00
High DP subscores at the end of PGY-1	18/21 (86 %)	9/17 (53 %)	.04
High DP incidence ^a	12/15 (80 %)	6/13 (46 %)	.11
Emotional exhaustion			
High EE subscores at the start of training	5/21 (24 %)	3/17 (18 %)	.71
High EE subscores at the end of PGY-1	13/21 (62 %)	12/17 (71 %)	.73
High EE incidence ^b	10/16 (63 %)	9/14 (64 %)	1.00

Abbreviations: PGY-1 indicates postgraduate year 1; DP depersonalization; EE, emotional exhaustion.

a Percentage of residents who start training without burnout or high DP and develop burnout and high DP by the end of PGY-1.

b Percentage of residents who start training without burnout or high EE and develop burnout and high EE by the end of PGY-1.

A RANDOMIZED TRIAL OF SELF-SAMPLING FOR HUMAN PAPILLOMA VIRUS AMONG MINORITY IMMIGRANT WOMEN IN NEED OF CERVICAL CANCER SCREENING: FINDINGS FROM THE SOUTH FLORIDA CENTER FOR REDUCING CANCER DISPARITIES Olveen Carrasquillo; Erin N. Kobetz-Kerman; Yisel Alonzo. University of Miami, Miami, FL. (Tracking ID #2199041)

BACKGROUND: Latina immigrants and Haitian women are 15–30 percentage points less likely to be screened for cervical cancer than Non-Hispanics whites (NHWs). Testing for the Human Papilloma Virus (HPV) is gaining increased acceptance for cervical cancer screening. A major advantage of this approach is that with minimal instruction women can perform the sampling themselves.

METHODS: Our study was conducted using the Community Based Participatory Research framework in three ethnic communities in Miami-Dade County: Hispanic, Haitian and one mixed. Each of three trained Community Health Workers (CHWs) recruited 200 women aged 30–65 years from various community-based locations and scheduled a subsequent 30-min assessment. Women were randomized to one of three arms: 1) culturally tailored health education materials 2) an individualized 60 min CHW led health education session followed by CHW navigation to a participating health center for a Pap Smear 3) Individualized health education and the option of having HPV home self-sampling or CHW navigation for a Pap smear at a health center. Our primary outcome was self-report of having cervical cancer screening assessed at 6 months after the initial evaluation done by a research assistant blinded to allocation status. Women lost to follow-up were considered as not screened. At study exit, all women not having had screening were offered HPV self-sampling.

RESULTS: We assessed 4608 women of whom 1156 were study eligible. Having had a Pap smear in the last 3 years (51 %) and age (15 %) were the primary reasons for study ineligibility. We were unable to schedule an initial baseline assessment with 38 % of study eligible women and 11 % declined to participate. Among the 601 women randomized, mean age was 47+9 years, 67 % had household incomes under \$20,000, and 76 % lacked health insurance. These characteristics and loss to follow-up at 6 months (9–12 %) were similar across all three arms. Using intention to treat, at 6 months 29 % of women randomized to health education reported being screened for cervical cancer versus 38 % in the CHW navigation group and 73 % in the HPV sampling group ($P < 0.05$ for group 2 versus group 1, and < 0.01 for group 3 versus group 2 or 1. In pre-planned subgroup analysis, in one community (mixed) where barriers to traditional pap smears screening were minimized, rates of screening were more attenuated in groups 2 versus 3, 58 and 73 %, respectively as compared to 27 % in group 1 ($p < 0.01$ for all three comparisons). Rates of HPV positivity were highest in the Haitian community 25 % versus 10 % and 13 % in the other two locations ($p < 0.05$). CHWs were able to confirm follow-up and treatment (when needed) in over 90 % women having an abnormal screen.

CONCLUSIONS: We found that among a sample of immigrant predominantly low income and uninsured women, HPV self sampling was considerably superior to health education and CHW navigation to achieve cervical cancer screening. Our findings lend strong support for this screening strategy among hard to reach minority populations.

A RANDOMIZED TRIAL OF SOCIAL NORMS FEEDBACK AND FINANCIAL INCENTIVES FOR PHYSICAL ACTIVITY USING A TEAM-BASED APPROACH Mitesh Patel^{1, 2}; Kevin G. Volpp^{1, 2}; Roy Rosin¹; Dylan Small¹; Scarlett Bellamy¹; Nancy Haff³; Samantha Lee¹; Lisa Wesby¹; Karen Hoffer¹; David Shuttlesworth¹; Devon Taylor¹; Victoria Ulrich¹; Jingsan Zhu¹; Lin Yang¹; Xingmei Wang¹; David A. Asch^{1, 2}. ¹University of Pennsylvania, New York, NY; ²Philadelphia VA Medical Center, Philadelphia, PA; ³Massachusetts General Hospital, Boston, MA. (Tracking ID #2196543)

BACKGROUND: More than half of adults in the United States do not achieve the minimum recommended level of physical activity to achieve health benefits. Social comparisons and incentives may provide potent new ways to increase engagement but the optimal type of feedback is unknown. Insights from behavioral economics may offer new strategies to frame feedback and design incentives to change behavior. The objective of this study was to evaluate the effectiveness of using social norms feedback and financial incentives for physical activity using a team-based approach.

METHODS: Two hundred eighty-eight employees from a large corporation in Philadelphia formed 72 four-member teams randomized to 4 arms: 50th percentile feedback (weekly feedback compared to other teams in the same arm), 75th percentile feedback, 50th percentile feedback with incentives, 75th percentile feedback with incentives—with

reward eligibility based on achieving at least 7000 steps per day, a level endorsed by the American College of Sports Medicine as meeting federal guidelines for the minimum level of physical activity to achieve health benefits. Financial incentives with a daily expected value of \$1.40 were offered during the 13 week intervention period using a weekly regret lottery in which participants had an 18 % chance to win \$35 and a 1 % chance to win \$350. Social norms feedback on performance relative to other teams was delivered weekly for all 26 weeks. Step counts were tracked by smartphone accelerometers using an application that ran passively in the background. The primary outcome measure was the proportion of participant-days that the goal was achieved during the intervention. The intent-to-treat analysis used generalized linear and mixed-models to adjust for the repeated measures of participant step counts and clustering by team. All hypothesis tests were two-sided. To maintain the type I error rate while testing 3 pairwise comparisons, we used a Bonferroni correction to define an alpha of 0.0167 as our threshold for statistical significance. We estimated that a sample of at least 280 participants would ensure 80 % power to detect a 20 % difference between arms.

RESULTS: Participants in the study sample had a mean body mass index of 28.4 (standard deviation [SD]: 6.5), mean age of 41.3 (SD 12.0), and were 80.1 % female. During the intervention period, the 50th percentile framing with incentives had the greatest proportion achieving the goal and was significantly more effective than feedback compared to the 75th percentile without incentives (0.45 vs. 0.27, Difference: 0.18, 95 % confidence interval [CI]: 0.04–0.32, $P=0.012$). Compared to the 75th percentile without incentives, there were no significant differences for 75th percentile with incentives (0.38 vs. 0.27, Difference: 0.11, 95 % CI: –0.05–0.27, $P=0.19$) or the 50th percentile without incentives (0.30 vs. 0.27, Difference: 0.03, 95 % CI: –0.10–0.16, $P=0.67$). The 50th percentile with incentives arm had the greatest level of daily steps during the intervention period but it was not significantly different than the 75th percentile without incentives arm (Difference: 1078, 95 % CI: –71–2188, $P=0.07$). There were no significant differences between arms during the follow-up period.

CONCLUSIONS: A team-based approach was effective for increasing physical activity when framing team performance relative to the 50th percentile and using financial incentives. These findings highlight that the design of performance feedback has a significant impact on engagement levels.

A SECOND LOOK AT POST-INTERVIEW COMMUNICATION Jonah Feldman^{1,2}; Eugene Medvedev¹; Jamie Yedowitz-Freeman¹; Stanislaw Klek¹; Nicholas Berbari¹; Shirley Hanna¹; Mark Corapi¹. ¹Winthrop University Hospital, Mineola, NY; ²Stony Brook University School of Medicine, Stony Brook, NY. (Tracking ID #2197567)

BACKGROUND: In response to concerns about the variability of and challenges with post-interview communications between applicants and programs, an APDIM task force was convened to establish guidelines for communications during the NRMP match. The recommendations proposed by the task force include a provision that programs should advise applicants that second looks are “neither required nor encouraged”, but there exists no previously published studies that inform on this specific guidance. The aim of this study was to evaluate applicants’ attitudes toward a Formal Second Visit (FSV) at a large Internal Medicine Residency Program.

METHODS: An anonymous, four-question survey was distributed online to applicants following their FSV at a 600 bed University Hospital. Responses were collected prior to the 2014 Match Day and reflected both multiple choice and free-text answers. Characteristics of the FSV at this institution include: a formal invitation sent to the residency program’s top candidates, a prescheduled experience with the medical floor teams, planned participation in two of the program’s daily didactic sessions, individual meetings scheduled with the Program Directors, and a dinner with the Department Chair.

RESULTS: The survey response rate was 62.3 % (33/53). Among respondents, 97 % reported being happy they spent the time to take a second visit to the program, and 59.3 % felt their opinion changed in a positive way because of new information about the program learned during the FSV. When asked whether they felt pressured to attend an FSV once offered, the majority of respondent (75.8 %) said “no”. Similarly, when asked whether a policy advocating for the discontinuation of second visits would benefit Internal Medicine applicants, the majority (71.9 %) of respondents stated “no”.

CONCLUSIONS: Previous studies have reported that post-interview communication was stressful for applicants and, in some cases, undermined the integrity and spirit of the match. These studies focus on email or phone contact with applicants after interview day. There have been no previous studies evaluating second look visits in general, or FSVs in particular, at an internal medicine residency program. Second visits are different from other forms of post-interview communication as there is an opportunity for applicants to experience residency programs in a more intimate way than that which would be afforded to them on interview day. Our single center study found that FSVs as a particular form of post-interview contact was overwhelmingly supported by participants, though a significant minority felt pressure to attend the second visit once invited. Further research is

needed to determine the optimal way to offer applicants the option of a second visit without contributing to the overall stress of the application process.

A SMARTPHONE-BASED ONLINE SUPPORT GROUP FOR PEOPLE LIVING WITH HIV Tabor E. Flickinger²; Claire DeBolt²; Erin Wispelwey³; Colleen Laurence⁴; Erin Plews-Ogan²; Ava Lena Waldman²; George Reynolds⁵; Wendy F. Cohn²; Mary Catherine Beach¹; Karen Ingersoll²; Rebecca Dillingham². ¹Johns Hopkins University, Baltimore, MD; ²University of Virginia, Charlottesville, VA; ³University of London, London, United Kingdom; ⁴Wake Forest School of Medicine, Winston Salem, NC; ⁵Health Decision Technologies, Oakland, CA. (Tracking ID #2198786)

BACKGROUND: Although there is growing interest in mobile applications and online support groups (OSGs) to enhance chronic disease self-management, little is known about the potential impact of these tools for people living with HIV (PLWH). Our study analyzes an innovative OSG delivered through a community message board (CMB) within a clinic-affiliated Smartphone application (Positive Links, PL). Our objectives were to 1) compare characteristics of posters and non-posters to the CMB and 2) evaluate content posted to the CMB.

METHODS: For this pilot study, 38 HIV-infected patients were recruited through provider referrals at a university-based clinic and from area AIDS service organizations (ASOs) and HIV testing sites. Participants received cell phones with the PL application that included the opportunity to interact with other users on a CMB. Logistic regressions investigated associations between participant characteristics and posting on the CMB. CMB messages were downloaded and analyzed qualitatively by two independent coders using a Grounded Theory approach.

RESULTS: Mean age was 34.1 years (SD 11.5) and the majority of participants were male (74 %). Seventeen participants identified as black, non-Hispanic (45 %), and 13 as white, non-Hispanic (34 %). Sixty-one percent of participants were unemployed; 37 % had public insurance (such as Medicare or Medicaid) and 32 % had no insurance; and 45 % were below 100 % of the federal poverty level. Twenty-four participants posted to the CMB; 14 did not. Participants had lower odds of posting if they were white [OR 0.20 (0.05–0.84), $p=0.028$] and had private insurance [OR 0.07 (0.01–0.41), $p=0.003$]. Participants had higher odds of posting if they had unsuppressed viral loads [OR 5.13 (1.13–23.30), $p=0.034$]. In multivariable analyses, having private insurance remained the strongest association with not posting on the CMB [OR 0.09 (0.01–0.71), $p=0.023$]. Of the 840 CMB messages over 8 months, 62 % had psychosocial content, followed by community chat (29 %), and biomedical content (10 %). Of psychosocial content, posts frequently described stressors (including relationships outside the CMB, disclosure, stigma, and both geographic and social isolation) and discussed coping strategies. Of community chat content, greetings were most common and included messages welcoming new members, greetings to individual users and greetings to the entire group. Of biomedical content, most posts discussed medications, followed by seeing a healthcare provider and laboratory results. Posts on medications were centered on the importance of adherence and support for others having difficulty.

CONCLUSIONS: The dominance of psychosocial over biomedical content may be unique to this CMB, in contrast to other studies identifying informational support as the primary content on online forums for chronic illness. Participants who posted on the CMB expressed support for each other, appreciation for the community, and a perception that the app played a positive role in their struggles with HIV. This CMB on a clinic-affiliated mobile app may reach vulnerable populations, including racial/ethnic minorities and those of lower socio-economic status, and potentially provide psychosocial support to PLWH. Further development of this app and CMB will include investigation of possible benefits in improving social support, linkage and retention in HIV care, and health outcomes for PLWH.

A STATISTICAL MODEL FOR PREDICTING NEUTROPENIC FEVER Ariel Nelson; Dan Eastwood; Tao Wang; Karen Carlson; Laura Michaelis; Marcelo Pasquini; Parameswaran Hari; Christopher Chitambar; Timothy Fenske; Mary Beth Graham; Mehdi Hamadani; Anita D’Souza; Ehab Atallah. Medical College of Wisconsin, Milwaukee, WI. (Tracking ID #2191299)

BACKGROUND: Febrile neutropenia (FN) is a common occurrence associated with chemotherapy regimens used in patients with acute myelogenous leukemia (AML). Febrile neutropenia is presently defined as a single temperature of $\geq 38.3^{\circ}\text{C}$ (101°F) or a temperature of $\geq 38.0^{\circ}\text{C}$ (100.4°F) for >1 h in a patient with an absolute neutrophil count $<500/\text{mm}^3$. Due to the potential for life threatening infections, fever in a patient with neutropenia is considered an oncologic emergency. Initiating appropriate antibiotic therapy as soon as possible in these patients leads to better outcomes. However, to our knowledge, there is no evidence that supports the current definition of neutropenic fever. The goal of this pilot study was to analyze patient fever data and utilizing statistical analyses, develop a prediction model which would predict febrile neutropenia.

METHODS: After obtaining IRB approval we retrospectively obtained demographic and temperature data from hospitalized patients with AML undergoing chemotherapy who were admitted to our institution between 12/8/2012 and 12/7/2013. Temperature data was recorded at intervals per physician order and nursing discretion during admission. We identified fever as a single temperature $\geq 38.3^\circ\text{C}$ (101°F) or consecutive temperatures recorded 1 h apart $\geq 38.06^\circ\text{C}$ (100.5°F). Data was obtained for 68 patients containing 137 fever events. Plots were created showing temperature over time leading up to a fever event. Our data consists of unequal interval time series data and does not lend itself to the usual methods of statistical ROC analysis. The data was simplified to perform an ROC-like analysis to estimate sensitivity and specificity of decision rules that predict oncoming episodes of FN. Statistics on each patient series were used as variables in predicting fever onset in logistic regression analysis. The variables included were maximum temperature within 24 h, minimum temperature within 24 h, average of positive increases between subsequent measurements, and largest 24 h increase. Statistical analysis consisted of a generalized linear model with logit link (logistic regression) predicting fever at least 4 h before onset, and used generalized estimating equations to adjust for correlated temperature measures within patient.

RESULTS: Of the 68 patients identified, 47 % were male, 53 % were female with a mean age of 56.3 ± 15.1 years. Our fever curve plots suggest that there is an increase in average temperature at least 24 h before the onset of fever in those patients that will go on to develop a fever by current definition (Figure 1). Significant identified predictors of fever included; maximum and minimum temperature within 24 h, and the average of positive increases in temperature between subsequent measurements. A prediction score including, maximum temperature within 24 h, minimum temperature within 24 h, average of positive increases between subsequent measurements, and largest 24 h increase was able to predict 86.1 % of oncoming FN events 4 to 28 h before onset and reject 67.4 % of non-FN events. This rule has a negative predictive value of 96.2 % and a positive predictive value of 33.7 %.

CONCLUSIONS: Our analysis demonstrates the feasibility of using temperature series data for early prediction of FN. A more comprehensive analysis is planned and is expected to result in higher sensitivities. If subsequent analysis proves to be significant this data may be used to develop future prospective clinical studies to evaluate new fever criteria and may alter our current definition and management of patients with FN.

Figure 1. Fever curve plot of 96 h of temperature series data preceding the onset of fever or end of series if no fever. The dark lines are LOESS smoothed average temperatures for series ending in fever (dash) or non-fever (solid).

A STUDY OF THE LOCATION OF RESEARCH FUNDING DISCLOSURE IN HIGH IMPACT SCIENTIFIC JOURNALS ¹Jonah Feldman^{1, 2}; Christopher Garcia¹; gary carpenter¹; Brahmhatt Saloni¹. ¹Winthrop University Hospital, Mineola, NY; ²Stony Brook School of Medicine, Stony Brook, NY. (Tracking ID #2199149)

BACKGROUND: Recently published reports have demonstrated that disclosure of industry sponsorship negatively influences physicians' perception of the methodological quality of a study. Though there is consensus on the importance of sponsorship disclosure, and a growing understanding of the effect of disclosure on readership, the actual disclosure

practices of leading scientific journals have not been well characterized. The purpose of our study is to evaluate funding disclosure practices in top scientific journals, specifically focusing on the location of funding disclosure within the journal article.

METHODS: We reviewed the 221 scientific journals with an impact factor equal to or greater than 6, as categorized by the Thomas Reuters Journal Citation Report. The location of financial disclosure was determined by direct examination of print or online copies of a 2013 dated volume of the journal. Journals were categorized as having disclosures at the end of the article, at the end of the abstract, or no disclosure at all. The primary outcome was the percentage of journals with disclosures in each of these three categories.

RESULTS: It was found that 9 of 221 journals did not list disclosures (4.12 %). One hundred seventy-six of 221 journals (80.73 %) listed financial disclosures at the end of the article, and 33 of 221 journals listed financial disclosures in the abstract (15.13 %).

CONCLUSIONS: In this cross sectional study we show that the great majority of top scientific journals practice disclosure of funding sources, but there is heterogeneity among these journals with regards to disclosure location. The majority of journals listed funding disclosures at the end of the article, while a small but significant minority listed funding within the abstract. This finding is important as studies of medical journal readership have shown that almost half the time readers will scan an abstract and skip the rest of the paper. If sponsorship disclosure is placed at the end of the paper the impact of these disclosures may be blunted. Our findings raise important ethical questions about appropriate sponsorship disclosure practices, and open up many avenues for further research and discussion.

A TALE OF TWO CONSTITUENCIES: PATIENT AND CLINICIAN ENGAGEMENT IN RESEARCH Crispin N. Goytia¹; Donna Shelley²; Rainu Kaushal³; Isaac Kastenbaum⁴; Carol R. Horowitz¹. ¹Mount Sinai School of Medicine, New York, NY; ²NYU School of Medicine, New York, NY; ³Weill Cornell Medical College, New York, NY; ⁴New York Presbyterian, New York, NY. (Tracking ID #2198586)

BACKGROUND: Patients and front-line clinicians are not adequately engaged in key aspects of research, including idea generation, recruitment and dissemination. An increasing focus on and funding for patient-centered research has uncovered gaps in our understanding of how patients and clinicians should be involved in the research enterprise. The NYC Clinical Data Research Network aims to create a large electronic data infrastructure for conducting patient-centered, clinical outcomes research. As part of this process, we explored patient, advocate, and clinician experiences with research, how they would like to be involved, recruitment challenges and suggestions, and study ideas.

METHODS: A team of researchers, patients, clinicians, and privacy and technology experts developed a question guide. We identified pre-existing patient, community and clinician groups that meet regularly throughout NYC hospitals and neighborhoods, and asked to speak with them at one of their meetings for 15 min. A facilitator and note-taker met with 20 such groups (11 clinician; 9 patient/community). The research team analyzed meeting notes to identify themes of discussions and compare results of patient and clinician groups.

RESULTS: Fully 272 individuals participated in these listening sessions (49 % generalist and specialist clinicians, 51 % patients/families/advocates). Most (67 %) were non-white (90 % of patients and 44 % of clinicians). Few had personally participated in research (34 % of patients; 0 % of clinicians), but most were interested in future involvement as participants or collaborators. Patients and clinicians shared most themes: 1) To improve research-related recruitment, perceptions, awareness and interest, there should be "warm handoffs" from clinicians to patients, and accessibility to general research and specific study information through community education campaigns and patient and clinician-friendly portals; 2) Both wanted training to translate their thoughts and concerns into concrete research questions; 3) They were most interested in studies comparing outcomes of interest between practices and between neighborhoods; and 4) Concerns included the potential for data inaccuracy, and research findings not being shared with them and their geographic or clinical communities. Clinicians expressed concerns about research recruitment taking time and disrupting workflow, and study findings contradicting clinical recommendations they provide. Finally, patients' negative attitudes toward clinical care readily translated into negative attitudes toward research at sites of care, and they were worried that data could never be truly de-identified and that research to date has not had enough impact.

CONCLUSIONS: While 15 min discussions only opened small windows to explore patient and clinician-centered research involvement, they afforded an opportunity to learn from diverse groups who can be difficult to engage in such efforts. These stakeholder groups shared many hopes, ideas and concerns about research, including strong interest in expanding their research literacy, social marketing to bolster research interest, and learning how to transform their experiences into study questions or outcomes of interest. Concerns about data inaccuracies, maintaining privacy, and failures in receiving past study findings and enjoying tangible research benefits dampened enthusiasm for participation. These

findings may assist research teams in identifying areas for further research and building engagement and recruitment strategies.

ABERRANT BEHAVIOR IN CHRONIC NON-CANCER PAIN PATIENTS PRESCRIBED SCHEDULE II NARCOTICS Mohamed Rezik; Alex Garbarino; Grace Choe; Sheetal Patel; Sam Tingari; Joshua Collins. Henry Ford Hospital, Dearborn, MI. (Tracking ID #2191810)

BACKGROUND: An estimated 100 million US patients suffer from chronic pain, a condition that is now largely treated with narcotics. The availability of these drugs has led to an increase in their adverse effects, misuse and abuse. This, in turn, has led to various attempts to reduce the potential for aberrant behavior including the use of patient-provider agreements. In an effort to reduce aberrant behavior in an urban academic primary care clinic, patient-provider agreements were instituted as part of a larger policy to monitor patients being treated for chronic non-cancer pain with schedule II narcotics. The primary aim of this study was to determine the rate of aberrant behavior in patients receiving schedule II narcotics 1 year after the implementation of this chronic pain policy.

METHODS: This was a retrospective cohort study involving manual electronic medical record (EMR) and Michigan Automated Prescription Review (MAPS) review of 952 patients. The inclusion criteria were adult patients with active chronic prescription for a schedule II narcotic with either two or more clinic visits from January 2014 through August 2014 or with faculty physicians listed as primary care physician in the EMR. Aberrant behavior was defined as: MAPS revealing early refills or prescriptions from a non-clinic provider and urine toxicology (UTox) results with illicit or unprescribed substances or absence of prescribed opiates. The primary outcome was the rate of aberrant behavior.

RESULTS: Two hundred seven patients were included in the study after full manual review. One hundred five patients (51 %) met the definition of aberrant behavior with 47 patients having early refills (45 %), 44 with multiple prescribers (42 %), and 54 with unexpected urine toxicology results (51 %). Secondary analyses revealed that predictors of identifying aberrant behavior included: missed pain visit in the prior year (1.4 vs. 0.8, $p=0.03$) and a UTox being performed within the last 1 year (86 % vs. 68 %, $p=0.002$).

CONCLUSIONS: The rate of aberrant behavior identified in our study was higher than similar studies. However, the definition of aberrant behavior varies widely in the existing literature. The most common aberrant behavior identified was an unexpected UTox result. Semi-synthetic opioids, even when taken as prescribed, often show up negative on UTox and require a confirmatory test. This was not a common practice in this clinic prior to our study. Furthermore, the accepted (and legal in Michigan) use of marijuana for analgesic purposes is inconsistent among providers in the clinic. When removing these patients whose only aberrant behavior was testing negative for opiates or positive for marijuana, the rate of aberrant behavior fell to 37 %. This figure is more in line with previous literature. An interesting observation was that patients with aberrant behavior were more likely to have missed a pain visit, either by cancelling or not showing. The only significant predictor of aberrant behavior was an obtained UTox, which can be presumed to be ascertainment bias. Implications of this study include changes to the formal clinic policy to encourage providers to follow up unexpected UTox results, particularly an unexpected negative test for prescribed opiates. Further secondary outcomes have informed internal quality improvement initiatives to optimize patient care and management of patients treated for chronic non-cancer pain with opiates.

ACCEPTED WISDOM: NOT NECESSARILY CORRECT. Julian M. Rios²; Thomas Higgins²; Orlando L. Torres¹. ¹Baystate Health, Springfield, MA, MA; ²Baystate Medical Center, Springfield, MA. (Tracking ID #2198850)

BACKGROUND: Hispanics and non-English proficient patients have a lower rate of CRC screening at the national level. This is concerning, because colorectal cancer (CRC) is the second leading cause of cancer death, and the third most common cancer found in men and women. Screening has a potentially significant impact on preventing mortality and morbidity with up to 60 % of deaths from CRC prevented if appropriate screening was done regularly and findings treated appropriately. According to the CDC, the overall rate of CRC screening is 58.6 % in the general population, but it is only 46.5 % in Hispanics, indicating significant disparities in the delivery of care. Lower cancer screening rates have been associated with less education and non-English speaking status. The objective of this study is to determine if non-English proficient Hispanics adults, primarily Spanish speaking, are less likely to undergo CRC screening.

METHODS: Baystate High Street health Center-Adult Medicine (BHSCH-A) is an urban, academic, patient centered medical home practice serving a primarily Puerto Rican population (51.8 %). A large proportion of the patient population self-identified as Spanish speaking (23.9 %). We used BHSCH-A Preventive Health Registry in October 2014 to identify Spanish speaking adults ages 50 to 75 years who were overdue for CRC screening. We then performed a chart review to verify their actual CRC screening status. Each chart was checked for evidence of CRC screening, either by endoscopy or by fecal

occult blood testing (FOBT) by looking at the procedure notes, outside hospital records scanned, and laboratory results from October 2004 to October 2014.

RESULTS: Of 9294 individuals in the registry, we identified 3296 between the ages of 50 to 75 years; of these, 1038 reported Spanish as their primary spoken language. Of these, 60 % were female, and 40 % male. The percentage of men who had had up-to-date CRC screening was 74.4 %, while the percent of women with up-to-date CRC screening was 76.6 %. In average 75.7 % of the Spanish-speaking population ages 50 to 75 years at BHSCH-A were current on their CRC screening.

CONCLUSIONS: At a single health center, more than 75 % of eligible non-English proficient Hispanics were found to be current on their CRC screening, which is above the Healthy People 2020 target of 70.5 % set by the Department of Health and Human Services. This demonstrates that National HEDIS Top 10 percentile CRC screening rates can be achieved despite serving a socioeconomically disadvantaged population that is primarily Hispanic and non-English proficient.

ACCOMMODATIONS FOR MEDICAL STUDENTS WITH DISABILITIES: EXPLORING U.S. MEDICAL SCHOOLS' TECHNICAL STANDARDS. Christopher Moreland¹; Philip Zazove²; Benjamin Case²; Missy Plegue²; Anne Hoekstra²; Alicia Oulette³; Ananda Sen²; Michael Fettes². ¹The University of Texas HSC - San Antonio, San Antonio, TX; ²University of Michigan, Ann Arbor, MI; ³Albany School of Law, Albany, NY. (Tracking ID #2191968)

BACKGROUND: Medical education literature increasingly supports correlations between diverse medical professionals, including physicians with disabilities, and higher quality care for underserved populations. However, about 20 % of the general population has a disability, while only about 1 % of medical students do. Moreover, the Americans with Disabilities Act (ADA) requires medical schools to provide reasonable accommodations to learners with disabilities. Medical schools, per accrediting organizations, have enacted technical standards (TS) that vary in scope, requirement, and compliance with ADA spirit. Despite recent case law, some schools have refused to provide accommodations. We sought to examine U.S. medical schools' TS to assess apparent willingness to comply with and factors that predict compliance with federal antidiscrimination laws, including the ADA.

METHODS: From 2012 to 2014, we conducted a web-based search of existing websites (along with follow-up to schools without posted information) of 138 MD-granting medical schools (as listed by the Association of American Medical Colleges) to identify required TS for medical students, focusing on hearing, visual, and mobility disabilities. Two authors iteratively coded each school's TS for the themes below; disagreements were resolved by consensus or, if none was reached, further review with 2 other authors. Themes, studied included the willingness of medical schools to provide reasonable accommodations, locus of responsibility for accommodations, and acceptability of intermediaries or auxiliary aids for students with disabilities. The process was later repeated for DO-granting schools.

RESULTS: One hundred sixteen (84.1 %) of 138 schools made technical standards available on their websites, of which 84 (59.4 %) were easily accessible; 9 of the remaining schools provided the standards upon direct request. Forty (29.0 %) schools had technical standards supportive of providing reasonable accommodations as required by the ADA to students with at least 1 of the 3 disabilities listed above; sixty (43.5 %) schools did not, 6 (4.3 %) were equivocal, and 32 (23.2 %) were unclear. Most schools provided no information on the locus of responsibility for providing accommodations, although 1 school placed it solely on the student and 8 (5.8 %) had joint responsibility between the school and student. Only 35 % allowed the use of auxiliary aids by students with hearing, visual, or mobility disabilities, and less than 10 % of all schools allowed the use of intermediaries such as a sign language interpreter.

CONCLUSIONS: Medical schools often do not provide easy online access to TS; some did not provide TS despite direct requests. Both create barriers for potential applicants with disabilities. Most TS are at best equivocal when it comes to reasonable accommodations; <35 % are openly supportive, while some overtly restrict accommodations. Few openly allow intermediaries. Further research should explore actual experiences with accommodations from the school, learner, and faculty perspectives. Medical schools and administrative organizations should reevaluate and modernize technical standards in light of the legal landscape, particularly the ADA.

ACQUISITION OF CARDIOVASCULAR DISEASE RISK FACTORS AMONG REFUGEES AND IMMIGRANTS: A LONGITUDINAL STUDY Gabriel E. Fabreau^{2,4}; Seth A. Berkowitz³; Wei He³; Chantal Kayitesi¹; Sarah Oo¹; Steven J. Atlas³; Sanja Percac-Lima³. ¹Massachusetts General Hospital, Chelsea, MA; ²University of Calgary, Calgary, AB, Canada; ³Massachusetts General Hospital, Boston, MA; ⁴Brigham and Women's Hospital, Boston, MA. (Tracking ID #2196070)

BACKGROUND: Acquisition of cardiovascular disease risk factors such as obesity, hypertension and hyperlipidemia among refugees and immigrants living in the same community as American-born patients may differ partly due to acclimating into a new

culture. Understanding risk factor differences between these populations has important implications for implementing cardiovascular disease prevention programs for refugee and immigrant populations.

METHODS: We conducted a longitudinal cohort study of adult refugee patients ≥ 18 years old entering the US between 2004 and 2013. We matched these patients by age, sex and date of initiation of care in a 1:3 ratio to 1) Spanish speaking non-refugee immigrants and 2) English speaking US-born controls. The cohort was limited to primary care patients within the same community health center, a state designated refugee clinic, located in a low-income, culturally diverse community in Eastern Massachusetts. Electronic medical record data were used to follow patients longitudinally for the acquisition of obesity (body mass index [BMI] >30 kg/m²), hypertension and hyperlipidemia using validated algorithms. Additionally, we collected information on age at cohort entry, sex, baseline BMI, education (< vs. high school diploma vs. any post-secondary), insurance type, and, to account for neighborhood differences, census tract level median household income. We used multivariable Cox regression to estimate the risk of acquiring obesity, hypertension and hyperlipidemia for refugees and immigrants compared with English-speaking controls. We excluded patients with risk factors at baseline from the risk factor acquisition analyses.

RESULTS: A total of 3174 patients were included in our analysis. Mean (SD) age at cohort entry was 34.6 (12.3) years, and 51.7 % (1642/3174) were female. Among refugees, the most common countries of origin were Somalia (17.8 %), Iraq (16.7 %) and Bhutan (8.8 %). At baseline, 14.6 % (88/604) of refugees, 15.3 % (200/1310) of immigrants and 12.4 % (156/1260) of controls ($p=0.09$) were obese, and the prevalence of hypertension was similar: 9.1 % (55/604) of refugees, 9.7 % (127/1310) of immigrants, and 8.6 % (108/1260) of controls ($p=0.61$). Baseline hyperlipidemia was less common in

refugees: 2.5 % (15/604) of refugees compared with 6.0 % (79/1310) of immigrants and 6.8 % (85/1260) of control patients ($p<0.01$). Median follow-up time was 3.7 years [IQR, 1.3–7.4] during which 21.1 %, 8.0 %, and 11 % of refugees, 32.8 %, 10.1 %, and 20 % of immigrants and 31.3 %, 11.6 %, and 15.1 % of controls developed obesity, hypertension and hyperlipidemia respectively. In unadjusted Cox regression models, immigrant patients had higher risks of acquiring obesity (HR 1.21, 95 % CI 1.04–1.40) and hyperlipidemia (HR 1.52, 95 % CI 1.25–1.84) compared to controls. In contrast, refugee patients had no increased unadjusted risks of acquiring any risk factor compared to controls. In Cox models adjusting for the aforementioned covariates, both refugee and immigrant statuses were associated with an increased risk of obesity compared with English-speaking controls (Table 1). Immigrant status alone was associated with an increased risk for hyperlipidemia compared to controls (Table 1), and additionally when compared to refugees (HR 1.46, 95 % CI 1.01–1.98). There were no other significant differences in risk factor acquisition between refugees and immigrants in the adjusted analyses.

CONCLUSIONS: The acquisition of cardiovascular risk factors was observed in all study cohorts during follow-up. In particular, refugee and immigrant patients were at increased risk of becoming obese and immigrants were at increased risk of developing hyperlipidemia compared with both age and gender matched controls and refugees in the same community. These risk factors developed over a relatively short time span in a cohort of young patients and have significant implications for long-term health. Targeted and culturally tailored education and lifestyle interventions early after arrival of refugee and immigrant patients may mitigate the acquisition of these cardiovascular risk factors.

Frequencies of and Risk of developing obesity, hypertension and hyperlipidemia among refugee and immigrant patients compared with English-speaking controls

Risk Factor	Patient Group	Risk Factor Frequency at Baseline (%)	Risk Factor Frequency at Follow up (%)	Adjusted Hazard Ratio* [95 % CI]
Obesity	Refugees	14.6	32.6	1.33 [1.04–1.72]
	Immigrants	15.3	43.1	1.22 [1.01–1.46]
	Controls	12.4	39.9	–
Hypertension	Refugees	9.1	16.4	0.97 [0.65–1.45]
	Immigrants	9.7	18.8	0.96 [0.70–1.31]
	Controls	8.0	19.2	–
Hyperlipidemia	Refugees	2.5	13.2	1.00 [0.72–1.39]
	Immigrants	6.0	24.9	1.46 [1.13–1.88]
	Controls	6.8	20.9	–

*model adjusted for age at entry, gender, baseline BMI, education, insurance and median household income.

ADDRESSING A GROWING NEED FOR LANGUAGE SERVICES: HOW WELL ARE WE DOING? Alissa Detz¹, Julie Brown², Mark Hanson², Karin Liu², Mary Slaughter³, Robert Weech-Maldonado⁴, Neil Wenger^{1, 2}, David Ganz^{2, 1}. ¹University of California, Los Angeles, Los Angeles, CA; ²RAND Corporation, Santa Monica, CA; ³RAND Corporation, Pittsburgh, PA; ⁴University of Alabama, Birmingham, AL. (Tracking ID #2198047)

BACKGROUND: Approximately 9 % of individuals in the U.S. have limited English proficiency (LEP), defined as speaking English less than “very well” by self-report. Title VI of the Civil Rights Act requires agencies receiving federal funding to provide interpreters to individuals in need, and prior research indicates that providing professional interpreters for LEP patients improves satisfaction and health outcomes. Nonetheless, previous studies suggest that access to interpreters is low across many healthcare settings. Because patient perception of access to interpreters and unmet need has not been fully explored, we pilot tested a set of survey items to evaluate patient perception of language services among Spanish-speaking LEP individuals.

METHODS: We modified existing Consumer Assessment of Healthcare Providers and Systems (CAHPS) items from the Cultural Competence Item Set based on cognitive interviews with older Spanish-speaking persons. These items were then embedded in a CAHPS survey conducted for the purpose of pilot testing new items. To optimize Spanish survey responses, 6 Medicare Advantage plans in Florida and California were identified for pilot testing due to having 30 % or more survey responses in Spanish during prior CAHPS surveys. Individuals were included in this study if they were 18 years or older and had been enrolled in these selected Medicare Advantage health plans for 6 months continuously prior to survey administration. Individuals known to be institutionalized were excluded. Surveys were administered by mail, with telephone administration as the secondary or non-response mode. Our analysis focused on individuals who completed the

survey in Spanish. First, we conducted descriptive analyses of responses to the survey items addressing interpreter services. Second, we determined if individual or geographic level variables could predict the need for an interpreter using bivariate analysis and logistic regression. Third, we performed bivariate analysis followed by exploratory linear regression to determine the association between needing an interpreter and validated CAHPS measures regarding communication and overall ratings of physician, specialists, health plan, and healthcare, as well as a survey item regarding physician sensitivity to beliefs.

RESULTS: Total survey response rate was 40 %. The 991 individuals who completed the survey items regarding interpreters were primarily female (58 %), had less than a college education (81 %), and 93 % were 65 years or older. Fourteen percent ($N=134$) of the 991 individuals completing the Spanish version of the survey reported needing a medical interpreter. Within this group, 47 (37 %) reported not being informed of their right to free interpreter services and 30 (23 %) reported an encounter when they needed an interpreter but were unable to get one. Among individuals reporting a need for an interpreter, 72 (56 %) always used an interpreter provided by the doctor’s office and 42 (33 %) used a family member or friends to interpret at least sometimes. Younger age and lower education were individual level predictors of the need for an interpreter. Multivariate models that also included state and health plan-related variables suggested that membership in a Medicare Advantage special needs plan (SNP) and state of residency were also important predictors. Individuals not in a SNP had a relative risk of needing an interpreter of 2.01 (95 % CI 1.04–3.89) compared to individuals enrolled in a SNP. Individuals from California had a relative risk for needing an interpreter of 6.34 (95 % CI 4.13–9.73) compared to those in Florida. Individuals who needed an interpreter rated their personal physician more poorly and were less likely to feel that their physician valued their beliefs.

CONCLUSIONS: A relatively small proportion of respondents needed an interpreter, but many of these individuals were unaware of their right to medical interpreters and had difficulty accessing interpreters when needed. Those needing interpreters had lower ratings of their personal physician. Our data support the importance of measuring access to interpreter services. Patients should be better informed about their right to interpreters, and health systems should devise targeted interventions to ensure timely access to interpreters for all patients with language barriers.

ADDRESSING BASIC RESOURCE NEEDS IN PRIMARY CARE IMPROVES BLOOD PRESSURE AND CHOLESTEROL CONTROL: A PRAGMATIC INTERVENTION

Seth A. Berkowitz¹; Carine Y. Traore²; Steven J. Atlas². ¹MGH, Boston, MA; ²Massachusetts General Hospital, Boston, MA. (Tracking ID #2191912)

BACKGROUND: Unmet basic resource needs, such as difficulty affording food, housing, or medications, are associated with poor health. However, it is unclear if helping patients meet those needs improves clinical outcomes.

METHODS: We conducted a pragmatic evaluation of the HealthLeads program in two academic primary care practices in Eastern Massachusetts, using data from October 1, 2012 (1 year prior to the program's start on October 1, 2013) through October 1, 2014. HealthLeads (HL) uses trained 'advocates' to screen patients at visit check-in for healthcare, employment, financial, food, transportation, utilities, housing, or legal needs, and then connect patients to community resources to meet those needs. Data on systolic and diastolic blood pressure (SBP and DBP), low-density lipoprotein cholesterol (LDL-C), and hemoglobin A1c (HbA1c), along with sociodemographic and clinical characteristics, were collected from electronic sources. We used chi-squared and t-tests to compare baseline demographic and clinical characteristics. We used unadjusted and multivariable difference-in-differences linear mixed modeling to compare changes in SBP and DBP (in those with hypertension), LDL-C (in those with increased cardiovascular event risk, including diabetes, hypertension, coronary heart disease, and hyperlipidemia), and HbA1c (in those with diabetes) between HL patients and those seen in the same practices, but who were not enrolled in HL. All patients also received usual clinical care.

RESULTS: Overall, 416 patients enrolled in HealthLeads and were compared with 2750 control patients. At baseline, HL patients were similar in age (mean age 56.3 vs. 54.9 years, $p=.13$), more likely to be women (51.9 % vs. 46.8 %, $p=.048$), be racial or ethnic minorities (24.7 and 18.4 % non-Hispanic black and Hispanic, respectively, vs. 16.4 and 11.2 %, $p<.001$), and have Medicaid (30.8 % vs. 20.0 %) or no insurance (9.2 % vs. 4.6 %), $p<.001$. HL patients most commonly reported difficulty affording healthcare and medications (46.5 %), food (40.0 %), and utilities (36.3 %). Hypertension (54.3 % vs. 46.3 %, $p=.002$) and diabetes (32.7 % vs. 20.4 %, $p<.001$) were more common in HL patients, but mean baseline SBP (135.3 vs. 135.2 mm/Hg in HL vs. non-HL patients, $p=.96$), DBP (79.2 vs. 78.0 mm/Hg, $p=.19$), LDL-C (111.0 vs. 106.3 mg/dL, $p=.10$), and HbA1c (7.7 % vs. 7.5 %, $p=.39$) were similar. In unadjusted models, HL participation was associated with greater reductions in SBP (3.8 mm/Hg lower in HL participants, 95%Confidence Interval [95%CI] 1.7–5.8 mm/Hg lower), DBP (2.0 mm/Hg lower in HL participants, 95%CI 0.8–3.1 mm/Hg lower), and LDL-C (10.5 mg/dL lower in HL participants, 95%CI 3.4–17.3 mg/dL lower), but not HbA1c (0.1 % higher in HL participants, 95%CI 0.2 % lower to 0.3 % higher). In models adjusted for age, gender, race/ethnicity, education, primary language, insurance, and Charlson comorbidity score, HL participation remained associated with significantly greater improvements in SBP (3.0 mm/Hg lower in HL participants, 95%CI 1.0–5.1 mm/Hg lower), DBP (1.8 mm/Hg lower in HL participants, 95%CI 0.6–3.0 mm/Hg lower), and LDL-C (11.5 mg/dL lower in HL participants, 95%CI 4.6–18.4 mg/dL lower). In adjusted models, improvement was not greater for HbA1c (0.1 % higher in HL participants, 95%CI 0.2 % lower to 0.3 % higher).

CONCLUSIONS: Addressing unmet basic resource needs as part of primary care was associated with clinically meaningful improvements in blood pressure and LDL-C, but not HbA1c. Future research should clarify which elements of the program were effective, make programmatic modifications to improve HbA1c, and evaluate whether changes in blood pressure and LDL-C achieved by meeting basic resource needs are associated with fewer cardiovascular events.

ADDRESSING RACIAL DISPARITIES IN HOSPICE USE: RESULTS FROM AN EDUCATIONAL INITIATIVE FOR RELIGIOUS LEADERS IN BALTIMORE CITY, MARYLAND

Kerry Schnell¹; Arnold Eppel²; G.I. Johnson³; Aruna Chandran^{4,2}. ¹Johns Hopkins Bayview Medical Center, Baltimore, MD; ²Baltimore City Health Department, Baltimore, MD; ³Maryland State Department of Aging, Baltimore, MD; ⁴Johns Hopkins University School of Public Health, Baltimore, MD. (Tracking ID #2198748)

BACKGROUND: Hospice organizations provide comprehensive, compassionate, interdisciplinary care to dying patients and their loved ones, with the goal of helping patients achieve a dignified, pain-free death. Despite the fact that many public and private insurers pay for hospice care, there is a well-documented racial disparity in hospice use in the United States. In Baltimore City, Maryland, African American residents use hospice services at half the rate of white residents. Data suggest lack of knowledge about hospice is a barrier to hospice use. However, there is little published on evidence-based interventions to reduce hospice use disparities. Given this absence of data, our objective was to assess the feasibility, acceptability, and perceived efficacy of an educational seminar for religious leaders about hospice.

METHODS: Seminar planning was informed by the hospice use disparities literature and followed a previously described framework for health disparities research. Planning

occurred with extensive input from local stakeholders and religious leaders. Following the seminar in November 2013, a survey was sent to all participants who registered for the event online with a valid email address. Results were analyzed by frequency of common responses and broader thematic categories.

RESULTS: Approximately 325 community and religious leaders attended the seminar; 15 % (38/247) of eligible participants completed a substantive portion of the survey. Following the seminar, 85 % were more likely to recommend a family member enroll in hospice, 79 % felt better prepared to counsel families about end-of-life care, and 91 % would participate in a similar event in the future. Two important themes emerged: (1) there is a need and desire in Baltimore communities for information about hospice and (2) respondents planned to share what they learned with their communities (table 1).

CONCLUSIONS: This novel, evidence-based educational seminar provides an example of a feasible, acceptable, and likely effective hospice outreach intervention, and suggests that religious leaders are important members of African American communities to engage in efforts to reduce hospice use disparities.

Summary of themes and select respondent answers

Theme	Responses
There is a need and desire for information about hospice	<p>"The information shared was very informative and helpful. I felt empowered by just being in the same room with so many members of the faith community who shared my experiences. Thank you for the investment in our ministries. It was much needed."</p> <p>"[The] information is vital."</p> <p>"I WOULD LOVE TO PARTICIPATE in any similar event you may offer in the future to help me be informed with my ministry as a Missionary in my church."</p> <p>"I believe the more correct knowledge we have allows the community to utilize services that enhance a good quality of life even as that life takes a turn toward the end of life."</p> <p>"We need to know about this for our members."</p>
Respondents planned to share what they learned with their churches and communities	<p>"A lot of good information... that I can use in my practice."</p> <p>"I feel better able to address the issues with family members because of all that was shared."</p> <p>"I now feel more comfortable referring clients to hospice."</p> <p>"I feel more comfortable counseling families because I am more informed."</p> <p>I attended the seminar to learn "effective ways to impact end of life care in the community"</p> <p>I attended the seminar to learn "information on ways to help others and take that information back to my church."</p>

ADHERENCE TO DIABETES MEDICATION: A QUALITATIVE STUDY OF BARRIERS AND FACILITATORS AMONG URBAN, LOW INCOME MEXICAN-AMERICANS WITH TYPE 2 DIABETES

Sara Baghikar^{1,2}; Amanda Benitez¹; Patty Fernandez Pineros¹; Yue Gao¹; Arshiya A. Baig¹. ¹University of Chicago, Chicago, IL; ²University of Illinois at Chicago, Chicago, IL. (Tracking ID #2198282)

BACKGROUND: Poor adherence to medication is an important barrier to metabolic control for Mexican-Americans with type 2 diabetes and contributes to adverse health outcomes in this population. Medication adherence is influenced by a complex interplay of different factors, including medication beliefs. The purpose of this study is to explore beliefs and perspectives on diabetes medications among urban, Mexican-Americans with type 2 diabetes in order to inform strategies to improve diabetes self-management.

METHODS: Face-to-face, in-depth interviews were conducted in Spanish with a sample of 27 individuals (25 Mexican-Americans and 2 Latinos of other origin) with type 2 diabetes as part of a church-based, randomized controlled trial for diabetes self-management in a low-income, Latino neighborhood of Chicago. Interviews were audio-recorded, transcribed verbatim and translated by bilingual staff. Systematic qualitative methods were used for analysis.

RESULTS: The sample included 5 males (19 %) and 22 females (81 %), the mean age was 57±11 years and the mean duration of diabetes was 8.8±7.5 years. 85 % of participants were on oral hypoglycemic medication and 30 % were on insulin therapy. Barriers to adherence were lack of knowledge and skills in managing medication, forgetfulness, social stressors, cost of medication and mental health problems. Furthermore, beliefs about harmfulness of medication, concerns with efficacy of medication and the perception that there is less need of medication when eating healthy and being physically active were present among many participants and emerged as important barriers to adherence. Family support emerged as the main facilitator to medication adherence.

CONCLUSIONS: Mexican-Americans with type 2 diabetes face multiple barriers to adherence, including lack of knowledge and skills to manage treatment and beliefs about harmfulness and lack of efficacy of medication. Healthcare providers need to assess and address patients' perspectives and beliefs in order to improve medication adherence.

ADHERENCE TO SAFETY GUIDELINES FOR PRESCRIBING OPIOIDS FOR CHRONIC NONCANCER PAIN IN AN ACADEMIC PRIMARY CARE CLINIC

Scott Steiger; Scott R. Bauer; John Gerstenberger; Hannah Harrison; Lily Hitchner. University of California, San Francisco, San Francisco, CA. (Tracking ID #2199490)

BACKGROUND: Several guidelines recommend dose limits and urine drug testing for patients prescribed opioids for chronic noncancer pain (CNC). Higher prescribed doses increase the risk of adverse effects, complications, and overdose. Drug testing appears to modestly decrease opioid misuse.

METHODS: To assess patient and provider characteristics associated with safer practices prior to implementation of quality improvement initiatives, we performed a retrospective cohort analysis of patients prescribed opioids for CNC at two academic primary care clinics. We evaluated odds of high dose and urine drug testing using multivariate logistic models. Covariates included age, sex, race/ethnicity, marital status, city of residence, language, insurance, provider level, substance use disorders, smoking, and mental or physical comorbidities.

RESULTS: Among 842 patients prescribed opioids for CNC (3.4 % of clinic population), 47 and 23 % were prescribed ≥50 and ≥180 mg morphine equivalents per day, respectively. Tables 1 shows adjusted odds ratio for each variable's association with high dose. Associations were robust to sensitivity analysis using a 180 mg threshold. Thirty-five percent completed urine drug testing in the last 2 years. Table 2 shows adjusted odds ratio for each variable's association with urine drug testing.

CONCLUSIONS: Patients managed by resident physicians were more likely to be treated in accordance with published guidelines, with lower doses of opioids for CNC and greater odds of urine drug testing. High doses were less common in some groups and more common in nonlocal patients. Urine drug testing was uncommon and unequal utilization may have reflected biases and unsupported assumptions about risk of opioid misuse.

ADVANCED FUNCTIONAL IMPAIRMENT IS ASSOCIATED WITH HIGHER POST-ACUTE COSTS OF CARE IN MEDICARE SENIORS

S. Ryan R. Greysen¹; Irena S. Cencer²; Ken Covinsky². ¹University of California, San Francisco, San Francisco, CA; ²University of California San Francisco, San Francisco, CA. (Tracking ID #2199473)

BACKGROUND: Background: Hospitalization identifies patients who are particularly costly to the Medicare system and current policy efforts to reduce costs focus on the 30 days after discharge; however, much less is known about which patients will have the greatest long-term Medicare costs. Given the prevalence of functional impairment in Medicare seniors and impact on clinical outcomes of hospitalization, we hypothesized that functional impairment would be significantly associated with higher costs of care up to a year after discharge.

METHODS: Methods: We studied 7854 Health and Retirement Study (HRS) subjects who were hospitalized at least once from 2000 to 2010 (18,598 hospitalizations). Our outcome was total post-acute costs for up to 365 days after hospital discharge, assessed by Medicare claims and adjusted for inflation. Main predictor was functional limitations as determined from the HRS interview immediately before the hospitalization and stratified into 5 levels: no functional impairments, difficulty with ≥1 instrumental activity of daily living (IADL), difficulty with ≥1 activity of daily living (ADL), dependency (need for help) in 1–2 ADLs, and dependency in ≥3 ADLs. Adjustment variables included age, race, gender, income, and net worth (obtained from HRS) and comorbid conditions (Elixhauser calculated from Medicare claims), and prior history of admission. We performed

descriptive statistics and multivariable regression analysis adjusted for clustering at patient level to characterize the association of functional limitations and post-acute costs of care.

RESULTS: Results: Mean age was 78 (65–105), 44 % male, 77 % White, 90 % reported ≥ 3 comorbidities, 61 % with ≥ 1 hospitalization in previous year; 48 % had had some level of functional impairment prior to hospital admission. Unadjusted analyses show an increase in post-acute costs as the severity of impairment increases in a dose-response fashion; however, adjusted analyses suggest that this effect applies only to patients with more advanced impairments. While patients with IADL or ADL difficulty did not have significantly higher adjusted costs, those with any level of dependency in ADLs had much

higher adjusted post-acute costs at 1 year: patients with 1–2 ADL dependencies cost \$3235 more (95 % CI \$857–\$5613) and those ≥ 3 ADL dependencies cost \$8289 more (\$4940–\$11,637) compared to patients with no impairments (Table 1).

CONCLUSIONS: Conclusions: Advanced functional impairment (ADL dependency) is associated with significantly higher post-acute costs in Medicare seniors; less severe impairments (ADL or IADL difficulty) are not. Our findings suggest the need for Medicare policy to expand beyond the traditional focus on chronic disease management and explore initiatives to manage advanced functional impairment in order to reduce overall costs of post-acute care for community-dwelling seniors.

Table 1: Association of Functional Impairments with Higher Post-Acute Costs

	Unadjusted N (%)	Adjusted* Mean Total Cost (\$)	Mean Absolute Change (\$)	95 % CI	Mean Absolute Change (\$)	95 % CI

AFTER HOSPITALIZATION, FOLLOW-UP WITH YOUR (AND ONLY YOUR) PRIMARY CARE PHYSICIAN IS ASSOCIATED WITH REDUCED READMISSIONS

Ryan D. Schulte^{1,2}, David Simel^{1,2}. ¹Duke University Medical Center, Durham, NC; ²Durham VA Medical Center, Durham, NC. (Tracking ID #2198618)

BACKGROUND: One intervention that is oft proposed to reduce hospital readmissions is arrangement of early follow-up visits. Studies examining the impact of post-hospital follow-up, however, have not shown an association with reduced readmissions. Furthermore, no studies, to our knowledge, have compared the effect of follow-up visits to Primary Care Physicians (PCPs) vs. non-Primary Care Physicians (non-PCPs). In this study, we measure the impact of the following follow-up visit types on a patient's timing of readmission: 1) Follow-up with the patient's own PCP; 2) Follow-up with another PCP that is not the patient's own; and, 3) Follow-up with a non-PCP.

METHODS: We included patients discharged from the Durham VAMC Medicine service to the community over 43 months. For each, we recorded the time (in days) from discharge to readmission. To measure the associations of readmission with varying types of clinic visits, we recorded the times from discharge to the first follow-up visit with 1) a patient's own PCP; 2) a PCP that was not the patient's own; and, 3) a non-PCP physician. Using survival analysis with the Cox regression method, we measured the association of the various follow-up visits with time to readmission. We controlled for patients' baseline predicted readmission risk. We generated time-dependent predictors to avoid producing artificially low, biased estimates of readmission risk otherwise generated when those patients at the highest risk of readmission are readmitted early and thus unable to arrive for a follow-up visit.

RESULTS: The predicted probability of readmission was positively associated with readmission risk. A visit with one's own PCP was protective and associated with a reduced risk of readmission (HR 0.79, $p < 0.001$, Table 1, Figure 1). This effect was independent of the baseline predicted risk of readmission. The effect of a visit with a non-PCP was hazardous and associated with a significant and near 3-fold increase in risk (HR 2.63, Table 1, Figure 1). There was no apparent effect of follow-up with a PCP that was not the patient's own on readmission (HR 1.00, $p = 0.97$).

CONCLUSIONS: These results are consistent with previous studies in demonstrating that follow-up with an unspecified PCP is not associated with any alteration in the risk of readmission. However, unlike previous studies, we were able to measure the effect of follow-up with one's own PCP on readmission and found it to be protective (and associated with a readmission risk reduction of 25 %). Furthermore, we found that follow-up in the clinic of a non-PCP physician was associated with a near 3-fold increase in readmission risk. These results suggest that efforts to reduce readmissions through post-hospital follow-up should focus on improving access of patients to their own PCPs in the weeks following discharge. Furthermore, we have evidence that follow-up with unfamiliar PCPs are ineffective; worse, follow-up visits with non-PCPs following hospitalization are associated with, and may cause, increased readmissions.

Table 1: Effect of Type of Follow-Up Visit on Readmission: Adjusted Hazard Ratios (HR) from Multivariate Analysis

	HR	95 % CI	p-value
Predicted Probability of Readmission	1.03	1.02–1.04	<0.001
Follow-up Visit with One's Own PCP	0.79	0.69–0.91	<0.001
Follow-up Visit with Another PCP	1.00	0.88–1.14	0.97
Follow-up Visit with non-PCP	2.63	2.27–3.05	<0.001

Figure 1: Predicted survival to readmission for a cohort of patients each of whom has a clinic visit with their own PCP at day 7 (red curve) and a cohort of patients each of whom is seen by a non-PCP at day 21 (blue curve).

ALIGNING CLINICAL WITH EDUCATIONAL VALUE: A MULTI-SITE ASSESSMENT OF PATIENTS' NEEDS AND POTENTIAL FOR STUDENT PATIENT NAVIGATORS

Bobbie Johannes; Deanna Graaf; Barbara Blatt; Jed Gonzalo. Penn State College of Medicine, Hershey, PA. (Tracking ID #2200306)

BACKGROUND: Targeting patient needs beyond traditional clinic walls is becoming a primary focus of healthcare reform. New models of health care delivery, such as Accountable Care Organizations, Patient Centered Medical Homes and clinically integrated networks, are being used to address gaps in high-value care delivery. One healthcare delivery role, patient navigation (PN), has been used to improve patient outcomes, and has the potential to be used even more in evolving healthcare models. Although PN is well established in oncology, less is known about the value of PN in other patient populations, including medicine and surgery. Additionally, with the increasing need to provide medical

students with authentic, value-added roles contextualized in systems sciences, we embarked on this project to develop a network of clinical sites within health systems in south-central Pennsylvania able to integrate medical students as PNs in a year-long educational experience. In this study, we explored the views of clinical site leadership regarding: (1) the key systems-related barriers encountered by their patients, and, (2) their perceptions regarding the potential to embed students as PNs to work with these patient populations in need.

METHODS: From January–November 2014, we performed an inductive content analysis of data obtained for the purpose of assessing clinical site willingness to collaborate in student PN. After identifying potential clinical sites within our region, we contacted site leaders, explained the student PN program, and requested a site visit to discuss opportunities. During site visits, we sought to understand the mission of each site, services provided, reported needs of site leaders as to care barriers encountered by patients, and potential for embedding students as PNs. Immediately following each visit, two investigators recorded a reflection on issues discussed and perceptions of receptivity of the program. Following each visit, a digitally-recorded key informant telephone interview with a site member was performed, exploring site demographics, current PN activities performed, and perceived value of student PNs. From these two data sources, the process of constant comparative analyses was used to identify initial themes and categories, and generate a preliminary codebook. Two investigators independently analyzed transcripts and compared codes for agreement. The research team had regular adjudication meetings to review codes, reconcile disagreements, and update the codebook.

RESULTS: To date, 20 site visits and follow-up informant interviews have been completed, with a wide variation in clinical site type, including primary care clinics, inpatient medicine discharge programs, a surgical-oncology transitions program, breast cancer survivorship program, and a state-run Tuberculosis clinic. Each site identified specific patient populations in need of PN, but notably the systems barriers encountered were variable and specific to each clinical site. In our preliminary analysis, several themes of systems barriers were identified, including un-/underinsured, poor access to medications and mental health services, and health literacy. Sites have processes in place to assist patients with specific barriers, including financial assistance programs, medical assistance education by attorneys, medical reconciliation programs, and transportation services; however, they report insufficient resources/staffing to fully realize the benefit of these strategies. Overall, sites had positive perceptions regarding the value-added role for student PNs, specifically with the anticipation of improved patient outcomes from performing tasks such as education about disease, medications, and follow-up appointments, coordinating appointments, linking patients to insurance exchanges, and performing home safety assessments.

CONCLUSIONS: Despite the popularity of PN for cancer populations, our results highlight the potential for expanding PN to a wide range of clinical sites, including outpatient and inpatient settings that care for both medical and surgical patients. Key systems barriers were not consistent across this range of clinical sites, suggesting each local setting must identify and address these factors in developing PN tasks to improve outcomes. Clinics are engaged in closing the gap between delivering care for all facets of patients' needs and the lack of necessary resources needed to accomplish this goal. Despite our initial concerns regarding the receptivity for integrating students in PN roles, site leadership had a positive attitude and willingness to collaborate, specifically because of the perceived impact these roles could have on patient outcomes. With the increasing need to educate collaboratively effective systems physicians, student PN roles that optimize high-value care in our health systems may be an innovative and value-added experience for both students and the health system.

ALLOPURINOL FOR PRIMARY AND SECONDARY PREVENTION OF CARDIOVASCULAR DISEASE Rakshita Chandrashekar¹; Karthik Kannegolla²; Louis Toledo¹; Craig Beam¹. ¹Western Michigan school of medicine, Kalamazoo, MI; ²Western Michigan university, Kalamazoo, MI. (Tracking ID #2199405)

BACKGROUND: Allopurinol is a xanthine oxidase inhibitor with anti-inflammatory properties and hence its key effects would include reducing superoxide anions and other free radicals which exert oxidative stress (OS); to increase tissue oxygen, and to increase hypoxanthine. This paper investigates the effect of allopurinol on cardiovascular events in patients with gout and hyperuricemia.

METHODS: We conducted a retrospective, cross-sectional study of patients at Bronson Methodist Hospital in Kalamazoo, MI, who were diagnosed with gout according to International Classification of Diseases. The protocol was approved by the Institutional Review Board of the hospital. Test group were patients who have been on allopurinol (100–300 mg per day) for at least 5 years and the control group with patients not on allopurinol. Demographics and cardiovascular comorbidities were collected by electronic medical record review. The primary outcome was a composite of hospital admissions for unstable angina, Myocardial Infarction and Congestive heart failure.

RESULTS: To assess the association between allopurinol use and number of admissions for cardiovascular events, a Poisson regression model was fit using data from 124 patients who were diagnosed with gout. Of these, 73 patients had been using allopurinol to manage gout for at least 5 years, while 51 patients who did not use allopurinol in gout management served as the control group. Both groups were controlled for diabetes mellitus, statin use, hypertension, and smoking status. It was found that allopurinol reduced hospital admission for cardiovascular events by nearly 50 % ($p=0.0003$). The mean incidence of cardiovascular admissions in the allopurinol group was estimated to be 0.55 per patient/year while that in the control group was 1.11 per patient/year. These findings provide statistically significant evidence that allopurinol use ($p=0.0003$) related to the incidence of cardiovascular admissions at the $\alpha=0.05$ level when controlling for statin use ($p=0.0192$), hypertension ($p=0.3642$), smoking status ($p<0.0001$), and diabetes mellitus ($p=0.7150$). The insignificance of hypertension and diabetes mellitus indicate these two factors do not add additional predictive ability to the model when allopurinol use, statin use, and smoking status are already present in the model. It is also important to note that the observed sample had only $n=7$ non-hypertensive cases and $n=124$ hypertensive cases. The small n for the non-hypertensive group may have played a role in the lack of significance for hypertension.

CONCLUSIONS: In this study, patients with gout who did not take allopurinol had twice the incidence (50 %) of hospital admissions for cardiovascular events and all-cause morbidity compared to those who took allopurinol. Allopurinol should be considered for primary and secondary prevention of cardiovascular events in patients who have been diagnosed with gout or hyperuricemia. The possible influence of confounding factors is being investigated.

Poisson regression model

Effect	Num DF	Den DF	F value	Pr>F
Allopurinol use	1	118	14.23	0.0003
Statin use	1	118	5.63	0.0192
Hypertension	1	118	0.83	0.3642
Smoking status	1	118	20.18	<0.0001
Diabetes Mellitus	1	118	0.13	0.7150

This table provides the results of fitting the Poisson model. In this model, the effect of allopurinol use is tested while controlling for the effect of statin use, hypertension, smoking status and diabetes mellitus.

AN ANALYSIS OF RECRUITMENT FOR AN ADVANCE CARE PLANNING STUDY IN ADVANCED CANCER PATIENTS Renee R. Stewart; Benjamin Levi; Jane Schubart; Lauren J. Van Scoy; Chengwu Yang; Elana Farace; Michael Green. Penn State College of Medicine, Hershey, PA. (Tracking ID #2198547)

BACKGROUND: Recruitment of participants is an essential component of any research study, yet is a particularly challenging when investigating patients with life-limiting illnesses. Recruiting for advance care planning (ACP) research presents additional challenges due to the inherent sensitivity of end-of-life issues, particularly in the context of terminal cancer. Minimal research exists on how to efficiently recruit individuals for ACP studies. We investigated specific barriers to enrollment for a non-treatment based intervention for end-stage cancer patients.

METHODS: We examined recruitment data from a randomized controlled study that compared efficacy of a novel, interactive online decision aid to a standard advance directive tool. Patients were referred by their oncologists based on the following inclusion criterion: 1) age >18 years 2) stage IV cancer, and/or 3) a life expectancy of less than 2 years. Basic demographics, referring provider, date of recruitment attempts, and recruitment outcomes were recorded. Referrals were categorized by season as follows: winter (Dec–Feb), spring (Mar–May), summer (June–Aug) and fall (Sept–Nov). Eligible referrals were mailed a personalized recruitment letter with self-addressed opt-out cards and subsequently contacted via the telephone 3 weeks later to explain the study, answer questions, and schedule a study visit if interested. We compared characteristics of enrolled patients to those of non-participants using chi-square tests and Mann–Whitney–Wilcoxon tests.

RESULTS: Referrals were provided from thirty oncologists over a 5-year period. Of the 1988 referrals, 90 % ($n=1788$) of patients were classified as non-participants. Among these non-participants, 31 % ($n=545$) returned the opt-out card, 30 % ($n=530$) declined participation via phone, 12 % ($n=217$) were unreachable, 10 % ($n=180$) reported being too ill, 6 % ($n=107$) died prior to contact, 6 % ($n=100$) expressed interest but did not follow-up, 4 % did not attend their scheduled appointment, and 2 % were deemed ineligible after referral. Non-participants were slightly older than enrolled participants (mean 64.2 years (SD 13.1) and mean 62.0 (SD 13.5) respectively, $p=0.02$). Compared to participants, a higher percentage of non-participants were of minority backgrounds (8 %

versus 4 %, respectively, $p=0.03$). On average, non-participants lived further away (50.5 miles, SD 151.6) from the study site than did participants (38.4 miles, SD 52.8, $p=0.01$). Two-thirds of all enrolled participants were recruited after no more than one phone call, whereas only 5 % were enrolled after three follow-up calls. The number of referrals received was significantly lower in winter (13 %) than other seasons (28 % spring, 31 % summer, 28 % fall, $p<0.001$), yet there were no differences in enrollment based on season of referral ($p=0.22$). There were no significant differences between participants and non-participants based on gender ($p=0.881$) or referring specialist ($p=0.07$).

CONCLUSIONS: We found that patients who enrolled in an ACP study lived closer to the study site than non-participants. We identified a diminishing return on time investment with multiple recruitment calls since the majority of patients enrolled within the first phone call. Thus, recruiters with limited time should consider prioritizing efforts on patients who live closest to the study site and towards making initial contact with potential participants.

AN ETHNOGRAPHIC STUDY OF GENERAL MEDICINE INTERPROFESSIONAL ROUNDS: EXPLORING INTERPROFESSIONAL COMPETENCIES

Heather A. Ward¹; Sylvia Abonyi¹; Mitchell Anderson¹; Christina Sparrow²; Petrina McGrath²; M. Suzanne Sheppard². ¹University of Saskatchewan, Saskatoon, SK, Canada; ²Saskatoon Health Region, Saskatoon, SK, Canada. (Tracking ID #2198540)

BACKGROUND: The changing landscape of healthcare service delivery is resulting in expansion of interprofessional collaborative care that address a broad spectrum of medical and social issues. In the setting of a fast paced hospital environment, achieving team function is challenging. Interprofessional rounds are one process for facilitating care coordination in an acute care setting by multiple healthcare providers. Recommended competencies and processes to facilitate interprofessional collaboration, including rounds, are based on theoretical frameworks, such as the CIHC (Canadian Interprofessional Health Collaborative 2010) Interprofessional Competency Framework. This theoretical framework has not been fully validated. We undertook an ethnographic study of interprofessional rounds to identify components (processes or competencies) identified by participants as facilitating this interprofessional activity and compared the identified themes to the CIHC competency framework.

METHODS: This study took place in an academic acute care setting, a general medicine clinical teaching unit (CTU). Each CTU provides care for an average of 25 to 30 patients with multisystem chronic disease. Daily interprofessional 'bullet' rounds are 15 min in duration for each CTU. Participants include the RN coordinator, MD/senior internal medicine residents, RN/LPNs, physical therapy, occupational therapy, speech language pathology, social work, pharmacy, registered dietician, and home care coordinator. An experienced ethnographer observed 8 days of bullet rounds (3 per day) and completed 8 interviews with individual participants following rounds. Thematic analysis of both the rounds observations and interviews was completed.

RESULTS: This ethnographic study focused on themes identified by participants as supporting or hindering the effectiveness of the interprofessional rounds. These themes were then compared to recommended competencies from the CIHC framework. Two themes were clearly identified to facilitate the effectiveness of team function during bullet rounds, and one that limited effectiveness: Team processes that *facilitated* interprofessional rounds: 1. Strength in one's own role: Knowledge of full scope of professional practice that meets individual patient care needs. Being familiar with what each professional brings to the care of an individual patient, rather than familiarity with the roles of other healthcare professionals, brings more depth to the patient care discussion at interprofessional rounds. 2. Cognitive conflict regarding roles for each patient: facilitates information sharing and discussion of care coordination. Cognitive conflict arises as each profession applies their expertise in providing care for an individual patient, sometimes with different perspective on care needs. Resolving this cognitive conflict adds to care coordination and increases job satisfaction during rounds. Team processes that *hindered* interprofessional rounds: 1. Differing objectives for the round by participants: Acute care care coordination vs rounds with the intent of discharge. These two different objectives resulted in different perspectives on information to be discussed and intended outcomes of the discussion. Focusing on discharge limited participation in discussion by several healthcare professionals who brought information to discuss regarding acute care coordination during the hospital stay. The key components of the CIHC framework are role clarification, interprofessional conflict resolution, collaborative leadership and team functioning. Role clarification is defined as "learners/practitioners understand their role and roles of others..." In our study, the emphasis was on being familiar with one's own role and to bring this knowledge to rounds. Being familiar with the roles of others was not identified by any of the participants. Cognitive conflict supports role clarification of one's own role and introduced a different aspect to interprofessional conflict resolution with positive outcomes to interprofessional discussion of care. Collaborative leadership needs to include shared objectives or intended outcomes of interprofessional activities such as bullet rounds.

CONCLUSIONS: Competency frameworks provide a guide for developing components of interprofessional healthcare delivery; however, further validation, both for establishing interprofessional practices in individual healthcare settings and for furthering interprofessional education, needs to occur through in depth qualitative research methods.

AN EVALUATION OF COMPUTERIZED MEDICATION ALERT OVERRIDE BEHAVIOR IN INPATIENT AND AMBULATORY CARE

Michael Swerdlow^{7, 6}; Diane L. Seger⁵; Mary Amato³; Nivethietha Maniam⁴; Olivia Dalleur²; Julie Fiskio⁷; Qoua L. Her²; Sarah P. Slight¹; Patrick E. Beeler²; Tewodros Eguale²; Karen C. Nanji⁷; Patricia C. Dykes⁶; David W. Bates¹. ¹Brigham and Women, Boston, MA; ²Brigham and Women's Hospital, Boston, MA; ³Brigham and Women's Hospital/MCPHS, Boston, MA; ⁴Partners HealthCare, Cambridge, MA; ⁵Partners Healthcare System, Wellesley, MA; ⁶The Center for Patient Safety and Practice, Boston, MA; ⁷Partners Healthcare, Wellesley, MA. (Tracking ID #2198007)

BACKGROUND: Evidence suggests that computerized decision support (CDS) improves care, but the amount of improvement achieved is typically a fraction of what is possible. Understanding how physicians respond to CDS alerts is a critical factor in improving care with the electronic health records (EHRs). Application of the CDS alert functionality has been variable between inpatient and outpatient providers and we continue to observe a high level of medication alert overrides for many prescription domains. While many overrides are justified clinically, some are not. It is important to reach out to those providers who are not prescribing optimally and understand their reasons for overriding alerts, and how they differ in inpatient and ambulatory care.

METHODS: We evaluated all Level 2 alert overrides that required a coded reason to be provided at the time of prescribing between January 2009 and December 2011. We limited our sample to providers who had received 20 or more alerts in any of the prescribing domains (drug-drug interaction alerts, drug-allergy interaction alerts, renal suggestion alerts, non-formulary alerts and age-based alerts) and the number of times each provider override these alerts was calculated. Of the 2495 providers eligible for the study, 1770 inpatient and 725 ambulatory, those with a high inappropriate override rate were targeted for academic detailing sessions. Research pharmacists trained in effective counter-detailing techniques conducted these sessions, each of which was tailored to the provider's particular overrides. Graphical material including performance level data, a list of their inappropriate overrides and supporting evidence-based summaries, was presented to each provider and this was used as the prime basis for a two-way discussion. A robust and complete analysis of the data was carried out and prevalent concepts related to general views on alert functionality and specific prescribing behavior identified.

RESULTS: We conducted 42 total academic detailing sessions, 34 with outpatient and 8 with inpatient providers. Overall, clinicians were generally favorable towards the alerts and felt that they were helpful in identifying possible adverse events. Providers were especially grateful for alerts informing them about the risk of drugs they infrequently use. However, many providers in the inpatient setting felt that alerts that reminded them to monitor the patient were extraneous. Providers ignored these warnings in the hospital because they were seeing their patients regularly independent of the alerts. They would like the option to disable alerts they consistently override and ignore. Regarding non-formulary alerts in the inpatient setting, physicians would like to see alternatives that are on formulary as well as the cost differential between the two options built into the alerts. Clinicians in the inpatient setting would rather override a drug allergy alert than make changes to a patient's allergy record if it was incorrect. They felt that responsibility should lie with the patient's primary care provider. In the outpatient setting, providers found that the clinical relevance of the alerts could be improved by providing recent laboratory values, as well as the ability to order additional tests directly from the alert.

CONCLUSIONS: A number of insights were identified through academic detailing sessions including that alert fatigue existed for warnings deemed irrelevant, and frustration that repetitive alerts cannot be disabled. Providers in the inpatient setting were more frustrated than those in the ambulatory environment when prompted to monitor their patients. The alerts were appreciated when the provider first saw the patient, however subsequent alerting was seen as frustrating and time consuming. Clinicians would like to see repetitive inpatient alerts less frequently. By incorporating provider preferences, customizing alerts to the context of the visit and considering the increased attention patients receive in a hospital; providers felt that CDS alerts would be less likely to be overridden providing more effective, efficient care.

AN EVALUATION OF THE IMPACT OF CALIFORNIA'S TRANSITION TO MANAGED CARE ON HEALTH CARE UTILIZATION BY MEDICAID SENIORS AND PERSONS WITH DISABILITIES

Lhasa Ray^{3, 4}; David Zingmond^{1, 4}; Sitaram Vangala³; Jennifer N. Sayles⁵; Michael Tu⁶; Li-Hao Chu⁶; Bruce A. Pollack⁶; Demetria Malloy⁶; Debra Saliba^{2, 4}. ¹UCLA, Los Angeles, CA; ²UCLA Borun Center, VA GRECC, RAND, Los Angeles, CA; ³University of California, Los Angeles, Culver City, CA; ⁴Veterans Affairs Greater Los Angeles Healthcare System, Los Angeles, CA; ⁵Los Angeles County, Los Angeles, CA; ⁶L.A. Care Health Plan, Los Angeles, CA. (Tracking ID #2193338)

BACKGROUND: Moving high-cost, medically complex Medicaid enrollees into managed care is a strategy states have used to stabilize health care spending and improve access, service coordination, and care outcomes for vulnerable populations. Little data exist to ensure that such transitions are effective in achieving these goals. California's recent transition of Medicaid seniors and persons with disabilities (SPDs) in 16 counties from traditional fee-for-service to

managed care offers an opportunity to evaluate the impact of a managed care expansion on health-related outcomes for this important patient population.

METHODS: L.A. Care Health Plan in Los Angeles County, the nation's largest not-for-profit provider of Medicaid managed care, was assigned over half of the SPDs transitioned in the state during the 12-month implementation between June, 2011 and May, 2012. We matched 12 months of pre-transition paid claims obtained from California's Department of Health Care Services to 12 months of post-transition managed care encounter-level data provided the plan. Monthly rates of outpatient physician visits, emergency department visits, and hospital admissions were calculated based on the number of eligible individuals each month, yielding events per 1000 member months (PMM). Utilization rates are reported with respect to each individual's transition month. We used negative binomial GEE regression models to compare rates between the four six-month pre- and post-transition intervals while accounting for repeated measurements. Differences in rates were evaluated using contrasts.

RESULTS: Of 148,923 individuals assigned to L.A. Care through the transition, we identified 103,656 (69.6%) matched individuals with at least one month of post-transition plan enrollment. The final sample includes 94,772 individuals ≥ 18 years. The sample's mean pre-transition Medicaid eligibility and post-transition plan enrollment was 11 months

in both periods. Outpatient physician visits (Fig. 1) were stable for the 12 months preceding the transition at approximately 370 visits PMM ($p=0.64$ for -12 to -6 months vs. -6 to 0 months contrast), then reached a new steady state of 250 visits PMM after the early post-transition period when visits dropped as low as 160 visits PMM ($p<0.001$ for the contrast). Inpatient hospital admissions (Fig. 2) rose from 30 to 35 admissions PMM pre-transition ($p<0.001$), then dropped post-transition to approximately 25 admissions PMM ($p<0.001$). The drop in inpatient hospitalizations appears to be primarily due to fewer elective admissions. ED visit rates were variable, rising from approximately 67 PMM pre-transition to 79 PMM immediately prior to managed care enrollment ($p<0.001$). Post-transition, ED visits fell to approximately 73 visits PMM after the second post-transition month, and were relatively stable thereafter ($p=0.02$).

CONCLUSIONS: The transition of Medicaid SPDs in Los Angeles County to managed care was associated with overall reductions in ambulatory care visits and acute hospital admissions. Utilization patterns occurring around the transition period raises concerns that beneficiaries may have attempted to manage potential loss of access during the transition. Future analyses using these data will include examination of additional months of post-transition utilization data, types and appropriateness of care, and subgroup effects.

AN INTERVENTION TO IMPROVE HOSPITAL CARE DELIVERED ON WEEKENDS Saul Blecker^{1, 2}; Keith Goldfeld¹; Hannah Park¹; Martha J. Radford^{1, 2}; Sarah Munson¹; Fritz Francois^{1, 2}; Jonathan Austrian^{1, 2}; R. Scott Braithwaite^{1, 2}; Katherine A. Hochman^{1, 2}; Richard Donoghue²; Bernard Birnbaum²; Marc N. Gourevitch^{1, 2}. ¹New York University School of Medicine, New York, NY; ²NYU Langone Medical Center, New York, NY. (Tracking ID #2195188)

BACKGROUND: Hospital care on weekends has been associated with delays in care, reduced quality, and poor clinical outcomes. The “7-Day Hospital Initiative” was a hospital-based intervention designed to improve patient throughput and quality of care delivered on weekends. The purpose of this study was to evaluate the impact of the intervention on processes of care and clinical outcomes at an academic medical center.

METHODS: The multifaceted inpatient intervention consisted of the following components: 1) expanded access on weekends to diagnostic procedures (echocardiography, cardiac stress tests, radiological services including interventional radiology); 2) expanded hospitalist coverage on the Medicine service on weekends, with improved structure for patient handoffs from weekday to weekend providers; 3) increased care management staffing on weekends; 4) implementation of standard weekend interdisciplinary rounds; 5) increased elective weekend surgeries (primarily outpatient). To study the impact of the intervention, we performed an interrupted time series observational study of adult non-obstetrical patients between January 2011 and January 2014. The primary outcome was average length of stay. Secondary outcomes included percent of patients discharged on weekends, 30-day readmission rate, and in-hospital mortality rate. We used segmented regression analysis with adjustment for confounders to determine associations between the intervention and outcomes.

RESULTS: The study included 57,163 hospitalizations. Following implementation of the intervention in July 2012, average length of stay decreased by 13 % and continued to decrease by 1 %/month as compared to the underlying time trend (Figure). The reductions in length of stay were observed on the Medicine service but not on Surgery ($p < 0.001$ for difference; Figure). The percent of weekend discharges increased by 12 % at the time of the intervention and continued to increase by 2 %/month thereafter (Table). The intervention had no impact on readmissions or mortality (Table). During the post-implementation period, the hospital was evacuated and closed for 2 months due to damage from Hurricane Sandy and a new electronic health record was introduced in our medical center. We observed a lower inpatient census and found differences in patient characteristics, including higher rates of Medicaid insurance and comorbidities, in the post-Hurricane Sandy period as compared to the pre-Sandy period.

CONCLUSIONS: The 7-Day Hospital Initiative, a multi-component intervention to increase hospital services on weekends, was associated with a reduction in length of stay and an increase in weekend discharges. The study also illuminated the challenges of evaluating the effectiveness of a large scale intervention in a real world hospital setting.

Results of the interrupted time series analysis evaluating the effect of the 7-Day Hospital Initiative on outcomes. The Change in Level and Change in Rate indicate whether the intervention had an immediate or ongoing effect on the outcome of interest, respectively.

Outcome	Rate of Change, pre-Intervention	Change in Level, Introduction of Intervention	Change in Rate, post-Intervention
Length of Stay	1.01 (1.01, 1.02)	0.87 (0.85, 0.90)	0.99 (0.98, 0.99)
% Weekend Discharges	0.99 (0.99, 1.00)	1.12 (1.02, 1.22)	1.02 (1.01, 1.03)
Readmission	0.99 (0.99, 1.00)	0.90 (0.81, 1.01)	1.01 (0.99, 1.02)
Mortality	0.99 (0.97, 1.00)	1.10 (0.84, 1.44)	1.02 (0.99, 1.05)

Trends in adjusted length of stay, by month. July 2012 represents the beginning of the 7-Day Hospital Initiative. Data from November and December 2012 are missing due to hospital closure related to Hurricane Sandy.

ANALYSIS OF 510,713 ALCOHOL DEPENDENT PATIENTS LEAVING AGAINST MEDICAL ADVICE IN THE LAST 10 YEARS: BURDEN ON HEALTH ECONOMY Rakshita Chandrasekar¹; Karthik Kannegolla². ¹Western Michigan school of medicine, Kalamazoo, MI; ²Western Michigan university, Kalamazoo, MI. (Tracking ID #2199191)

BACKGROUND: Alcohol dependence is a condition resulting from prolonged and usually intense consumption of alcohol which has resulted in psychological and/or physiological dependence on alcohol consumption. This dependence results in significant problems in one or more areas of the person's life. Millions of dollars are spent on these patients initially for their treatment but the patients decide to leave against medical advice (AMA) with incomplete treatment causing significant financial losses in the economy. Our aim is to assess the demographics of alcohol dependent patients that left AMA in 2012 and to also assess the trend of discharges from 2002–2012.

METHODS: Nationwide Inpatient Sample (NIS) database is developed through Agency of Healthcare and Research quality through federal-state funded partnership and represents 20 % of all the hospitalizations in USA. NIS data was used to extract demographics of alcoholic patients who left AMA for the year 2012 like the number of discharges, location and teaching status of hospitals, hospital regions, mean length of stays (LOS) in hospitals, mean hospital charges (in dollars), insurance payers and the trends of discharges from 2002 to 2012 using Diagnosis Related Group (DRG).

RESULTS: We extracted data for 43,440 alcohol dependent patients who left AMA in 2012. Their mean LOS was 2.4 days. Majority of patients (57.29 %) were between age group of 18–44 years, followed by patients between 45 and 64 years (40.07 %) with men leaving AMA three more often than women. Most patients were admitted in private, not for profit hospitals (77.04 %), in urban teaching hospitals (56.54 %), hospitals with large bed size (49.01 %) and were covered for by Medicaid (39.05 %) or private insurance (20.03 %). Most patients were from northeastern part of USA (50.06 %) followed by Western part (12.13 %). The cost of hospitalization in the West is more when compared to Hospitals from the Northeast (\$16,000 vs \$9825) though the former have far less cases reported. The mean hospitalization charge per patient was \$10,415 and the total national aggregate charge was close to 453 million dollars. There were 510,700 patients who left AMA between 2002 and 2012. The maximum number of cases were in the year 2006 (53,073 cases), and minimum in 2003 with 41,041 cases. There has been no change in median LOS in hospitals in the last 10 years but the mean charges have increased from \$6000 in 2002 to greater than \$10,000 per patient.

CONCLUSIONS: Our study reports the demographic distribution that greater than 55 % of cases that left AMA are treated by urban teaching hospitals and close to 50 % cases are from the Northeast due to unknown factors. More than 452 million dollars are being spent annually on this subset of the population who leave before the completion of treatment is accomplished. By investing in programs dealing with social and psychological factors that lead to them leaving AMA, recurrent admissions for partially completed treatments could be limited, thereby reducing burden of millions of dollars on healthcare economy.

ARE RESEARCH ETHICS COMMITTEES PREPARED FOR COMMUNITY BASED PARTICIPATORY RESEARCH? Leonardo Tamariz; Ana M. Palacio; Olveen Carrasquillo. University of Miami, Miami, FL. (Tracking ID #2199123)

BACKGROUND: Community-based participatory research (CBPR) is a collaborative approach to research that involves all partners in the research process and recognizes the unique strengths that each brings. This new research methodology presents a variety of challenges for research ethics committees (RECs). The purpose of this study is to summarize the evidence supporting the level of preparedness that RECs have when reviewing CBPR projects.

METHODS: We performed a search of the MEDLINE database (1966 to December 2014) supplemented by manual searches of bibliographies of key relevant articles. We included studies that used surveys of researchers or REC members, evaluations of the forms and procedures of the REC and case studies reporting on experiences when submitting a CBPR project through a REC.

RESULTS: The search strategy yielded 42 studies, of which only 8 met our eligibility criteria. Five studies reported results of surveys of researchers and REC members and three studies reported on qualitative experiences of case studies when submitting a CBPR project through a REC. Three studies evaluated the REC's submission/reviewer forms and found that the community involvement could be elicited in a median of 5 % (range 0–

15 %) of all forms in 131 RECs from the US and Canada. One study surveyed community partners of CBPR projects who reported that common challenges when working with RECs were delays and lack of understanding of CBPR principles. One study surveyed REC members and found that they felt prepared to review CBPR projects. Facilitators of approval of CBPR projects were adequate communication between the REC and the community, use of community advisory boards, and having a large number of research projects. The case studies of researchers trying to submit CBPR projects to RECs, consistently reported frustration related to delays and refusal to approve, lack of understanding of community ethics, dealing with multiple RECs, risk determination, and research protection oversight.

CONCLUSIONS: RECs are not prepared to evaluate CBPR projects based on evaluation of the REC forms and process. This lack of preparedness leads to unnecessary delays in the approval process and is related to REC members not being familiar with the CBPR principles. CBPR training and better communication with the community are key to improving the process.

ASSESSING LEARNER ENGAGEMENT AND KNOWLEDGE: USE OF TEAM BASED LEARNING FOR INTERNAL MEDICINE AMBULATORY RESIDENT TEACHING Sandy Balwan²; Alice Fornari¹; Paola Dimarzio²; Jennifer Verbsky²; Renee Pekmezaris²; Saima Chaudhry³. ¹Hofstra NSLIJ SOM, Hempstead, NY; ²North Shore LIJ Health System, Great Neck, NY; ³nslij, Manhasset, NY. (Tracking ID #2185058)

BACKGROUND: Traditional resident teaching is a passive process that does not model the “active learning” strategies currently promoted in medical education. Team Based Learning (TBL) is an active strategy commonly used in Undergraduate Medical Education (UME) to facilitate higher order content learning, promote high levels of learner engagement and collaboration, and foster positive learner attitudes. However, there is little data on the effect of TBL in Graduate Medical Education (GME) on medical resident and faculty engagement and satisfaction, and residents’ medical knowledge.

METHODS: In 2012, we replaced our didactic based ambulatory medicine curriculum with a TBL pedagogical approach to support our ambulatory curriculum. We are a large internal medicine residency program using two different ambulatory sites. The specific aims of this study was to determine whether TBL improves: 1) medical resident and faculty engagement and satisfaction, and 2) residents’ medical knowledge assessed by multiple readiness assurance tests. We assessed medical knowledge using individual (IRAT) and group readiness assurance (GRAT) tests. A prior validated survey was used to measure resident involvement, contribution, participation, and engagement. We used a modified Nominal Group Technique (NGT) to provide semi-quantitative, rank-ordered feedback on participant perceptions of medical education experiences. Residents and faculty who experienced both the traditional model and the TBL approach were asked the following: “Compared to the traditional didactic based ambulatory learning sessions used last academic year, please comment on the strengths and weaknesses of the TBL curriculum used this academic year.”

RESULTS: For all modules, the average GRAT score was significantly higher than the average IRAT score, with a range of improvement from 10 to 31 points (Wilcoxon signed rank tests for all matched pairs ($p < 0.0001$ for all seven modules). The survey response rate for residents and faculty was 61 and 85 %, respectively. The vast majority of faculty and residents agreed or strongly agreed that: 1) most residents were actively involved in TBL sessions, 2) contributed meaningfully to group discussions 3) talked with other residents about the material in each session, 4) contributed their fair share to the TBL session; 5) paid attention 6) participated in session discussions and 7) were perceived to be learners in the discussion. Results from our NGT show that both residents and faculty thought the most important strength of the TBL curriculum was the interactive format with group work. Residents and faculty also reported that the competition between residents was a positive aspect of TBL. Interestingly, residents and faculty both ranked the format of TBL as both a strength and a weakness.

CONCLUSIONS: Both our survey and NGT results support our hypothesis that TBL promotes resident engagement. Positive feedback from the NGT data, from both residents and faculty, support the premise that learning in teams is favorable and creates a teaching environment where learners are engaged. In terms of knowledge, GRAT scores consistently increased for each clinical topic and overall composite knowledge scores increased by approximately 22 %. Survey results reported residents being actively involved in TBL sessions, contributing to group discussions and actively discussing the subject material with other residents. Faculty echoed similar responses and both residents and faculty reported that they would like more teaching session to be offered using the TBL pedagogy. In conclusion, TBL resulted in active resident engagement, improved group medical knowledge, and increased satisfaction by residents and faculty with learning specifically focused on the care of patients in the ambulatory setting.

Table 1: TBL Process

Session	Activity
Pre TBL Session	Residents emailed relevant articles and cases
Day 1	Administration of IRAT/GRAT with faculty facilitating the discussions of the questions. IRAT/GRAT collected.
Day 2	Clinical vignette with eight learning objectives distributed to residents. Faculty facilitates residents reading of case and choosing two additional learning objectives.
Day 3	Residents report out on all learning objectives.
Post TBL Session	Residents complete peer evaluations and peer evaluations distributed to respective residents

ASSESSING SENIORS’ NORMATIVE BELIEFS AND SHARING OF HEALTH INFORMATION ABOUT THE PNEUMOCOCCAL VACCINATION Crystal T. Doan¹; Shira N. Goldman¹; Tiffany Brown¹; Stephen D. Persell¹; Alpa Patel²; Kenzie A. Cameron¹. ¹Northwestern University Feinberg School of Medicine, Chicago, IL; ²Northwestern Medicine, Chicago, IL. (Tracking ID #2195864)

BACKGROUND: In 2012, only 59.9 % of seniors were vaccinated against invasive pneumococcal disease, despite the Healthy People 2020 goal of 90 % vaccination. Prior research has found that physician recommendations and patient attitudes may be more powerful predictors of pneumococcal vaccination (PnVx) than patient access to medical services. It remains unclear how patients’ normative beliefs about PnVx influence their vaccination decisions. Normative beliefs are perceptions of how the general population behaves and judgments toward these behaviors. They can be divided into: 1) injunctive norms, i.e., individuals’ perceptions of what should be done, based on what is socially acceptable; and 2) descriptive norms, i.e., individuals’ perceptions about the prevalence of a behavior. We assessed individuals’ normative beliefs, and explored differences by race and receipt of PnVx. We also assessed if patients discussed pneumonia and PnVx with anyone following a clinic visit.

METHODS: English-speaking patients age 65 and 66 from an academic general internal medicine clinic were recruited to participate in a telephone survey to assess their normative beliefs about pneumonia and PnVx approximately 1 week following their clinic visit. As part of a larger study, these patients had been shown a brief, 2-min educational video about PnVx at that visit. To assess normative beliefs, we created a 4-item injunctive norm scale ($\alpha = 0.69$; e.g. “In general, most people think it is a good idea to get the pneumonia shot”) and a 3-item descriptive norm scale ($\alpha = 0.78$; e.g. “I think that most people who are 65 or older get the pneumonia shot”). Patients responded on a 5-point Likert scale from 1 (strongly disagree) to 5 (strongly agree).

RESULTS: Participants ($N = 72$) had a mean age of 65.2, were 62.5 % female, 36.1 % identified their race as Black and 55.6 % as White, and 94.4 % had at least some college education. There was no variation by race on receipt of PnVx, with 52.8 % of patients reporting receipt at their recent clinic visit. Patients’ injunctive norms slightly supported receipt of PnVx ($M = 3.70$, $sd = 0.84$), but their descriptive norms toward receipt of PnVx were neutral ($M = 3.13$, $sd = 1.20$). Overall, neither injunctive nor descriptive norms differed between Black (injunctive norms: $M = 3.44$, $sd = 0.93$; descriptive norms: $M = 2.84$, $sd = 1.47$) and White patients (injunctive norms: $M = 3.81$, $sd = 0.76$; descriptive norms: $M = 3.25$, $sd = 1.01$). In addition, neither injunctive nor descriptive normative beliefs differed among participants based on self-reported PnVx vaccination status. Overall, participants had high agreement with the statement “My doctor thinks I should get the pneumonia shot” ($M = 4.63$, $sd = 0.83$). Compared to participants who did not receive the vaccine, those who received PnVx at their clinic visit were significantly more likely to discuss pneumonia and PnVx with others ($\chi^2 = 8.30$, $p = 0.016$). Participants discussed pneumonia and PnVx after their clinic visit with friends and acquaintances ($n = 22$), family members ($n = 19$), partners or spouses ($n = 17$), and other medical professionals ($n = 5$). However, half (55.6 %) of patients reported being unaware that PnVx was covered by Medicare.

CONCLUSIONS: In our sample, we discovered no racial differences when exploring participants’ injunctive and descriptive norms toward receipt of PnVx. Not surprisingly, participants strongly agreed that their physicians supported receipt of PnVx. However, only half of those eligible received PnVx at their recent visit, and over half were unaware that Medicare covers the cost. These findings from our small sample at a single site could suggest that factors other

than injunctive and normative beliefs are driving vaccination behavior. It is notable that those who received PnVx were likely to share information regarding pneumonia and PnVx with others after their visit, showing the proliferation of health communication beyond the medical encounter. Further research should explore both the content of this shared information as well as how best to utilize social networks to improve PnVx rates.

ASSESSMENT OF OPERATIONAL DEFINITIONS FOR MEDICATION ADHERENCE USING LONG-TERM OUTCOMES IN PATIENTS WITH HYPERTENSION Karen Tang; Hude Quan; Doreen Rabi. University of Calgary, Calgary, AB, Canada. (Tracking ID #2195940)

BACKGROUND: Medication adherence is defined as the extent to which a patient takes prescribed medications according to the dosage and frequency recommended by the provider. Research studies examining medication adherence tend to use pharmacy data, indirectly measuring adherence using the “medication possession ratio” [MPR] or the “proportion of days covered” [PDC]. Despite widespread use of these terms, there are in fact no standard operational definitions for adherence, nor is there a standard method of measuring adherence in patients using concurrent medications (termed “polytherapy”). In order to determine whether the use of different operational definitions results in different conclusions regarding adherence and outcomes, we aimed to compare and contrast adherence rates and association with mortality using MPR and PDC definitions of adherence, and using various methods of handling polytherapy.

METHODS: We conducted a cohort study of patients aged ≥ 65 years from Manitoba, Canada, with incident hypertension diagnosed in 2004, and followed up to 2009. Drug data were obtained from the Manitoba Pharmacare prescription database. We calculated and compared adherence rates to anti-hypertensive medications using the following operational definitions for medication adherence: MPR using a fixed observation interval of 1 year (“MPR_i”=days supply/365 days), MPR using a prescription based interval (“MPR_p”=days supply excluding last refill / (last refill date - first fill date)), and PDC (calculated as the number of days where at least one medication is available / 365 days). For patients on polytherapy, four different MPR_i and MPR_p’s were calculated: 1) MPR to any antihypertensive medication (“sum MPR”); 2) mean of the class-specific MPR’s for each anti-hypertensive medication prescribed (“mean MPR”); 3) the lowest of the class-specific MPR’s (“low MPR”); and 4) the highest of the class-specific MPR’s (“high MPR”). All adherence measures were dichotomized using the standard threshold of 0.80 such that patients with MPR’s or PDC’s greater than 0.80 were considered “adherent” to their medications. Logistic regression and Cox regression were performed to determine the association between medication adherence using these operational definitions and mortality.

RESULTS: Our final cohort consisted of 2199 patients. Mean age (SD) was 75.2 (7.0) years, 45.5 % were male, and 64.7 % were on monotherapy. For those on monotherapy, 71.8 % were considered adherent when using MPR_i or PDC definitions, and 76.7 % were considered adherent when using the MPR_p definition. For those on polytherapy, the proportion considered adherent ranged from 24.1 to 90.5 % using MPR_i, depending on the method used to manage concurrent medications, compared to 71.2 to 92.7 % using MPR_p measures. Using the “mean MPR_i” and “mean MPR_p” measures, the proportion considered adherent were 33.7 and 81.0 % respectively. Adjusted logistic regression showed a trend toward adherence being inversely associated with death for all definitions, with the association being strongest for MPR_p measures (adjusted OR 0.71 to 0.78 [95 % confidence interval (CI) 0.53, 0.86 to 0.58, 1.03] for MPR_p measures; aOR 0.80 to 0.90 [95 % CI 0.59, 1.09 to 0.68, 1.19] for MPR_i measures). For patients on polytherapy, this association was significant only with mean MPR_p [aOR 0.71, 95 % CI 0.53, 0.95] and sum MPR_p [aOR 0.72, 95 % CI 0.51, 0.99] measures, but not with the highest or lowest class-specific MPR_p’s, or with any MPR_i or PDC measures.

CONCLUSIONS: The range of adherence estimates varies widely depending on the operational definition for adherence used, especially for patients taking more than one medication concurrently. The use of fixed observation intervals versus prescription based intervals as the denominator in MPR definitions also results in substantially different conclusions about medication adherence. These findings call for transparency in medication adherence research, such that the operational definition used is clearly defined, as well as for the development of a harmonized and accepted standard operational definition of adherence. Given less variation in adherence rates calculated by MPR_p measures and its stronger association against mortality,

MPR_p (specifically mean or sum MPR_p for those on polytherapy) are the recommended operational definitions for medication adherence.

ASSOCIATION BETWEEN DIABETES SELF-CARE AND PERCEIVED SUPPORT IN A SAMPLE OF LOW-INCOME AFRICAN AMERICANS Brittany D. Payne²; Robert Oster¹; John P. Shelley¹; April A. Agne¹; Andrea Cherrington¹. ¹University of Alabama Birmingham, Birmingham, AL; ²University of Alabama at Birmingham, Birmingham, AL. (Tracking ID #2199151)

BACKGROUND: Self-care behaviors are important to diabetes care and health outcomes. Studies suggest that social support is positively linked to self-care behaviors in patients with diabetes; however, the research examining social support and diabetes in minority communities is more limited. The purpose of this study was to investigate the multiple dimensions of social support and its relationship with diabetes self-care behaviors among African Americans. Specifically, we measured perceived support from health care professionals, as well as family and friends, and its relationship to medication adherence and an additional five diabetes self-care behaviors.

METHODS: We surveyed 119 low-income African American adults diagnosed with type II diabetes living in Birmingham, AL as part of the baseline assessment for a study examining the influence of community health workers on diabetes-related self-care, education, and outcomes. Participants were recruited from a local safety net health system and were included if they had diagnosed diabetes, poor glycemic control (HbA1c >7.5), and had been seen at the clinic within the last 2 years. Using previously validated measures, participants were queried regarding self-care activities (general diet, specific diet, exercise, blood glucose testing, and foot care), medication adherence, diabetes distress, depression, and social support. Support from the health care team was assessed using two items, one regarding perceived support and the other, satisfaction with support received. Perceived support from family and friends was assessed using a 5 item scale. Spearman (nonparametric) correlation analysis was used to determine bivariate associations. Statistical tests were two-tailed and were performed using a significance level of 5 %.

RESULTS: Our study population comprised 80 female and 39 male participants, age 31 and older (mean=55, SD=8), with about 1/2 having completed at least a high school level education. Participants had average HbA1c=10 % and had been diagnosed with diabetes for about 9 years. While a majority of study participants (88 %) use cell phones, about 65 % never or rarely use text messaging or internet. Satisfaction with the support from the health care team was significantly associated with all 5 self-care behaviors ($p=.001, .048, .001, .049, .042$, respectively) as well as medication adherence. Perceived amount of social support from the health care team was significantly associated with general diet and exercise ($p=.008$ and $.045$, respectively). Both amount of support and satisfaction from the health care team were positively associated with age, education, and the extent to which the participant used text messaging and internet ($p=.002$ and $.011$ for amount of social support, and $p=.001$ and $.001$ for satisfaction with social support). Perceived social support from family and friends was positively associated with medication adherence ($p=.001$) but not the other self-care behaviors. Women were more likely to report support from family and friends ($p=.041$) and depression was inversely related to such support ($p=.001$). Higher levels of support from the health care team and from family and friends were associated with less diabetes distress ($p=.004$).

CONCLUSIONS: Findings in this study of low income African Americans with diabetes indicate that perceived support influences diabetes self-care. Satisfaction with the health care team was associated with the highest number of self-care behaviors, though perceived amount of support from the health care team and support from family and friends were both positively associated with some behaviors. While overall use of text messaging and internet was low, individuals engaging in these behaviors reported higher levels of social support. Diabetes specific distress was mitigated by support from both the health care team and family and friends.

ASSOCIATION BETWEEN FRAILTY AND 30-DAY OUTCOMES AFTER DISCHARGE FROM GENERAL INTERNAL MEDICINE WARDS: A MULTI-SITE PROSPECTIVE COHORT STUDY Sharry Kahlon; Sumit R. Majumdar; Jenelle Pedersen; Sara Belga; Darren Lau; Miriam Fradette; Debbie Boyko; Jeffery Bakal; Curt Johnson; Raj S. Padwal; Finlay A. McAlister. University of Alberta, Edmonton, AB, Canada. (Tracking ID #2198558)

BACKGROUND: Readmissions within 30-days of hospital discharge are common and costly but prediction models are poor at identifying those at high risk of being readmitted. Frailty is a multi-dimensional syndrome not routinely captured by administrative databases that may improve clinical prognostication.

METHODS: We prospectively enrolled 500 patients discharged from 7 GIM wards at 2 teaching hospitals in Edmonton, Alberta Canada. "Frailty" was defined as 5-points or more on the previously validated 9-point Clinical Frailty Score (CFS). The primary outcome was the composite of 30-day readmission or death. Multiple logistic regression analyses, adjusted for age and sex, were undertaken to compare 30 day outcomes between frail and non-frail patients.

RESULTS: Of the 500 patients we recruited, 164 (33 %) met the CFS definition of frailty: 93 (19 %) were mild (CFS score 5), 60 (12 %) were moderate (CFS score 6), and 11 (2 %) were severely frail (CFS score 7 and 8). Frail individuals were older, more likely to be female, had more comorbidities and lower EQ-5D scores, and higher LACE scores at discharge, but had similar mean serum albumins and mean scores on depression, cognitive, and anxiety scales as non-frail subjects. Overall, 96 patients were readmitted or died within 30 days of discharge, and frail patients exhibited higher event rates: 44 (27.2 %) vs. 52 (15.6 %), OR 2.02 (1.28–3.18). Even after adjusting for age and sex, frailty remained associated with 30 day outcomes (aOR 2.01, 95%CI 1.21–3.33 for frailty and aOR 2.12, 95%CI 1.18–3.81 for moderate-severe frailty).

CONCLUSIONS: In individuals discharged from general medical units, frailty was common, was associated with substantially increased risk of adverse events, and the CFS could potentially be used to identify those individuals in whom to target interventions to reduce hospital readmissions.

ASSOCIATION BETWEEN NEIGHBORHOOD SOCIAL SUPPORT AND QUALITY OF DIABETES CARE

Roberto O. Diaz Del Carpio; Wudeneh Mulugeta; Scott Stewart. University at Buffalo, Buffalo, NY. (Tracking ID #2192948)

BACKGROUND: Diabetes is among the 10 leading causes of death in the U.S., with Type 2 diabetes representing almost ninety five percent of cases. Effective disease management comprised of medical care, self-management education, and ongoing diabetes support is key to improving quality of life and reducing acute and long-term complications. There is growing evidence that social support in the community is related to better long-term self-management and better health outcomes. We conducted this study to assess the relationship between neighborhood social support and diabetes management in our urban safety-net clinic, hypothesizing that higher perceived neighborhood support would be associated with improved diabetes management.

METHODS: The present report represents initial findings in an ongoing study examining the impact of social support and social resources in the treatment and outcomes of adult patients with type 2 diabetes who live in the city of Buffalo, New York. The Chronic Illness Resource Survey (CIRS) was used to measure support and resources for diabetes management across eight domains including neighborhood social support (NSS). This social support level includes 6 questions probed the amount of support received from patient's neighborhood on a 5-point Likert scale (1: not at all- 5: a great deal). NSS index was created by computing the means of the subscale items. Patients were asked to complete the CIRS survey during their regular appointments to one of our teaching outpatient clinics. Diabetes process and outcomes measures were abstracted from the electronic medical record. Linear and logistic regression analyses were used to model the associations between the NSS and Physician Quality Reporting System outcome and process measures (A1c, microalbuminuria, and ophthalmology visits) adjusting for income, education and self-reported race/ethnicity.

RESULTS: Subject characteristics are shown in Table 1. The average NSS score was 2.6 (SD:0.6). We did not find any statistically significant associations between the NSS and outcome measures. As far as point estimates, there was a slight negative association between A1C and neighborhood social support (β : -0.05, 95 % CI: -0.13, 0.03, p : 0.21). The odds of having an ophthalmology visit (OR: 0.97, 95 % CI: 0.88, 1.05, p : 0.43), and the odds of having microalbuminuria (OR: 0.97, 95 % CI: 0.88, 1.07, p : 0.55) were not associated with NSS.

CONCLUSIONS: Our initial results suggest that there is no strong association between perceived NSS and the selected outcome measures. Future work will

include confirming these findings following study completion, evaluating other aspects of social support, and evaluating more complex relationships between NSS and diabetes outcomes.

ASSOCIATION BETWEEN SUBJECTIVE SOCIAL STATUS AND CARDIOVASCULAR DISEASE AND CARDIOVASCULAR RISK FACTORS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Karen Tang; Ruksana Rashid; William A. Ghali. University of Calgary, Calgary, AB, Canada. (Tracking ID #2197861)

BACKGROUND: Subjective social status (SSS) is an individual's perception of his own position in the social hierarchy and has been shown to be associated with health outcomes, with lower SSS being associated with worse self-rated and mental health. These health associations may be due in part to its close correlation with objective socioeconomic measures (SES) such as income, education or occupation, though SSS may also exert effects independent of SES. Through internalization of perceptions of inferiority, resulting in activation of stress-related neuroendocrine mechanisms and increased unhealthy behaviors, low SSS may lead also to increased cardiovascular risk. Our objective was to determine the association between lower SSS and odds of coronary artery disease (CAD) and CAD risk factors, including hypertension, diabetes, obesity, and dyslipidemia.

METHODS: We performed a systematic review and meta-analysis. Our search strategy combined the themes “perception” and “social status”, searching PubMed, MEDLINE, EMBASE, CINAHL, PsycINFO, SocINDEX, Web of Science, and reference lists of included studies up to October 2014. Inclusion criteria included: 1) original studies in adults aged 18 years and over; 2) odds, risk, or hazard ratios between “lower” SSS groups and “higher” SSS groups reported for at least one outcome of interest (CAD, hypertension, diabetes, obesity, or dyslipidemia); and 3) SSS is measured on a self-anchoring ladder. Only observational (case-control, cohort, and cross-sectional) study designs were considered. Two reviewers independently assessed studies identified by the search strategy for inclusion into the systematic review. One reviewer extracted data, with a second reviewer corroborating data extraction for 20 % of included studies. Both reviewers independently assessed study quality for all studies. For studies reporting only stratified estimates, a single weighted odds ratio (OR) for each outcome of interest was derived. All ORs were transformed to be expressed per rung decrease on the SSS ladder. Using random-effects models, odds ratios across studies were pooled for each outcome. Stratified analysis and meta-regression were completed for subgroups representing different patient characteristics and study quality criteria. We assessed publication bias through visual inspection of funnel plots, Begg’s test, and through the trim and fill procedure for outcomes where funnel plots suggested visual asymmetry.

RESULTS: Our search strategy identified 7842 citations, 45 of which underwent full-text review, of which ten were included in the systematic review and meta-analysis. Nine studies had a cross-sectional design while one was a prospective cohort study. In analyses adjusted for demographics but not adjusted for objective SES measures, the pooled OR per rung decrease in SSS was 1.06 [95 % confidence interval (CI) 1.01, 1.12] for CAD, 1.06 [95 % CI 1.03, 1.10] for hypertension, 1.07 [95 % CI 1.02, 1.11] for diabetes, 1.14 [95 % CI 1.07, 1.21] for dyslipidemia, and 1.05 [95 % CI 0.99, 1.10] for obesity. The corresponding ORs comparing the bottom versus the top of the ten-rung SSS ladder for CAD, hypertension, diabetes, and dyslipidemia were 1.82 [95 % CI, 1.10, 2.99], 1.77 [95 % CI, 1.29, 2.44], 1.90 [95 % CI, 1.25, 2.87], and 3.68 [95 % CI, 2.03, 6.64] respectively. The associations were attenuated when adjusting for actual SES measures (income, education, and occupation), though all pooled ORs remained greater than 1.0; dyslipidemia was the only outcome to maintain statistical significance with an OR of 1.08 [95 % CI 1.01, 1.15] per rung decrease in SSS, or 2.10 [95 % CI 1.09, 4.06] when comparing the bottom to the top of the SSS ladder. Stratified meta-analysis revealed increased effect sizes for the outcomes of hypertension, diabetes, and obesity for studies with a predominantly Caucasian sample compared with studies without a predominantly Caucasian sample. Better quality studies, with adequate adjustment of non-SES confounders and lower risk of selection bias, reported greater effect sizes compared with lower quality studies. Meta-regression on the same variables did not however result in any significant *p*-values, likely due to being underpowered. There was no evidence of significant publication bias.

CONCLUSIONS: Lower SSS is associated with significantly increased odds of CAD, hypertension, diabetes, and dyslipidemia, and a trend toward increased odds of obesity. Though there is attenuation of these associations when adjusting for income, education, and occupation, the trend remains. Our findings provide further evidence that inequality in the socioeconomic hierarchy may have adverse health effects, not only through objective SES factors and material deprivation, but also through perceptions of social standing. Though there is likely substantial overlap between SES and SSS constructs, they appear to be distinct concepts; further understanding of this complicated relationship and their individual and combined effects on health are needed.

ASSOCIATION OF EATING HABITS WITH WEIGHT LOSS AND DIET SELF-MONITORING IN AN ONLINE WEIGHT LOSS TRIAL: RESULTS FROM THE OCELOT-PC STUDY Bethany Scanlan; Kathleen M. McTigue; Li Wang; Daniel Winger; Molly B. Conroy. University of Pittsburgh, Pittsburgh, PA. (*Tracking ID #2198139*)

BACKGROUND: Traditional, in-person weight loss interventions have emphasized rigorous self-monitoring of daily energy intake to help achieve weight loss. Additionally, studies have shown long-term weight loss and maintenance to be associated with decreased eating in restaurants and snacking, and decreased consumption of fried foods, desserts, sweetened beverages, and high-fat dairy products. With the growth of online resources and interventions, it is important to determine if similar associations are found in the setting of an online weight loss intervention done in coordination with primary care.

METHODS: The Online Counseling to Enable Lifestyle-focused Obesity Counseling in Primary Care (OCELOT-PC) study is an online adaptation of the Diabetes Prevention Program. We recruited 373 primary care patients. Two hundred fifty-seven were randomized to a 12-month structured, online intervention while the remaining patients had access to online group resources (OGR) alone. The online intervention included lessons, weight, diet, and physical activity self-monitoring, and feedback from a coach. Diet self-monitoring was done for both total daily calories and fat grams. Physical measures including weight and diet habits were measured at baseline, 6 months, and 1 year. Diet habits were assessed using a version of the previously validated Connor Diet Habit Survey. This survey provides scores for Meat, Dairy, Fats/Oils, Sweets/Snacks, Grains/Fruits/Vegetables, Beverages, Restaurants, and Seafood. Self-monitoring data was available from intervention participants only and was measured objectively by assessing participant entries into the online program. Changes in diet scores of all participants who achieved $\geq 5\%$ weight loss at 1 year were compared to those that did not achieve 5% weight loss using Mann-Whitney U test. For intervention participants, diet score changes of those who were self-monitoring diet at 1 year were compared to those who were not self-monitoring using Mann-Whitney U test.

RESULTS: Two hundred fifty-four participants had 1 year weight and Connor Diet Habit Survey data available for analysis (mean age 50 years old, 76 % female, 78.1 % white, mean BMI of 37.8 kg/m²), including 166 intervention participants who also had self-monitoring data available. Connor Diet Habit Survey scores at baseline were corresponded to a diet of 30–37 % fat. At 1 year, participants that had $\geq 5\%$ weight loss (*n*=78) had statistically significant greater improvements in their diet scores in Meat (2.8 vs. 1.2; *p*=0.001), Dairy (3.9 vs. 1.9; *p*<0.001), Fats/Oils (4.0 vs. 1.5; *p*<0.001), Sweets/Snacks (1.8 vs. 0.7; *p*=0.005), Beverages (1.0 vs. 0; *p*=0.002), and Restaurants (3.0 vs. 1.0; *p*<0.001), compared to those who lost less than 5 % or gained weight (*n*=176). Intervention participants that did self-monitor diet at 1 year (*n*=35) showed greater improvements in Meat (3.7 vs. 1.7; *p*=0.005), Dairy (4.3 vs. 2.3; *p*=0.04), and Fats/Oils scores (4.0 vs. 2.0; *p*=0.02) at 1 year compared to those that did not self-monitor (*n*=131).

CONCLUSIONS: Weight loss was associated with improvements in various dietary components, corresponding to a reduction in total calories consumed as well as healthier food choices. Additionally, diet self-monitoring was associated with improvements in eating habits, particularly in categories such as meat and dairy where foods tend to be higher in fat. While it is not possible to assess the self-monitoring component of the intervention apart from the other intervention components, our results suggest that online tools to monitor fat and calories may help primary care patients achieve weight loss goals.

ASSOCIATION OF MEDICAL STUDENT EMPATHY WITH CLINICAL COMPETENCE Rachel S. Casas; Lorraine Stanfield; Nanette Harvey; Angela Jackson; Daniel Chen. Boston University School of Medicine, Boston, MA. (*Tracking ID #2180666*)

BACKGROUND: Empathy is a crucial component of physician-patient interactions, and evaluating this skill is integral to medical education. Prior research has shown that empathy scores of medical students are associated with grades in core clerkships but not the Medical College Admissions Test (MCAT) or the United States Medical Licensing Examinations (USMLE) Step exams. Additionally, prior studies have shown conflicting associations between empathy scores and Objective Structured Clinical Examinations (OSCEs). No prior studies have evaluated all of these measures of clinical competence in the same cohort of students or evaluated if empathy scores early in medical school are predictive of later clinical performance. We hypothesized that empathy scores would be positively associated with OSCE and core clerkship performance but not standardized test scores.

METHODS: This longitudinal, cohort study compared clinical competence and empathy scores of 265 first year and 590 third year medical students enrolled at the Boston University School of Medicine from 2007 through 2010. Self-reported empathy scores were collected through the Jefferson Scale of Physician Empathy (JSPE) - Student Version, a validated, 20-item tool with higher scores corresponding to higher empathy (score range 20 to 140). Measures of clinical competence included grades from core third year clinical clerkships, third year OSCEs, and national standardized tests (MCAT and USMLE Step exams 1, 2 CS, and 2 CK). Data analysis was completed with JSPE score as a predictor for categorical outcomes using logistic regression and for continuous outcomes using linear regression. The associations between JSPE scores and grades were also evaluated with multiple regression analysis to control for demographic variables.

RESULTS: First year medical students were of median (IQR) age 23 (3) years, had a median (IQR) empathy score of 117 (15), and were 53 % percent female. Empathy scores of medical students in their third year were associated with higher performance in OSCEs and lower performance on Step 1, but were not associated with other standardized test or core clerkship grades. The relationship between third year empathy and OSCE score remained significant when controlling for age, gender, debt, and future career interest. Empathy scores in the first year of medical school were negatively associated with MCAT scores and not predictive of OSCE, Step 1, or Step 2 CK scores. The relationship between first year empathy and MCAT scores did not remain significant when controlling for demographic factors. Regression analysis for first year empathy scores and Step 2 CS or clinical clerkships could not be completed due to the limited number of students who failed these evaluations.

CONCLUSIONS: Self-reported empathy scores in the third year of medical school are associated with higher performance on OSCEs but not standardized tests or clinical clerkship grades. Further research is needed to determine if tools like the JSPE are useful in identifying medical students needing early intervention to improve communication skills.

ASSOCIATION OF PHYSICIANS' FINANCIAL RELATIONSHIPS WITH PHARMACEUTICAL COMPANIES AND THEIR LIPID-LOWERING MEDICATION PRESCRIBING PATTERNS James S. Yeh^{1,2}; Jessica M. Franklin^{1,2}; Jerry Avorn^{1,2}; Joan Landon^{1,2}; Aaron Kesselheim^{1,2}. ¹Brigham and Women's Hospital, Boston, MA; ²Harvard Medical School, Boston, MA. (Tracking ID #2196307)

BACKGROUND: Physicians' financial relationships with pharmaceutical companies have long been controversial. These relationships can consist of receipt of industry-sponsored meals, money for continuing medical education (CME) activities, reimbursements for consulting and participation on speaking bureaus, grants, and payments for education and training. Numerous small studies and surveys suggest that these financial relationships affect prescribing practices, but many physicians and policymakers remain unconvinced. Using a comprehensive Massachusetts medical conflicts of interest database and a prescription claims database, we sought to evaluate the association between physicians' financial relationships and their prescribing of brand-name versus generic cholesterol-lowering medications.

METHODS: We manually linked Medicare prescription claims data prepared by the Centers for Medicare and Medicaid Services relating to Massachusetts physicians with the Massachusetts physician open-payment database from 2011. The exposure variable was the listing of physicians' financial relationship and outcome measurement was physicians' prescribing of any brand-name-only cholesterol-lowering medication. The analysis was limited to physicians who had at least 50 claims of a particular drug. We used chi-square and ANOVA tests to analyze the association between the intensity of physician-industry relationships (determined by monetary value of payments) and physicians' prescribing practices. We used logistic regression model to determine the relationship between the types of physician-industry relationships and their brand-name prescribing behavior.

RESULTS: Our analysis included 2444 physicians. Approximately one-third (899, 37 %) had some sort of financial relationship with a pharmaceutical company, while 63 % (1546) had no industry payments in 2011. The most common payment type was for company-sponsored meals (639, 71 %), followed by grants (458, 51 %), consulting and speaking bureau (236, 26 %), and educational training grants (95, 11 %). Compared to physicians without pharmaceutical company payments, physicians in the top quartile of total value of payments (>\$1188) had higher rates of brand-name cholesterol-lowering medication prescriptions (21 % versus 18 %, $p<0.01$). When physicians were categorized by quartiles based on their rates of brand-name prescribing, there was a significant positive relationship between the average total monetary value of drug company payments (\$3696, \$1419, \$701, and \$542, $p<0.01$) and brand-name prescribing percentage (39 %, 19 %, 10 %, and 4 %, $p<0.01$), respectively. Among physicians who received pharmaceutical company payments, educational training payments were significantly associated with increased brand-name prescribing (18 % versus 22 %, $p<0.01$), but the other payment types were not.

CONCLUSIONS: Physicians who have financial relationships with pharmaceutical companies have higher brand-name cholesterol-lowering medication prescribing than physicians who do not have such relationships. The rate of brand-name prescribing was associated with the intensity of physician-industry relationships measured by the total value of monetary payments. The receipt of educational training payments may be a significant predictor of brand-name prescribing. The study findings only apply to physicians prescribing substantial numbers of cholesterol-lowering medication each year and may be limited by the integrity of pharmaceutical companies' self-reporting of physician payments.

ASSOCIATION OF THE BUILT ENVIRONMENT AND NEIGHBORHOOD RESOURCES WITH OBESITY-RELATED HEALTH BEHAVIOR Natalie N. Albanese¹; Jennifer P. Friedberg^{1,3}; Andrew Rundle⁴; James Quinn⁴; Kathryn Neckerman⁴; Stuart R. Lipsitz²; Sundar Natarajan^{3,1}. ¹New York University Medical Center, New York, NY; ²Northwestern University, Boston, MA; ³VA New York Harbor Healthcare System, New York, NY; ⁴Columbia University, New York, NY. (Tracking ID #2199242)

BACKGROUND: The neighborhood may influence obesity-related health behaviors. In this project, we evaluated associations between neighborhood characteristics and physical activity, dietary intake, and body mass index (BMI) in high-risk patients with uncontrolled hypertension.

METHODS: Person-level data were collected at baseline from 533 veterans with uncontrolled hypertension participating in a randomized controlled trial. The two neighborhood measures were census tract level Walkability, measured using built environment features that promote walking (components were z-scored and summed to create tertiles), and healthy food proximity (HFP), a 0–100 score reflecting proximity of grocery stores and farmers' markets. The exercise outcomes were: number of hours of exercise per week (continuous), assessed using the 7-day Physical Activity Recall (PAR); exercise adherence (dichotomous), designated as aerobic activity ≥ 3 days/week from PAR; and Stage of Change (SOC) for exercise (dichotomous), using valid measures. The diet outcomes were: adherence to saturated fat and total fat intake recommendations (continuous), measured by an adherence index (0–10) with 10 being maximal adherence using the Willett Food Frequency Questionnaire (FFQ); and Stage of Change (SOC) for DASH diet (dichotomous). The obesity measure was BMI. Robust or logistic regression (adjusting for age, race, education) clustered by provider were used to evaluate the association between the neighborhood measures (Walkability and HFP) and the exercise, diet, or BMI outcomes.

RESULTS: There was a positive association between Walkability and increased adherence to dietary recommendations for fat intake; for each tertile increase in Walkability, there was a 1.02-point increase in the saturated fat adherence index (95 % CI: 0.03, 2.02, $p=.04$) and a 0.84-point increase in the total fat adherence index (95 % CI: 0.23, 1.44, $p=.007$). Patients in the highest Walkability tertile were also 75 % more likely to be in the Action or Maintenance SOC for exercise than those in the lowest Walkability tertile (OR 1.75, 95 % CI: 1.14, 2.69, $p=.01$). Walkability was negatively associated with BMI, with each tertile increase in Walkability being associated with 1.13 decrease in BMI (95 % CI: -2.04, -0.23, $p=.01$). HFP was positively associated with increased exercise duration, with each point increase in HFP being associated with 0.63 additional hours of exercise (95 % CI: 0.047, 1.22, $p=.03$). Patients in the highest HFP tertile were also 66 % more likely to be adherent to exercise recommendations (OR 1.66, 95 % CI: 1.01, 2.75, $p=.05$), and 67 % more likely to be in Action or Maintenance SOC for exercise (OR 1.67, 95 % CI: 1.10, 2.52, $p=.01$) compared to those in the lowest HFP tertile. There was also a positive trend between HFP and increased dietary adherence to saturated fat, such that each point increase in HFP was associated with a 0.84 increase in saturated fat adherence index (95 % confidence interval [CI]: -0.11, 1.79, $p=.08$). There were no significant associations between neighborhood measures and SOC for DASH diet.

CONCLUSIONS: Neighborhood is associated with people's eating and exercise habits. Environmentally-tailored health recommendations and interventions may lead to healthier lifestyles and potentially decrease obesity rates.

ASSOCIATIONS BETWEEN MENTAL HEALTH BURDEN, SMOKING AND CARDIOVASCULAR DISEASE IN WOMEN VETERANS OVER 45 Megan R. Gerber^{1,4}; Matthew King^{3,4}; Suzanne Pineles^{3,4}; Katherine Iverson^{3,4}; Sally G. Haskell². ¹Boston University, Jamaica Plain, MA; ²Yale University, VA CT; and VA Central Office, Madison, CT; ³VA Boston Healthcare System, Jamaica Plain, MA; ⁴Boston University School of Medicine, Boston, MA. (Tracking ID #2198075)

BACKGROUND: Understanding the health and health care needs of aging Veterans is a key priority of the Veterans Health Administration (VHA). Currently, women Veterans (WV) aged 45–64 represent the highest proportion of female VHA users. WV experience significant mental health (MH) burden. MH and race are known risk factors for cardiovascular disease (CVD), but the impact of increasing MH burden on CVD for WV has not been described. Our study aims were to 1) determine which MH conditions have the strongest association with CV disease, and 2) quantify the impact of increasing MH burden on CV disease in WV over age 45. A secondary aim was to report smoking prevalence in this group.

METHODS: VHA National Patient Care Data (2009) were used to identify women Veterans over age 45. ICD-9-CM codes were used to categorize medical and psychiatric conditions. MH diagnoses examined were: alcohol and drug use, psychotic, bipolar, depressive, anxiety, somatization, eating disorders and PTSD. Smoking data was culled

from clinical reminder data. We used stepwise logistic regression (LR) modeling to identify MH predictors of CVD, adjusting for age, race and smoking. Analyses were conducted using R statistical software.

RESULTS: One hundred fifty-seven thousand one hundred ninety-five WV were identified, their mean age was 59.4 years (SD 12.2, range 46–110). The majority (61 %) of the sample was white. Thirty-six percent reported current smoking and 19 % were past smokers. The majority of WV (69 %) had no mental health diagnosis, 18 % had one, and 12 % carried two or more. Logistic regression analyses (Table) demonstrated that depression, anxiety and psychotic disorder were the strongest mental health predictors of CVD.

CONCLUSIONS: Controlling for age, race and current smoking, each MH diagnosis increased CVD odds by 54 % in WV over age 45. Depression had the strongest association with CV disease, with higher odds than those for smoking. Tobacco use is prevalent among women Veterans over 45; a strength of this study was use of clinically-derived smoking data. The study findings are limited, however, by lack of information on psychiatric medication. In summary, interventions to reduce CVD among older WV must take into account MH comorbidity, and efforts at addressing smoking cessation in this population are critical. With its primary care-mental health integration model, VHA is well-positioned to improve medical outcomes for WV with MH comorbidity. To optimize the health of older WV with co-morbid MH conditions, future trials of multidisciplinary interventions to reduce CVD risk and smoking are warranted.

Adjusted stepwise logistic regression: diagnoses associated with CV disease

MODEL 1

Control variables (% sample)	OR [95 % CI]
Age	1.06 [1.06, 1.06]
Race Black (25 %)	1.02 [0.95, 1.10]
Race Hispanic (6 %)	0.54 [0.45, 0.63]
Current smoker (36 %)	1.61 [1.51, 1.71]
Past smoker (19 %)	1.15 [1.08, 1.23]

MH Diagnoses

Depression (21 %)	1.82 [1.71, 1.94]
Anxiety (7 %)	1.30 [1.18, 1.42]
Psychotic Disorder (5 %)	1.30 [1.18, 1.43]

MODEL 2 *

MH diagnosis count (0–3)	1.54 [1.48, 1.60]
--------------------------	-------------------

* Adjusted for age, race, smoking, substituted MH diagnosis count for individual diagnoses.

ASSOCIATIONS BETWEEN SOCIAL MEDIA USE AND DEPRESSIVE SYMPTOMS AMONG US YOUNG ADULTS Liu yi Lin²; Ariel Shensa²; Jason Colditz²; Ana Radovic³; Elizabeth Miller¹; Beth Hoffman²; Brian A. Primack². ¹Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA; ²University of Pittsburgh, Pittsburgh, PA; ³Children's Hospital of Pittsburgh, Pittsburgh, PA. (Tracking ID #2198215)

BACKGROUND: Over the last decade, use of social networking sites (SNSs) such as Facebook have and revolutionized the way people interact and communicate. Nearly all (90 %) of young adults use SNSs, and the majority of users visit these sites at least once daily. The association between social media use and depression is unclear. Some studies suggest that social media users may experience an increase in social connectedness and a related decrease in emotional health problems. Other studies, however, suggest that frequent use of social media may be associated with declines in subjective well-being, life satisfaction, and real-life social community. Prior studies have been limited by use of small, localized samples. In addition, they have tended to focus on one specific platform, Facebook, while real-life usage, especially among young adults, has broadened to include use of multiple other platforms such as Twitter, Google+, Instagram, Tumblr, Snapchat, and Vine. Therefore, the purpose of our study was to determine independent associations between social media use across multiple platforms and depressive symptoms in a large, nationally-representative sample of young adults.

METHODS: We surveyed a nationally-representative sample of the US population between the ages of 18 to 30 regarding social media use and depressive symptoms. We recruited participants via random-digit-dialing and address-based sampling frames representing over 97 % of the US population. Participants responded to online surveys over a 1-month period in October–November of 2014. We assessed our independent variable, social media use, in three different ways, including self-reported total time spent with online social networks per day, average number of social network site visits per week, and responses on a global frequency scale that was adopted from the Pew Internet Research Questionnaire. Each of these latter two scales prompted participants regarding the most commonly used 11 SNSs and combined response data. Our primary dependent

variable was depressive symptoms as measured by the brief Patient-Reported Outcomes Measurement Information System (PROMIS) depression scale. The scale consisted of 4 items, each of which was assessed on a 5-point Likert scale. Based upon the distribution of data, scale values were collapsed into tertiles for primary analyses. We used ordered logistic regression with sample weights to assess multivariable associations between SNS use and depression and while controlling for relevant socio-demographic, personal and environmental factors. We developed separate models for each of the methods of assessing the independent variable (SNS use). All ordered logistic regression models satisfied the required proportional odds assumption.

RESULTS: Our sample of 1781 participants was 61.8 % female, 64.1 % Caucasian, 10.0 % African American, 16.6 % Hispanic and 9.3 % of mixed or other race. Our primary fully-adjusted multivariable models included all covariates, including age, sex, race and ethnicity, relationship status, living situation, household income, and education level. These analyses demonstrated that, compared to those in the lowest quartile for total time on SNS use per day, participants in the highest quartile had increased odds of having greater depressive symptoms (AOR=1.66, 95 % CI=1.14, 2.42). Results were also significant for each of the other independent variables. In particular, compared with those in the lowest quartiles, those in the highest quartiles of SNSs visits per week (AOR=2.74, 95 % CI=1.86, 4.04) and the global frequency scale (AOR=3.05, 95 % CI=2.03, 4.59) reported greater depressive symptoms. All associations between independent variables and depressive symptoms demonstrated strong, linear, dose-response trends ($P<.001$ for all). Results were robust to all sensitivity analyses.

CONCLUSIONS: Regardless of the particular method of operationalizing the variable of SNS use, we found a strong, linear, and significant association between SNS use and depressive symptoms, even after controlling for multiple relevant socio-demographic variables. Importantly, the cross-sectional design of this study inhibits our ability to infer directionality of this association. For example, while it could be that depressed individuals seek out social networking sites, it may also be that those who frequent social networking sites develop depressive symptoms. Other researchers have suggested that this latter explanation may result from frequent exposure to idealized, non-realistic images and messages from “friends” to which end-users may feel inferior. Longitudinal studies may help to tease out this directionality. Regardless of directionality, however, this study highlights an important association, especially given the increasing prevalence of SNS use and the substantial morbidity associated with depression. It also suggests that it may be valuable to use SNSs to identify individuals at risk for mood disorders.

ASSOCIATIONS BETWEEN SOCIAL MEDIA USE AND EATING DISORDER RISK AMONG US YOUNG ADULTS Jaime Sidani; Ariel Shensa; Mercy Baffour; Beth Hoffman; Brian A. Primack. University of Pittsburgh, Pittsburgh, PA. (Tracking ID #2198304)

BACKGROUND: Eating disorders represent a growing public health concern, especially among female young adults in developed nations. Prevalence estimates in the U.S. are approximately 0.8 % for anorexia nervosa (AN), 2.6 % for bulimia nervosa (BN), 3 % for binge eating disorder (BED), and 11.5 % for Feeding or Eating Disorder Not Elsewhere Classified (FEDNEC). Although the etiology of eating disorders is multi-factorial, exposure to media portrayals of idealized bodies is considered to be a significant contributor. While traditional media, such as television and magazines, have been examined extensively in relation to eating disorder risk, the influence of social media has received relatively less attention. Considering the proliferation of social media platforms and their popularity with the young adult population, investigation into their potential association with eating disorders should be examined. Therefore, we conducted a large scale, nationally representative study to assess associations between social media use and eating disorder risk among US young adults.

METHODS: We collected web-administered survey data from 1765 young adults who were part of a national probability-based online non-volunteer access panel randomly selected to participate in a study of health behaviors. For this study, we developed a composite 5-item eating disorder risk scale with items adapted for this population from two validated measures: the SCOFF Questionnaire and the Eating Disorder Screen for Primary Care (ESP). Each item was assessed on a 5-point Likert scale. We performed a factor analysis to assess the underlying structure of these items. The total scale ranged from 0 to 25 with higher numbers indicating greater eating disorder risk. Based on the distribution of this variable, eating disorder risk was subsequently collapsed into quartiles for analyses. Participants' social media use was assessed in three ways. First, participants were asked to self-report total time per day using social media. Second, we estimated total average social media visits per week based on responses to self-report items. Finally, we used a global frequency scale based on a Pew Internet Research item which assessed use of each of the most commonly used 11 social media platforms. To assess independent associations between social media use and eating disorder risk, we used ordered logistic regression while controlling for socio-demographic variables including age, sex,

race/ethnicity, relationship status, living situation, household income, and maternal education.

RESULTS: Our sample was 62 % female, 64 % Caucasian non-Hispanic, 10 % African-American non-Hispanic, 17 % Hispanic, and 9 % of mixed or other race. Factor analysis suggested that the 5 eating disorder risk items represented one underlying construct. These items were also internally consistent (Cronbach's $\alpha=0.81$). Results from fully-adjusted multivariable ordered logistic regression models indicated that increased social media use was significantly associated with increased odds of greater eating disorder risk. This was true for each of the 3 different methods of measuring social media use. In particular, compared with those in the lowest quartile, those in the highest quartile for each social media use variable had significantly greater odds of having increased eating disorder symptoms, with AORs of 2.05 (95 % CI=1.43, 2.94) for total minutes per day, 2.75 (95 % CI=1.89, 4.02) for average visits per week, and 3.39 (95 % CI=2.34, 4.91) for the global frequency scale. As required for ordered logistic regression, the proportional odds assumption was met for each model.

CONCLUSIONS: These findings suggest that individuals with greater use of social media are at greater odds of being at increased risk for eating disorders, even when controlling for multiple relevant socio-demographic variables. Second, these associations were consistent regardless of how social media use was measured, suggesting robustness of findings. However, it is noteworthy that these cross-sectional data cannot disentangle directionality. In particular, while it may be that individuals with eating problems seek out information on social media, it may also be that those exposed to social media subsequently develop eating concerns. Future longitudinal examinations will be helpful to determine directionality of these associations. In either case, however, it is useful to know that social media may be a particularly valuable medium to reach individuals at risk for eating disorders.

ASSOCIATIONS BETWEEN SOCIAL MEDIA USE AND PERCEIVED EMOTIONAL SUPPORT AMONG A NATIONALLY-REPRESENTATIVE COHORT OF YOUNG ADULTS Ariel Shensa¹; Jaime Sidani¹; Jason Colditz²; Zhongying Xu¹; Kaleab Abebe¹; Liu yi Lin²; Brian A. Primack¹. ¹University of Pittsburgh, Pittsburgh, PA; ²University of Pittsburgh School of Medicine, Pittsburgh, PA. (Tracking ID #2198738)

BACKGROUND: Decreased emotional support has been associated with poor physical health, poor mental health, and increased mortality. With the explosion of Internet and social media use, opportunities for connectedness and support have become more complex. From 2005 to 2013, the percent of adults ages 18–29 who use social media increased from 9 to 90 %, with over 74 % of all online adults now reporting some social media use. Leveraging this ubiquitous medium may be helpful in increasing opportunities for emotional support related to health conditions. For example, social media platforms may help connect people with shared conditions, facilitating support groups and sharing of information. However, it is not known whether overall social media use is associated with increased emotional support for a general population of users. Therefore, the purpose of this study was to assess associations between social media use and perceived emotional support in a large, nationally-representative population.

METHODS: We collected survey data from a nationally-representative sample of 1796 young adults ages 18–30 recruited via random-digit-dialing and address-based sampling methods from October to November 2014. We assessed our independent variable, social media use, in three different ways, including self-reported total time spent with online social networks per day, average number of social network site visits per week, and responses on a global frequency scale adopted from the Pew Internet Research Questionnaire. Each of these latter two scales prompted participants regarding the most commonly used 11 social networking sites (e.g., Facebook, Twitter, Instagram, Tumblr, and Reddit) and combined response data. Our primary dependent variable was emotional support as measured by the brief Patient-Reported Outcomes Measurement Information System (PROMIS) emotional support scale. The scale consisted of 4 items, each of which was assessed on a 5-point Likert scale. Based upon the distribution of data, scale values were dichotomized into those with low vs. high emotional support. Subsequently, we used logistic regression with sampling weights to assess multivariable associations between social media use and emotional support. Our primary models controlled for all relevant socio-demographic variables, including age, sex, race and ethnicity, relationship status, living situation, household income, and education level.

RESULTS: Our sample of 1785 individuals was 62 % female, 64 % Caucasian and non-Hispanic, 10 % African-American and non-Hispanic, 17 % Hispanic,

and 9 % of mixed or other race. Just over half (58 %) of respondents reported being in a committed relationship and 41 % reported that they lived with a significant other. A multivariable model including all measured covariates demonstrated that being in the highest quartile of total minutes per day of social media use was significantly associated with decreased odds of having high perceived emotional support (AOR=0.62, 95 % CI=0.40, 0.94). A second fully adjusted model demonstrated that being in the highest quartile of social media use on the global frequency scale was also significantly associated with decreased odds of having high perceived emotional support (AOR=0.60, 95 % CI=0.38, 0.94). However, being in the highest quartile for social media visits per day was not significantly associated with decreased odds of having high perceived emotional support (AOR=0.70, 95 % CI=0.45, 1.09), although the point estimate was below 1. Tests for trend demonstrated significant linear dose–response relationships for independent variables of total social media time ($P=.019$) and the global frequency scale ($P=.011$), but not for the number of visits per week ($P=.17$).

CONCLUSIONS: Participants in the highest quartiles of two different social media use frequency measures had significantly decreased odds of reporting higher levels of perceived emotional support. A third independent variable, which quantified social media visits per week, was associated with a lower point estimate for perceived emotional support but was non-significant. These results suggest that, while we might expect individuals who engage in frequent social media to feel more emotional support, it seems that heavy users may actually feel less emotional support. However, it should be emphasized that the cross-sectional nature of these data hinders our ability to infer directionality. In particular, while it may be that individuals with low emotional support tend to increase their social media use to compensate, it may also be that individuals who start to use increased social media ultimately feel less true emotional support and connection. Longitudinal analyses may help assess directionality of these findings. In either case, however, these findings are notable not only because of known associations between low emotional support and poor health outcomes but also because of the rapid rise in social media use among nearly all US adults.

AST: A SIMPLIFIED TOOL FOR MANAGING ALCOHOL WITHDRAWAL Samuel B. Holzman; Darius Rastegar. Johns Hopkins University, Baltimore, MD. (Tracking ID #2148096)

BACKGROUND: Alcohol withdrawal syndrome (AWS) is a common and potentially serious medical problem. The standard of care is symptom-triggered dosing of benzodiazepines. The “gold standard” for monitoring withdrawal is the Revised Clinical Institute Withdrawal Assessment Scale (CIWA-Ar), which is a 10-item scale that can take up to 5 min to complete. There have been efforts to develop simpler scales; a recent one is the Glasgow Modified Alcohol Withdrawal Scale (GMAWS), a 5-item scale reported to perform well in a previous report.

METHODS: This project took place in the Johns Hopkins Bayview Medical Center Chemical Dependence Unit in Baltimore, Maryland. Initially, the GMAWS was piloted and compared with CIWA-Ar. Based on initial evaluation of the GMAWS and nursing feedback, the “Anxiety Sweats Tremor” scale (AST) was developed by removing 2 of the 5 items that were rarely used and expanding the scoring range from 0–2 to 0–3. The AST was then piloted and compared with simultaneous CIWA-Ar scores. Internal consistency of each test was measured by Cronbach's alpha and the adequacy of AST in predicting CIWA-Ar ≥ 8 (the cutoff for treatment) was assessed by Receiver Operator Characteristics (ROC) curve.

RESULTS: In the initial phase, the mean CIWA-Ar score was 5.3 and GMAWS 2.0. The internal consistency of CIWA-Ar and GMAWS were both poor, with Cronbach's alpha scores of 0.46 ($N=156$) and 0.41 ($N=156$) respectively. The internal consistency of our modified AST scale was significantly better with a Cronbach's alpha of 0.68 ($N=176$) and good corrected item-total correlation (>0.4 for all components). AST was effective in identifying individuals with CIWA-Ar ≥ 8 with an area under the ROC curve (AUC) of 0.83 (95 % CI 0.77–0.89), compared to 0.8 (95 % CI 0.74–0.88) seen with GMAWS. An AST score of ≥ 3 (out of a possible 9) predicted CIWA-Ar ≥ 8 with a sensitivity of 93 % and specificity of 63 %, while the GMAWS operated with a sensitivity and specificity of 98 and 39 %, respectively, based on previously defined cutoffs.

CONCLUSIONS: Our simplified scale, AST, easily remembered by the transaminase elevated in acute alcoholic hepatitis, measures withdrawal based on three domains: anxiety, sweat and tremor. Overall, the scale performed well, demonstrating good internal consistency and reliably identified individuals experiencing significant withdrawal based on CIWA-Ar scores. Its operating characteristics were at least as good as GMAWS, with an improved specificity, and benefited from a simpler and more streamlined design.

Table 1. Comparison of Alcohol Withdrawal Scales

	CIWA	GMAWS	AST
Number of observations	156	156	176
Number of items	10	5	3
Range for each item	0–7*	0–2	0–3
Maximum score	67	10	9
Score triggering drug administration	≥8	≥1 ¹	≥3 ²
Sensitivity	–	98 %	93 %
Specificity	–	39 %	63 %
Mean score (SD)	5.3 (2.6)	2.0 (1.0)	2.9 (1.7)
Range	0–13	0–5	0–7
Cronbach's alpha	0.46	0.41	0.68

CIWA=Revised Clinical Institute Withdrawal Assessment Scale

GMAWS=Glasgow Modified Alcohol Withdrawal Scale

AST=Anxiety, Sweat, Tremor

*One item is scored 0–4.

ATTITUDES ABOUT LUNG CANCER SCREENING AMONG PRIMARY CARE PROVIDERS Dhvani Doshi; Alexandra Rosenberg; Juan P. Wisnivesky; Jenny Lin. Icahn School of Medicine at Mount Sinai, New York City, NY. (Tracking ID #2196761)

BACKGROUND: Lung cancer screening has been shown to reduce lung cancer mortality among high risk smokers but is also associated with many false positives results which may trigger lengthy and invasive evaluations. Primary care providers (PCPs) will be responsible for implementing current recommendations for screening. However, there is limited information regarding their attitudes about lung cancer screening.

METHODS: PCPs practicing at an academic hospital in New York City were surveyed anonymously about their knowledge of and attitudes toward lung cancer screening guidelines and the likelihood they would recommend lung cancer screening to their patients. The survey items were developed based on findings of a multidisciplinary focus group. Descriptive and univariate analyses were used to assess differences in attitudes about lung cancer screening between PCPs who reported they would be likely to order screening CT scans vs. those who would not be likely to screen.

RESULTS: A total of 69 surveys were completed. Of the respondents, 40 % were attendings, and 67 % were female. Almost all PCPs were familiar or very familiar with USPSTF guidelines for breast cancer (99 %), cervical cancer (94 %), or colon cancer (99 %) screening compared with only 53 % reporting familiarity with lung cancer screening guidelines. Most PCPs reported ordering breast, cervical, and colon cancer screening tests for >75 % of their eligible patients compared to ordering CT screening for <25 % of their eligible smokers. Three-quarters (81 %) of PCPs were concerned about not being able to order chest CTs due to insurance reasons, 48 % were concerned about the overall healthcare dollars associated with screening, but only 9 % felt that lung cancer screening was not cost effective. Only 28 % of PCPs believe that the recommended yearly screening interval is feasible and less than 15 % felt they have sufficient time to counsel patients about CT scan screening. An overwhelming majority (≥90 %) worried about incidental findings associated with CT screening or about the number of follow up procedures resulting from positive results, and all (100 %) believed that positive screening results can cause distress to patients. Most PCPs (64 %) were confused about how to apply lung cancer screening guidelines for patients with multiple comorbidities and only half (52 %) felt confident in their abilities to decide on the workup of patients with positive CT findings. PCPs who reported they would be very likely to order a screening CT scan in the next year for their high-risk smokers were more likely to be familiar or very familiar with screening guidelines (91 % vs. 46 %, $p=0.01$), to be confident in their ability to decide on the workup of patients with positive CT findings (82 % vs. 47 %, $p=0.03$), and to state that they were able to identify the appropriate patients for lung cancer screening (100 % vs. 56 %, $p=0.01$).

CONCLUSIONS: While most PCPs agree that lung cancer screening with low-dose CT scans for high risk smokers is cost effective, many are still not familiar with the USPSTF lung cancer screening guidelines. Multiple barriers such as concerns about insurance coverage, frequency of recommended screening intervals, time needed for counseling patients and concerns about consequences of positive screening results may limit PCPs

from ordering screening chest CTs. PCPs clearly need further education and support to improve lung cancer screening.

BARRIERS TO GREATER CIVIC ENGAGEMENT AMONG PHYSICIANS James M. Kuo; Tara F. Bishop. Weill Cornell Medical College, New York, NY. (Tracking ID #2194095)

BACKGROUND: Professional organizations, scholars, and leaders argue that it is a privilege and responsibility for physicians to be active members of their communities through civic engagement to influence the social determinants of health and increase public trust in the medical profession. However, a survey of US physicians found that 95 % rated community participation as important but only 54 % volunteered and 26 % participated in political involvement other than voting. Additionally, when controlling for socioeconomic factors, physicians are less likely to vote and volunteer than the general population. The objective of this study was to explore the types of civic activities physicians engage in and the barriers to and facilitators for physician participation.

METHODS: We performed a qualitative telephone interview study of physicians practicing in the community from a convenience sample through personal contacts. Our sample was limited to physicians who had completed training and provide at least 20 h per week of patient care. We used a semi-structured interview tool that focused on five topic areas: 1) definition and knowledge of civic engagement, 2) experience with civic engagement 3) reasons for not engaging in civic activities, 4) reasons for engagement in civic activities, and 5) views on civic engagement and professionalism. Transcripts were analyzed using the constant comparison method.

RESULTS: We interviewed 10 physicians and intend to interview 10 to 15 more. Participants to date were from 7 specialties and 6 states. Most viewed civic engagement as some combination of voting, volunteering, and advocacy. All viewed civic engagement favorably, but most saw it as something to be encouraged but not required. Interviewees participated in a variety of activities including advocating for healthcare issues, volunteering in the community, and donating money. Those who saw Medicaid or uninsured patients viewed these activities as a form of service. The most common barrier to greater participation was lack of time. Interviewees also stated that money was a factor and could not justify non-reimbursable activities. Some felt that they had inadequate training or expertise in advocacy or that their views were not valued by society. There was a significant group of interviewees who felt that seeing patients fulfilled any responsibility for civic engagement. One respondent felt that their compassion and empathy had already been consumed by her patients and that there was nothing left to give to their communities. A respondent cited liability fear while another cited fear of retaliation for advocating for reproductive rights. Facilitators of engagement included having a more established practice of patients and concomitantly working less hours.

CONCLUSIONS: In this qualitative study, we found that time and money were the most common reasons that physicians do not engage in civic activities. The nature of our study limits generalizability, but greater insight into physician views on civic engagement will allow the medical community to combat barriers to involvement to contribute to a more active and engaged populace of physicians that is better able to improve the health of their patients beyond the walls of the clinic.

BARRIERS TO PATIENT EMPOWERMENT AND SHARED DECISION-MAKING (SDM): HEALTHCARE PROVIDER (HCP) PERSPECTIVES Sarita Kundrod²; Joseph Plaksin²; Andrew B. Wallach¹; Sondra Zabar²; Lisa Altshuler²; Adina Kalet². ¹Bellevue Hospital, New York, NY; ²NYU School of Medicine, New York, NY. (Tracking ID #2198543)

BACKGROUND: Participation in shared decision-making (SDM) requires patients to ask questions, effectively communicate their values and preferences to healthcare providers (HCPs), and collaborate with HCPs to make medical decisions. Despite its benefits, many patients do not take a more active role in SDM because of desires to be a “good patient” and the difference in knowledge and power between patients and HCPs. We aim to develop a Patient Empowerment Program (PEP) that will address these barriers and allow patients to fully participate in SDM. However, the potential benefits of PEP could be limited by barriers to SDM from the HCP perspective, such as time constraints and misconceptions about patients' ability or willingness to participate in SDM. To examine how to overcome these potential barriers, we conducted a qualitative study to explore HCP 1) experiences with patients who have varying levels of empowerment, 2) opinions on the role of patients and HCPs in SDM, and 3) approaches to treating patients who are highly empowered.

METHODS: Internal Medicine faculty at two NYC public hospitals, NYU Primary Care residents, and 3rd-4th year NYU medical students with at least 1 year of experience on clinical rotations were invited via email to attend focus groups. The same interview

questions were asked at all levels of training and medical students were also asked about how their views had changed over the course of their core clinical rotations. All sessions were audio-recorded and transcribed by a professional company. Two independent coders reviewed one segmented transcript to develop a coding schema, then met to negotiate a finalized set of codes that were applied to the remaining transcripts. Dedoose software was used to assist with coding and thematic analysis.

RESULTS: A total of 38 participants attended the focus groups: 11 faculty, 16 residents, and 11 medical students. In order to protect the anonymity of participants, no demographic data was collected. Thematic analyses focus on characteristics of the ideal and difficult patient, the role of the HCP in SDM, and barriers to patient activation in the medical encounter. Across all levels of training, ideal patients were described as those who are prepared for their appointments and were knowledgeable about medical conditions, allowing the HCP to “focus on their medical issues...and also see progress” as well as those who “actually make efforts to participate in their care.” HCPs generally supported the idea of a PEP that helped patients achieve these goals. Difficult patients could be split into two broad categories. The first included patients who are non-English speaking or who HCPs perceive as not being empowered, such as those with poor social supports, serious psychological illnesses, or whose attitudes get in the way of their care, such as patients who perceive themselves as “victims: where everything bad that’s happening to them is because it’s somebody else’s fault.” The second category of difficult patients shares some characteristics with empowered patients; they believe they have a significant role in their care but they do not seem to value the knowledge and expertise of HCPs. Faculty and residents describe these patients as being entitled or “people who think they just walked into McDonald’s and they know what’s on the menu and they’re going to order it...they don’t really want to have any advice from [the HCP].” Medical students describe difficult patients who “have the information [about their labs or test results] but not what these values mean and then [they] make really incorrect assumptions” that are hard to dispel later. When discussing the role of the HCP in SDM, both faculty and residents believe that they “do many things that are not in their job description [in order to] get the patient’s health a little better.” Medical students echoed this sentiment, but were more surprised, saying “I didn’t think that physicians would even have to necessarily deal with all of this extra stuff,” which includes coordinating appointments and dealing with patients’ social issues. Systemic barriers to SDM included lack of time, difficulties navigating the system, and taking on additional roles due to limited support staff or limited trust in support staff.

CONCLUSIONS: HCPs across all levels of training considered more empowered patients ideal compared to less empowered patients. But they described patients who are “entitled” or have “too high of expectations” as difficult as well. These perspectives support the need for a PEP that helps equalize the power differential between HCPs and patients, while still valuing HCP expertise. HCPs also highlighted a number of systemic barriers that must be addressed, in addition to both HCP and patient barriers, in order to support opportunities for SDM.

BARRIERS TO PRIMARY ADHERENCE AT HOSPITAL DISCHARGE AMONG AN UNINSURED POPULATION IN NYC Alice Tang; Cassia Wells; Emily Milam; Michael Janjigian. New York University, New York, NY. (Tracking ID #2199177)

BACKGROUND: It is estimated that medication nonadherence increases healthcare costs by \$170 billion annually. While there is literature illustrating causes of secondary adherence—defined as correct use of medications as prescribed—there have been limited studies on primary adherence, or the act of filling initial prescriptions. Our study attempted to identify predictors of primary nonadherence upon hospital discharge among a cohort of uninsured patients. We investigated whether patient characteristics (homelessness, psychiatric comorbidities, limited English language proficiency and age), prescription characteristics (number and whether medications were essential or new) and/or system characteristics (discharge time and whether medications were faxed prior to discharge) predicted poor rates of primary adherence at hospital discharge.

METHODS: We conducted an observational, prospective cohort study examining primary nonadherence rates among uninsured patients discharged from a large, high-volume, urban public hospital. The hospital has a pharmacy dedicated to providing free medications to the uninsured upon discharge. Our primary outcome of interest was whether the patients discharged with new prescriptions picked up their medication(s) from the discharge pharmacy within 24 h of discharge. We collected data on patients admitted to a medical service from April to June 2014 at Bellevue Hospital Center in New York City. Patients with

insurance and those transferred to another facility were excluded. Patients who had medications delivered to the bedside were also excluded. Data was obtained through pharmacy records and chart review. Chi-squared and logistic regression analysis was used to determine significant predictors of nonadherence.

RESULTS: In total, 335 patients met inclusion criteria. Of this cohort, 66.6 % were male, 24.2 % had limited English language proficiency, 12.2 % were undomiciled, and 24.2 % had a psychiatric comorbidity. The average age was 48.7 (SD 14). Only 176 patients (52.5 %) picked up their discharge prescription(s) from the hospital pharmacy within 24 h, leaving 47.5 % with primary nonadherence. Of the prescriptions that were not picked up, 123 (77.4 %) were considered essential for the patient’s post discharge care, defined as necessary for ongoing treatment of medical conditions, the absence of which could predictably lead to poor clinical outcomes. Only 9 (5.6 %) of nonadherent patients had their prescriptions faxed to the pharmacy and only 32 (9.6 %) of all prescriptions were faxed within the optimal time frame for the pharmacy (prior to the day before discharge). The greatest predictor of primary adherence was whether the prescription was faxed in advance, with 91.5 % of patients picking up faxed prescriptions, compared to 34.5 % picking up those that had not been faxed ($p<0.0001$). Other significant predictors of adherence were time of discharge (67.4 % of patients discharged in the morning, 53.7 % in the afternoon and 35 % in the evening, $p=0.004$) and age group (46.5 % of those aged <39, 51.2 % aged 40–64 and 70.5 % in those aged >65, $p=0.029$). Patient characteristics such as race, gender, English language proficiency, number of medical comorbidities, psychiatric comorbidities, homelessness, and distance from the hospital did not prove to be significant predictors of adherence. The number of prescriptions or whether the medication was essential or new also did not significantly predict adherence.

CONCLUSIONS: Primary adherence is enhanced by timely delivery of prescriptions to the pharmacy prior to discharge and a discharge time earlier in the day. Providing advanced notice to the pharmacy and discharging patients earlier in the day decreases wait times and increases likelihood of primary adherence. This illustrates the importance of early discharge planning for hospitalized patients and coordination across multiple disciplines responsible for facilitating this transition in care. Apart from increased age, patient characteristics were not predictive of primary adherence. This may be a consequence of selection bias by inpatient providers, who could opt to provide bedside delivery of medications to patients they predicted would have difficulties navigating the hospital. Additional studies evaluating outcomes, such as re-hospitalizations or mortality, amongst this cohort of nonadherent individuals are necessary to establish the clinical and financial significance of these findings.

BENEFITS AND RISKS OF WARFARIN WITH AND WITHOUT ASPIRIN FOR PREVENTION OF STROKE IN CORONARY ARTERY DISEASE OR CEREBROVASCULAR DISEASE: A META-ANALYSIS Abhishek Deshpande²; Gaurav Alreja³; Krishna Patel²; Vinay Pasupuleti¹; Michael B. Rothberg². ¹Case Western Reserve University, Cleveland, OH; ²Cleveland Clinic, Cleveland, OH; ³Baystate Medical Center, Springfield, MA. (Tracking ID #2199136)

BACKGROUND: Options for secondary prophylaxis of non-embolic stroke are limited. Randomized controlled trials (RCTs) evaluating warfarin with or without aspirin to prevent stroke have yielded mixed results. We conducted a meta-analysis of RCTs to evaluate the benefits and risks of warfarin (with and without aspirin) in patients with coronary artery disease (CAD) or cerebrovascular disease (CVD).

METHODS: We searched PubMed, Scopus, Cochrane Library, Embase and the Web of Science electronic databases for randomized trials published from January 1980 to December 2014. We did not include earlier trials, as they would not reflect the current standards of care for secondary prevention of acute coronary syndrome or cerebrovascular accident. RCTs reporting the benefits (reduced incidence of stroke) and risks (mortality, intracranial bleeds, major and minor bleeds) of warfarin (with and without aspirin) therapy were included. We excluded trials that studied the use of warfarin for atrial fibrillation, heart valves and peripheral vascular disease. Trials were stratified by the intensity of the therapeutic international normalized ratio (INR): low (INR <2), moderate (INR 2–3) and high (INR >3.0). Data were pooled across studies using the fixed and random-effects models. We expressed the associations as risk ratios (RRs) and their 95 % confidence intervals (CIs). We used the chi square test to evaluate heterogeneity among trial outcomes.

RESULTS: The initial search yielded 3572 articles of which 26 RCTs (34,983 patients) met our inclusion criteria. The duration of treatment varied from 10 weeks to 4.6 years. In 6 trials of 19,000 patients, low intensity warfarin, either alone or plus aspirin vs. aspirin alone did not reduce stroke in patients with CAD (RR 0.84, 95 % CI 0.62 to 1.13) or CVD (RR 1.21, 95 % CI 0.99 to 1.52). In 9 trials with 5869 CAD patients, moderate intensity warfarin plus aspirin vs. aspirin alone reduced stroke (RR 0.48, 95 % CI 0.29 to 0.80) but increased major bleeding (RR 2.54, 95 % CI 1.70–3.79). There were no trials of this

regimen in CVD patients. In 4 studies with 4455 patients, high intensity warfarin vs. aspirin did not decrease stroke in either patients with CAD (RR 0.41, 95 % CI 0.12 to 1.36) or CVD (RR 1.02, 95 % CI 0.49–2.13), but did increase the risk of intracranial bleeds (RR 8.68, 95 % CI 1.99–37.87).

CONCLUSIONS: The effectiveness of warfarin in secondary prevention of stroke was dependent on the target INR, as well as whether aspirin was used in conjunction with warfarin. Use of moderate intensity warfarin with aspirin reduced the risk of stroke at the price of increased bleeding. Trials of moderate intensity warfarin (or other oral anticoagulant) plus aspirin for secondary prevention of stroke should be considered.

BETA BLOCKERS AND THE RISK OF SUICIDE IN THE ELDERLY Jonathan S. Zipursky^{3,4}; Erin M. Macdonald⁵; Simon Hollands⁵; Tara Gomes^{1,5}; Muhammad Mamdani^{1,5}; Michael Paterson²; David N. Juurlink^{4,5}. ¹St. Michael's Hospital, Toronto, ON, Canada; ²Institute for Clinical Evaluative Sciences, Toronto, ON, Canada; ³University of Toronto, Toronto, ON, Canada; ⁴Sunnybrook Health Sciences Centre, Toronto, ON, Canada; ⁵Institute of Clinical Evaluative Sciences, Toronto, ON, Canada. (Tracking ID #2160069)

BACKGROUND: Beta-adrenergic antagonists (β -blockers) are commonly used among the elderly but concerns have been raised about their potential association with suicide risk. Lipophilic β -blockers enter the central nervous system readily, and may increase the risk of depression and suicidality relative to hydrophilic β -blockers. We examined the relationship between β -blocker lipophilicity and the risk of suicide in the elderly.

METHODS: We conducted a population based case-control study of multiple healthcare databases in Ontario, Canada, from January 1, 1993 to December 31, 2011. Cases were Ontarians aged 66 years or older who died of suicide within 100 days of receipt of a prescription for a β -blocker. For each case, we identified up to 4 controls who also received a β -blocker prescription in the preceding 100 days, matching on age, sex, documented hypertension and a hospitalization for coronary artery disease in the preceding year. We identified all outpatient prescriptions for oral β -blockers, categorizing each as high, intermediate or low lipophilicity based on the partition coefficient for each. We used conditional logistic regression to estimate the odds ratio for the association between suicide and type of β -blocker prescribed, with hydrophilic β -blockers as the reference group. To test the specificity of our findings, we examined the association between β -blocker lipophilicity and death from lymphoma.

RESULTS: We identified 385 individuals who died of suicide within 100 days of receiving a prescription for a β -blocker and 1540 matched controls. Use of lipophilic β -blockers (propranolol or labetalol) was associated with a more than two-fold increase in the risk of suicide (adjusted odds ratio 2.42; 95 % confidence interval 1.40 to 4.19) relative to hydrophilic β -blockers (Table 1). No increased risk was observed with β -blockers of intermediate lipophilicity. In stratified analyses, the increased risk of suicide with lipophilic β -blockers persisted in men (adjusted odds ratio 3.04; 95 % confidence interval 1.58 to 5.84) and individuals greater than the age of 76 (adjusted odds ratio 2.41; 95 % confidence interval 1.16 to 5.02). As expected, we found no association between β -blocker lipophilicity and death from lymphoma.

CONCLUSIONS: The lipophilic β -blockers propranolol and labetalol are associated with an increased risk of suicide in the elderly. Clinicians should be aware of this association, particularly in elderly individuals with other risk factors for suicide.

β -blocker lipophilicity and risk of suicide

Lipophilicity	No (%) of patients with exposure		Odds Ratio (95 % Confidence Interval)

BEYOND “GREAT JOB”: CONTENT AND QUALITY OF FEEDBACK AMONG STUDENTS ON INTERPROFESSIONAL LEARNING TEAMS Jennifer Mandal¹; Maria A. Wamsley³; Sandrijn van Schaik². ¹UCSF, San Francisco, CA; ²University of California San Francisco, San Francisco, CA; ³University of California, San Francisco, San Francisco, CA. (Tracking ID #2199391)

BACKGROUND: The ability to exchange instructive feedback with team members is considered one of the core competencies of interprofessional collaboration. Yet little is known about how and when healthcare trainees develop the skills to give substantive, useful interprofessional feedback. The objective of this study is to analyze the content and quality of peer-to-peer feedback among health professional students working in interprofessional teams.

METHODS: Students from 7 health professional schools (Dentistry, Nursing, Nutrition, Medicine, Pharmacy, Physical Therapy, and Social Work) worked in teams during a 4-h Interprofessional Standardized Patient Exercise (ISPE) to interview and develop a care plan for a complex patient. After the exercise, students were asked to provide written feedback for each of their teammates on 1) their interviewing skills and 2) their teamwork skills. We developed a scoring grid to rate the quality of the de-identified feedback comments, based on whether the comments included specific statements to continue, initiate, or discontinue certain behaviors (referred to as “keep”, “start”, or “stop” statements, respectively) as well as an anchored global usefulness score. Two independent raters scored all comments and reconciled differences in ratings. In addition, we analyzed the length of feedback comments based on word count. We calculated descriptive statistics for quality scores and comment length and compared mean scores and length between comments on interviewing skills versus those on teamwork skills with paired t-tests.

RESULTS: We analyzed 1650 feedback comments from 353 students. Of all comments, 98.1 % included a “keep statement”, 29.6 % included a “start statement” and 4.7 % contained a “stop statement”. Global usefulness scores were higher for comments on interviewing skills than on teamwork skills (3.0±0.8 vs 2.5±0.8, 4-point scale; $p<.0001$). Students wrote longer comments about interviewing skills than about teamwork skills (45±27 vs 30±19 words per comment, $P<.0001$).

CONCLUSIONS: Students participating in the ISPE were able to provide each other with reasonable quality feedback, although overall they were far more likely to provide positive, reinforcing feedback (“keep statements”) than to provide suggestions for change (“start or stop statements”). Students provided longer, higher quality feedback on their colleagues’ interviewing skills, and were more vague and brief in feedback on teamwork skills. This may reflect that students have a better understanding of, and more experience with, interviewing skills than with teamwork skills. Our results indicate a need for explicit education about interprofessional teamwork as well as training in effective feedback provision.

BRIEF MEASURES FOR EVALUATING ENGAGEMENT AND PERCEIVED USEFULNESS OF HEALTH APPS FOR PATIENTS Joseph J. Sudano^{1,3}; Adam T. Perzynski²; Misty Harris². ¹Case Western Reserve University, Cleveland, OH; ²Case Western Reserve University at MetroHealth, Cleveland, OH; ³The MetroHealth System, Cleveland, OH. (Tracking ID #2200039)

BACKGROUND: We evaluated the measurement properties of newly adapted self-report scales designed to evaluate the extent to which patients benefit from web-based, mobile and tablet health applications. While existing scales measure satisfaction with computer tools, we sought to evaluate brief measures that examine additional dimensions of user experience, notably patient engagement and patient ratings of the utility of the applications themselves.

METHODS: A sample of 105 patients, visitors and health professionals was recruited from a safety net hospital, two community organizations, and meetings of health professionals. Participants completed a health risk assessment (available at <http://healthylifeHRA.org>). Participants had the option of using a laptop or tablet for completing the HRA. Items measure Engagement (4 items; 1-not at all to 5-very), perceived usefulness (9 items; 1-disagree to 10-agree), and End User Computer Satisfaction (12 items; yes/no). A three item measure screened participants for poor/adequate numeracy.

RESULTS: Participants were 64 % female; 41 % white, 29 % black, 12 % other, 18 % did not report race; average age was 42 (range 18–86). Participants were highly satisfied with the software; 97 % responded “yes” on “easy to use,” and 100 % yes on “quick enough”, useful format and clear report. Factor analysis results supported a 3-factor model of usefulness and engagement. Cronbach’s alpha internal consistency was >0.8 for all scales. Participants rated the software as engaging them in caring for their health Mean=4.2, SD=1.0 on the 1–5 scale. The majority of patients agreed that the software is useful (Mean=7.1, SD=2.0). Numeracy screening indicated that 66 % had adequate and 34 % poor numeracy. Participants with poor numeracy rated the software as *more useful* (8.1 vs 6.7,

$p=.007$) than participants with adequate numeracy. Usefulness and Engagement had moderate associations with an existing measure of computer satisfaction.

CONCLUSIONS: Brief, easy to administer self-report questions can be used to evaluate the extent to which health applications are found to be useful and engaging by patients and

other users. Variability on these adapted measures is sufficient to capture differences according to key variables (such as numeracy for understanding the potential unintended consequence for apps to increase inequality via the “digital divide”). Future work is necessary to examine these measures in larger samples and with other health apps.

BRING IT TO THE BEDSIDE: TABLET COMPUTERS INCREASE TEAM-PATIENT INTERACTIONS Blake R. Barker; Brett Moran; James M. Wagner. UT Southwestern Medical Center at Dallas, Dallas, TX. (Tracking ID #2194116)

BACKGROUND: Once the primary form of care delivery and medical education in academic medical centers, rounding at the patient's bedside has become an increasingly infrequent rounding style. Prior investigators have observed that bedside rounding occurred less than 25 % of the time. Concerned medical educators have advocated for curricula that increase the frequency of bedside rounding. The impact of technology, including electronic medical records (EHR), on rounding styles is unknown. However, medical educators have expressed concern that it may detract from patient interactions. In a prior observational study at our institution, two distinct rounding patterns of general internal medicine inpatient teaching teams were identified: “Room rounders”, which represented 27 % of the team rounding styles observed, stayed in a conference room for the majority of the patient presentations. This pattern was found to be associated with significantly greater use of the EHR and fewer distractions. Contrasting this were the “ward rounders” who primarily presented patients in the hallway or in the patient room. “Ward rounders” were found to access the EHR and use electronic technology much less but had significantly more patient interaction, including discussion the plan of care with the patient and attending examination of the patient in the presence of the team. The

hypothesis that the provision of tablet computers and encouraging ward rounding would provide equivalent EHR access with an increase in team-patient bedside interactions was explored.

METHODS: Over two consecutive months in 2013, an intervention study was conducted on ten general medicine teaching teams at Parkland Memorial Hospital, a large county hospital and primary teaching site of UT Southwestern. Five of the ten teams were randomly selected to receive four tablet computers each. These teams were provided a brief introduction on tablet functionality and were asked to conduct rounds outside of the conference room. Behaviors of intervention and control teams were recorded by observers utilizing a standardized checklist codifying team rounding patterns, including patient interaction, EHR use, teaching time and team distractions. Data were analyzed using chi-square and Fisher's Exact Tests with p -value<0.05 as an indicator for statistical significance.

RESULTS: Intervention teams were observed using tablet computers and rounding outside of the conference room more frequently than control teams (50 % vs 18 %, $p<0.0001$; 71 % vs. 34 %, $p<0.0001$, respectively). Observed EHR access during patient encounters was similar between intervention and control groups (50 % for both groups). Intervention teams visited the bedside of a similar number of patients (75 % vs. 71 %, $p=0.33$) and spent a similar amount of time with patients (222 s vs. 197 s, $p=0.64$). Attendings of intervention teams were observed examining patients more often than control teams, but this did not

reach statistical significance (57 % vs. 48 %, $p=0.05$). Intervention teams were observed exchanging information with patients and discussing the plan of care with patients significantly more often than control teams (75 % vs 65 %, $p=0.03$; 71 % vs 61 %, $p=0.03$, respectively). Intervention teams spent a similar amount of time teaching but also encountered more distractions per patient encounter (2.6 vs 1.8, $p=0.005$).

CONCLUSIONS: By simply providing handheld technology in the form of tablet computers and a recommendation to round outside of the conference room, internal medicine teaching teams at a large academic hospital were observed exchanging more information with and more often discussing plans of care with patients. There was also a trend towards increased examination of the patient by the attending during rounds. Access of EHR, visits to the bedside during rounds, time spent with patients and teaching time were all similar. We feel this study suggests that tablet computers can add value to patient care teams and particularly medical education through increased team-patient bedside interactions and role modeling while providing similar degree of EHR access. This may come at the cost of increased team distractions.

Comparison of Control and Intervention Groups Rounding Behaviors

Variable	Control	Intervention	P value
Tablet used during rounds (y/n)	18.13 %	50.31 %	< 0.0001
Rounds occurred outside conference room	34.38 %	71.17 %	< 0.0001
Total time spent rounding (min)	742	637	0.0118
Percent of patients visited during rounds	70.63 %	75.46 %	0.3274
Time spent with each visited patient	197 s	222 s	0.6358
Examination of patient by the attending during rounds	47.94 %	56.98 %	0.0532
Exchange of information with the patient during rounds	65.40 %	74.86 %	0.0291
Discussion of plan with patients during rounds	60.95 %	70.95	0.0255
Access of EHR during rounds	49.54 %	50.46 %	0.2379
Patient-related teaching time (sec)	141	100	0.12
Non-patient related teaching time (sec)	260	408	0.9415
Distractions per patient encounter	1.84	2.60	0.0045

BUILDING INFRASTRUCTURE: LESSONS LEARNED FROM A PARTNERED COMMUNITY-ACADEMIC GRANT WRITING SERIES Keyonna M. King¹; Yvette-Janine Pardo²; Keith Norris¹; D'Ann Morris³; Arleen F. Brown¹. ¹UCLA, Los Angeles, CA; ²Assist Management Consulting, LLC, Pasadena, CA; ³Los Angeles Urban League, Los Angeles, CA. (Tracking ID #2196498)

BACKGROUND: Many new funding opportunities to improve community/population health require substantial community and academic partnership. To strengthen community and academic infrastructure for sustainable partnered research, the UCLA CTSI Community Engagement and Research Program (CERP) developed a Partnered Community-Academic Grant Writing Series.

METHODS: We implemented a novel, no-cost, 13-week grant writing workshop focused on paired community-academic partners. The workshop was conducted between April and June 2013 and had three goals: 1) to identify teams of community stakeholders and academic investigators who were ready to write a partnered proposal, 2) to introduce these partnered grant writing teams to diverse sources of funding and standard grant writing language, and 3) to assist the teams in writing proposals that effectively demonstrate evidence of partnership. The series curriculum was modified from traditional grant writing workshops originally designed as separate courses for community organizations or for academic investigators. A half-day introduction session (Are you grant ready?) was held to promote the intensive grant writing workshop and introduce partnered grant writing to community and academic organizations interested in learning how to partner to write proposals. The modules of the intensive grant writing workshop were: 1) Community-based participatory research (CBPR) and collaborative community-academic grant writing; 2) writing corporate, community, and private foundation grant writing; and 3) NIH unsolicited grant writing. Eligible teams for the intensive grant writing sessions were required to have at least 2 representatives from the partnering community organization (to enhance capacity building) and an academic investigator. Teams were selected by the CERP leadership and staff. Teams were tracked to determine outcomes. At six- and 12-months teams were asked to complete an online post-workshop evaluation asking questions about partnered proposal submissions.

RESULTS: Of the 16 teams that submitted LOIs, 10 with varying levels of grant writing experience were invited to participate. Weekly feedback helped CERP staff iteratively

review goals/needs and modify the program. On average, 22 people attended each week, and all teams were represented each week. At the end of the 13-week intensive grant writing series, the majority of attendees (93.3 %) indicated they understood the benefits of partnering, could identify appropriate grant funding opportunities (86.6 %), and understood foundation and NIH grant writing language (84.2 and 68.8 %, respectively). At 12 month follow up, 2 teams submitted one proposal, 1 team had submitted two proposals, and 1 team had submitted 3 proposals. Three of the teams were awarded funds totaling \$1.87 million. One team is revising their proposal for a different funding agency.

CONCLUSIONS: We developed a novel and innovative approach to community-academic partnered grant writing with early evidence that participating in the workshop enhanced capacity for partnered research, building both team self-efficacy and success in applying for available research funding. We will continue to track the features of the partnerships and their products and will modify the series based on these early experiences and the recommendations of the participants.

BUILDING SUSTAINABLE SCREENING, BRIEF INTERVENTION, AND REFERRAL TO TREATMENT (SBIRT) WITHIN PRIMARY CARE IN AN INTEGRATED HOSPITAL SYSTEM IN NEW YORK, NYSBIRT-II: AN IMPLEMENTATION MODEL Jeanne Morley⁵; Sandeep Kapoor^{5,1}; Megan O'Grady²; Nancy Kwon³; Mark Auerbach⁴; Jon Morgenstern³; Charles Neighbors²; Joseph Conigliaro⁵. ¹The Feinstein Institute for Medical Research, Manhasset, NY; ²The National Center on Addiction and Substance Abuse at Columbia University (CASAColumbia), New York, NY; ³North Shore Long Island Jewish Health System, New Hyde Park, NY; ⁴North Shore Long Island Jewish Health System, Bay Shore, NY; ⁵North Shore Long Island Jewish Health System, Manhasset, NY. (Tracking ID #2196410)

BACKGROUND: Screening, Brief Intervention, and Referral to Treatment (SBIRT) for substance misuse has received a great deal of empirical support. Despite the strong evidence for effectiveness and a compelling rationale for its integration, the circumstances under which it is likely to be implemented and sustained remains elusive. In 2013, the North Shore LIJ Health System, the National Center on Addiction and Substance Abuse at Columbia University (CASAColumbia), and the Office of Alcoholism and Substance Abuse Services (OASAS) established a partnership funded by Substance Abuse and Mental Health Services Administration (SAMSHA), to build a sustainable SBIRT program within an integrated Hospital System in Hurricane Sandy affected areas of the New York metropolitan area, NYSBIRT-II. By the end of the 5-year funding, the model developed for Emergency Department and Primary Care sites will serve as the basis for subsequent dissemination of SBIRT services throughout New York State. Our objective is to describe the implementation process in NYSBIRT-II Primary Care sites during year one and to report our cumulative results.

METHODS: The SBIRT model was implemented as follows: 1) At every patient visit, Medical Office Assistants (MOA) administered a 5-question SBIRT Pre-Screen for alcohol, drug, and tobacco use while measuring vital signs prior to a Physician (MD) visit 2) Completed screens were then reviewed in real time by the SBIRT Health Coach (HC); 3) Patients with positive pre-screens were approached by the HC either during or at the end of the MD portion of the visit to complete a full screen (AUDIT and/or DAST-10); 4) Brief interventions and referrals to treatment were performed by the HC as indicated based on the full screen score.

RESULTS: Implementation has occurred in three Primary Care Sites including one designated Level III Patient Centered Medical Home (PCMH), with the initial site providing SBIRT services since December 2013. Initial implementation was evaluated using Government Performance and Results Act (GPRA) data. In the first year, 24,068 patients were PreScreened with an 11.8 % positive rate. The patients were diverse, with more women than men prescreened (63 % female) Age: 18–24 (3.7 %), 25–34 (10.2 %), 35–49 (24.8 %), 50–59 (24.9 %), ≥60 (36.3 %) Ethnicity: Latino (24.7 %) Race: Caucasian (38.2 %), African American (18.5 %), Asian (7.4 %), Other (35.9 %). Nearly 1875 full screens were conducted with a 33 % positive rate, resulting in 537 brief interventions and 114 referrals to brief or formal addiction treatment. Abuse of multiple substances was an issue for many patients, with 14.7 % of patients positive on both the AUDIT and the DAST10, with marijuana, cocaine and hallucinogens as the most commonly used drugs.

CONCLUSIONS: SBIRT services in a large, integrated health system are needed, and can be successfully implemented. SBIRT allows the clinical team to efficiently identify and address substance misuse at the point of service. Further research will focus on how to make SBIRT universally sustainable in the Primary Care setting and play a role in the continued integration of Behavioral Health in Primary Care.

BUPRENORPHINE INITIATION AND LINKAGE TO OUTPATIENT BUPRENORPHINE TREATMENT DOES NOT REDUCE FREQUENCY OF INJECTION DRUG USE FOR INPATIENT OPIOID-DEPENDENT INJECTION DRUG USERS: RESULTS OF A RANDOMIZED CLINICAL TRIAL Phoebe A. Cushman¹; Bradley J. Anderson^{2, 3}; Meredith Moreau⁴; Michael D. Stein^{2, 3}; Jane M. Liebschutz¹; ¹Boston University, Boston, MA; ²Butler Hospital, Providence, RI; ³The Warren Alpert Medical School of Brown University, Providence, RI; ⁴The Fenway Institute, Boston, MA. (Tracking ID #2190822)

BACKGROUND: Buprenorphine opioid agonist treatment has established effectiveness for patients with opioid substance use disorders who seek treatment in the outpatient setting. Our STOP (Suboxone Transition to Opiate Program) study showed that initiation of buprenorphine for hospitalized patients with opioid substance use disorders (both injection drug users and non-injection drug users) resulted in 72 % entry into outpatient treatment and decreased odds (0.6 aOR) of illicit opioid use over 6 months. The objective of this planned subgroup analysis of the injection drug users was to determine if buprenorphine initiation during hospitalization and linkage to outpatient-based buprenorphine treatment after discharge reduces injection drug users' number of injection drug days compared to an in-hospital buprenorphine detoxification.

METHODS: From August 1, 2009, through October 31, 2012, opioid-dependent inpatients at an urban safety-net hospital were enrolled in a randomized clinical trial (RCT) and randomized to either detoxification (5-day buprenorphine taper) or linkage (buprenorphine induction, bridge prescription, and facilitated referral to outpatient treatment within 1 week of discharge) conditions. The main outcome for this subgroup analysis of

injection drug users was prior 30-day injection of opioids (self-report) at 1, 3, and 6 months, measured using a standard 30-day timeline follow-back (TLFB) method. Intervention effects were estimated using a fixed-effects panel regression model; this method compares within-subject change over time and controls for all time-invariant between-subject differences. The intervention effect was estimated as the treatment-by-time interaction. We also measured the effectiveness of the linkage in terms of the percent of patients in each group who presented to an initial visit at an outpatient buprenorphine program after hospital discharge. Finally, we conducted a person-day analysis by using a generalized estimating equation (GEE) to evaluate the association between prescription buprenorphine use and injection drug use during follow-up.

RESULTS: A total of 139 eligible patients were randomized; we limited our analysis to those participants in the detoxification ($n=62$) and linkage groups ($n=51$) who reported baseline injection drug use. There were no significant differences with respect to age (mean 39.5 years; $t=-0.78$, $p=.440$), gender (69.0 % male; $X^2=0.81$, $p=.368$), ethnicity (48.7 % non-Latino Caucasian; 23.0 % African-American, 20.4 % Latino, 8.0 % other, $X^2=3.66$, $p=.301$), or baseline frequency of injection drug use (mean 67.8 % of TLFB days; $t=0.10$, $p=.923$) between the two groups. At follow-up, patients in the linkage group (70.6 %) were significantly ($X^2=44.46$, $p<.001$) more likely to present to an initial visit at a buprenorphine program than those in detoxification group (9.7 %). However, there was no statistically significant difference in the proportion of days of injection drug use between the linkage and detoxification groups at follow-up. The treatment-by-time interaction was not statistically significant ($LR^2=2.85$, $df=3$, $p=.415$). Individual coefficients for treatment effects at 1- ($b=0.03$, $t=0.48$, $p=.634$), 3- ($b=0.09$, $t=1.06$, $p=.288$), and 6-months ($b=-0.02$, $t=-0.27$, $p=.787$) were not statistically significant. Using a person-day analysis, participants self-reported injection drug use on 5.8 % of follow-up days in which they also reported prescription buprenorphine use and 37.5 % of days in which they did not report prescription buprenorphine use. Using GEE, the odds of injection drug use was estimated to be 4.57 ($z=-12.81$, $p<.001$) times higher on days when prescription buprenorphine was not used.

CONCLUSIONS: Despite the robust effectiveness of the linkage protocol in facilitating entry of hospitalized, opioid-dependent injection drug users into initial outpatient buprenorphine treatment, the intervention did not decrease their frequency of injection drug use. Injection drug users may require a more intensive buprenorphine treatment protocol than do non-injection misusers of opioids. In particular, many hospitalized injection drug users are not actively seeking treatment for substance misuse and are likely to have especially complex medical and social needs. Further research is needed to determine how to engage these highly vulnerable patients in sustained addiction treatment beyond the initial linkage.

BURDEN OF BENZODIAZEPINE AND OPIOID OVERDOSE ON HOSPITALS IN USA: ANALYSIS OF NATIONWIDE EMERGENCY DEPARTMENT SAMPLE DATA Sourabh Aggarwal²; Devin B. Malik²; Akshay Amaraneni²; Andrew Whipple¹; Christopher M. Begley¹. ¹Western Michigan University Homer Stryker M.D. School of Medicine, Kalamazoo, MI; ²Western Michigan University School of Medicine, Kalamazoo, MI. (Tracking ID #2197613)

BACKGROUND: Opioid and Benzodiazepine drug abuse has been an emerging health care problem. It has significant implications on healthcare with associated morbidity and mortality. The trend and impact of the opioid and BZD overdose on USA hospitals has never been studied.

METHODS: We queried Nationwide Emergency Department (ED) Sample data for all the patient visits with first listed diagnosis of BZD overdose and opioid overdose using International Classification Code 9 codes of 969.4 and 965.09 respectively. Data was extracted for the years 2006 to 2011. Admission rate to

hospitals during ED visits and in-hospital mortality for admitted patients was calculated.

RESULTS: We identified a total of 510,725 ED visits with first listed diagnosis of BZD overdose during 2006–2011 with rate of visits increasing from 25.7 per 100,000 total visits in 2006 to 28.7 per 100,000 total visits in 2011 with average admission rate of 46.94 % and in-hospital mortality rate of 0.78 %. We identified a total of 222,856 ED visits with first listed diagnosis of Opioid overdose during years 2006–2011 with rate of visits increasing from 9.9 per 100,000 total visits in 2006 to 13.8 per 100,000 total visits in 2011 with average admission rate of 48.54 % and in-hospital mortality of 1.77 %.

CONCLUSIONS: Our study reveals a significant burden of BZD and opioid overdose on hospitals in USA with increasing rate of hospitalizations. It indicates there is a large unmet need for interventions to regulate the use and prescription of controlled drugs.

BUT DOCTOR, I JUST ATE...THE RELATIONSHIP BETWEEN POST-PRANDIAL TIME AND RANDOM GLUCOSE VALUES Michael E. Bowen¹; Lei Xuan²; Ildiko Lingvay¹; Ethan Halm¹. ¹UT Southwestern Medical Center, Dallas, TX; ²University of Texas Southwestern Medical Center at Dallas, Dallas, TX. (Tracking ID #2199277)

BACKGROUND: Non-fasting, random blood glucose (RBG) values are common and can identify patients at risk for dysglycemia (diabetes-prediabetes) in clinical practice. However, evidence guiding the interpretation of RBG values is limited. We sought to characterize the relationship between RBG values and prandial time and determine the postprandial time at which RBG values can best differentiate individuals with dysglycemia.

METHODS: We conducted a cross-sectional analysis of merged data from the 2007–20012 National Health and Nutrition Examination Survey (NHANES). The study sample included non-pregnant, non-fasting adults age ≥ 18 without diagnosed diabetes who had both a RBG and hemoglobin A1C (A1C) available. Participants consuming anything other than water in the 9 h before lab testing were considered non-fasting. Glycemic status was characterized using A1C as normal < 5.7 % or undiagnosed dysglycemia ≥ 5.7 %. Prandial time was modeled as a predictor of RBG using linear regression. We utilized unadjusted models to demonstrate the usefulness of this approach to identify undiagnosed dysglycemia in a real-world ambulatory clinic setting. We present the estimated prediction of RBG values at different prandial times using predictive margins. RBG values ≥ 100 mg/dL were considered clinically relevant glucose elevations.

RESULTS: A total of 7483 participants met inclusion criteria. Those with dysglycemia ($n=2406$) were older (55.2 vs. 41.5; $p<0.001$), had higher BMIs (30.3 vs. 27.3; $p<0.001$), higher RBG values (103.6 vs. 89.2; $p<0.001$), and were more likely to be non-white (35.9 % vs. 28.1 %; $p<0.001$). Sex did not differ between groups. A statistically, but not clinically meaningful difference in prandial time of 12 min was observed between groups (2.9 vs. 2.7 h; $p<0.001$). The predicted marginal RBG values ranged from 7.6 to 18.3 mg/dL higher in the dysglycemia group and were significantly higher in the dysglycemia group at all time points ($p<0.001$; Figure). Predicted marginal RBG values in participants with normal glycemic status were always below 100 mg/dL in the first 9 h after intake. In the dysglycemia group, RBG values between 0 and 3 h after a meal were always significantly ≥ 100 mg/dL (Figure). If all individuals with a RBG ≥ 100 mg/dL between 0 and 5 h after a meal were screened with an A1C, 96.4 % of dysglycemia cases could be identified. Among those with dysglycemia, predicted RBG values at postprandial time ≥ 6 h were ≤ 100 mg/dL, which is below the fasting glucose cutpoint to diagnose dysglycemia.

CONCLUSIONS: RBG values ≥ 100 during 0–5 h after a meal are associated with dysglycemia and should prompt definitive diabetes testing. In routine clinical practice, RBG values could identify the majority of patients with dysglycemia, and fasting more than 6 h in clinical practice may not improve the detection of dysglycemia.

The Relationship Between RBG Values and Postprandial Time Stratified by Glycemic Status

Figure 1. The Relationship Between Random Glucose Values and Postprandial Time Stratified by Glycemic Status

CALLING IT LIKE YOU SEE IT: THREE-HOUR WORKSHOP IMPROVES

HOSPITALISTS OBSERVATION AND FEEDBACK SKILLS Margaret Horlick², Louis H. Miller³, Patrick M. Cocks⁴, Lynn Bui⁵, Mark D. Schwartz², Anne Dembitzer¹. ¹NY Harbor VA, New York, NY; ²NY Harbor VA Healthcare Center, Brooklyn, NY; ³NYU School of Medicine, New York, NY; ⁴NYU School of medicine, New York, NY; ⁵New York University, New York, NY. (Tracking ID #2197982)

BACKGROUND: The implementation of the New Accreditation System (NAS) by the ACGME requires that residency programs focus their assessment of trainees on developmental milestones in part via direct observation as they care for patients. Clinician Educators (CE) are the primary evaluators of graduate trainees and yet they have had little to no education in this area. The ABIM advocates a model that uses performance dimension training and the development of shared mental models. Participation in a daylong ABIM workshop was associated with improved confidence and performance of direct observations and assessments. We sought to create a workshop that could be easily integrated into the professional lives of CEs and evaluate the impact on faculty's confidence and skill in providing observation and feedback, and change in self-reported teaching behaviors.

METHODS: We recruited hospitalist physicians from three institutions to participate in a 3-h workshop. Participants were divided into small groups of 3–4 faculty. The workshop focused on interactive skill building using performance dimension training, shared mental models and role-plays. We evaluated the impact of this training on teaching confidence using pre and post surveys that asked faculty to rate their confidence on a 1–4 scale from “not confident” to “very confident.” Teaching performance was assessed using pre and post OSTE. Standardized learners rated teaching performance using a checklist that that included 10 items specifically to assess observation and feedback; items were rated as “not done,” “partly done,” or “well done”. Teaching behavior change was assessed by 4 month follow-up on faculty's commitment to change statements that were completed at the conclusion of the workshop.

RESULTS: Eighteen hospitalists completed the workshops and all assessments. Sixty-five percent were male with an average of 4 years in practice (range 1 to 8 years). Teaching confidence improved after participation in the workshop as the percentage of participants who reported themselves to be very confident in feedback and evaluation rose from 32 to 52 % ($p=0.006$). Teaching performance also improved—the percentage of participants that received a score of “well done” for observation and feedback in the OSTE improved from 42 to

85 % ($p=0.00003$). Participants improved their use of a shared mental model as the proportion of faculty rated “well done” on, “outlined to learner what you would be looking for during his/her exam” improved from 7 to 85 % ($p=0.00004$). Participants also improved in providing behaviorally specific positive feedback from 50 to 92 % well done ($p=0.008$). In addition, at four-month follow up, 81 % of participants reported they had partially or fully implemented the changes they had committed to in their teaching practice.

CONCLUSIONS: Focused, interactive faculty development can both improve faculty's observation and feedback skills and impact their teaching practice. Pragmatic NAS aligned medical center wide faculty workshops have the potential to change the culture of assessment in a residency program.

CAN PATIENT-CENTERED CARE INNOVATION AFFECT PATIENTS' EXPERIENCES OF CARE? Mark Meterko^{2,3}, Errol Baker², Corey Pilver², Anna M. Barker¹, A. Rani Elwy^{1,3}, Joel Reisman¹, Kelly Dvorin¹, Barbara G. Bokhour¹. ¹ENRM Veterans Affairs Medical Center, Bedford, MA; ²VA Boston Healthcare System, Boston, MA; ³Boston University School of Public Health, Boston, MA. (Tracking ID #2198142)

BACKGROUND: Providing patient-centered care (PCC) in an outpatient setting has become a priority for many medical centers, including the US Department of Veterans Affairs. A myriad of changes may lead to PCC, yet it is unclear as to the effectiveness of efforts to transform the culture of care. The VA Office of Patient-Centered Care and Cultural Transformation has designated certain medical centers as PCC Centers of Innovation (COI), noting them to be leaders in PCC transformation. Innovations have included changes in the physical environment, inclusion of complementary integrative medicine, education of staff to improve patient-centered communication, incorporation of health coaching, and a focus of care on patients' whole health and well-being. We sought to evaluate the impact of ongoing programmatic changes at one outpatient clinic at a VA Center of Innovation for PCC.

METHODS: We conducted a cross-sectional survey of patient-centered care attitudes at two sites, one of which was the PCC Center of Innovation and the other was a matched comparison site. To assess the impact of the natural experiment in PCC innovation at the PCC innovation site, we purposively selected a comparison site that had not been engaged in PCC transformation and was similar to the innovation site with regard to overall complexity, urban location and geographic region. Samples of 300 recent ambulatory care patients were randomly selected at each site to receive a mail survey. Adjusting for potential respondents who could not be contacted, response rates of 44.4 % ($n=118$) and 36.8 % ($n=106$) were obtained at the innovation and comparison sites, respectively. The survey consisted of several standardized measures of the extent to which interactions with the primary care team were experienced as patient-centered including 1) shared decision

making (CollaboRATE) and 2) patient-centered communication (Communication Assessment Tool). Additional standardized measures assessed perception of the physical environment (Perceived Environmental Quality Index - PEQI) and overall visit satisfaction. We measured more distal outcomes including 1) health and functional status (Patient Reported Outcomes Information System - 29); 2) self-care confidence (Self-Efficacy for Managing Chronic Disease); and 3) mindfulness (Mindful Attention Awareness Scale). Sites were compared using both simple bivariate analyses and multivariable models adjusted for observed site differences in patient health status, tenure with primary care provider, and ethnicity.

RESULTS: Scores for the innovation site were significantly more favorable than the comparison site on all measures of the perceived patient-centeredness of visit care processes. Scores on shared decision making (CollaboRATE) on a scale from 0 (no effort) to 10 (every effort), adjusted for demographic differences between the sites, were significantly higher among innovation site outpatients (9.2) compared to those at the comparison site (8.3; $p < .03$). Patients at the innovation site also significantly more frequently endorsed "Excellent" on CAT, relative to comparison site patients (59.3 % vs. 39.5 %, $p < .001$). Regarding overall visit satisfaction, when asked to think back on their most recent visit and rate it overall on a scale from 0 (worst possible) to 10 (best possible), about 73 % of innovation site outpatients rated their visit as a 9 or 10 compared to about 54 % of comparison site outpatients ($p < .01$). Adjustment for site differences in patient demographics and background using logistic regression confirmed these initial bivariate findings, indicating that intervention site outpatients were almost 2.5 times more likely than comparison site outpatients to rate their office visit as the best or almost best possible (odds ratio=2.43, $p < .01$). Scores on the perception of the environment (PEQI) on a 7-point scale (1–7, from negative to positive), adjusted for demographic differences between sites, were significantly higher among PCC innovation site outpatients (6.4) relative to the comparison site (5.7; $p < .01$). No significant differences were found for the distal outcome measures.

CONCLUSIONS: Results suggest that innovations at the VA Center of Innovation have had a positive impact on the extent to which Veterans experience the communication processes and the physical environment as patient-centered and on overall visit satisfaction, an immediate outcome of the outpatient care process and environment. We did not see evidence yet of an impact on longer-term outcomes measured for this evaluation, including self-reported health, functional status, or health-related attitudes. These findings indicate that efforts to transform care to being more patient-centered can positively impact patients' experience of the care they receive.

CAN WE IDENTIFY MINORITY PATIENTS AT RISK OF NON-ADHERENCE TO ANTIPLATELET MEDICATIONS AFTER CORONARY STENT PLACEMENT Leonardo Tamariz; Ana M. Palacio; Olveen Carrasquillo. University of Miami, Miami, FL. (Tracking ID #2199185)

BACKGROUND: Lack of medication adherence is associated with significant morbidity and mortality particularly among minority groups. Interventions shown to improve adherence are complex and difficult to sustain in real world settings. Learning how to identify and target subjects at risk of non-adherence is key to disseminate successful strategies. The purpose of this study was to identify predictors of non-adherence to antiplatelet medications post coronary stent placement among Black and Hispanics enrolled into a randomized clinical trial that compared two interventions to improve adherence.

METHODS: We used data collected for a randomized clinical trial that recruited 452 Black and Hispanic subjects with a coronary stent to compare a phone-based Motivational interviewing intervention to a mailed educational video. The primary outcome was 12-month adherence to antiplatelet medications measured by the claims based Medication Possession Ratio (MPR) and by the Medication Adherence Morisky Scale (MMAS-4). Adequate adherence was defined as $MPR \geq .80$ and a Morisky score of 4. At enrollment which occurred within 90 days of stent placement, we collected demographic information including race, income, marital status, education as well as health literacy, the PHQ-9 to screen for depression, the MMAS-4, Charlson comorbidity score, acculturation and pill burden. We used univariate and multivariate logistic regression to identify predictors of non-adherence. We also calculated the area under the curve of multiple combinations of baseline variables.

RESULTS: We recruited 452 subjects with an average age of 69.52 ± 8.8 . Of those 57 % were male and 57 % were Hispanic. Seventy eight percent had a median income below or equal to \$30,000 and 22 % completed high school or higher. Univariate analyses revealed that the MMAS-4 ($p = 0.01$), difficulty remembering to take medications ($p = 0.03$), not having a household partner ($p < 0.01$), PHQ2 ($p = 0.01$), PHQ9 ($p < 0.01$) were significantly associated with inadequate adherence. Low health literacy and speaking more Spanish than English had marginal significance ($p = 0.06$). The table reports the multivariate analyses. The combination of the Morisky Score score and the PHQ2 had the highest area under the curve $0.57(95\% \text{ CI } 0.51-0.61)$ however it was not significantly better ($p =$

0.07) than only the Morisky score $0.56(95\% \text{ CI } 0.48-0.57)$. Sixty three percent of those who had adequate adherence according to the baseline MMAS-4 and who screened negative for depression with the PHQ2 (less than 3 points) had adequate 12 month adherence compared to 48 % of those who had a MMAS-4 less than 4 and a PHQ2 of 3 points or more ($p < 0.01$)

CONCLUSIONS: Subjects with multiple comorbidities, particularly depression with suboptimal MMAS-4 at baseline are at higher risk of poor 12 month adherence after stent placement. The evaluation of the positive and negative predictive values of these variables in a non-intervened population could help in the development of a screening tool.

Multivariate evaluation of predictors

Variable	Odds ratio (95 % CI)	p-value
MMAS-4	1.7(1.0-2.6)	0.01
Difficulty remembering	0.2(0.1-0.4)	<0.01
Health literacy	1.7(0.9-3.1)	0.08
PHQ-9	0.9(0.8-1.0)	0.09
Motivational interviewing	3.5(1.9-6.7)	<0.01
Charlson score	0.8(0.8-0.9)	0.02

CAREGIVER BURDEN AND FAITH: SOCIO-DEMOGRAPHIC PREDICTORS OF STRAIN DURING END-OF-LIFE CARE. Jorge A. Dorantes²; Michael Green³; Benjamin Levi³; Jane Schubart³; Renee R. Stewart³; Alyssa Harlow¹; Lisa S. Lehmann². ¹Brigham and Women's Hospital, Cambridge, MA; ²Brigham and Women's Hospital, Boston, MA; ³Penn State College of Medicine, Hershey, PA. (Tracking ID #2200240)

BACKGROUND: Family caregiving for patients with end-stage medical conditions is a potentially transformative experience that can be both intensely burdensome and profoundly meaningful. The burden of caregiving may be related not only to the challenge of meeting medical demands, but also caregiver marital status, relationship with patient, and employment status. Despite an increasing awareness of the benefits in acknowledging a patient's personal values during the advance care planning process, limited attention has been given to the associated stressors of family caregivers. Previous studies report inadequate stress management and role conflict as substantial contributors to family caregiver burden, but the extent to which religious strength serves as a coping mechanism in alleviating caregiver strain and anxiety remains unclear. We hypothesized that caregivers with stronger of faith would have lower levels of caregiver strain and lower levels of burden. We additionally aimed to evaluate whether caregiver strain was associated with socio-demographic characteristics, including education, gender, ethnicity, marital status, and age.

METHODS: We recruited 92 severely ill patients from Brigham and Women's Hospital and Penn State Hershey Medical Center. Patients were included if they had a likely prognosis of less than 2 years with one of the following diagnoses: advanced cancer, severe congestive heart failure (New York Heart Association Class III or Class IV), severe lung disease (Stage III or Stage IV COPD by modified GOLD Spirometric Classification), or End Stage Renal Disease. We measured caregiver strain with a validated 12-item Zarit Burden Interview (ZBI) short form and a caregiver strain index form (FSI) comprised of 13 yes/no questions assessing the caregiver's role and associated experiences. Both the ZBI and the FSI were administered to the caregiver during the first visit (ZBI+FSI pre-intervention) and subsequently administered 8–12 weeks after the second visit through a phone interview (PI+ZBI+FSI post-intervention). Socio-demographic information was collected for all subjects. Descriptive analyses and ANOVA was used to assess predictors of caregiver burden and strain.

RESULTS: The mean age of caregivers (CG's) was 58 years ($SD \pm 14$), while the mean age of patients was 63 years ($SD \pm 14$). Fifty-one percent of patients had cancer, 24 % ($n = 42$) had COPD, 21 % ($n = 36$) had CHF, and 4 % ($n = 6$) had ESRD. Seventy-six percent of CG's were white ($n = 70$) and 13 % of were Black ($n = 12$). Sixty-nine percent of CG's ($n = 64$) reported having a strong religious faith, while 31 % ($n = 29$) reported having weak or no religious faith. ANOVA for pre and post intervention phone interviews showed that the mean change in family strain (FSI) (0–13, higher=more strain) was $2.88(95\% \text{ CI } 1.72-4.04)$ for unemployed caregivers ($n = 45$) as opposed to $1.00(95\% \text{ CI } .07-1.93)$ for employed caregivers ($n = 47$) ($P = 0.01$). ANOVA additionally revealed the following for pre and post intervention phone interviews: the mean change in family strain (FSI) between male CG's ($n = 27$) and female CG's ($n = 66$) was 2.83 and 1.37, respectively ($P = 0.065$). The mean change in family strain (FSI) between CG's who were married ($n = 66$) was $1.69(95\% \text{ CI } .87, 2.51)$ and $2.43(95\% \text{ CI } 0.17, 4.68)$ for CG's who were not married. The mean change in family strain (FSI) was $1.62(95\% \text{ CI } .90, 2.34)$ for CG's who made no important medical decisions for their loved ones ($n = 34$) as opposed to a mean change in family strain of $4.33(95\% \text{ CI } 2.38, 6.29)$ for CG's who did make an important medical decision for their loved one ($n = 7$) ($P = 0.03$). There was no significant

association between change in family strain and strength of religious faith, age, education, and ethnicity.

CONCLUSIONS: Strength of faith, contrary to our hypothesis, was not associated with change in CG strain in the pre and post-intervention phone interview. However, change in CG strain increased for CG's who had been involved in making an important medical decision. Interestingly, change in CG strain was higher for men than women, and was lower for CG's that are married and employed as opposed to CG's that are not married and unemployed. Our findings suggest that CG strain is dynamic and not only correlative with a patient's severity of illness or level of involvement in medical decisions. Caregiver gender, marital and employment status also contribute to differences in CG strain. Health care providers will be able to better support family caregivers if they are aware of the multiple factors contributing to CG strain while caring for patients at the end-of-life.

CENTOR SCORE PREDICTS COMMON BACTERIAL CAUSES OF SORE THROAT—NOT JUST GROUP A BETA HEMOLYTIC STREPTOCOCCUS.

Robert M. Centor¹; Thomas P. Atkinson²; Ken Waites²; Carlos Estrada^{3, 2}. ¹University of Alabama at Birmingham, Huntsville, AL; ²University of Alabama at Birmingham, Birmingham, AL; ³Birmingham VAMC, Birmingham, AL. (Tracking ID #2168431)

BACKGROUND: Group A beta hemolytic streptococcus (GAS), *Fusobacterium necrophorum*, and group C/G beta hemolytic streptococcus cause pharyngitis. However, whether Centor score predicts all such bacterial infections is unknown. We sought to determine whether Centor score also stratifies risk of bacterial infection in young adults with sore throat and to explore whether revised weights increased discrimination.

METHODS: In a prospective, cross-sectional study, students aged 15–30 years presenting to a student health clinic with acute sore throat were tested with polymerase chain reaction from throat swabs to detect the three bacteria. We calculated the Centor score by assigning one point each of four indicators (fever history, lack of cough, anterior cervical adenopathy and tonsillar exudates) prospectively collected and computed the Area Under the Receiver Operating Curve (AUROC). We then revised the Centor score weights based on logistic regression odds ratios [OR].

RESULTS: The prevalence of bacterial infection was 34 % (106/312). Each of the four Centor criteria significantly correlated with bacterial pharyngitis: fever history (OR 1.7; 95 % confidence interval [CI], 1.0 to 2.8; $p=0.04$), lack of cough (OR 2.1; 95 % CI, 1.3 to 3.4; $p=0.003$), anterior cervical adenopathy (OR 1.7; 95 % CI, 1.0 to 2.8; $p=0.04$), or tonsillar exudates (OR 3.1; CI, 1.7 to 5.7; $p<0.001$). The AUROC was 0.66 (95 % CI; 0.60 to 0.73). The risk of bacterial infection increased as the Centor score increased ($p<0.001$, Chi square for trend). For example, patients with scores 2–4 were twice as likely to have a bacterial pathogen (44 %, 74/169) as compared to patients with scores 0–1 (22 %, 32/143) ($p<0.001$). A new logistic regression analysis yielded these weights: 1 for fever history, 2 for lack of cough, 2 for anterior cervical adenopathy, and 3 for tonsillar exudates. The risk of bacterial infection also increased as the revised Centor score increased ($p<0.001$, Chi square for trend); scores 0–2 (22 %, 30/138), scores 3–5 (38 %, 51/133), and scores 6–8 (61 %, 25/41). However, the AUROC did not differ from the original criteria.

CONCLUSIONS: The Centor score stratifies the risk of any of 3 bacteria causing pharyngitis—(*F. necrophorum*, group A and group C/G beta hemolytic streptococci)—among young adults patients with sore throat.

CHANGE IN CARDIOMETABOLIC RISK FACTORS WITH POSTPARTUM CHANGES IN WEIGHT AND WAIST CIRCUMFERENCE IN WOMEN WITH RECENT GESTATIONAL DIABETES

Jacinda M. Nicklas²; Chloe A. Zera¹; Sue E. Levkoff³; Ellen W. Seely¹. ¹Brigham and Women's Hospital, Boston, MA; ²University of Colorado School of Medicine, Aurora, CO; ³University of South Carolina, Columbia, SC. (Tracking ID #2194704)

BACKGROUND: Women with gestational diabetes (GDM) have increased risk for the development of type 2 diabetes (T2DM) and cardiovascular disease (CVD), as well as high risk for repeat GDM. Although studies in older women suggest that weight loss may improve cardiometabolic risk factors, little is known about how weight changes modify these risk factors in the postpartum period. Some cohort studies suggest that women with GDM, despite their increased risk, do not lose weight and may even gain weight in the postpartum period. Given that cardiovascular disease and diabetes are the second and eighth leading causes of death, respectively, among women 45–54, the first decade following the childbearing decades, earlier weight changes may be important.

METHODS: In the *Balance after Baby (BAB)* trial of 75 women with recent GDM, women randomly allocated to a web-based year-long lifestyle intervention program lost significantly more weight than the control group. There was no significant impact of the intervention to decrease cardiometabolic risk factors. However, there was a large range of weight change in both groups (–16 kg to +10 kg). For this analysis, we sought to

determine if weight changes in the postpartum year were associated with changes in risk factors for T2DM and CVD, regardless of group assignment. In the *BAB* trial, we measured weight, height, waist circumference, blood pressure, fasting lipids, hsCRP, IL-6, fasting insulin, adiponectin, and conducted 75 g 2-h oral glucose tolerance tests at 6 weeks, 6 months, and 12 months postpartum. For this analysis, we include 59 women providing fasting blood samples at both 6 weeks and 12 months postpartum. We used JMP 11 Pro to conduct Spearman's correlations to determine the relationship between weight change and change in markers of cardiometabolic risk.

RESULTS: Among 59 participants, the mean age was 33±5 years; 6 week postpartum BMI was 31±6 kg/m²; and 58 % were White, 31 % African-American, 12 % Asian; with 20 % Hispanic. Median weight change from 6 weeks to 12 months postpartum was +0.4 kg (IQR –4.8 kg, +2.7 kg) and median change in waist circumference was –1.4 cm (IQR –7 cm, +2 cm). Changes in weight from 6 weeks to 12 months postpartum significantly correlated with changes in several T2DM risk factors: HbA1c (Spearman's $r=0.45$, $p<.001$), fasting glucose ($r=0.41$, $p<.005$), fasting insulin ($r=0.49$, $p<.001$), homeostasis model assessment of insulin sensitivity (HOMA) ($r=0.5$, $p<.001$), and adiponectin ($r=-0.38$, $p<.005$). Among CVD risk factors, weight changes were significantly correlated with changes in fasting triglycerides (Spearman's $r=0.28$, $p<.05$), but not with other CVD risk factors including blood pressure, LDL, or HDL, nor with the inflammatory markers hsCRP and IL-6. Changes in waist circumference significantly correlated with changes in HbA1c ($r=0.36$, $p<.01$), fasting insulin ($r=0.38$, $p<.005$), HOMA ($r=0.38$, $p<.005$), HDL ($r=-0.31$, $p<.05$), and hsCRP ($r=0.28$, $p<.05$).

CONCLUSIONS: Weight changes and changes in waist circumference in the postpartum period were significantly correlated with changes in certain cardiometabolic risk factors among women with recent GDM. Given the high risk for T2DM, CVD, and repeat GDM in this population, weight gain or loss, even in the first year postpartum, may have substantial impact on the development of future disease. Longer studies are needed to determine how postpartum weight changes affect the rate of development of T2DM, CVD, and repeat GDM. Supported by: CDC MM-1094-09/09; NIH BIRCWH 5K12HD057022-08; NIH NCAAM T32AT000051; NIH NHLBI K24HL096141

CHAOS AND CLINICAL COMPETENCE: ASSESSING THE INFLUENCE OF THE "BUSY-NESS" OF THE CLINIC ON RESIDENT PHYSICIANS' CORE CLINICAL COMPETENCE: USING UNANNOUNCED STANDARDIZED PATIENTS

Colleen Gillespie; Irina Nudelman; Kathleen Hanley; Amara Shaker-Brown; Ellen Wagner; Lisa Altshuler; Adina Kalet; Sondra Zabar. NYU School of Medicine, New York, NY. (Tracking ID #2198729)

BACKGROUND: Clinic functioning has been shown to influence quality of care. Less is known, however, about whether clinic functioning affects physicians' core clinical skills such as communication. In addition, residency training may not focus sufficiently on preparing residents for maintaining their competence in challenging clinical settings. We explore association between the functioning of the primary care clinic and medicine residents' core communication skills using Unannounced Standardized Patient (USP) visits as a method uniquely suited to capture both physician communication competence and in-the-moment "busy-ness" of the clinic.

METHODS: Three hundred three USP visits, focusing on 5 different common primary care clinical scenarios for new patients, were delivered to 120 medicine residents across two primary care clinics. Highly trained SPs showed up to the clinic as new patients, saw the resident physician, and completed a comprehensive assessment of both the functioning of the clinic, including clinic staff, and the competence of the resident physician in the core domains of communication, assessment, counseling, physical exam, treatment plan, and patient activation. Analyses focus on a single-item measure of how busy the clinic was ranging from 1-not busy at all to 5-hectic/chaotic with the midpoint of 3 anchored as busy but reasonable. Resident competence in communication was assessed using 14-items with behavioral anchors for not done, partly done and well done response options that included 3 sub-domains: information gathering, relationship development, and education/counseling. Summary scores were calculated as percent of items rated as well done and each domain and sub-domain score met minimum criteria (.80) for internal consistency.

RESULTS: Twenty-four percent of visits were rated as "calm", 22 % as between "calm" and "busy but reasonable", 41 % as "busy but reasonable", 11 % as between "busy but reasonable" and "hectic/chaotic" and 2 % as "hectic/chaotic" (overall mean=2.45, SD 1.03; 5-point scale). Mean overall communication scores differed significantly by chaos measure ($F=6.22$, $p=.013$) with those scores assessed on days that were rated as more than "busy but reasonable" being significantly lower than those assessed on days when the clinic was less busy (means for each value of the chaos measure: 1=64 %; 2=60 %; 3=58 %; 4=51 %; 5=44 %). Scores for the sub-domains of communication showed similar trends (information gathering $F=6.22$, $p=.013$); relationship development $F=7.26$, $p=.007$; patient education $F=3.38$, $p=.067$). Correlations supported these findings as a small but significant linear relationship was found between clinic chaos scores and overall

communication performance Spearman's ($r=-.11, p<.05$) and was slightly larger for relationship development ($r=-.15, p<.05$).

CONCLUSIONS: Resident physicians' communication performance in primary care visits was found to be negatively associated with clinic chaos—the busier the clinic, the lower their communication scores. Both assessments were made by the USP and so one limitation of our data is that some of this association could be due to the chaos of the clinic affecting the USP's rating. However, our results suggest that 1) preparing residents to communicate effectively even on more hectic, chaotic days may be one goal of training programs and 2) quality of communication at the individual provider level can be enhanced by improving the functioning of the clinic.

CHARACTERIZATING THE END OF LIFE CARE FOR THE UNINSURED AND UNDOCUMENTED IMMIGRANT PATIENTS IN A CITY HOSPITAL CENTER Janeen Marshall¹; Tita Castor^{2, 1}; Sapna Shah^{2, 1}; Nisha Viswanathan¹; Ali-John Zarabi¹. ¹The Mount Sinai Hospital, New York, NY; ²Elmhurst Hospital Center, Elmhurst, NY. (Tracking ID #2199239)

BACKGROUND: In 2014 the WHO mandated that access to palliative care and hospice be accessible for all. Here in the US care for the uninsured and undocumented (UAI) patients continues to be a struggle for many health systems yet limited data is available regarding the provision of service, clinical course and outcomes for these patients in need of palliative care and hospice services.

METHODS: Clinical and demographic data from UAI patients followed by the Palliative Care Consult Service (PCCS) at Elmhurst Hospital Center from 12/1/2013-11/30/2014 was obtained on intake to the service. Undocumented status was indicated on initial intake form and uninsured status was verified by chart review. The diagnoses, reason for consult, length of stay, PCCS interventions provided and discharge disposition were analyzed.

RESULTS: Four hundred twenty-eight total patients were referred to the PCCS. 40.2 % were 18–65 years old and 59.8 % were >65 years old. 49.8 % were Female. Approximately 11 % of these patients died within 2 days of completion of their PCCS consultation. Fourteen percent patients were identified as to be uninsured and undocumented. The most common reason for consult for these patients was discharge planning/placement and for 4 of these patients the ultimate determination was that they would remain in the city hospital until their death due to their lack of insurance and undocumented status. Mean number of days between admission and PCCS consultation for these patients was 7.4 days. Five percent of all PCCS patients remain hospitalized for more than 30 days after admission and 7 % remain after PCCS consultation.

CONCLUSIONS: To date very little data on the experience of undocumented and uninsured patients exists outside of anecdote and case report. Characterizing the end of life care in the uninsured and undocumented patients provides much needed data in assuring that hospital systems are able to provide palliation and discharge to appropriate care systems for this vulnerable population.

CHRONIC BENZODIAZEPINE PRESCRIBING IN AN ACADEMIC PRIMARY CARE CLINIC Maria Fan²; Scott Steiger¹. ¹UCSF, San Francisco, CA; ²University of California, San Francisco, San Francisco, CA. (Tracking ID #2195005)

BACKGROUND: Chronic benzodiazepine use is geographically variable and associated with several harms, including dementia, falls, hip fractures, increased mortality, and possibly cancer. There is growing interest in reducing chronic benzodiazepine use, particularly in high-risk populations such as the elderly. In this study, our objective was to characterize chronic benzodiazepine prescribing patterns in an academic primary care clinic.

METHODS: We performed a cross-sectional study of patients receiving chronic benzodiazepines at the University of California, San Francisco, General Internal Medicine Practice. We queried the electronic health record (EHR) to identify all patients who received two or more outpatient prescriptions for any benzodiazepine between 7/1/2013 and 8/25/14. We reviewed the charts of identified patients to determine the indication for prescribing. Demographic information, prescribed benzodiazepine amounts, co-morbid diagnoses, concomitant hypnotic and anti-depressant prescription, and urine drug testing information was extracted through EHR query. Mean 10-mg diazepam daily dose equivalents were calculated based on total number of tablets prescribed in the specified time frame, including refills. Descriptive statistics were calculated for the group of patients receiving chronic benzodiazepines and compared to descriptive statistics for the practice as a whole.

RESULTS: There were a total of 634 patients identified as receiving chronic benzodiazepines out of a total practice population of 26,805 patients (2.4 %). The mean age of patients prescribed chronic benzodiazepines was 58 years, with a range of 24 to 95 years. Thirty four percent of patients prescribed chronic benzodiazepines were aged 65 years or

older, compared to 27 % of the overall clinic population aged 65 or older. The most common indications for benzodiazepine prescriptions were anxiety (64 %) and insomnia (16 %) (Table 1). The mean 10-mg diazepam daily dose equivalent for the cohort was 1.47, with a range of 0.01 to 32.55. Forty-five percent of patients receiving chronic benzodiazepines were co-prescribed an anti-depressant. 23 % of patients receiving chronic benzodiazepines also received chronic opiates, compared to only 3 % of patients in the total practice population receiving chronic opiates. Fourteen percent of patients receiving chronic benzodiazepines had received urine drug testing at least once in the past year. Three percent of patients receiving chronic benzodiazepines had diagnoses of dementia or cognitive impairment.

CONCLUSIONS: Prevalence of chronic benzodiazepine prescribing in this academic primary care clinic was lower than recently reported national data, though our study was limited to prescriptions by primary care providers. Of patients receiving chronic benzodiazepines, a third were older than 65 years and a higher proportion of patients were simultaneously prescribed chronic opiates than compared to the general clinic population. This study characterizes prescribing patterns for chronic benzodiazepines in an academic primary care practice and identifies several potential areas for improving prescribing safety for chronic benzodiazepines.

Indications for benzodiazepine prescriptions

Indication*	Number of patients (%)
Anxiety	409 (64 %)
Insomnia	104 (16 %)
Muscle spasms	22 (3.5 %)
Anxiety or insomnia	21 (3.3 %)
No indication provided	16 (2.5 %)
Pain	11 (1.7 %)
Panic symptoms	9 (1.4 %)
Depression	6 (0.95 %)
Seizures	6 (0.95 %)
Anxiety or pain	4 (0.63 %)
Anxiety or depression	4 (0.63 %)
Stress	3 (0.47 %)
Bipolar disorder	2 (0.32 %)
Nausea and vomiting	2 (0.32 %)
Agitation	2 (0.32 %)
Dizziness	2 (0.32 %)

* Additional indications for which only one patient received a prescription in each category: paranoia; PTSD; insomnia or stress; anxiety or PTSD; anxiety or seizures; anxiety, insomnia, or tinnitus; REM sleep disorder; tics; dystonia; restless leg syndrome; and abdominal cramping.

CLINICAL CHARACTERISTICS OF UNDOCUMENTED IMMIGRANTS WITH HIV IN BRONX, NY Jonathan Ross²; David B. Hanna¹; Uriel R. Felsen²; Viraj V. Patel^{1, 2}. ¹Albert Einstein College of Medicine, Bronx, NY; ²Montefiore Medical Center, Bronx, NY. (Tracking ID #2193701)

BACKGROUND: An estimated 11.7 million immigrants living in the United States are undocumented, yet there is almost no information about how this population is affected by the human immunodeficiency virus (HIV). We sought to describe demographic and clinical characteristics of HIV-positive undocumented immigrants and to determine whether immigration status is associated with certain HIV-related outcomes.

METHODS: We conducted a retrospective cohort study of HIV-positive patients receiving care in a large urban health care system in the Bronx, NY, a county with an extremely high HIV prevalence of 1.7 %. We included patients whose medical records were available in a database of HIV-positive adults receiving care in our system, and who entered care between January 1, 1997 and December 31, 2013. To identify undocumented immigrants we searched the database for individuals who had no social security number and whose only medical insurance was provided by programs who offer services to patients regardless of immigration status, with a subset of these patients undergoing chart review to validate documentation status. Undocumented immigrants were compared to controls matched by age, sex, race/ethnicity and date of entry to care. The chi-squared test was used to compare undocumented immigrants and matched controls for HIV transmission risk factor and achievement of virologic suppression, while the signed-rank test was used to compare CD4 count on entry to care.

RESULTS: Out of 15,134 HIV+ adults with available records in the database, 151 patients (1.0 %) were identified as undocumented. The majority were male (108, 71.5 %) and Hispanic (84, 55.6 %), with a median age at entry to care of 37 years (range 18–77). Among patients with available data on HIV risk factor, only 2.0 % of undocumented immigrants reported a history of injection drug use compared to 10.6 % of

matched control patients ($P=0.01$). Median CD4 count at entry to care was 325 cells/uL (interquartile range 143–434) for undocumented immigrants and 374 cells/uL (interquartile range 135–534) for matched controls ($p<0.01$). Among patients with detectable viral loads at care entry who were followed for at least 90 days, 48.9 % of undocumented immigrants achieved virologic suppression by their last available viral load within one year compared to 47.4 % of matched controls ($P=0.84$).

CONCLUSIONS: Undocumented immigrants represent a small but important population of HIV-positive patients. Compared to matched controls, undocumented patients presented with more advanced disease; however, rates of virologic suppression were similar in both groups. This study included only patients with health insurance, and the results may not be generalizable to undocumented immigrants who are uninsured. Our findings suggest that in a setting where health insurance is available to undocumented immigrants, similar HIV-related outcomes may be achieved regardless of immigration status.

CLINICAL DECISION-MAKING AROUND THE GENOME SEQUENCING RESULTS OF HEALTHY ADULTS: PRELIMINARY RESULTS FROM THE MEDSEQ PROJECT Jason L. Vassy^{3, 2}; Kurt D. Christensen²; Jill Oliver Robinson¹; Michael F. Murray⁴; Amy L. McGuire¹; Robert C. Green². ¹Baylor College of Medicine, Houston, TX; ²Brigham and Women's Hospital and Harvard Medical School, Boston, MA; ³VA Boston Healthcare System, Boston, MA; ⁴Geisinger Health System, Danville, PA. (Tracking ID #2184434)

BACKGROUND: Excitement and controversy surround the potential use of genome sequencing (GS) as a screening tool for preventive care among healthy, asymptomatic adults. Knowledge of one's genetic makeup might guide personalized health screening and decision-making. However, the clinical significance of most of the 3–5 million variants that GS can identify remains unknown. Introducing GS to the clinical care of asymptomatic patients may thus increase healthcare costs but not value. Patient harm may also result if incidentally identified genetic variants with uncertain impact on human health precipitate unnecessary diagnostic and therapeutic procedures. To inform the research questions necessary to evaluate the role of GS in preventive medicine, we aimed to describe the clinical decision-making of primary care physicians (PCPs) around the GS results of their generally healthy patients.

METHODS: The MedSeq Project is an ongoing trial of integrating GS into primary care. We have enrolled PCPs from a network of practices at one academic center to participate in the study

with their patients. Patients are eligible for enrollment if they are 40–65 years old, do not have cardiovascular disease (CVD), diabetes, or significant anxiety or depression, and are deemed generally healthy by their PCPs. Patients are randomized to receive either 1) a comprehensive family history report (FmHx arm) or 2) this FmHx report plus an interpreted GS report (FmHx+GS arm). The GS reports include any concerning variants found in genes associated with monogenic disease, carrier states for autosomal recessive disorders, pharmacogenetic associations for the efficacy or safety of certain medications, and polygenic risk estimates for certain common diseases such as coronary disease and type 2 diabetes. A clinic visit is scheduled for the PCP and patient to meet, discuss the results, and determine the next steps in clinical management. One week after this visit, the PCP completes a brief survey asking him or her to identify any laboratory tests, cardiology tests, imaging tests, and referrals ordered as a result of the patient's FmHx and/or GS reports, in addition to the specific FmHx and/or GS result(s) prompting him or her to do so. Similarly, the PCP identifies any medication or health behavior changes recommended. For each FmHx+GS patient, the PCP reports on a 5-point Likert scale (from "Strongly disagree" to "Strongly agree") whether he or she agrees with the statement "The genome report improved the overall clinical care of this patient beyond what the family history report alone could have achieved."

RESULTS: Among 48 of 100 planned patients who have undergone results visits to date, the mean age was 54 years, 54 % were women, and 10 % were non-white or Hispanic. The table shows the clinical actions taken by these patients' 7 PCPs. The PCPs reported that the FmHx +/- GS reports prompted no additional clinical actions for 69 % of the patients overall but did prompt actions in 24 and 39 % of the FmHx-only and FmHx+GS arms, respectively ($p=0.26$). PCPs have ordered laboratory tests (2 vs. 2) and referrals (3 vs. 3) for as many patients in the FmHx-only arm as in the FmHx+GS arm. However, they tend to evaluate and manage potential CVD risk more aggressively in the FmHx+GS arm, as indicated by more recommendations for health behavior change and aspirin administration. PCPs disagreed that GS improved clinical care beyond FmHx alone for 10 patients (43 %) in the FmHx+GS arm, while they agreed for 9 (39 %).

CONCLUSIONS: Preliminary results from The MedSeq Project suggest that introducing GS to preventive medicine may impact clinical management compared to a FmHx assessment alone without increasing overall utilization of services. Future research should examine inter-provider variability and determine the appropriateness of such clinical actions, as measured by their impact on patient outcomes and cost to the healthcare system.

	Family History Only (n=25)	Family History + Genome Sequencing (n=23)
Laboratory tests	2	2
	BRCA testing (FmHx of breast cancer) C-reactive protein, homocysteine, lipoprotein A (FmHx of heart disease)	Repeated genetic testing (Monogenic risk for variegate porphyria) Iron, ferritin (Hemochromatosis carrier state)
Imaging studies	0	1
		Abdominal ultrasound (Polygenic risk for abdominal aortic aneurysm)
Cardiac studies	0	2
		EKG (Monogenic risk variant for Romano-Ward syndrome/long QT) Exercise stress test (Polygenic risk for coronary artery disease)
Referrals	3	3
	Genetic counseling (FmHx of breast cancer) Genetic counseling (FmHx of lung and esophageal cancer) Neurology (FmHx of Lewy body dementia)	Genetic counseling (Variant of unknown significance in a cardiomyopathy gene and carrier state for dermolytic bullous dystrophica) Genetic cardiologist (Monogenic risk variant for Romano-Ward syndrome/long QT) Genetic dermatologist (Monogenic risk for variegate porphyria)
Medication changes	0	3
		Begin aspirin 81 mg (FmHx and polygenic risk for coronary disease) Begin aspirin 81 mg (FmHx and polygenic risk for coronary disease) Begin aspirin 81 mg (FmHx and polygenic risk for coronary disease)
Health behavior recommendations	3	5
	Weight loss (FmHx of breast cancer) Weight loss (FmHx of coronary disease, hypertension, and hyperlipidemia) Smoking cessation (FmHx of coronary disease and cancer)	Diet and exercise (FmHx and polygenic risk of coronary disease) Diet and exercise (Polygenic risk for coronary disease and diabetes) Attention to medication choice (Monogenic risk variant for Romano-Ward syndrome/long QT) Healthy lifestyle (FmHx of heart disease and polygenic risk for coronary disease) Weight loss and exercise (Unspecified polygenic risk)

Counts of clinical actions made by PCPs in the care of their generally healthy adult patients randomized to receive a FmHx assessment only or a FmHx assessment plus genome sequencing. Parentheticals refer to result(s) identified by the PCP as prompting each clinical action.

CLINICAL IMPACT OF POST-DISCHARGE PHONE CALLS USING INTERACTIVE VOICE RESPONSE SYSTEM. Kelly A. Fung; Leah S. Karliner. UCSF, San Francisco, CA. (Tracking ID #2199500)

BACKGROUND: Post-discharge follow-up phone calls have been used to coordinate care in the transition period from hospital to home. These call programs have been limited because they are time and staff intensive. Interactive voice response systems (IVRS) enable a large number of patients to be called shortly after discharge with the potential of identifying and directing staff time to call those patients with post-discharge needs. We set out to determine how effective a post-discharge IVRS system is at reaching patients and identifying those with needs, and the impact reaching patients has on follow-up appointment attendance.

METHODS: We conducted a cohort study of established primary care patients at an urban academic medical center who were discharged to home from the Medicine service from December 2013 through September 2014 and had telephone contact information at the time of discharge. The IVRS was programmed to call patients and administer a simple survey 24 to 72 h after discharge. The survey's objective was to identify all patients having new or worsening symptoms, problems filling prescriptions or starting medications, questions about medications, problems with follow-up appointments, questions on discharge instructions, or dissatisfaction with their hospital stay. All patients flagged by the IVRS as having any of these concerns were then telephoned by a nurse to clarify and address the

problem(s). Patients were considered reached by the IVRS if they were able to identify themselves as the patient or caregiver and answer at least the first question of the survey. We used adjusted logistic regression models to examine the association between patient demographics (age, sex, payor, race/ethnicity, preferred language) and being reached by the IVRS. Additional models examined the association between IVRS reach and arrival to a scheduled primary care follow-up appointment within 14 days of discharge, adjusting for the same demographics.

RESULTS: Of 849 eligible discharges, 492 (58 %) were reached by the IVRS. Among those reached, 427 (87 %) answered all the survey questions, and 262 (53 %) triggered a call back from a nurse. The most common issue triggering a callback was need for help with follow-up (Figure). In multivariate analysis, the odds of being reached were higher for older patients (AOR Age 40–65 1.65, 95 % CI 1.05–2.69; Age >64 1.87, 95 % CI 1.09–3.21), and lower for patients with Medicaid insurance (AOR 0.43, 95 % CI 0.29–0.65). Overall, 516 (61 %) attended a primary care follow-up appointment within 14-days of discharge; this significantly differed between those in the 'reached' and 'not-reached' group (65 % vs. 55 %; $p=0.004$). Patients in the 'reached' group had higher odds of arriving to their 14-day follow-up appointment (AOR 1.48, 95 % CI 1.11–1.97).

CONCLUSIONS: Post-discharge IVRS phone calls are effective in identifying immediate follow-up and clinical needs of those patients who are reached and directing nurse phone call time to those patients with needs, as well as improving follow-up appointment attendance rates. However, a large proportion of patients are never reached, with a disproportionate number of Medicaid patients not being reached, and it is unknown how many of those patients have needs. Future efforts should examine risk stratification of patients with greatest socioeconomic and clinical vulnerability post-discharge to a real-time nurse call if they are not reached by the IVRS.

CLINICAL MANIFESTATION OF OSTEOARTICULAR TUBERCULOSIS AND ITS RELATIONSHIP TO COMPLICATION OF PULMONARY TUBERCULOSIS: A RETROSPECTIVE STUDY IN TWENTY-NINE CASES

Shigehisa Yanagi^{1, 2}; Toshihiko Ihi^{1, 2}; Arisa Sano^{1, 2}; Tsuyoshi Kodama^{1, 2}; Yuumi Ideguchi^{1, 2}; Hiroshi Kuroki¹; Toshinobu Higa¹; Masamitsu Nakazato². ¹National Hospital Organization Miyazaki Higashi Hospital, Miyazaki, Japan; ²University of Miyazaki, Miyazaki, Japan. (Tracking ID #2197300)

BACKGROUND: Osteoarticular tuberculosis, including spinal tuberculosis, is a rare clinical condition, but its incidence is increasing as a result of large proportion of the older patients with chronic debilitating disease,

especially in Japan. With early diagnosis and prompt treatment, the prognosis of osteoarticular tuberculosis is generally good. However, delay in diagnosis may lead to spread of the infection from bone into adjacent neural structures, joints and surrounding soft tissue that leads to significant functional disability and joint deformity. Patients with osteoarticular tuberculosis are frequently unaccompanied by pulmonary lesion, and chronic back pain is often only symptoms in patients with spinal tuberculosis. In the early stages of the disease, radiological imaging studies and laboratory tests are inconclusive, and the determination of the diagnosis is extremely difficult. The purpose of this study is to investigate the clinical features and outcome of osteoarticular tuberculosis and to clarify its relationship to complication of pulmonary tuberculosis.

METHODS: This is a retrospective study including all patients who were diagnosed as osteoarticular tuberculosis in our institution between January 1999 and October 2013. The diagnosis of osteoarticular tuberculosis was based on (1) the radiological findings and (2) the detection of *Mycobacterium tuberculosis* from either sputum, or the bone lesion, or both.

RESULTS: Twenty-nine patients were included, including 13 male and 16 female (ratio 1: 1.2). The mean age of patients was 75.2 ± 14.8 years old (range, 26 to 91 yd). Location of the disease was cervical (1 case), dorsal (13 cases), lumbar (11 cases), knee joint (1 case), hip joint (1 case), hand joint (1 case) and metacarpal bone (1 case). The most common symptoms at presentation were back pain or joint swelling (69 % of all cases) followed by fever elevation (28 % of all cases). In 25 cases with spinal tuberculosis, 8 cases demonstrated paraplegia. The most frequent manifestations of pulmonary lesion were military tuberculosis (41 % of all cases), while 6 cases (21 % of all cases) demonstrated normal chest CT findings. The positive rate of sputum smears for acid-fast bacilli was lower in patients with osteoarticular tuberculosis than that of in all of tuberculosis patients treated in our institution (41 % vs 64 %). Patients who were smear-negative in the sputum for acid-fast bacilli had longer duration of doctor's delay in the diagnosis of osteoarticular tuberculosis compared to the counterparts of patients who were smear-positive (99.8 ± 30.1 days vs 29.1 ± 26.7 days, $P < 0.05$). The positive rate of sputum smears for acid-fast bacilli was lower in patients with paraplegia than that of patients without paraplegia (12.5 % vs 64.7 %, $P < 0.05$).

CONCLUSIONS: Our results indicated that patients of osteoarticular tuberculosis without complication of pulmonary tuberculosis resulted in delayed diagnosis and subsequent functional disability. Osteoarticular tuberculosis is still an important public health issue, and it should be always considered as a differential diagnosis in patients with chronic back pain or chronic joint swelling, even if the findings on a chest X-ray are normal and sputum smears for acid-fast bacilli are negative. A high index of suspicion, accurate diagnostic approaches including imaging techniques such as MRI and the histological and microbiological examination after needle aspiration biopsy, and prompt treatment are key for the successful management of osteoarticular tuberculosis.

CLINICAL OUTCOMES OF INVASIVE BEDSIDE PROCEDURES Cynthia Kay², Erica M. Wozniak¹. ¹Medical College of Wisconsin, Milwaukee, WI; ²Clement J. Zablocki Veterans Affairs Medical Center, Milwaukee, WI. (Tracking ID #2193261)

BACKGROUND: Bedside procedures, such as lumbar puncture, paracentesis and thoracentesis, are now generally referred for completion. Possible explanations for this include changes in residency procedure training, new duty hour rules, and the emergence of specialists equipped and trained to perform procedures. Our study's aim was to assess the outcomes of bedside procedures at an academic medical center by referral status.

METHODS: A retrospective chart review was done on paracenteses, thoracenteses, and lumbar punctures performed on adults admitted to a resident or hospitalist service at an academic medical center over a 1 year period. Referred procedures were done by either radiology or the hospital procedure service. Non-referred procedures were those performed by the resident or hospitalist team. Immediate complications were defined as pneumothorax, hemothorax, pneumoperitoneum, hemoperitoneum, hypotension, uncontrolled bleeding and pain. Delayed complications included transfer to the ICU, infection at procedure site, and bleeding beyond 2 h post-procedure. Immediate and delayed complications were combined to create a binary indicator for occurrence of complications that served as the primary outcome of interest in this study. Procedure cost, length of hospitalization, and time from the decision to perform a procedure until its completion were secondary endpoints. Logistic regression was used to create a propensity score model that matched referred and non-referred patients according to demographic and clinical characteristics. The study was approved by our institution's IRB.

RESULTS: There were 391 procedures reviewed, with a complication rate of 7 % ($n=23$ referred and $n=4$ not referred). For the primary outcome, logistic regression using propensity score matching found there was no difference in the risk of complications by referral status; however, the study was underpowered to detect such differences due to the low rate of complications. For the continuous secondary outcomes, linear regression with propensity score matching was used to control for observable confounders. We found that referral did not have a significant effect on length of hospitalization. Referral, however, significantly increased the time until a procedure was performed ($p=0.03$) and the cost of the procedure ($p<0.001$). To account for non-normality, length of hospitalization and time to procedure were log-transformed, and a square-root transformation was used for procedure cost.

CONCLUSIONS: The clinical outcome of complications was not different regardless of whether or not the procedure was referred. On the other hand, time until a procedure was performed and procedure cost were significantly more when referred to other services. These findings suggest that procedure performance remains an important skill to learn,

despite changes in residency requirements. We also propose that the usual practice of referring procedures should be reconsidered both for patient care and for health care costs.

CLINICAL PROVIDER EXPERIENCES WITH MEDICATION DISCONTINUATION Amy Linsky^{1, 2}, Steven R. Simon¹, Kelly Stolzmann¹, Mark Meterko¹. ¹VA Boston Healthcare System, Boston, MA; ²Boston University School of Medicine, Boston, MA. (Tracking ID #2197763)

BACKGROUND: While medication adherence and medication reconciliation receive considerable attention, there has been less focus on improving intentional, proactive discontinuation of medications that may no longer be necessary or whose benefits no longer outweigh associated risks. Clinicians vary in their experience and attitudes related to medication management decisions; some are quite comfortable discontinuing medications that lack a clear indication, whereas others prefer to continue therapies that are not causing identifiable problems for the patient. Through the development and administration of a nationwide survey of Department of Veterans Affairs (VA) primary care providers, we assessed attitudes toward and experiences with discontinuing medications.

METHODS: We sampled 2475 VA primary care providers with prescribing privileges, including physicians, nurse practitioners (NPs), physicians' assistants (PAs) and clinical pharmacists, for an online survey. Providers were asked about the prevalence of polypharmacy (i.e., 5 or more medications) in their patients, their experience and comfort level with deciding to recommend medication discontinuation to a patient and their opinions regarding various factors related to such decisions. We examined the range of responses on these questions and the bivariate associations between various provider demographic characteristics and their medication-relevant attitudes. We then used a backward elimination linear regression analysis to build a multivariable model identifying the provider factors associated with recommending medication discontinuation.

RESULTS: A total of 409 (17 %) of clinicians responded: 73 % were physicians, 17 % NP/PAs, and 10 % pharmacists. Study participants were mostly white (72 %), female (52 %), age ≥ 50 years (64 %), had 8 or more clinic sessions per week (52 %), had worked in VA for less than 10 years (53 %), and also had prior experience working outside of the VA (79 %). Non-responders were more likely to be physicians but were otherwise similar. Nearly all clinicians (92 %) indicated that at least 20 % of their patients take 5 or more medications regularly. Overall, 38 % of respondents reported that 40 % or more of their patients had a medication that could potentially be stopped, and 78 % indicated that at least 1 in 5 of their patients had a medication that might be discontinued. However, not all providers recommended discontinuation; among providers who identified patients taking a medication that could potentially be stopped, 11 % of providers recommended medication discontinuation to fewer than 20 % of candidate patients, while only 30 % recommended it for more than 80 % of candidates. In multivariable analyses, factors associated with recommending medication discontinuation included self-rated comfort level with medication discontinuation ($p < 0.0001$) and prior non-VA clinical experience ($p=0.048$).

CONCLUSIONS: Nearly all clinicians identified patients who had medications that could potentially be stopped, yet whether they actually made a recommendation to do so varied among providers. When providers fail to act upon opportunities for discontinuation, patients may continue to take medications with low potential benefit-to-risk ratios. Given that self-rated comfort with discontinuation and practice experience were associated with taking action, it is essential to understand the factors that contribute to comfort level in order to develop education and interventions that lead to safer prescribing patterns.

CLINICIANS' JUSTIFICATIONS FOR ANTIBIOTIC PRESCRIBING: A NEW TYPE OF QUALITY MEASURE Mark W. Friedberg^{1, 2}, Samuel Hirshman¹, Jason N. Doctor³, Daniella Meeker³, Jeffrey A. Linder². ¹RAND, Boston, MA; ²Brigham and Women's Hospital, Boston, MA; ³University of Southern California, Los Angeles, CA. (Tracking ID #2196370)

BACKGROUND: Nearly all measures of quality of care assess processes or outcomes of care that are not completely under individual clinicians' control. Moreover, such measures may not accurately reflect the quality of clinical reasoning. By assessing clinicians' justifications for prescribing antibiotics to patients with acute respiratory infections (ARIs), we sought to develop a new type of quality measure that directly assesses clinical reasoning—a construct that should be completely under individual clinicians' control.

METHODS: From November 2011 to October 2013, we exposed 81 Boston-area primary care clinicians to an electronic health record (EHR)-based intervention that asked them to justify, in a free-text window, their decision each time they prescribed an antibiotic to treat a patient's ARI. These justifications appeared as "Antibiotic Justification Notes" in the EHR, were viewable by other users, and contained default text stating "No justification was given" if prescribers did not enter a justification. Each time a justification was solicited, the EHR displayed guidelines from professional societies and the Centers for Disease Control and Prevention corresponding to the ARI for which the antibiotic was

being prescribed (non-specific upper respiratory infection, acute sinusitis, acute pharyngitis, or acute bronchitis). Two physician reviewers independently coded each antibiotic prescribing justification as “good” (a guideline-concordant antibiotic prescribing rationale; or a reason why the guideline does not apply) or “bad” (a guideline does apply but does not support the prescriber’s antibiotic prescribing rationale), resolving all disagreements by consensus. Each antibiotic prescription could have one or more distinct justifications; each was coded separately. For each clinician, we calculated a justification quality score: the percentage of antibiotic prescriptions having at least one good justification. We excluded clinicians who wrote fewer than 10 antibiotic prescriptions, accounted for varying per-clinician sample sizes using empirical Bayes shrinkage estimators, computed the measurement reliability (i.e., the “signal-to-noise ratio”) and 95 % confidence bounds of each clinician’s justification score, and assessed associations between clinician characteristics and justification scores using bivariate regression model.

RESULTS: The full sample of 81 clinicians wrote 3435 antibiotic prescriptions for ARIs. Physician reviewers’ independent assessments were identical for 81 % of justifications, and the remaining 19 % were coded by consensus. Sixty-three clinicians (54 physicians, 7 NPs, and 2 PAs) wrote 10 or more antibiotic prescriptions. Among these clinicians, 28 % of prescriptions had good justifications and 72 % had bad justifications (including 4 % of prescriptions for which clinicians entered no justification). The range of individual clinicians’ justification quality scores was 16 to 58 %. The most frequent type of bad justification was to report a symptom irrelevant to guidelines (e.g., hoarseness, malaise; 19 % of all justifications). Relative to the mean, 2 clinicians had justification quality scores that were statistically significantly lower and 14 had justification quality scores that were statistically significantly higher. The reliability of justification quality scores was >0.7 for 36 clinicians (57 % of the sample). The mean justification quality score was 33 % among physicians and 25 % among NPs and PAs ($P=0.11$ for difference). Justification quality scores were not statistically significantly associated with clinicians’ seniority (years since professional school graduation), full-time or part-time status, or rates of antibiotic prescribing for ARIs.

CONCLUSIONS: Using an EHR prompt to elicit justifications, it is possible to assess clinicians’ reasons for decision-making in patient care. For the decision to prescribe antibiotics for ARIs, justification quality scores had desirable measurement characteristics, including a wide range of scores, high reliability for a majority of primary care clinicians, and independence from underlying antibiotic prescribing rates—suggesting that justification scores may measure a distinct dimension of clinical performance.

CLOSING THE LOOP WITH AN ENHANCED REFERRAL MANAGEMENT SYSTEM Harley Ramelson^{1, 3}; Amanda V. Taube¹; Pamela M. Nerz². ¹Partners HealthCare, Wellesley, MA; ²Partners Healthcare Systems, Inc., Wellesley, MA; ³Brigham and Women’s Hospital, Boston, MA. (Tracking ID #2187686)

BACKGROUND: Outpatient referrals made by primary care physicians (PCPs) involve multiple sequential steps requiring provider-to-provider and provider-to-patient communication. Analysis of malpractice claims has shown that the referral process in the ambulatory setting is prone to incomplete follow-up and communication break-down.¹ An enhanced electronic referral management system (ERMS) was developed in an ambulatory EHR to meet a series of best practice steps for referral management.² The objectives of this study were to assess PCP and staff satisfaction with the ERMS and to evaluate whether PCPs and their practice staff would find it easier to complete individual steps in the referral process and whether they would find it easier to identify when a problem has occurred in the process.¹ Gandhi TK, Keating NL, Ditmore M, et al. Improving referral communication using a referral tool within an electronic medical record. *Advances in Patient Safety: New Directions and Alternative Approaches*. 2008;3:1–12. ² Hoffman J. Managing risk in the referral lifecycle. 2012; <https://www.rmf.harvard.edu/Clinician-Resources/Article/2012/SPS-Managing-Risk-in-the-Referral-Lifecycle>. Accessed January 5, 2015.

METHODS: The ERMS was launched in two separate releases in 2014. The first release focused on functionality to create, transmit and track referrals as well as the ability to indicate that a referral was complete (“close the loop”) and to identify when a referral was overdue. The second release primarily focused on a series of reports allowing retrospective analysis of referral patterns. This study enrolled nine ambulatory primary care practices affiliated with an integrated delivery system in the Northeast. Approximately 100 practice staff members, including physicians, medical assistants, nurses, and administrative staff involved in the referral process were recruited across these practices to participate in surveys and interviews conducted pre-and post-implementation of both releases. Data reported here reflect results of the surveys conducted at baseline and following the first release. Ease of use and usefulness of specific functions were evaluated on a five-point Likert scale while satisfaction was evaluated on a seven-point scale.

RESULTS: In the first 5 months following the release of the new ERMS module in the EHR, almost 3000 total referrals were generated. At baseline, 74 % reported that it was easy or fairly easy to create a referral. This increased to 91 % on the follow-up survey. At

baseline, 33 % reported that it was easy/fairly easy to schedule an appointment with a specialist. This increased to 64 % on the follow-up survey. At baseline, the percent who reported that it was easy/fairly easy to identify when an appointment was not made with the specialist, when an appointment was missed or when an appointment was cancelled was 34, 22 and 12 % respectively. These increased on the follow-up survey to 54, 45 and 36 %, respectively. When asked about their overall satisfaction with the referral process, 36 % of respondents reported they were satisfied or very satisfied at baseline compared to 92 % at follow-up. The new functionality was also assessed in the follow-up survey to determine the usefulness of 15 major new functions in the referral module. Nine functions were found by 90 % or more of respondents to be useful or somewhat useful. These include the following: 1. Ability to refer to a practice in addition to an individual specialist 2. Search functionality for a specialist 3. Favorite list of specialists and practices to whom PCPs commonly refer their patients 4. Supporting the intra-practice workflow of a staff person creating the electronic referral and sending to the PCP to authorize 5. Ability of the system to automatically fill in the appointment date based on interfaces with scheduling systems 6. Ability of the system to automatically link the specialist’s consult note to the referral based on the linkage with the notes module in the EHR 7. Ability of the system to identify when a referral is overdue at various stages in the referral life cycle 8. Ability to acknowledge the consult note in the referral module 9. Ability to document the closing of the referral

CONCLUSIONS: The results from the surveys after the new release of the enhanced referral management module show there is enhanced user satisfaction with the referral process and that most of the functionality was considered to be useful by a majority of the respondents. Users of the module found that previously difficult tasks such as the ability to identify when an appointment with the specialist was not made or missed or cancelled became easier with the new module. The implications for quality of care and patient safety are clear: when practice staff are able to track referrals in a more effective and efficient way and be able to intervene when appropriate, fewer patients will experience delayed specialty care potentially leading to improved patient satisfaction and patient safety.

CODE STATUS DISCUSSION AND FREQUENCY OF INAPPROPRIATE CARDIOPULMONARY RESUSCITATION AMONG TERMINALLY ILL HOSPITALIZED PATIENTS IN JAPAN. Akinori Sasaki²; Eiji Hiraoka¹. ¹Tokyo Bay Urayasu Ichikawa Medical Center, Urayasu, Japan; ²Tokyo Bay Urayasu Ichikawa Medical Center, Urayasu, Japan. (Tracking ID #2191504)

BACKGROUND: In the U.S.A., physician should discuss code status with all patients and officially order it when they are admitted to a hospital. On the other hand, it usually does not occur in Japan. Some doctors discuss it and others do not. We often observe inappropriate cardiopulmonary resuscitation (CPR) for terminally ill patients, including malignancy, dementia, and heart failure, etc. We also observe some physicians not perform CPR without discussion with patients if it appears to be futile or inappropriate. Because it has not been reported whether code status is discussed with patients on admission decreases the futile or inappropriate CPR for terminally ill patients.

METHODS: Objective: To explore the association between whether physicians discuss code status with patients on admission is associated with decrease futile CPR among patients with terminal illness. Design: retrospective cohort study Setting: One city hospital in Japan Patients: We included patients if they were admitted and died in Ito city hospital, Shizuoka, in Japan between April 1 and September 30 2014. Patients also should be terminally ill on admission. We use less than 70 points in Palliative Performance Scale (PPS) score as the definition of terminal cancer. And we use reference 1 for the definition of terminal stage of various diseases other than cancer. Main outcome: Whether cardiopulmonary resuscitation (chest compression for CPA), intubation with mechanical ventilation for pulmonary arrest, electrical cardioversion were performed was assessed as a main outcome. The incidence of these procedures were compared between in the presence and absence of discussion of code status on admission by chi square analysis. (1)Shelly R. Salpeter E.J.L., et al. Systematic Review of Noncancer Presentations with a Median Survival of 6 Months or Less. *Am J Med* 2012;125:e1-e16.

RESULTS: Eighty-one patients met the inclusion criteria. Code status was discussed on admission for 43 patients. It was not discussed for the remaining 38. Table 1 presents the characteristics in two groups. Both groups are similar except the rate of cerebrovascular accident. As shown table 2, the rate of CPR was 1.9 % in the group with whom the code status was discussed on admission and 14.6 % in the group with whom it was not discussed. The odds ratio was 9.0 (95 % confidence interval, 1.10–76.9). Intubation and central venous catheter placement occurred more frequently among no discussion group. Discussion: Code status discussion is routine process on admission in the U.S.A.; however it is not the case in Japan. It was shown here that even among terminally ill patients, code status was not discussed with 38 patients (46 %).

Not discussing code status on admission was associated with increase in incidence of CPR (OR 9.0). Code status discussion is likely to decrease unwanted CPR among terminally ill patients. One of the reasons is that probably most people would like to avoid futile aggressive care of CPR just to prolong life in Japan. Even if people would like full code on admission, the discussion of code status might give them a chance to rethink of the meaning of CPR and might change their code while hospitalization. To individualize the end of life care, we need to convey all information to the patients and discuss the end of life care, including code status in Japan. Limitation: this is small retrospective cohort study in one city hospital. Although it is definitely unethical to perform randomized controlled trial to investigate whether code status discussion decrease futile CPR, larger prospective observational study should be performed in Japan.

CONCLUSIONS: The code status discussion with terminally ill patients on admission is associated with decrease CPR before death. We need educate physicians about code status to improve end of life care.

Characteristics of study subjects

	Presence of code status discussion (43)	Absence of code status discussion (38)	P value
Age	81.8±11.0a	77.8±10.7	0.10
Gender			0.11
Male	23	27	
Female	20	11	
ADL^a	2.9±2.1 ^b	2.8±2.0 ^b	0.73
Primary diagnosis			
Cancer	20 %	13 %	
Liver disease	4 %	2 %	
Heart disease	3 %	5 %	
Neuromuscular disease	3 %	8 %	
Respiratory illness	10 %	8 %	
Geriatric syndrome	3 %	2 %	

aADL: activity of daily life

b: number of ADLs patients can perform independently out of 5 ADLs; dressing, eating, ambulating, toileting, hygiene.

Result

	Presence of code status discussion (43)	Presence of code status discussion (38)	P value	Odds ratio
CPR	1.9 %	14.6 %	.025	9.0[1.10–76.9]
Intubation	3.7 %	20.8 %	.012	6.8[1.40–33.3]
CVC	7.4 %	20.8 %	.081	3.3[0.96–1.12]
Cardioversion	0 %	0 %	–	–

CPR: cardiopulmonary resuscitation

CVC: central venous catheter

COMBINATION WEIGHT MANAGEMENT PHARMACOTHERAPY WITH LORCaserin AND IMMEDIATE RELEASE PHENTERMINE Steven R. Smith^{2,3}; W. Timothy Garvey¹; Frank L. Greenway⁴; William Soliman⁵; Sharon Zhou⁵; Randi Fain⁵; Ken Fujioka⁶; Louis Aronne⁷. ¹University of Alabama at Birmingham, Birmingham, AL; ²Sanford/Burnham Medical Research Institute at Lake Nona, Orlando, FL; ³Florida Hospital, Orlando, FL; ⁴Pennington Biomedical Research Center, Baton Rouge, LA; ⁵Eisai Inc, Woodcliff Lake, NJ; ⁶Scripps Clinic, La Jolla, CA; ⁷Weill Cornell Medical College, New York, NY. (Tracking ID #2198196)

BACKGROUND: Pharmacotherapy for weight management may involve combining drugs targeting different signaling pathways. This pilot study was sized to assess the primary outcome of impact of lorcaserin (LOR), a specific 5-HT_{2C} receptor agonist, and immediate release (IR) phentermine (phenIR) on pre-selected potentially serotonergic (5-HT) adverse events (AEs) compared to LOR alone.

METHODS: Two hundred thirty-eight patients with BMI >30 kg/m², or >27 kg/m² with a comorbidity, but without type 2 diabetes mellitus (T2DM), were randomized in a 12-week study comparing LOR 10 mg twice daily (BID) alone, LOR 10 mg BID with phenIR 15 mg QD (LOR/phenIR QD), or LOR 10 mg BID with phenIR 15 mg BID (LOR/phenIR BID). All received a standard diet and exercise program with adherence self-reported by study subjects. The primary endpoint evaluated whether short-term LOR/phenIR treatment is associated with exacerbation of potential 5-HT AEs compared to LOR alone. Secondary objectives included safety, tolerability, pharmacokinetics, and weight loss.

RESULTS: 37.2 % (LOR), 42.3 % (LOR/phenIR QD), and 40.5 % (LOR/phenIR BID) patients reported potential 5-HT AEs. 5.1 % (LOR), 2.6 % (LOR/phenIR QD), and 10.1 % (LOR/phenIR BID) patients discontinued due to AEs. At week 12, mean changes in blood pressure (systolic/diastolic) and pulse were –5.5/–2.5 mmHg and –1.9 bpm (LOR), –3.3/–1.4 mmHg and 1.1 bpm (LOR/phenIR QD), and –3.4/–1.7 mmHg and 3.1 bpm (LOR/phenIR BID). Mean change from baseline weight loss (kg/%) in 12-week completers was 4.0/3.8 (LOR), 7.6/7.3 (LOR/phenIR QD), and 8.9/8.7 (LOR/phenIR BID). 33.3 % (LOR), 68.2 % (LOR/phenIR QD), and 84.2 % (LOR/phenIR BID) patients achieved ≥5 % weight loss (12-week completers).

CONCLUSIONS: Treatment with LOR plus phenIR was not associated with exacerbation of potential 5-HT AEs compared to LOR alone. Common AEs during the trial were consistent with prior experience with these agents. The combination of LOR BID and phenIR BID more than doubled weight loss achieved compared to LOR alone.

COMBINED ANTIPLATELET AND ANTICOAGULANT THERAPY IN PATIENTS WITH ATRIAL FIBRILLATION—A DESCRIPTIVE STUDY Charlotte So; Mark H. Eckman. University of Cincinnati Medical Center, Cincinnati, OH. (Tracking ID #2194459)

BACKGROUND: As part of a system-wide performance improvement initiative focused on improving antithrombotic therapy decisions for patients with atrial fibrillation (AF), we discovered a large number of patients who were receiving dual therapy with both aspirin and warfarin. Our goal was to determine the indications for dual therapy and possibly identify patients who might reasonably be treated with oral anticoagulant therapy alone. We hypothesized that the majority of these patients likely had a prior indication for antiplatelet therapy, such as stable coronary artery disease or diabetes, subsequently developed AF and had warfarin added to their regimen without discontinuing aspirin. There have been multiple studies examining outcomes of dual therapy in patients with indications for both antiplatelet and anticoagulant therapy. All have demonstrated an increased risk of major bleeding compared with either treatment alone; and among patients with stable CAD, in particular, dual therapy has not been shown to reduce ischemic events. The 2012 AF guidelines from the American College of Chest Physicians (ACCP) recommends against the use of dual therapy for AF patients with stable CAD, indicating that warfarin alone within a therapeutic INR range of 2–3 is sufficient.

METHODS: We identified 348 patients (23 % of the total AF cohort) in the UC Health Primary Care Network who were receiving dual therapy with an antiplatelet as well as antithrombotic agent as of 1/7/2014. We randomly sampled 200 charts to evaluate and categorize the indication(s) for dual antithrombotic therapy and collected information describing the time course of events that led to the initiation this treatment.

RESULTS: Of the 200 patients reviewed, 77 (38.5 %) had stable CAD and 48 (24 %) had DM as co-morbidities resulting in dual therapy. Forty-one patients (20.5 %) were classified as unknown, meaning patients whose charts had insufficient information to determine the reason for dual therapy. Thirty-six patients (18 %) had diagnoses of both CAD and DM and were counted in both categories. Thus the total added up to more than 100 %.

CONCLUSIONS: Our data show that the majority of patients receiving dual antithrombotic therapy had a diagnosis of stable CAD or DM. Of interest, in a significant proportion of patients aspirin had been initiated due to a prior diagnosis of either stable CAD or DM and was not discontinued when warfarin was started for their AF (73 and 14.58 % respectively). The 2012 ACCP guidelines indicate that there is insufficient evidence to warrant dual therapy in AF patients with stable CAD. A number of recent studies have examined outcomes in AF patients with stable CAD receiving dual therapy, and have concluded that dual therapy increased bleeding risk without reducing the risk of ischemic events, defined as stroke or myocardial infarction. Withdrawing aspirin

from the antithrombotic regimens of these patients may provide an opportunity to improve clinical outcomes.

COMMUNICATION ACCESS: WHY SOME PATIENTS CAN EMAIL THEIR DOCTORS AND OTHERS CAN'T Joy L. Lee¹; Mary Catherine Beach²; Albert W. Wu². ¹Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; ²Johns Hopkins University, Baltimore, MD. (Tracking ID #2192490)

BACKGROUND: Primary care physicians have different modes to choose from in communicating with patients outside of the clinic. In particular, cellphone, email, and secure-messaging portals are now widely available. Yet use of these technologies are used unevenly across physicians and physicians may not grant the same access to all their patients. This work seeks to understand the disparity in use of communication modalities between physicians and the disparity in use by each physician within a patient panel.

METHODS: Semi-structured key informant interviews were conducted with 25 primary care physicians at a large academic medical center, practicing at several clinic settings. We recruited faculty participants from the Division of General Internal Medicine via email, and performed thematic analysis on the transcribed interview data.

RESULTS: Cellphone numbers were most privileged and often only given to patients who needed close monitoring; whether patients could “handle” access without abuse was often considered. A few respondents were adamant about never providing cellphone numbers to patients. While respondents acknowledged the deficiencies of email use, email access was more prevalent and accepted. Granting patients email access was characterized by circumstance (e.g. patients traveling abroad), status/familiarity (e.g. patients employed within the same hospital system), and patient initiative (e.g. patients who asked for email access). Respondents encouraged patients toward the secure-message feature of the newly electronic health record system and away from email. Challenges with communicating with patients with mental illness and setting boundaries for such patients were also raised. For example, one respondent noted “I had a patient with pathologies who would write paragraph after paragraph after paragraph in emails. So I actively do not give out my email.”

CONCLUSIONS: Primary care physicians do not use communication technologies interchangeably. Factors such as patient health, patient relationship with physicians, and patient demand are all considered as physicians grant differential patient access to cellphone and email within their panel.

COMMUNITY HEALTH WORKERS UNDERSTANDING OF AND ATTITUDES REGARDING INTIMATE PARTNER VIOLENCE IN THE DOMINICAN REPUBLIC Nisha Viswanathan¹; Leo Carretero¹; Omara Afzal¹; Janeen Marshall²; Taraneh Shirazian¹. ¹The Mount Sinai Hospital, New York, NY; ²Mount Sinai Hospital, New York, NY. (Tracking ID #2199090)

BACKGROUND: Intimate partner violence (IPV) is prevalent in Latin America and is a leading cause of death for women. A population survey of Latin American and Caribbean countries reveals that 17–53 % of women in the region have experienced physical or sexual violence by an intimate partner, and many women do not seek help or report abuse. Health care providers may not have the knowledge or education regarding IPV to be a

resource for affected women. Our objective is to explore the understanding and attitudes surrounding IPV among community health workers (cooperadoras) in the Dominican Republic, as well as determine the rates of the most common types of IPV in their respective communities.

METHODS: This project consisted of two components: focus groups and a survey component. Investigators planned to conduct five focus groups of cooperadoras representing various regions of the Dominican Republic. Participants were recruited randomly during a medical conference. A moderator script was developed using prior IPV-related research with community health workers. Participants were verbally consented for participation and to protect confidentiality, participants were asked to refrain from discussing responses outside of focus group. Nine open-ended questions were asked regarding domestic violence within their communities, including knowledge of and attitudes toward IPV in the community, understanding of causes and available resources, and the relationship between healthcare and affected women. Answers were audio recorded and transcribed. Data was analyzed using a grounded theory approach to coding, categorization and thematic generation/saturation. The cooperadoras were then trained to deliver existing validated surveys regarding types of IPV to women in their communities. Participants in the surveys were women in urban and rural communities and responses were anonymously recorded. Participants were recruited via door-to-door request creating a convenience sample of the community population. Results were analyzed as descriptive data to describe the prevalence of different types of IPV in various communities.

RESULTS: Five focus groups were conducted, for a total of thirty-five cooperadoras, representing 9 regions in the Dominican Republic and 110 distinct rural communities. Focus groups included both male and female adult participants (7 male and 28 female participants). Five common themes emerged from these focus groups. Cooperadoras 1. believed IPV is a social issue, not a medical one, 2. reported that women are at fault and felt that conflict between partners was due to poor communication, 3. stated that IPV is prevalent and that death was frequently an outcome, 4. felt they did not know the appropriate resources for affected women. 5. believed they did not know how to help affected women. Three hundred eighty-five IPV survey responses were collected. Analysis showed that urban and rural women were just as likely to suffer physical abuse (81 % urban and 85 % rural women), although urban women were more likely have suffered sexual abuse (81 % urban and 72 % rural; $p=0.04$). Rural women were more likely to experience coercive control (77 % urban and 88 % rural; $p=0.01$) versus urban women who were more likely to experience psychological abuse (88 % urban and 80 % rural; $p=0.03$).

CONCLUSIONS: Community health workers in the Dominican Republic could be a potential resource for women affected by IPV, but currently do not view themselves as such because of limited knowledge and resources. Limitations of the study include selection bias, and the possibility for recall and/or cultural biases. Strengths are that this study offers insights into the beliefs of cooperadoras in an area where little research has been done. This study also established the high prevalence of IPV in Dominican communities serviced by cooperadoras. By recognizing the different types of IPV present in these communities, future interventions include education for community health care workers to identify and advocate for women, appropriate referral of women to resources, and discussions with community members regarding management and prevention of intimate partner violence.

COMPARING HOSPITALIZATION CHARGES OF TEACHING VS NON-TEACHING HOSPITALS: ANALYSIS OF THE LEADING 30 DIAGNOSES OF ADMISSION Andrew Whipple¹; Mark Loehrke²; Christopher M. Begley¹; Akshay Amarani². ¹Western Michigan University Homer Stryker M.D. School of Medicine, Kalamazoo, MI; ²Western Michigan University School of Medicine, Kalamazoo, MI. (Tracking ID #2192576)

BACKGROUND: Teaching hospitals have classically been regarded as inefficient and financially burdensome, although to our knowledge no study has specifically addressed individual diagnoses in their assessment of hospitalization charges. Since teaching hospitals are reimbursed by the Inpatient Prospective Payment Services (IPPS) at a higher rate than non-teaching institutions, hospital-related expenses should more accurately be represented by hospital charges than cost. Hospitalization charges rely upon a variety of factors including admission diagnosis, extent of testing, length of stay, and treatment decisions. Therefore, this study aims to identify which admission related diagnoses are associated with differences between teaching versus non-teaching hospitalization charges.

METHODS: Using the Healthcare Cost and Utilization Project's online query system, summary data was collected regarding mean total hospitalization charges for teaching vs. non-teaching urban hospitals in 2012 through the Nationwide Inpatient Sample (NIS). The NIS contains data on 5,557,703 discharge events among 4324 U.S. hospitals in 44 states. Data was collected for discharges that had a non-neonatal, non-maternal primary admission diagnosis of one of the top 30 most common hospital admission diagnoses. For each of these diagnoses, a z-test was used to compare average hospitalization charges at urban

teaching hospitals and urban non-teachings hospitals. To control for multiple testing, a Bonferroni correction was applied and a significance level of $\alpha=0.05/30$ (0.0017) was used to determine statistical significance.

RESULTS: Of the 30 diagnoses tested, 12 resulted in statistical significance. Teaching hospitals, on average, had higher charges for: congestive heart failure (non-hypertensive) ($p<.0001$), mood disorders ($p<.0001$), cardiac dysrhythmias ($p<.0001$), complication of device/implant/graft ($p=.0010$), acute cerebrovascular disease ($p<.0001$), schizophrenia and other psychotic disorders ($p<.0001$), respiratory failure/insufficiency/arrest (adult) ($p=.0002$), and pancreatic disorders (not diabetes) ($p=.0007$). Non-teaching hospitals, on average, had higher charges for: skin and subcutaneous tissue infections ($p=.0010$), nonspecific chest pain ($p<.0001$), biliary tract disease ($p=.0009$), and asthma ($p<.0001$). Reliability and validity of these results are limited as the online query system provides only summary data which shows large differences between mean and median values and may indicate a skewing of the distribution of total charges.

CONCLUSIONS: There is statistically significant evidence that total charges differ for several of the most common diagnoses due to hospital teaching status. For 8 of the top 30 diagnoses, teaching hospitals had higher average charges while non-teaching hospitals had higher average charges on 4 of the top 30 diagnoses. There were no statistically significant differences in charges between teaching versus non-teaching hospitals for the remaining 18 diagnoses. This study is to serve as a pilot to open discussion regarding differences in charges due to teaching status. Subsequent analyses are needed to account for other various factors such as age, length of stay, gender, race, number of comorbidities, primary payer and primary procedure.

COMPARING USE OF LOW VALUE HEALTHCARE SERVICES AMONG U.S. ADVANCED PRACTICE CLINICIANS AND PHYSICIANS John N. Mafi¹; Christina C. Wee¹; Roger B. Davis¹; Bruce E. Landon^{2, 1}. ¹Beth Israel Deaconess Medical Center, Brookline, MA; ²Harvard Medical School, Boston, MA. (Tracking ID #2190292)

BACKGROUND: Evidence suggests that advanced practice clinicians (physician assistants and nurse practitioners, or APCs) provide similar quality of care when compared to physicians. Little is known, however, regarding differences in the use of potentially low value healthcare services.

METHODS: Using nationally representative data from the National Ambulatory Medical Care Survey and National Hospital Ambulatory Medical Care Survey we examined ambulatory visits for four common chief complaint categories: upper respiratory (e.g., sore throat, sinusitis), orthopedic (e.g., back pain, knee pain), neurologic (e.g., headache, vertigo), and skin conditions (e.g., rash, dermatitis) from 1997–2010. Outcomes included use of antibiotics (upper respiratory and skin complaints), CT/MRI (neurologic and orthopedic complaints), referrals to other physicians (all complaints), x-rays (upper respiratory and orthopedic complaints), and laboratory testing (all except orthopedic complaints). We used logistic regression models focusing on APC provider as the exposure of interest, adjusting for patient and physician characteristics and year, and weighted results to reflect national estimates. We also stratified our results based on acute vs. non-acute presentations and primary care provider (PCP) vs. non-PCP visits.

RESULTS: We identified 9940 APC visits and 101,063 physician visits with the study complaints, representing an estimated 2.2 billion U.S. ambulatory visits during the study period. Patients seen by APCs were typically younger (mean age 49.6 vs. 51.8 years, $p<.0001$), more frequently presented with acute symptoms (74.6 % vs. 70.4 % of visits, $p=0.005$), and were less commonly located in urban settings (76.1 % vs. 84.6 %, $p=0.005$) when compared to patients seen by physicians. APCs generally used more antibiotics than physicians for upper respiratory and dermatologic complaints (39.3 % vs. 33.3 % of visits, unadjusted $p=0.001$) and referred to other physicians more frequently than physicians (10.5 % vs. 7.8 %, $p=0.001$). Additionally, APCs ordered x-rays more often than physicians, particularly for orthopedic complaints (29.7 % vs. 23.8 %, $p=0.001$). CT/MRI and laboratory use were similar between provider groups. After multivariable adjustment results remained largely unchanged (Table). Stratification revealed that differences in utilization were especially apparent during acute presentations and visits with non-PCPs (e.g., subspecialists), where the adjusted proportions of antibiotic use during non-PCP visits were 29.5 % of APC visits vs. 22.8 % of physician visits, aOR 1.41 [CI 1.08, 1.84]; referrals to other physicians, 9.1 % of APC visits vs. 6.5 % of physician visits, aOR 1.43 [1.08, 1.89]; x-ray use, 23.7 % of APC visits vs. 19.8 % of physician visits, aOR 1.26 [1.01, 1.58]; and laboratory testing, 11.3 % of APC visits vs. 7.9 % of physician visits, aOR 1.48 [1.01, 2.15].

CONCLUSIONS: In this nationally representative analysis comparing APCs and physicians in the management of common ambulatory conditions, APCs generally used potentially low value healthcare services and referred patients to other providers more frequently than physicians. Differences in utilization primarily occurred during acute

presentations and were largely driven by subspecialists. As APCs continue to expand their role in ambulatory medicine these findings have important implications for containing costs and improving quality in the U.S. healthcare system.

Multivariable Adjusted* Frequencies of Use and Adjusted Odds Ratios of Use Comparing APC vs. Physician

	Adjusted Proportions of Use (%)	Adjusted Odds Ratio [95 % CI]	
	APC (n=9940)	Physician (n=101,063)	
Antibiotics	35.7	32.1	1.17 [1.01, 1.36]
Upper Respiratory	42.5	39.2	1.14 [0.97, 1.35]
Skin	10.0	8.1	1.25 [0.79, 2.01]
CT/MRI	7.2	7.6	0.94 [0.73, 1.20]
Orthopedic	7.2	7.4	0.98 [0.74, 1.28]
Neurologic	6.5	8.0	0.80 [0.50, 1.29]
Refer to Other Physician	8.8	7.2	1.26 [1.04, 1.52]
Upper Respiratory	6.4	4.5	1.46 [1.05, 2.04]
Orthopedic	10.0	8.4	1.22 [0.97, 1.53]
Neurologic	12.4	8.7	1.49 [1.05, 2.10]
Skin	5.8	5.3	1.10 [0.65, 1.86]
X-ray	18.0	15.3	1.21 [1.02, 1.45]

CONCEPTS UNDERLYING EFFECTIVE USE OF THE ARTS IN MEDICAL EDUCATION: A QUALITATIVE SYNTHESIS OF THE LITERATURE Paul Haidet¹; Jodi Jarecke¹; Nancy Adams¹; Michael Green¹; Heather Stuckey²; Daniel Shapiro¹; Daniel R. Wolpaw¹. ¹Penn State College of Medicine, Hershey, PA; ²Penn State University College of Medicine, Hershey, PA. (Tracking ID #2199128)

BACKGROUND: Despite widespread use of the arts in medical education as a tool to promote diverse skills related to patient-centered care, educators often lack guidance for incorporating arts into educational designs. The purpose of this study was to systematically review and synthesize the literature in order to: 1) identify how the arts promote learning; 2) identify strategies used by educators to facilitate arts-based learning; 3) create a conceptual model that guides implementation and evaluation of the arts in medical education.

METHODS: Our project team includes both clinicians and researchers with expertise in medical humanities, library sciences and education. We performed searches of the PubMed and ERIC databases using various combinations of terms related to teaching, the arts, humanism, and theoretical models. We included articles that described the use of the arts to promote skills or knowledge acquisition, or that introduced models or theoretical frameworks incorporating arts-based approaches to facilitate humanism or individual change. The PubMed searches yielded 825 articles, and ERIC searches yielded 179 articles. Upon review of the abstracts of all identified articles, 143 were selected for further review. We read the entire text of these 143 articles, and identified 46 that met our inclusion criteria. We performed a qualitative analysis of the text and data of these selected articles. We used Atlas.ti 7.1 software to categorize, code, and review key passages and qualitative data presented in the articles. Two of the investigators independently coded the article texts and data. Weekly phone calls were conducted to discuss emergent themes and coding practices. We constructed a conceptual model to guide usage of the arts in education through repeated iterations of review and discussion of coded passages.

RESULTS: We identified three areas of focus related to using the arts in teaching: a) unique qualities of the arts that promote learning, b) intermediate or process outcomes that result from arts-based teaching, and c) downstream impacts of arts-based teaching. Unique qualities of the arts included activating and cultivating imagination, engaging emotions, providing new ways of seeing and processing everyday phenomena, and experiencing facets of the human condition that students would not normally recognize. Intermediate and process-based outcomes included the breakdown of hierarchies and fostering community among diverse groups of learners, increased emotional awareness and intelligence, high degrees of engagement, and personal awareness and surfacing of assumptions.

Downstream impacts included increased empathy, narrative competence, better understanding of patients' perspectives, and enhanced communication skills. Our emerging conceptual model suggests that particular design choices and teaching behaviors, such as creating activities explicitly aimed at helping students translate lessons learned from the arts to medical practice, are critical for unlocking the unique qualities of the arts and achieving important process-based outcomes and downstream impacts.

CONCLUSIONS: The arts provide a unique and powerful tool for fostering medical trainees' knowledge, skills, and attitudes related to the human experience of illness. However, just incorporating the arts alone is unlikely to achieve such outcomes. Our conceptual model suggests that optimum incorporation of the arts in medical education requires an understanding of the aesthetic and observational processes inherent to the art being used, strategic use of the art to motivate engagement of students with the art and each other, and skillful translation of lessons learned from such engagement to students' practice of medicine.

CONCEPTUAL MODEL OF HOUSE STAFF WORKLOAD IN THE INPATIENT SETTING

Jennifer M. Schmidt²; onur asan²; Laurie Simonds²; Kathryn Fletcher¹.
¹Medical College of Wisconsin/Milwaukee VAMC, Milwaukee, WI; ²Medical College of Wisconsin, Milwaukee, WI. (Tracking ID #2198319)

BACKGROUND: Workload is a complex concept that involves the cognitive, physical and emotional capacity to handle the tasks necessary to accomplish a goal. Medical education lacks a robust model for explaining the workload encountered by house staff. Our objective was to create a conceptual model of perceived contributors to house staff workload in the inpatient setting.

METHODS: We conducted focus groups with internal medicine interns and residents from a single program that includes 3 hospitals. The semi-structured focus group guide consisted of 19 open-ended questions with prompts. We audiotaped and transcribed the focus groups verbatim. We used the constant comparative method for data analysis. We started with open-coding to identify unique and unexpected codes. These were grouped into broader categories. We then applied a previously described model (the Systems Engineering Initiative for Patient Safety (SEIPS) model), for further categorization of the codes to one of the five SEIPS themes: Person, Environment, Technology, Organization, or Task. We used NVivo, a qualitative software package, for analysis. The line-by-line analysis was conducted by two members of the study team; one coded all of the transcripts; the other independently coded 2 of the transcripts. The entire study team met to discuss the emerging coding structure. Agreement between the two coders was calculated based on two of the transcripts.

RESULTS: We conducted five focus groups with a total of 19 internal medicine house staff. The coding scheme included 88 unique codes that encompassed traditional workload contributors (individual provider census) as well as more novel concepts (concern about physician physiologic needs—i.e., food). We sorted these codes into 18 categories, such as "Distractions," "Patient Factors," and "Electronic Health Record." All of the codes fit into the SEIPS model (Table), although some encompassed more than one SEIPS factor. Agreement between the two reviewers was 79 %.

CONCLUSIONS: The emerging conceptual model derived from these focus groups confirms that workload is a complex construct, composed of much more than census. The SEIPS model is a good starting point, but there are many nuanced contributors to workload within each of the SEIPS factors. Exploring this model in other residency programs is the next step in this work. Practically speaking, this detailed conceptual model may help to identify potentially important and modifiable contributors so that interventions to mitigate them can be developed and tested.

Contributors to House Staff Workload: SEIPS Factors and Corresponding Categories

SEIPS factor	Examples of Categories of Workload Contributors	Examples of Individual Codes within Each Category
Person	Ancillary Staff Attending Physician Medicine Team Patient Resident Characteristics	Knowledge of ancillary staff Supervision style Ability to work together Acuity; family characteristics Presence of physiologic needs
Environment	Distractions Location Resources Charting	Noise in team room Geographic localization of pts Wi-Fi Locating a computer

CONFIDENCE IN SMOKING CESSATION: SOCIAL SUPPORT TRUMPS HOUSEHOLD ENVIRONMENT

Cassia Wells²; Natalie Albanese²; Jesse Cohen²; Alice Tang²; Yixin Fang²; Ellie Grossman¹. ¹NYU School of Medicine, New York, NY; ²New York University, New York, NY. (Tracking ID #2198921)

BACKGROUND: Home environment and social support are important tools for behavior change. However, the relative influence of each in successful smoking cessation is unclear. Confidence in smoking cessation has also been shown to be strong predictor of successful quit attempts. In this study we examined the independent and combined effects of social support and home smoking environment on confidence in smoking cessation to help target future quit interventions.

METHODS: A secondary analysis was performed on a baseline survey of active smokers admitted to Bellevue Hospital Center and the Manhattan VA in New York City from 2011–2014 ($N=1619$). We examined the relationship of participants' home smoking environment and perceived social support to their confidence in quitting. Home smoking environment was defined as five categories: 1) participants who live alone; 2) participants who live with a non-smoker; 3) participants who live with a smoker who wants to quit; 4) participants who live with a smoker and do not know if they want to quit; 5) participants who live with a smoker who does not want to quit. Perceived social support for smoking cessation was a dichotomous variable (some support vs. no support). Confidence in smoking cessation was measured through a five-option ordinal scale, adapted from the California Tobacco Survey. The independent relationship between our predictors (home smoking environment and social support) and our outcome variable (confidence in quitting) were initially assessed in a univariate analysis. A multivariate linear regression was then performed using our two primary predictors, adjusting for age, gender, race, ethnicity, country of origin, education, recruitment site, and stable housing.

RESULTS: The majority of participants reported some social support for quitting (80 %) and only 22 % lived alone. Half of those who lived with someone lived with a smoker. Both increased social support ($p<0.0001$) and home quit environment ($p=0.037$) independently predicted increased confidence in smoking cessation. However, after a multivariate linear regression, only perceived social support remained significant ($p<0.0001$) whereas smoking environment did not ($p=0.91$). Other demographic variables significant in this model were race ($p=0.034$), recruitment site ($p=0.001$) and stable housing prior to admission ($p=0.001$).

CONCLUSIONS: Both social support and a positive home smoking environment increase smoking cessation confidence, however the effect of the home environment appears to be mediated through a sense social support. This also suggests that a significant amount of support may be coming from outside the home. Future interventions should focus on enhancing general social support and expand beyond the home.

Home Smoking Environment and Social Support vs. Confidence (Chi-square)

	Not at all confident	A little confident	Somewhat confident	Fairly confident	Very confident	P Value (χ^2)
Support

CONSISTENCY OF RESPONSE IN THE COMPASS STUDY [BREATH POWERED™ NASAL DELIVERY OF 22 MG SUMATRIPTAN POWDER (AVP-825) VERSUS 100 MG ORAL SUMATRIPTAN IN ACUTE MIGRAINE: A COMPARATIVE CLINICAL TRIAL] Richard B. Lipton²; Dawn C. Buse²; Ken Shulman¹; Joao Siffert¹; Scott Siegert¹. ¹Avanir Pharmaceuticals, Inc., Aliso Viejo, CA; ²Albert Einstein College of Medicine and Montefiore Medical Center, Bronx, NY. (Tracking ID #2188702)

BACKGROUND: AVP-825 is an investigational Breath Powered™ Bi-Directional™ product containing low-dose sumatriptan powder (22 mg) that delivers drug to the upper posterior segments of the nasal cavity, enabling rapid systemic absorption. Compared with 100 mg oral sumatriptan, AVP-825 showed significantly greater benefits on the COMPASS primary endpoint, the SPID-30 (results presented previously). In a real-life clinical setting, the consistency of a treatment effect across multiple migraines is a priority among patients. Measures of consistency have been reported for many migraine therapies, though the specific design and analyses used have varied. The purpose of this report is to evaluate consistency of pain response at early timepoints across multiple migraine attacks for AVP-825 vs. sumatriptan 100 mg oral tablets in the COMPASS study.

METHODS: Multicenter, double-dummy, crossover study with two 12-week treatment periods. Patients received AVP-825 or oral sumatriptan 100 mg tablets plus complementary placebos in period 1 then switched treatment for period 2. Patients treated ≤ 5 qualifying migraines/period within 1 h of headache onset, even if pain was mild. Multi-attack pain relief and pain freedom rates were estimated for the first 2 attacks, ≥ 2 of the first 3 attacks, and 3 of the first 3 attacks in each period. Comparisons assessed using McNemar's test.

RESULTS: A total of 185 patients were treated in both periods (full analysis set; 1531 migraine attacks treated). For patients treating ≥ 2 attacks in each period ($n=165$ patients each group), AVP-825 was superior to 100 mg oral sumatriptan in rate of pain relief (37.6 % vs. 18.8 %, $p<.0001$) and pain freedom (10.9 % vs. 3.0 %, $P=.0072$) at 30-min post-dose for the first two attacks. For patients treating ≥ 3 attacks in each period ($n=140$ patients each group), AVP-825 was superior to oral sumatriptan at 30 min post-dose for

pain relief (51.4 % vs. 33.6 %, $P=.0002$) and pain freedom (15.7 % vs. 6.4 %, $P=.015$) in ≥ 2 of the first 3 migraine attacks treated, and for pain relief (27.1 % vs. 12.1 %, $P=.0002$) at 30 min post-dose in 3 of the first 3 migraine attacks treated.

CONCLUSIONS: Compared with 100 mg oral sumatriptan, AVP-825 (22 mg sumatriptan nasal powder) resulted in more consistent pain freedom and pain relief across multiple migraine attacks within 30 min of treatment. Consistent rapid relief suggests the pharmacokinetic advantage of Breath Powered delivery of sumatriptan powder.

CONTRIBUTION OF PATIENTS' CLINICAL AND SOCIAL CHARACTERISTICS TO DIFFERENCES IN HOSPITAL READMISSION RATES Michael Barnett^{1, 2}; John Hsu^{3, 2}; J. Michael McWilliams^{2, 1}. ¹Brigham and Women's Hospital, Brookline, MA; ²Harvard Medical School, Boston, MA; ³Massachusetts General Hospital, Boston, MA. (Tracking ID #2193546)

BACKGROUND: To reduce hospital readmissions, Medicare penalizes hospitals with higher than expected 30-day readmission rates by up to 3 % of inpatient payments through the Hospital Readmission Reduction Program, implemented in 2012. The program determines a hospital's adjusted readmission rate using a statistical model that accounts only for patients' age and inpatient diagnoses in the prior 12 months. The extent to which adjustment for a comprehensive set of patients' clinical and social characteristics accounts for differences in hospital readmission rates has not been described.

METHODS: We analyzed survey data from the nationally representative Health and Retirement Study (HRS) and linked Medicare claims. Our study sample included respondents to biennial HRS surveys from 2000–2010 who had at least 1 admission during the survey year or 2 subsequent years after survey completion. We assessed a range of patient factors as potentially predictive of readmission when added to the standard model used to generate publicly reported hospital-wide readmission rates (HWRRs). Specifically, we estimated logistic regression models predicting 30-day readmission as a function of patient factors included in the HWRR model (age and 31 condition indicators constructed from the preceding 12 months of inpatient claims). We then added patient characteristics from 3 additional categories: 1) eligibility and demographic information from Medicare enrollment files (sex, Medicaid status, disability and end-stage renal disease); 2) diagnoses from all claims, including the hierarchical condition category (HCC) score from claims in the preceding calendar year, and 26 Chronic Condition Warehouse (CCW) indicators describing a patient's total chronic disease burden; and 3) 27 social and health variables from HRS survey items, including race, education, finances, health behaviors, functional status, family structure, and social supports. We assessed whether these variables were predictive of readmission when added to predictors from the HWRR model. We then compared differences in readmission rates between patients admitted to high vs. low performing hospitals, before vs. after adjusting for each category of characteristics in succession. Specifically, we categorized hospitals into quartiles according to their publicly reported HWRR in 2011–2012 and compared readmission rates between patients admitted to hospitals in the highest vs. lowest quartiles. To better match the study period with the publicly reported HWRR period, we limited this analysis to discharges from 2008–2012. We used design-based variance estimators to account for clustering within geographic areas, hospitals, and patients.

RESULTS: The full study sample included 9055 patients with 32,610 discharges from 2000–2012. In univariate analyses, 26 of 31 additional variables from claims and enrollment files and 25 of 27 HRS survey variables significantly predicted readmission. When added individually to a model including all predictors from the HWRR model, most of these additional variables remained significantly predictive of readmission. Restricting the analysis to 2008–2012

left 11,419 discharges among 4481 patients for comparing readmission rates by publicly reported HWRR. There were significant differences between patients discharged from hospitals in the highest vs. lowest HWRR quartile across most additional variables, including HCC score (2.47 vs. 2.24 for highest vs. lowest), CCW condition count (11.1 vs. 10.5), race (27.6 vs. 9.6 % black), education (34.7 vs. 25.0 % without high school degree), percent needing assistance with an activity of daily living (45.5 vs. 36.9 %), and total assets (36.8 vs. 26.4 % in lowest quartile of assets; $p < 0.001$ for all). Patients discharged from hospitals in the highest quartile of publicly reported HWRRs were significantly more likely than those discharged from hospitals in the lowest quartile to be readmitted within 30 days (unadjusted odds ratio (OR)=1.28; $p=0.001$). As expected, adjusting for HWRR model predictors minimally changed this estimate (OR=1.26; $p=0.002$), because publicly reported HWRRs already account for these factors. Adjusting for all additional patient characteristics from claims and HRS surveys reduced this OR by 38 % to 1.16 ($p=0.08$), with both claims-based diagnosis and HRS survey variables contributing independently to this reduction.

CONCLUSIONS: Much of the difference in risk of readmission between patients discharged from hospitals with higher versus lower publicly reported readmission rates was explained by differences in patients' clinical and social characteristics that are not considered in current risk adjustment of hospital readmission rates. This implies that current policy penalizes hospitals in large part for serving sicker and more socially disadvantaged patients. To avoid potentially unintended consequences of these penalties, such as exacerbating disparities, more robust adjustment for patient factors or alternative payment models may be required.

COORDINATED PERFORMANCE MEASUREMENT AND IMPROVEMENT EFFORTS IN CALIFORNIA'S SAFETY NET SYSTEMS: EARLY EXPERIENCE AND LESSONS: PUBLIC HEALTHCARE SYSTEMS EVIDENCE NETWORK AND INNOVATION EXCHANGE (PHOENIX) Courtney R. Lyles²; David Lown⁴; Gato I. Gourley²; Sara Ackerman¹; Dean Schillinger^{2, 3}; Margaret A. Handley²; Urmimala Sarkar^{3, 2}. ¹UCSF, San Francisco, CA; ²University of California San Francisco, San Francisco, CA; ³University of California, San Francisco, San Francisco, CA; ⁴CAPH/SNI, Oakland, CA. (Tracking ID #2198232)

BACKGROUND: Safety-net health systems serving predominantly Medicaid and uninsured populations often lack incentives and resources to support performance measurement and improvement activities. However, the California Delivery System Reform Incentive Program (DSRIP) is the first of its kind pay-for-performance Medicaid waiver that incentivizes the state's public health care systems to improve quality of care in both inpatient and outpatient settings. To enhance DSRIP participants' capacity to engage in (1) best practices to improve quality of care and (2) reporting of DSRIP-required metrics, the California Association of Public Hospitals and UCSF established the Public Healthcare Systems Evidence Network and Innovation eXchange (PHoENIX). Some of the first PHoENIX priorities were to work together to meet high population-based targets for two metrics in particular: mammography screening (76.6 %) and LDL control (<100 mg/dL) for diabetes (62.2 %).

METHODS: All 17 public hospital systems across the state engaged in the DSRIP program. We used both qualitative and quantitative methods to monitor the performance measurement activities and outcomes over a 1-year period, guided by the Consolidated Framework for Implementation Research. We conducted 21 in-depth interviews and 6 focus groups ($n=40$) with hospital leaders, as well as attended 4 in-person or web convenings about performance improvement activities. During these sessions, we characterized improvement efforts and identified barriers and enablers for meeting the performance metrics. In addition, we assessed participation in each performance improvement activity and reviewed quarterly outcome reports. We evaluated total 1-year improvements for the mammography and cholesterol metrics, classifying systems who improved by 2 %, 5 %, or had no change (± 2 %) over time.

RESULTS: Participation in improvement was high across the public hospital systems, as every system engaged in at least one performance activity. Similarly, each of the 4 convenings included representatives from at least 75 % of systems and 40–55 participants in total. However, our qualitative work uncovered a wide range of success across systems. The most common perceived barriers to change reported included: lack of personnel for data reporting/management; structural barriers, such as fragmented electronic health records, lack of equipment (e.g., mammogram machines); competing priorities, such as providing access to care for the newly insured; and a change in the national guideline for cholesterol control. Enablers included strong leadership, use of registry/panel management systems, and integrated data/information technology systems. To date, 59 % ($n=10$) of the health systems reported improvements their performance on mammography by 2 percentage points or more, 53 % ($n=9$) by 5 percentage points or more, and 1 system (6 %) had no change.

For LDL, 41 % ($n=7$) reported improvements in LDL by 2 % or more, 35 % ($n=6$) improved by 5 percentage points or more, and 24 % ($n=4$) had no change. However, only 1 system met the ultimate mammography target and no systems met the LDL target in this first year.

CONCLUSIONS: This project was one of the first collective efforts among safety net hospitals to work systematically and collectively on performance measurement and improvement. While our findings are early, they suggest that public health systems can engage in this area, but likely need more structural support to have sufficient staffing and information technology systems to reach these goals. Implementation science methods helped to identify barriers and enablers of change which can be applied to real-world improvement efforts, especially as we leverage PHoENIX in future quality improvement efforts.

Total improvements on Mammography and LDL metrics

COST-CONSCIOUS CARE IN THE UNCONSCIOUS: THE FINANCIAL IMPLICATIONS OF DIAGNOSTIC NEUROLOGIC TESTING IN PATIENTS PRESENTING WITH SYNCOPES Connor Healey¹; Jonah Feldman^{1, 2}; Thomas Coppola¹; Brahmabhatt Saloni¹. ¹Winthrop University Hospital, Mineola, NY; ²Stony Brook School of Medicine, Stony Brook, NY. (Tracking ID #2199332)

BACKGROUND: The presenting complaint of syncope represents a substantial burden on healthcare resources. Diagnostic neurologic testing is frequently ordered by clinicians in the evaluation of these patients, despite the paucity of evidence substantiating their utility. We aim to quantify the frequency and cost of neurologic testing of patients who present with syncope without a neurologic deficit, a practice that is not supported by major society guidelines.

METHODS: The medical records of 500 randomly selected patients admitted to a single community-based, university hospital during the 2012 calendar year with a diagnosis of Syncope and Collapse (ICD code 780.2) were analyzed. Exclusion criteria include transfer from another facility, elective admission, presyncope, mechanical fall without loss of consciousness, and syncope following admission to the hospital. The admission documentation was reviewed for evidence of a neurologic finding (ie. focal neurologic deficit or seizure activity) by history or exam to warrant further diagnostic testing. Subsequent testing with Carotid Ultrasound, Head CT, Brain MRI and EEG were noted. Costs of these investigations were determined using the 2012 billing information for the facility, adjusted for the cost-to-charge ratio.

RESULTS: Only 237 of the 500 patients did not meet exclusion criteria, with presyncope being the most common reason for exclusion. Among the 237 patients head CT was the most frequently performed neurologic test ($n=191$, 81 %), followed by Carotid US ($n=105$, 44 %), EEG ($n=69$, 29 %) and Brain MRI ($n=57$, 24 %). The proportion of tests that were deemed appropriate because they corresponded to a neurologic finding was low, and exhibited an inverse trend with the most utilized tests being the least likely to be associated with an appropriate indication. Evidence of a neurologic indication was found for ordering a CT head in only 15 % of patients (25/191), Carotid US 16 % (17/105), EEG 20 % (14/

69), and Brain MRI 30 % (17/57). The direct costs of the unwarranted tests amongst the 237 patients were \$113,886 for Head CT, \$28,072 for Carotid US, \$13,475 for EEG, and \$54,680 for Brain MR.

CONCLUSIONS: Neurologic testing in patients admitted to the hospital with syncope, but without a neurologic finding inflicts a substantial cost and represents an area of considerable waist for the healthcare system. Additional research is needed to identify reliable ways to change provider practice patterns in order to address this important problem.

CROSS-CULTURAL INTER-PROFESSIONAL FACULTY DEVELOPMENT IN JAPAN: RESULTS OF AN INTEGRATED WORKSHOP FOR CLINICAL TEACHERS Jeffrey G. Wong¹; Daisuke Son²; Wakako Miura². ¹Medical University of South Carolina, Charleston, SC; ²University of Tokyo School of Medicine, Tokyo, Japan. (Tracking ID #2198627)

BACKGROUND: Faculty development programs have proven useful for improving the clinical teaching skills of clinicians within medicine. One particular faculty development program, created at the Stanford Faculty Development Center (SFDC), has been successfully implemented in some foreign cultures, but has not been studied in Japan. Furthermore, joint inter-professional faculty development activities are less commonly reported and are infrequently studied. We wondered whether the SFDC faculty development program could be used to improve the clinical teaching of Japanese physician and nurse educators in a joint faculty development workshop series.

METHODS: A series of 7 small group interactive workshops, based on the SFDC model, were presented to 19 educators at the University of Tokyo-School of Medicine. Each seminar was 120 min long and was presented in English by one author (JGW) who is a trained SFDC facilitator. The seminars consisted of a mini-lecture introducing the educational topic, video-taped reviews of actual clinical teaching scenarios, interactive role-playing performed by the workshop participants, and the formulation of personal learning

goals by each participant. The written seminar materials were translated into Japanese and the video-tape scenarios were over-dubbed into Japanese by two of the authors (DS and WM). The role plays were also performed in Japanese and the commentary was translated into English as necessary by one of the authors (DS). There were three main outcome measures: 1) the seminar participants' satisfaction with the workshops; 2) their self-reported teaching abilities assessed through the use of a well-studied retrospective pre- post-questionnaire administered at 2 different times (1 month and at 12 months after the workshops); and 3) whether or not the participants were successful in completing "commitment to change (CTC)" statements at 1 year's time. Statistically, the numerical mean scores from each of the two sections of the questionnaire ("Global Assessment" and "Specific Teaching Behaviors") were compared using the two-tailed student *t*-test and standard deviation of mean scores were calculated. The actual percentage of successfully incorporated CTC statements was also reported.

RESULTS: There were 12 physicians, 6 nurses and 1 English-language teacher who participated (10 men and 9 women - 2 physicians, all of the nurses and the English teacher were women). All participants valued the seminars and the inter-professional aspects of the sessions. Summative mean self-reported ratings of Global Assessment improved between retrospective pre- and post- test scores at 1 month and at 12 months (**pre**=27.3, **post(1)**=36.8, $p<0.001$, **post(12)**=34.9, $p<0.001$) and for specific teaching behaviors (**pre**=82.1, **post(1)**=111.1, $p<0.001$, **post(12)**=104.3, $p<0.001$). There was non-significant degradation of improvement between the 1 month and 12 month values. In total, 24/39 CTC statements were successfully achieved at 1 year (61.5 %).

CONCLUSIONS: While limited to a single institution of clinical educators, we were able to demonstrate self-reported improvement in clinical teaching skills for both medicine and nursing faculty teachers that endured at least 1 year after the educational intervention. Inter-professional faculty development across both cultures and health profession disciplines can be achieved.

CROWDSOURCING THE DIAGNOSIS: RESULTS OF A NATIONAL SURVEY OF PATIENT ATTITUDES TOWARDS PHYSICIANS SHARING DEIDENTIFIED PATIENT IMAGES ONLINE

James Colbert^{2, 5}; Eliyahu Lehmann⁶; Priyanka Agarwal³; Joy L. Lee¹; Katherine C. Chretien⁴; Lisa S. Lehmann⁵. ¹Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; ²Newton-Wellesley Hospital, Newton, MA; ³University of California, San Francisco, San Francisco, CA; ⁴Washington DC VAMC, Washington, DC; ⁵Brigham and Women's Hospital, Boston, MA; ⁶Cornell University, Ithaca, NY. (Tracking ID #2196426)

BACKGROUND: Physicians have traditionally used case conferences, scientific meetings, and medical journals as opportunities to improve their own knowledge and advance

medical research. The Internet and social media now offer new opportunities for physicians to share information with each other and to learn through virtual interactions. For example, smartphone apps now enable physicians to easily upload and share deidentified patient images with health care professionals around the world. While such smartphone apps have the potential to foster medical education, improve patient care and advance medical knowledge, little is known about patient preferences towards physicians sharing deidentified patient information via online forums.

METHODS: We conducted a paper-based cross-sectional survey of patients at four academic primary care centers in Boston, Washington DC, and San Francisco. The survey was conducted in English, and patients were asked about their usage of technology and social media for healthcare. As part of the survey, participants were presented with the

following scenario: Let's say you have a worrisome rash on your back and your doctor would like to post a picture of just your back (no one could tell it was you) on a public website that's mainly viewed by physicians and scientists. Participants were asked if they would give permission to have their picture posted online for the following reasons: 1) to improve their own medical care, 2) to educate other doctors, and 3) to advance scientific knowledge. Respondents were also asked whether they would prefer their doctor to obtain written consent, verbal consent or no formal consent prior to posting the picture online. Data were also collected on patient demographics, including age, gender, education, race, ethnicity, and health status.

RESULTS: A total of 491 patients completed the survey. Fifty-nine percent (289) of respondents were women, 41 % (199) were white, 32 % (156) were black, and 10 % (50) were Hispanic. Forty-one percent were younger than age 50 and 27 % were age 65 or older; 56 % (273) had at least a college degree; and 33 % (164) rated their health as excellent or very good. Overall, a majority of surveyed patients would give permission to their primary care provider to post a deidentified image of their rash online to improve their care, educate other doctors or advance medical knowledge (80 %, 82 %, 82 % respectively). The remaining 20 % of surveyed patients would never allow the image to be posted. Among the respondents who were willing to have their physician post their picture online if it would improve their doctor's ability to identify and treat the rash, 31 % felt that no formal consent was required, 43 % felt that verbal consent should be obtained, and 26 % felt that written consent was needed. Responses were similar when patients were asked what type of consent should be obtained for their doctors to use their image online to advance medical education or research (see Table). Multivariate regression analysis showed that white respondents were three times more likely than other races to give permission to post a picture (OR 3.17, $p=0.03$). Patients who report posting about their own health on social media were more than twice as likely to give permission to their doctor to post (OR=2.5, $p=0.03$). Further analysis found that patients aged 65 or older were more likely to indicate that no permission is necessary for their physician to post a picture online when compared with younger patients (OR 4.5, $p<0.01$). However, younger patients (age 18–34) were significantly more likely than older patients to believe that verbal consent was sufficient rather than written consent (OR 3.7, $p<0.01$). Education, self-reported health status, and age had no significant impact on whether a patient would give permission to post their picture on social media.

CONCLUSIONS: Most respondents would allow physicians to post a deidentified image of them online if doing so could help improve their medical care, contribute to medical education or advance medical research. Among those who would allow their physicians to post their picture online, nearly half felt that verbal consent should be obtained prior to posting the picture. Smaller numbers felt that written consent or no consent would be most appropriate. These data suggest that while patients in general are supportive of physicians sharing medical images online, hospitals and medical clinics will need to carefully consider how best to implement patient consent policies that protect patient privacy without restricting the ability of physicians to benefit from online sharing of information. Patient attitudes towards a physician posting a deidentified image of them online

CURBING ANTIMICROBIAL RESISTANCE: DO PHYSICIANS RECEIVE ADEQUATE TRAINING ABOUT ANTIBIOGRAMS? <!--ENDFRAGMENT--> Priya Nand; Stuart Cohen; Machelle D. Wilson; Jennifer Brown. University of California, Davis, Sacramento, CA. (Tracking ID #2199142)

BACKGROUND: Antibiotics are among the most common classes of medications prescribed in health care settings. The U.S. Centers for Disease Control and Prevention (CDC) estimates that up to 50 % of antimicrobial use in health care settings is inappropriate or unnecessary. Antibiotic overuse and misuse is fueling an alarming upsurge in the rates of antimicrobial resistance and deaths attributable to antibiotic-resistant organisms. As part of the national strategy for combating this public health crisis, the CDC recommends the use of local antibiograms to guide judicious prescribing practices. We aimed to assess whether physicians are receiving adequate training about antibiograms. <!--EndFragment-->

METHODS: From April 2014 to October 2014, a 20-item, internet-based survey was sent to house staff physicians in Internal Medicine training programs throughout the U.S. Questions focused on antibiogram knowledge, interpretive skills, and training practices. <!--EndFragment-->

RESULTS: Overall, 266/1293 (21 %) invited house staff responded; 178 (67 %) were residents and 87 (33 %) were interns. Eighty-seven percent of respondents were from academic institutions and the remainder were from community-based programs. For respondents who completed the antibiogram interpretation questions, the mean correct score was higher for residents ($n=164$) than for interns ($n=72$) (85 % vs 74 %, $P=0.011$). The mean score was also higher for respondents who had completed an infectious diseases (ID) rotation ($n=164$) as compared to those who had not ($n=72$) (85 % vs 75 %, $P=0.018$). Almost 83 % of respondents felt confident in their ability to interpret antibiograms

however, 30 % had never received any formal antibiogram training or were self-taught. Only 89/140 (64 %) respondents who completed an ID rotation were taught about antibiograms during the rotation. About one-fifth of respondents did not know how to obtain their institution's antibiogram. Overall, 71 % of respondents wanted to receive more training in antibiograms; of these, most (91 %) preferred training during internship or residency lectures. <!--EndFragment-->

CONCLUSIONS: Physicians are not receiving adequate training about antibiograms. We encourage medical training programs to evaluate their curricula and to optimize house staff education regarding antibiograms. A multi-faceted approach, including didactic lectures and the practical application of antibiograms during clinical rounds, should be considered. Improving house staff training about antibiograms and the judicious use of antimicrobials is essential to curb the growing crisis of antimicrobial resistance. <!--EndFragment-->

DECLINING PASS RATES OF THE AMERICAN BOARD OF INTERNAL MEDICINE CERTIFICATION EXAMINATION: PROGRAM DIRECTORS' PERSPECTIVES Lisa L. Willet⁶; Andrew J. Halvorsen⁴; Michael Adams³; Vineet M. Arora⁷; Karen Chacko⁵; Furman S. McDonald⁴; Amy Oxentenko⁴; Sara L. Swenson¹; Aimee K. Zaas²; Saima Chaudhry⁸. ¹California Pacific Medical Center, San Francisco, CA; ²Duke University, Durham, NC; ³Georgetown University Hospital, Washington, DC; ⁴Mayo Clinic, Rochester, MN; ⁵University of Colorado Denver, Aurora, CO; ⁶University of Alabama at Birmingham, Birmingham, AL; ⁷University of Chicago, Chicago IL, IL; ⁸nslij, Manhasset, NY. (Tracking ID #2200724)

BACKGROUND: The American Board of Internal Medicine (ABIM) is a high stakes exam. Since 2007, the percentage of first time test takers who passed the ABIM has fallen. To understand reasons for the decline, we administered a national survey to Internal Medicine (IM) PDs to determine their views on why the pass rates have fallen.

METHODS: The Association of Program Directors in Internal Medicine (APDIM) Survey Committee develops yearly questionnaires to address current issues facing IM residency programs. With the 2013 Web-based electronic survey, we assess PD perspective of the ABIM declining pass rates. We assessed differences in pass rates by program demographics (program description, region, size, PD tenure), and resident demographics (percentage of US medical graduates, women, and underrepresented minorities [URM]). We assessed PD agreement with: reasons for ABIM pass rate decline; why residents did not pass; methods to prepare residents; and use of InTraining Examination (ITE). We asked PDs to free text reasons why the pass rate declined, if given statements did not capture their thoughts. These responses were coded for qualitative data.

RESULTS: Our response rate was 67.8 % (265/391). We found no difference in ABIM pass rate by program type (79.5 % average pass rate). There were differences by region, program size, and PD tenure. Regionally, the pass rate was 71.8 % for Continental US and Unincorporated Territories ($p=0.001$); when only Continental US was included, regional differences were no longer significant ($p=0.27$). Smaller size residency programs had lower pass rates: <40 residents 82.5 %, 40–73 residents 85.3 %, >73 residents 86.8 % pass rate ($p=0.004$). PDs with shorter tenure had lower pass rates: tenure <2 years 83.2 %; 2–7 years 84.2 %; >7 years 87.4 % ($p=0.003$). Of resident demographics (% of US medical graduates [USMG], women, and URM), the only differences were found in programs with lower percentage of USMGs. Pass rates for programs with <12 % USMGs were 85.3 %, and >80 % USMGs 88.6 % ($p<0.001$). **Reasons for pass rate decline:** Most PDs feel pass rate decline is most attributable to residents spending less time independently reading (73 % agree/strongly disagree) and reflecting about their patients (67 % agree/strongly agree). Fifty-one PDs used the free text box, citing 42 additional reasons, of which the most common were: less qualified trainees taking the ABIM, societal factors/generational differences in learning and studying, and logistics of the clinical environment. **Reasons specific residents did not pass the exam:** PDs communicated with all (18 %) or some (49 %) of the residents who failed the exam. Top reasons why residents felt they failed were: resident was "poor standardized test taker" (67.9 %), didn't study enough (65.4 %), and had competing personal responsibilities (pregnancy, children)(48.4 %). The top three reasons PDs felt the resident(s) did not pass were low performance on the ITE each post graduate year (PGY)-3, 72.5 %; PGY2 68.7 %; PGY1 55.5 %. **Methods to prepare residents for ABIM exam:** The majority of programs provide a board review program (86 %), for a mean of 57.9 h/year, including: Medical Knowledge Self-Assessment Program (MKSAP) (96.2 %), MKSAP incorporated into other regular teaching sessions (62.9 %), and independent designated lectures (58.1 %). These sessions target PGY-3s (98.1 %), PGY2s (69.0 %) and PGY1s (42.4 %). Programs provide funding for MKSAP (61.1 %), for independent study materials (49.8 %) and commercial board review course registration (26 %). **Use of In Training Examination (ITE):** Programs administer the ITE to all PGY levels (PGY2 93.6 %, PGY3 91.7 %, and PGY1 86.4 %). Ninety-one percent of PDs use a threshold score on the ITE to identify a resident at risk for failing the ABIM; 77 % have not changed the threshold in the past 3 years. The majority of PDs use the national percentile rank (86 %) to identify an at-risk resident, versus total percent of

questions correct (14 %). The mean percentile rank score used by PDs is 32.6. Most (69.8 %) use the same threshold score regardless of PGY. **Program response to ABIM failures:** Seventy percent of PDs have made changes to their board preparation methods because of ABIM failures. Those who have made changes are more likely to have lower pass rates (83.7 % pass rate) compared to PDs that have not made changes (92.7 % pass rate) ($p < 0.0001$). Sixty-seven percent of PDs give stronger consideration to US Medical Licensing Examination scores for ranking medical students than in years' past.

CONCLUSIONS: The ABIM is important for our profession, and the declining pass rates warrant study. We identified characteristics of programs with lower pass rates and IM PD perspectives on reasons for the decline. The level of detail we discovered will inform the IM community of key areas for further study to help our trainees succeed in certification.

DECREASING THE FRICTION BETWEEN TEAMS: PERSPECTIVES OF MEDICINE RESIDENTS AND SUBSPECIALTY CONSULTANTS ON THE CONSULTATION PROCESS. Amar Kohli; Michael Elnicki. University of Pittsburgh, Pittsburgh, PA. (Tracking ID #2193176)

BACKGROUND: Consulting a colleague is an integral task for medicine residents. Although long known to be suboptimal, the process continues to be characterized by a lack of didactic teaching in doctor-to-doctor communication. Physicians are still not "inherently" able to communicate consultation needs effectively with other physicians, and this inability can lead to dissension or frank hostility among colleagues. Earlier studies indicate that the paramount elements to a consult call are patient identifier, consult urgency and consult question. These criteria were recapitulated several times as physicians tried to make consultation communication more effective. Numerous changes in resident education have occurred over the past decade. Resident duty hours and competency based developmental milestones have placed a spotlight on the importance of inter-professional communication. The consultation process lends itself extremely well to the assessment of this competency.

METHODS: In order to assess stakeholder opinions about the consult process, distinct web-based surveys were created and electronically disseminated to all categorical internal medicine residents and subspecialty medicine fellows during May 2014. We assessed barriers to communication at our institution, as well as if the key pieces of information in the consultation process remained the same. Finally, we asked participants if they felt that identified barriers were negatively impacting patient care. The survey was a compilation of 5-point Likert scale questions, Yes/No questions, and text box short answers. Descriptive statistics, student *t*-test and chi squared analysis were implemented.

RESULTS: Of 157 residents, 81 responded (52 %) and of 154 subspecialty consultants, 97 responded (63 %). Both groups agreed ($p > 0.20$ for all comparisons) that consult question, consult urgency, and whom to call with an answer were the three most important elements of a consult call. Resident confidence to convey a consult question (4.24) was statistically different from consultants' perceived competence of those residents' abilities (3.34), ($p < 0.01$). Similarly, resident perceived confidence to convey the urgency of a consult (4.32) and the consultant's perception of the residents' capacity (3.13) differed ($p < 0.01$). When choosing not to follow consultant recommendations, residents said that they called consultants 21 %, wrote in their note 75.3 %, and did nothing further 3.7 % of the time. Consultants stated that residents called them 3.1 %, wrote in their note 27.1 %, and did nothing 69.8 % of the time ($p < 0.01$ for all 3 comparisons between groups). Both groups felt that interactions were educationally rewarding (3.86 vs. 3.64, $p = 0.17$). They agreed that poor communication through the consultation process increased patient length of stay (3.67 vs. 3.21, $p = 0.07$), but tended to disagree that it caused more adverse patient outcomes (2.71 vs. 2.63, $p = 0.38$). One consultant's sentiment revealed this difference, "It is sometimes difficult to find the correct person to speak with about a patient and to give recommendations for what to do; this sometimes delays therapy or discharge."

CONCLUSIONS: Calling a consult continues to be an essential part of residency training. There is general agreement about the important aspects of consultation, but disagreement about the competence of those involved. The ACGME has placed an increased emphasis on this skill by delineating milestones that help to establish competency in inter-professional communication. A disconnect between residents and consultants is highlighted by the perceived communication differences when recommendations are not followed. Medicine subspecialty consultants felt that residents were unable to develop consult questions or determine consult urgency as well as the residents did. Direct observation of residents by experienced medical

educators may be a way to remedy this gap. Previously, consult question, consult urgency and patient identifier were shown to be the most important criteria of a consult call. Our survey has shown that "whom to call" has become even more important than the patient identifier. This correlates to the increased duty hour restrictions enforced for residents since 2011. It has become less commonplace for the daytime resident team to be available to speak with consultants who round in the late evening or nighttime hours. Our research highlights the communicative discord between residents and consultants. Potentially, hospital dynamics, work flow and patient length of stay could be negatively affected. This suggests the need for a formal curriculum for both residents and consultants, in order to improve consultation communication.

DEFINING PRIMARY CARE TEAM EFFORT FROM THE PRIMARY CARE PHYSICIAN'S PERSPECTIVE Johan S. Hong²; Steven J. Atlas¹; Jeffrey M. Ashburner¹; Clemens S. Hong¹. ¹Massachusetts General Hospital, Boston, MA; ²Brigham and Women's Hospital, Boston, MA. (Tracking ID #2199904)

BACKGROUND: Some patients require greater effort from primary care teams. Understanding the characteristics of such patients might help us better direct resources and redesign care to both improve patient care and reduce primary care team burnout. We characterized patients requiring greater primary care team effort as defined by their primary care physicians (PCPs).

METHODS: We recruited all PCPs, from a large academic, primary care practice-based research network, who managed a panel of at least 100 patients in 2013. Participating physicians used an electronic survey tool to review a list of 100 of their randomly selected patients. After verifying that the patient was in their panel, the PCP answered the following question on 4-response scale (a lot of effort; a moderate amount of effort; a little effort; no effort at all): "How much effort does it take you and your team to care for this patient?" For higher-effort patients (that PCPs designated as requiring a lot or a moderate amount of effort), PCPs were asked what factors (medical/care coordination, behavioral health, and/or socioeconomic) contributed to the presumed high effort requirement. We compared sociodemographic, clinical, and utilization characteristics for higher-effort versus lower-effort patients using chi-square, Wilcoxon rank sum, and student *t*-tests. We also created eight adult age strata and assessed change in frequency with which PCPs identified medical/care coordination, behavioral health, and socioeconomic issues as contributors to "physician-defined" effort.

RESULTS: Among eligible PCPs, 54 % (99/184), representing 90 % (17/19) of network primary care practices completed the patient list review. The average age of PCPs was 49.3 years, 56 % were female, 35 % practiced in a community health center, and PCPs had worked an average of 14.9 years in their practice. These characteristics did not differ from non-participating PCPs. PCPs reviewed 9832 patients and designated 238 (2.4 %) as not one of their patients. Among the remaining 9594 patients, PCPs classified 23.7 % (range 3.0-55.8 %) as higher-effort. Among higher-effort patients, PCPs selected medical/care coordination (79.4 %), behavioral health (59.7 %), and socioeconomic issues (31.5 %) as contributors to higher physician-defined effort. With increasing age strata, medical/care coordination issues were more often cited, and behavioral health issues less often cited, as a contributors to physician-defined effort (Figure 1). Compared to lower-effort patients, higher-effort patients were older (60.9 vs 51.2 years old, $p < 0.001$), and more likely to be women (64.7 % vs 59.8 %, $p < 0.001$), reside in neighborhoods with lower median household income (\$58,892 vs \$69,798, $p < 0.001$) and be insured by Medicare (40.1 % vs 15.5 %, $p < 0.001$) or Medicaid (13.7 % vs 8.7 %, $p < 0.001$) rather than commercial insurers (44.0 % vs 72.7 %, $p < 0.001$). Compared to lower-effort patients, a greater proportion of higher-effort patients had a last serum creatinine level > 2.5 mg/dl (3.8 % vs 0.2 %, $p < 0.001$) and a greater proportion of higher-effort patients with diabetes that had last HbA1c levels greater than 9 % (6.1 % vs 1.2 %, $p < 0.001$). Higher-efforts patients also were more likely to carry a diagnosis of atrial fibrillation (11.9 % vs 2.8 %, $p < 0.001$), bipolar disorder (4.5 % vs 1.0 %, $p < 0.001$), have an alcohol-related problem (7.4 % vs 3.5 %, $p < 0.001$), or be prescribed selective serotonin reuptake inhibitors (3.6 % vs 0.7 %, $p < 0.001$), benzodiazepines (55.4 % vs 32.4 %, $p < 0.001$), or antipsychotics (0.6 vs 0.1 %, $p < 0.001$). Finally, a greater proportion of higher-effort patients had an emergency department visit (25.8 % vs 7.7 %, $p < 0.001$) in the last year.

CONCLUSIONS: PCPs in a large academic, primary care practices-based research reported that a quarter of a randomly selected subset of their patients required higher effort from their primary care teams. They identified medical,

behavioral health, and socioeconomic issues as contributors to primary care team effort. An improved understanding of the factors that contribute to primary

care team effort will help us appropriately allocate resources and redesign primary care to improve care and provider experience.

Medical, Behavioral Health, and Socioeconomic Issues Contributing to Primary Care Physician-defined Effort across Age Strata

DEFINING QUALITY OF RESIDENT WORK ROUNDS: IMPACT OF TEAM SIZE AND PGY-LEVEL Mayce Mansour²; Sheira Schlair¹; Sharon Leung³; Danit Arad³; Darlene LeFrancois³. ¹Albert Einstein College of Medicine/Montefiore Medical Center, Bronx, NY; ²Montefiore Medical Center, New York, NY; ³Montefiore Medical Center, Bronx, NY. (Tracking ID #2194001)

BACKGROUND: Resident work rounds are an opportunity for internal medicine residents to oversee patient care, exercise leadership, and expand their knowledge base. Additionally, rounds are perceived as the primary venue for residents to develop their teaching skills, with prior work suggesting that feedback on directly-observed work rounds improves residents' confidence as educators. However, data on the content and quality of rounds is lacking, and the impact of resident training level and team size is not clear. We aimed to identify modifiable variables that may facilitate more effective resident work rounds. We hypothesized that smaller teams led by PGY3-residents would create a more educational work environment.

METHODS: We conducted this study on the inpatient service at Montefiore Medical Center (Bronx, NY), an urban, academic, tertiary-care hospital with 96 senior internal medicine residents. Resident work rounds occur every morning for approximately 45 min prior to attending rounds. The format of these rounds is determined by the supervising resident on the team. Medical teams consist of a senior resident, 1-4 interns and medical students, with 8-16 patients on a team. Individual resident work rounds were assessed by trained core faculty using the Teaching on Work Rounds (ToWR) feedback tool, a 31-item checklist consisting of five domains: (1) learning climate (8 items, e.g., allowing learners to articulate questions and plans without interruption); (2) teaching techniques (15 items, e.g., probing learners' understanding of cases and explaining clinical reasoning and supporting evidence); (3) leadership (5 items, e.g., time-management and role-modeling professionalism); (4) providing effective feedback (2 items, i.e., reinforcing feedback and noting errors/mistakes); and (5) lifelong learning (2 items, i.e., assigning questions to self and learner). A multivariate linear regression model was employed to examine the impact of team size (large teams >3 learners, small teams ≤3 learners), and PGY-level of team leader (PGY2, PGY3). Analysis was performed using STATA version 11.2. P-values <0.05 were considered significant.

RESULTS: Fifty-three resident work rounds were observed from 2012 to 2014; 64 % were PGY2-led and 36 % were PGY3-led. Overall, 57 % of learning climate items, 38 % of teaching technique items, 53 % of leadership items, 29 % of feedback items, and 14 % of lifelong learning items were employed. Residents most frequently employed checklist items in learning climate and teaching technique domains, while infrequently employing checklist items in feedback and fostering lifelong learning domains. Utilization of more

items in learning climate was associated with large teams and PGY2-led teams ($p=0.03$ and $p=0.05$, respectively). Comparing between PGY2s and PGY3s on small teams, PGY2s utilized more items in the learning climate and teaching techniques domains than their seniors ($p=0.02$ and $p=0.05$ respectively), whereas PGY3s more frequently gave effective feedback ($p<0.05$). Comparing small and large teams, both PGY2s and PGY3s leading large teams employed more items in the learning climate domain ($p=0.01$).

CONCLUSIONS: In our study, which focused on the content of resident work rounds using a validated feedback tool, we assessed the frequency of items utilized in five teaching domains and evaluated differences based on team-size and PGY-level. While our findings suggest that PGY2s may use a broader array of teaching techniques and promote a healthier learning climate as compared to PGY3s, PGY3s may more frequently demonstrate the advanced skill of providing feedback to their peers. Overall, residents were observed to infrequently provide feedback and promote lifelong learning. In the hierarchical and rushed climate of resident work rounds, these behaviors may involve more risk by requiring residents to admit gaps in knowledge-base and to role model self-doubt. Further, in contrast to some previous literature, residents who led work rounds on larger teams were observed to promote better learning environments. Study limitations include lack of randomization of team assignment, potential observer bias, and limited number of observations. Our analysis suggests potential areas for improvement of inpatient team-building and resident development. Programs may consider creating new curricula on effective feedback-giving and promoting habits of lifelong learning. Additionally, more focus placed on the transition from PGY2 to PGY3 years may promote the ongoing development of medical educator skills. Finally, our study suggests that composing larger inpatient teams with multilevel learners may foster an environment more conducive to academic development.

DEFINING THE INCIDENCE OF LACTIC ACIDOSIS IN PATIENTS PRESCRIBED METFORMIN WITH AND WITHOUT RISK FACTORS FOR LACTIC ACIDOSIS Katy E. Trinkley¹; Heather Anderson¹; Daniel Malone²; Kavita Nair¹; Joseph J. Saseen¹. ¹University of Colorado, Aurora, CO; ²University of Arizona, Tucson, AZ. (Tracking ID #2200814)

BACKGROUND: Metformin is the first line medication for type 2 diabetes (T2DM) because it has demonstrated reductions in both cardiovascular morbidity and mortality. Despite these overwhelming benefits of metformin, prescribing is suboptimal. Although the reasons for sub-optimal metformin use are unknown, it is likely that fear of precipitating lactic acidosis potentially hinders metformin use in certain at-risk patients (e.g., those with kidney or hepatic impairment, heart failure, older age, alcohol abuse, chronic obstructive pulmonary disease, history of lactic acidosis). It is also likely that prescribing is influenced by metformin's labeling, which includes contraindications and precautions for use in certain patients at-risk for lactic acidosis further hindering prescribing. In general, the risk of lactic acidosis with metformin use is minimal and similar to the general

population. Evidence suggests the risk of lactic acidosis is higher with sulfonylureas, which are commonly prescribed as an alternative to metformin when the risk of lactic acidosis is perceived to be high. Data assessing the risk of lactic acidosis with metformin are limited by small samples and the fact that these analyses did not attempt to quantify lactic acidosis risk factors. The purpose of this study was to describe the incidence of lactic acidosis in a large cohort of patients with T2DM and to estimate the association between metformin use, lactic acidosis, and risk factors for lactic acidosis.

METHODS: We conducted a retrospective cohort study of patients with newly diagnosed T2DM utilizing a 10% random sample of the IMS LifeLink Health Plan Claims Database. Patients with and without risk factors for lactic acidosis were included. T2DM medication exposure was classified as metformin only, other non-metformin medication(s), or no medication based on the first medication(s) filled following the index diabetes diagnosis. Risk factors for lactic acidosis were measured during the 6 months prior to index T2DM diagnosis. Incidence rates (IR) were calculated as the number of patients with lactic acidosis at least once during their follow-up divided by the total person-time at risk, reported as per 10,000 person-months. Incidence rates were stratified by medication group (metformin only, non-metformin, or no medication), and calculated for subsets of patients with each risk factor. Associations between diabetes medication exposure (metformin versus non-metformin versus no therapy) and lactic acidosis were estimated using relative risk (RR).

RESULTS: A total of 109,656 subjects met the definition of newly diagnosed T2DM: 18% were prescribed metformin monotherapy, 12% were prescribed non-metformin T2DM medications and 70% were prescribed no T2DM medications. The median age was 56 years (range 18–99) and 49% were female. There were a total of 211 patients with lactic acidosis diagnosed during the study period (mean follow-up=9.7 months). The mean number or risk factors per patient was 0.2 (14% of patients had one or more risk factors). The overall incidence of lactic acidosis was 2 per 10,000 person-months (95% confidence interval (CI): 1.7, 2.3). Incidence of lactic acidosis was significantly higher in the non-metformin medication group (IR=4.2, 95%CI: 2.8–6.3) compared to the metformin only group (IR=0.9, 95% CI: 0.5–1.8) and the no medication group (IR=1.9, 95% CI: 1.7–2.3). Risk of lactic acidosis was highest among patients with CKD (17.4 per 10,000 person-months) and with a history of lactic acidosis (42.1 per 10,000 person-months). The incidence of lactic acidosis was lower in the metformin group than the non-metformin and no medication groups for patients with all risk factors, except alcohol abuse (70.9 vs. 0 vs. 5.1 per 10,000 person-months, respectively). Each risk factor significantly increased risk of lactic acidosis, with RR estimates ranging from 2.3 (95% CI: 1.6, 3.5) for age \geq 80 years to 21.5 (95% CI: 5.3, 87.7) for having a history of lactic acidosis; however, this risk did not differ significantly across medication groups for any of the risk factors ($p\geq 0.05$). Adjusting for the number of risk factors did not significantly change the incidence of lactic acidosis within each medication group ($p\geq 0.05$).

CONCLUSIONS: The incidence of lactic acidosis was significantly lower among patients prescribed metformin compared to those prescribed other T2DM medications or no medication. When considering risk factors for lactic acidosis, the IR of lactic acidosis varies by comorbid conditions. Our results refute the notion that there is an increased risk of lactic acidosis with metformin use; rather, the estimated risk was lower when compared to no treatment or other medications. Based on these data clinicians should consider prescribing metformin among patients with risk factors for lactic acidosis.

DEMONSTRATING MEDICAL STUDENT COMPETENCY IN PRIMARY PALLIATIVE CARE: DEVELOPMENT AND EVALUATION OF A NEW “OSCE” STATION Andrew T. Putnam¹; Margaret Bia¹; Carol Pfeiffer²; Michael Green¹; Matthew S. Ellman¹. ¹Yale School of Medicine, New Haven, CT; ²University of Connecticut School of Medicine, Farmington, CT. (Tracking ID #2192194)

BACKGROUND: To meet the needs of the many patients living with complex and life-limiting illness, all physicians should achieve competency in primary palliative care. Diverse approaches to palliative care education exist in medical school curricula. In order to assess the effectiveness of teaching strategies and students skills, we need tools to evaluate students' competency in palliative care. Objective Structured Clinical Examinations (OSCEs), a widely accepted for evaluating student competency, have not been reported for primary palliative care. Our goal was to develop, implement, and assess the characteristics of a palliative care OSCE for 4th year medical students at our school who had completed a curriculum in palliative care.

METHODS: We created a representative clinical case and a performance checklist addressing 3 core, observable palliative care domains: Symptom management; Communication; Psychosocial, spiritual, and cultural aspects of care. We trained an experienced standardized patients (SP) then piloted and further refined the case and checklist. Over 2 consecutive years (pilot year and implementation year), all rising 4th year students completed the OSCE as the eighth case in a required 7 station assessment. The SP used the checklist to mark items as either performed or not performed. To evaluate the SP and ensure reliability, SP-student interactions were videotaped, monitored by remote observers

who independently scored 10% of the encounters. Based on reviews of the pilot year videotapes, analysis of students' performances, feedback from the SP and from 6 palliative care clinicians who completed the OSCE, we further refined the case and checklist for the implementation year. Inter-rater reliability of the OSCE stations was determined as the percent agreement between the SP and the remote observer. We performed standard item analyses including the difficulty index (percent students performing each item) and the discrimination index (point biserial correlations). We collected validity evidence related to content, internal consistency (Cronbach alpha), and relationship to other variables (correlation of palliative care OSCE scores with communication and history scores in the 7 other stations).

RESULTS: During the pilot year, 94 students (56% F, 44% M; mean age 27 [range 25–34]) scored an average of 64% (SD=12%) on 16 history items. There was 94% agreement in ratings on history items between the SP patient and the remote observer. The difficulty index ranged from 0.20 to 0.98 and the discrimination index for 15 of the 16 items was 0.16 to 0.52 (one question had a negative discrimination index of –0.18). For internal consistency, the Cronbach alpha was 0.34. The palliative care history scores correlated with overall communication (MIRS) score ($R=0.29$, $p=0.005$), but not with overall history scores ($R=0.12$, $p=0.24$) in the other 7 stations. In the implementation year, 95 students (47% F 53% M; mean age 28 [range 24–37]) scored an average of 74% (SD=13%) on the 14 history items. There was 95% agreement in ratings on history items between the standardized patient and the remote observer. The difficulty index on the 14 items ranged from 0.35 to 1.0. (Mean=0.606). The Cronbach alpha was 0.53, demonstrating moderate internal consistency. The palliative care history scores correlated well with both communication ($R=0.29$, $p=0.01$) and history scores ($R=0.61$, $p=0.01$) in the other 7 stations.

CONCLUSIONS: A new OSCE station to evaluate medical student competencies in palliative care was feasible to implement with high inter-rater reliability, moderate internal consistency and favorable correlations with communication and history scores in 7 other OSCE stations. Several challenges are instructive to highlight. Unlike a single problem encounter (e.g., back pain) amenable to a highly specific checklist of questions aimed at arriving at a differential diagnosis, the palliative care interview aims to expand the inquiry to larger domains in the patient's life. We developed a strategy to balance the desirability for open-ended questions with the need for the SP scorer to ascertain if students demonstrated the knowledge and skills to cover important palliative care domains. We also learned about the special challenges this type of case posed for even a highly experienced SP, who at the end of the pilot year felt proud of her accomplishments, but “burned out.” Using a professional actor as the SP for the implementation year as well as fictionalizing more aspects of the case mitigated this problem. We believe this OSCE is generalizable for use in other medical schools. Beyond its specific focus on palliative care, the OSCE emphasis on evaluation of a patient-centered, holistic bio-psycho-social-spiritual approach addresses competencies relevant to many types of clinical encounters.

DEPRESSION CARE MANAGEMENT: RESULTS FROM THE FIRST YEAR OF A COLLABORATIVE CARE MODEL IN AN URBAN ACADEMIC PRIMARY CARE CLINIC Susan Truong¹; Lauren Peccoraro². ¹Mount Sinai Medical Center, New York, NY; ²Mount Sinai School of Medicine, New York, NY. (Tracking ID #2192985)

BACKGROUND: Major depressive disorders are common and are often encountered by primary care practitioners. Yet many primary care providers in national surveys cite lack of access to mental health services and shortage of mental health providers as barriers to providing their patients with optimal care. Collaborative care models have been designed to address this growing need. The model consists of interventions that utilize non-physician case managers who work closely with primary care physicians and mental health specialists. Interventions vary from development of care management plans in order to improve medication adherence to more multifaceted models involving intensive management in psychotherapy programs. While the success of these programs has been shown in a number of clinical settings, little is known about the impact of such a program in an academic training clinic where primary care providers range in their experience from trainees to attendings. The purpose of this study is to determine whether the implementation of a collaborative care program improves depression outcomes for patients in an urban academic primary care clinic.

METHODS: Patients at the Internal Medicine Associates (IMA) practice at the Mount Sinai Medical Center were invited to participate in the Depression Care Management Program who met the following criteria: Age over 18, clinically significant depression as measured by a Patient Health Questionnaire 9 (PHQ-9) score greater than 10 and meeting criteria for major depressive disorder by the DSM IV definition. The program consisted of universal depression screening, weekly to bi-weekly sessions with a behavioral health social worker trained in Problem Solving Therapy, Interpersonal Therapy and Behavioral Activation Therapy. Their symptoms were measured by PHQ9 questionnaires at each follow up visit and at the end of treatment. New and complex cases were reviewed weekly

with two primary care physicians and a psychiatrist consultant. Recommendations and updates regarding the patient's status were relayed back to the patient's primary care provider. The data for screening were analyzed as descriptive data. The data for patient outcomes were analyzed as intention to treat by a paired student's *t*-test using Microsoft Excel software.

RESULTS: From July 2013 through June 2014, screening rates improved from 22 % in July 2013 to 72 % in June 2014. From Jan 2014 to June 2014 a total of 7076 patients were screened for depression (72 % screening rate), with 1802 screening positive by the PHQ2 (25 %) and 648 diagnosed with depression (9 %). Five hundred twenty-seven patients were referred to the Depression Care Management Program in the study period. Of these patients, 124 enrolled. The mean initial PHQ9 score was 13.5 (SD 3.7). Data were available for 115 participants by the end of the year period. Seventy-five patients (60 %) were in active treatment and 49 (40 %) had completed treatment and were in relapse prevention. The mean follow up PHQ9 score was 8.3 (SD 4.3) for a decrease in PHQ9 score by 5.2 or 39 % ($p < 0.001$). One hundred one patients had an improvement in their PHQ9 scores (82 %). Forty-eight patients had a > 50 % decrease in their PHQ9 scores (40 %) and 75 patients had PHQ9 scores < 10 (60 %).

CONCLUSIONS: Patients referred to the Depression Care Management Program had significant improvement in their depression as measured by their PHQ9 scores. These data support findings from previous studies of collaborative care models for the treatment. Further research is needed to determine the long term effect of these care models on patients' mental health outcomes as well as the impact on medical comorbidities and comparisons with those patients not enrolled in the program.

DEPRESSIVE SYMPTOMS ARE ASSOCIATED WITH POORER ANTIRETROVIRAL ADHERENCE AND LESS VIRAL SUPPRESSION AMONG HAZARDOUSLY DRINKING HIV-INFECTED WOMEN Kristin C. Darwin; Heidi Hutton; Geetanjali Chander. Johns Hopkins University, Baltimore, MD. (Tracking ID #2199121)

BACKGROUND: We sought to determine socio-demographic, substance use, and mental health correlates of antiretroviral therapy (ART) adherence and HIV RNA viral suppression among hazardously drinking HIV-infected women.

METHODS: We performed a secondary analysis of baseline, 6-month, and 12-month data collected from HIV-infected women receiving care in the Johns Hopkins HIV Clinic between 2006 and 2011. We defined hazardous alcohol use as ≥ 7 drinks/week or binge drinking in the last 90 days. Outcomes included ART adherence (binary variable determined with the question: "Have you missed a dose of your HIV medication in the last 3 days?") and HIV1-RNA suppression (undetectable if < 400 copies/mL). We assessed anxiety and depressive symptoms using Hospital Anxiety and Depression Scale (HADS) cumulative scores. Other independent variables included age, race, housing status, marijuana use, cocaine use, and heroin use. Stratifying by hazardous alcohol use, we performed multivariable logistic regression using Generalized Estimating Equations to account for clustering.

RESULTS: Of 385 women, 115 were hazardous drinkers at baseline. The median age of the sample was 46 and 86 % were African American. Hazardous drinkers were more likely to use cocaine ($p < 0.001$), marijuana ($p = 0.002$), heroin ($p < 0.001$), were less likely to have stable housing ($p = 0.002$), and had higher anxiety ($p = 0.003$) and depressive symptoms ($p = 0.003$). In multivariable analysis, depressive symptoms among hazardous drinkers were associated with higher odds of ART nonadherence (OR 1.18; $p = 0.03$) and lower odds of viral suppression (OR 0.86; $p = 0.05$). Hazardously drinking women with stable housing were more likely to have an undetectable viral load (OR 2.46; $p = 0.04$) compared to those living in someone else's house/apartment, a hotel, a shelter, or a halfway house/transitional housing. Among non-hazardous drinkers, cocaine (OR 0.53; $p = 0.04$) and marijuana use (OR 0.64; $p = 0.05$) were associated with decreased viral suppression. Other independent variables were not significantly associated with outcomes.

CONCLUSIONS: Among hazardously drinking HIV-infected women, depressive symptoms are associated with lower antiretroviral adherence and viral suppression. These findings underscore the importance of screening for depressive symptoms among hazardously drinking women, and screening for hazardous drinking among women with depressive symptoms. Recognition and treatment of these co-occurring conditions among HIV-infected women may improve outcomes.

DESIGN AND VALIDATION OF AN INSTRUMENT TO DETECT DIAGNOSTIC ERRORS IN PRIMARY CARE SETTINGS Aymer Al-Mutairi^{1, 2}; Ashley N. Meyer²; Eric J. Thomas³; Jason M. Etchegaray⁴; Kevin M. Roy¹; Caridad Davalos¹; Hardeep Singh². ¹Baylor College of Medicine, Houston, TX; ²Michael E. DeBakey Veterans Affairs Medical Center and Baylor College of Medicine, Houston, TX; ³The University of Texas Medical School at Houston, Houston, TX; ⁴UT Medical School at Houston, Houston, TX. (Tracking ID #2198503)

BACKGROUND: Diagnostic errors in primary care are common and harmful but difficult to define and measure. Measurement of diagnostic errors depends mainly on detailed retrospective review of patients' medical records, a process that often results in reviewer disagreement and kappas of less than 0.4. We developed and validated a data collection instrument to detect diagnostic errors and improve reviewer agreement as a first step in informing a comprehensive future methodology of diagnostic error measurement in the primary care setting.

METHODS: We first culled questions from several instruments previously used in research on diagnostic error measurement. We then developed and refined an instrument to detect diagnostic errors using multidisciplinary group input and iterative medical record reviews. For testing the new instrument, we selected a sample of patients with and without diagnostic errors to represent the "gold standard". Primary care encounters of certain patients in this cohort were determined to contain diagnostic errors by at least 2 independent reviewers in a previous study. These reviewers evaluated the medical record in hindsight for missed opportunities to make a correct/timely diagnosis based on the available documented evidence. The tool was validated by comparing original gold standard results with new results of error determination by a single blinded physician who used the newly developed instrument. A total of 389 patient records were reviewed from the original study: 129 cases with diagnostic errors and 260 cases without.

RESULTS: The final tool consisted of 11 questions that objectively assessed the appropriateness of the patient-provider encounter in terms of diagnostic processes such as history, physical examination, and testing and 1 final question on presence or absence of diagnostic error as determined through a Likert-type scale of 1 to 6 (Table 1). When comparing presence of diagnostic error (final question rating 1-3 as determined by the single physician) to the gold standard, the tool yielded an overall accuracy of 84 %, sensitivity of 71 %, specificity of 90 %, negative predictive value of 86 %, and positive predictive value of 78 %. Using Spearman's correlations, all 11 items correlated significantly with the error outcome (all p -values $\leq .001$). The 11 diagnostic process questions clustered into three domains: initial diagnostic assessment, performance and interpretation of diagnostic tests, and patient factors, with Cronbach's alpha coefficients of 0.93, 0.92, and 0.38 associated with the three domains respectively.

CONCLUSIONS: We achieved a high degree of accuracy and positive predictive value for presence of diagnostic error using a new measurement tool. Because of reduced reliance on subjectivity, this tool could improve inter-physician agreement on diagnostic errors and be useful to enhance learning and feedback about diagnostic safety in primary care settings.

An instrument to determine presence or absence of diagnostic error on a primary care encounter.

Rate the following items for the episode of care under review[i]: 1—2—3—4—5—6

1=Strongly Agree 6=Strongly Disagree

1. The history that was documented at the patient-provider encounter was suggestive of an alternate diagnosis, which was not considered in the assessment.
2. The physical exam documented at the patient-provider encounter was suggestive of an alternate diagnosis, which was not considered in the assessment.
3. Diagnostic testing data (laboratory, radiology, pathology or other results) associated with the patient-provider encounter were suggestive of an alternate diagnosis which was not considered in the initial assessment.
4. The diagnostic process at the initial assessment was affected by incomplete or incorrect clinical information given to the care team by the patient or primary caregiver.
5. The clinical information (i.e. history, physical exam or diagnostic data) present at the initial assessment should have prompted additional diagnostic evaluation through tests or consults.
6. The initial assessment was appropriate given the patient's medical history and clinical presentation.
7. Alarm symptoms or "Red Flags" (i.e. features in the clinical presentation that are considered to predict serious disease) were not acted upon at the initial assessment.
8. Diagnostic data (laboratory, radiology, pathology or other results) available or documented at the initial assessment were misinterpreted in relation to the subsequent final diagnosis.
9. The differential diagnosis documented at the initial assessment included the subsequent final diagnosis.
10. The final diagnosis was an evolution of the initial presumed diagnosis.
11. The clinical presentation was not typical of the final diagnosis.
12. In conclusion, based on all the above questions, the episode of care under review had a diagnostic error.

[i] In all questions, a rating of 1 most likely represented a diagnostic error and a rating of 6 indicated that no error was identified, except question 6, 9 and 10 were rating was reversed.

DESPITE HIGH PREVALENCE, DEPRESSION IS ASSOCIATED WITH LESS HEALTHCARE UTILIZATION IN JAPAN Osamu Takahashi; Gautam A. Deshpande; Sachiko Ohde. St. Luke's Life Science Institute, Tokyo, Japan. (Tracking ID #2200343)

BACKGROUND: Depression is one of the most common mental disorders in the general population, and may be of particular importance in Japan, which has the 7th highest suicide rate globally. As previous literature suggests that depressed patients are often identified and treated by primary care physicians (PCP), access to primary care is important in the management of the disease. We aimed to evaluate the prevalence of depression in the general Japanese population, hospital utilization rates for depression, and factors related with access to PCPs among depressed patients.

METHODS: This was a cross-sectional study. A population weighted random sample from a nationally representative panel of adults (≥ 20 years) was used to estimate health care utilization based on a prospective health diary recorded over one month. A baseline, pre-diary questionnaire was used to capture demographic data, lifestyle habits, access to a PCP, and socioeconomic status (SES) parameters including family income, education level, and type of family. Depression was defined as a score of >9 on the Patient Health Questionnaire (PHQ-9).

RESULTS: Three thousand seven hundred twenty-two people were included in this study (mean age, 52 years old (SD, 18); 1758 (47.2 %) men.) The prevalence of depression was 27.1 % ($n=1007$), among whom 55 (5.5 %) were already diagnosed with depression. Using multivariate logistic regression, the risk factors for depression included female gender (OR: 1.2), lower educational attainment (OR: 1.1), low family annual income ($< \$30,000$, OR: 1.7), obesity (BMI ≥ 25 kg/m², OR: 1.3), and past history of depression (OR: 4.7). Of the 995 without a baseline diagnosis of depression, 308 (31 %) visited a hospital in the subsequent one month [f1]. Multivariate logistic regression revealed that factors related to non-utilization of healthcare services included living in a rural area (OR: 2.1), younger age (OR: 3.0), and not having a PCP (OR: 3.2); SES was not associated with healthcare utilization by those with depression in Japan.

CONCLUSIONS: Depressive disorders are highly prevalent in the Japanese general population. Most depressive patient demonstrated less access a PCP and underdiagnosis was common. Identification of depression in Japan may be improved by increasing access to PCPs.

DETERIORATION TO DOOR TIME: AN ANALYSIS OF DELAYS IN ESCALATION OF CARE FOR HOSPITALIZED PATIENTS Christopher Sankey^{1,2}; Gail McAvay¹; Jonathan M. Siner^{1,2}; Carol L. Barsky²; Sarwat Chaudhry^{1,2}. ¹Yale School of Medicine, New Haven, CT; ²Yale-New Haven Hospital, New Haven, CT. (Tracking ID #2196159)

BACKGROUND: The identification of clinically deteriorating patients on general inpatient floors and the timely escalation of their care continue to present significant challenges to medical providers and health systems. Clinical deterioration that occurs after admission

to a general floor has been associated with an increased risk of death. Unanticipated transfers from a general floor to the intensive care unit (ICU) are implicated in a considerable proportion of ICU admissions, hospital deaths, and hospital days. The early period of deterioration may represent a time at which admission to the ICU is associated with improved survival, particularly among patients who experience deterioration on hospital floors. The few existing studies examining the relationship between the delay from onset of clinical deterioration to ICU transfer and mortality were conducted over a decade ago; the prevalence of delays in escalation of care for deteriorating inpatients in the contemporary era of Hospital Medicine is therefore not currently known.

METHODS: This study is a retrospective data analysis of 728 included transfers from non-ICU inpatient floors to the medical intensive care unit (MICU), occurring from 2011 to 2013 at Yale-New Haven Hospital (YNHH). YNHH is an academic tertiary medical facility in New Haven, Connecticut with approximately 1000 bed capacity and 50,000 discharges annually. Deterioration to door time (DTDT) was defined as the time between onset of clinical deterioration (as evidenced by the presence of one or more vital sign indicators) and arrival in the MICU. Clinical deterioration was defined by the following vital sign abnormalities: respiratory rate greater than 28 or less than 8 breaths per minute, systolic blood pressure greater than 200 or less than 90 mmHg, and pulse greater than 130 or less than 40 beats per minute.

RESULTS: The overall in-hospital mortality was 17.9 %. 20.9 % of the sample had DTDTs of 3–4 h, the designated reference category; approximately one-fifth of patients had shorter DTDTs and 57 % had longer times. Starting at a DTDT of 5 h, there was a progressive increase in un-adjusted mortality with increasing DTDT. The association between DTDT and in-hospital mortality followed a similar pattern after adjustment for age, sex, and severity of illness. The observed mortality in the DTDT group of 0–2 h likely reflects high clinical acuity in the most clearly clinically decompensating (“crashing”) patients who appropriately experienced immediate care escalations.

CONCLUSIONS: Our study demonstrates that delays in the escalation of care for clinically deteriorating patients on general medical floors remain common in the contemporary era of Hospital Medicine, occurring in greater than 50 % of patients transferred to the MICU, and are associated with in-hospital mortality. Development of performance measures for the care of clinically deteriorating inpatients remains essential, and DTDT may be an appropriate metric.

Deterioration to Door Time (DTDT) and In-Hospital Mortality (N=728)

DTDT	Deaths	Un-adjusted Mortality: HR(95 % CI); p-value	Adjusted Mortality*: HR(95 % CI); p-value

DETERMINANTS OF FUNCTIONAL RECOVERY IN OLDER ADULTS WITH HIP FRACTURE Victoria Tang; Rebecca L. Sudore; Alexander K. Smith; Christine Ritchie; Margaret I. Wallhagen; Irena Stijacic Cenzer; Ken Covinsky. University of California, San Francisco, San Francisco, CA. (Tracking ID #2178217)

BACKGROUND: Although disability and death is common after hip fracture, and the majority of patients never return to their prefracture level of function, some patients do recover. Most studies assess functional status at the time of hip fracture. However, a more accurate comparison of pre to post functional status would include functional status data before a hip fracture has occurred. Using functional status assessments over time among a U.S. national sample, our goal was to determine the proportion of older adults who recover to their pre-hip-fracture function and to identify characteristics of recovery.

METHODS: We analyzed longitudinal data from the nationally-representative Health and Retirement Study (HRS) linked to Medicare claims. We included 733 participants who were ≥ 65 years of age and who sustained a hip fracture. To identify pre-fracture function we used the most proximal pre-fracture interview (11.6 months \pm 7.4 before hip fracture). To identify post-fracture function, we used the information from interviews conducted between 6-months to 2.5 years after their fracture (12.5 months \pm 8.1) or time of death. Our goal was to determine the proportion of patients who returned to their pre-fracture functional status as measured by two outcomes: (1) number of six activities of daily living (ADL, e.g., bathing, dressing, etc.) in which they needed assistance (scale of 0–6), and (2) level of mobility (scale of 0–2) defined by their ability to walk one block or across the room. Participants who died prior to their post fracture interview were categorized as not returning to their prior functional status. We examined demographic, clinical, and social determinants of recovery. For each determinant, we used logistic regression to calculate predicted recovery rates adjusting for age and gender.

RESULTS: The mean age of participants was 84 ± 7 years and 77 % were women. Thirty-one percent recovered to their pre-fracture ADL function and 34 % returned to their pre-fracture mobility level. ADL recovery was significantly associated with age younger than 85 vs ≥ 85 (39 % vs 22 %, $p=0.04$), female gender (33 % vs 23 %, $p<0.001$), no history of dementia vs dementia (35 % vs 10 %, $p<0.001$), residing in the community vs institutionalized (32 % vs 14 %, $p=0.006$), and having a Charlson comorbidity score of <3 vs ≥ 3 (37 % vs 22 %, $p<0.001$). These same patient characteristics were also significantly associated with returning to pre-fracture level of mobility ($p<0.05$). Being White vs Black (31 % vs 20 %, $p=0.04$), no prior falls vs a prior fall (34 % vs 26 %, $p=0.03$) and \geq high school education vs lower education (33 % vs 26 %, $p=0.04$) were also associated with ADL recovery, but not mobility recovery.

CONCLUSIONS: In this older adult cohort, one third of participants with hip fracture returned to their previous level of function. Understanding the demographic, clinical and social risk factors associated with recovery and non-recovery may allow clinicians to better design and tailor rehabilitation programs for the oldest old, set realistic expectations for recovery, and better plan for long-term discharge needs.

DEVELOPMENT AND VALIDATION OF THE SPANISH SHORT NUMERACY UNDERSTANDING IN MEDICINE INSTRUMENT Elizabeth Jacobs²; Cindy Walker⁶; Tamara Miller¹; Kathryn Fletcher²; Pamela S. Ganschow³; Diana Imbert³; Maria O'Connell³; Joan Neuner¹; Marilyn M. Schapira⁴. ¹Medical College of Wisconsin, Milwaukee, WI; ²Milwaukee VAMC/Medical College of Wisconsin, Milwaukee, WI; ³Stroger Hospital/Rush University Medical Center, Chicago, IL; ⁴University of Pennsylvania, Philadelphia, PA; ⁵University of Wisconsin School of Medicine and Public Health, Madison, WI; ⁶University of Wisconsin at Milwaukee, Milwaukee, WI. (Tracking ID #2196350)

BACKGROUND: The Spanish-speaking population in the US is large and growing. This population is known to have lower health literacy, a known risk factor for health disparities. Much less is known about health numeracy in this population because of a dearth of measures that have been developed for use in Spanish. Our objective in this work was to develop and validate a short and easy to use measure of health numeracy for Spanish-speaking adults in the United States: the Spanish Short Numeracy Understanding in Medicine Instrument (S-NUMi).

METHODS: Items were generated based upon qualitative studies with both English and Spanish-speaking adults. A 20-item NUMi and 8-item S-NUMi were first created and psychometrically evaluated and validated in English; both of these instruments have been published in the literature. We translated all items into Spanish using a group translation and consensus process and cognitive interviews were conducted to ensure we were measuring the same concepts in Spanish as in English. We then conducted Differential Item Functioning analyses to evaluate whether or not the items on the English S-NUMi functioned in the same way for Spanish speaking examinees, using a sample of 232 Spanish-speaking residents from Chicago and Milwaukee. To determine the reliability and validity of the measure, cronbach's alpha was computed as a measure of reliability and

scores on the Spanish S-NUMi were correlated with the Spanish Test of Functional Health Literacy (S-TOFHLA). In addition, differential validity was examined by comparing scores on the Spanish S-NUMi for examinees of different education levels.

RESULTS: The study population was diverse in age, gender, and level of education and 70 % reported Mexico as their country of origin. Two of the items originally included in the English S-NUMi demonstrated poor psychometric properties in Spanish, one was found to have differential item functioning while another was found to have low discrimination. These items were eliminated, leaving 6 items that measured the range of important numerical concepts used in healthcare communication: 4 from the number sense domain, 1 from the tables & graphs domain, and 1 from the probability domain. The 6-item Spanish NUMi demonstrating adequate reliability, with a Cronbach's alpha of 0.72. Items demonstrated a range of difficulty using classical test statistics (0.48 to 0.86) and adequate discrimination (0.34–0.49). Scores on the overall instrument were positively correlated with print literacy as measured by the S-TOFHLA (0.67) and varied as predicted across grade level; mean scores for up to 8th grade, 9–12th grade, and some college experience or more, respectively, were 2.48 (1.64), 4.15 (1.45), and 4.82 (0.37); with higher scores indicating higher numeracy.

CONCLUSIONS: We have documented that the Spanish S-NUMi is a reliable and valid measure of the range of important numerical concepts that are used in understanding and communicating health information. This is an easy to use, very brief measure of health literacy that could be used in a range of settings to assess the health numeracy of Spanish speakers, particularly in the United States.

DEVELOPMENT OF A TAILORED, 5A'S-BASED WEIGHT MANAGEMENT INTERVENTION FOR VETERANS WITHIN PRIMARY CARE Katrina F. Mateo^{1, 2}; Sandeep Sikerwar^{1, 2}; Allison Squires^{3, 2}; Adina Kalct²; Scott Sherman^{1, 2}; Melanie Jay^{1, 2}. ¹VA NY Harbor Healthcare System, New York, NY; ²NYU School of Medicine, New York, NY; ³New York University, New York, NY. (Tracking ID #2197583)

BACKGROUND: Obesity affects 36 % of patients in the Veterans Health Administration. The United States Preventive Services Task Force endorses the use of the 5As framework (Assess, Advise, Agree, Assist, Arrange) to deliver obesity counseling in primary care (PC). This study used qualitative methods to inform the development of a 5As-based weight management intervention to improve obesity care at Veterans Affairs (VA) Medical Centers.

METHODS: We conducted a secondary analysis of 6 focus group sessions with Veteran patients and 25 interviews with key VA staff in PC (physicians, nurses, and MOVE! staff) in order to guide intervention development. We asked Veterans and staff to provide feedback on a proposed 5As intervention initially conceived based on prior work and a systematic review of the literature. This proposed intervention would use an online tool to deliver the 5As by assessing health behaviors and barriers ("assess"), providing tailored advice ("advise"), and helping patients set goals ("agree"). Members of the healthcare team would then discuss goals further, focusing on addressing barriers ("assist") and providing follow-up/referral to more intensive support ("arrange"). Participants were also asked about their experiences with goal setting, weight management, and technology. Focus group and interview sessions were audio-recorded, professionally transcribed, and coded using a rigorous process previously described. To guide intervention development, transcription segments originally coded as "goal-setting," "proposed intervention," and/or "technology" were analyzed. The "proposed intervention" code had not been previously analyzed.

RESULTS: Both Veterans and VA staff held positive views toward the use of goal setting for healthy behavior change and stressed the importance of social support in achieving goals. Veterans particularly felt the need for someone to hold them accountable for their goals and give them consistent feedback on their progress. VA staff felt that the goals needed to come directly from the patient and that the providers' role was to support the process. Veterans and staff reported mixed attitudes toward technology, acknowledging that some patients were unfamiliar with or distrusting of technology. When asked to give feedback about the proposed intervention, Veterans and staff liked that it would provide individualized counseling and support from the healthcare team to achieve goals. However, some Veterans did not believe a computer could generate individualized advice and did not want technology to replace human support. Most healthcare team members felt that time constraints would be a barrier to implementation and indicated that they could not spend more than 3–5 min on weight management. As a result of these findings, our revised intervention includes the use of a health coach to provide in-person support while using the online tool. The health coach will also provide initial counseling about weight loss and lifestyle goals to allow the healthcare team to focus their time on performing brief counseling to address barriers and endorse the goals.

CONCLUSIONS: This study informed the development of a 5As intervention to improve the treatment of obesity in the PC setting. Usability testing of the online tool is currently ongoing, and pilot testing of the intervention will begin soon.

DEVELOPMENT OF AN ONLINE WEIGHT MANAGEMENT TOOL TO FACILITATE COLLABORATIVE GOAL SETTING FOR VETERANS IN PRIMARY CARE Katrina F. Mateo^{1,2}; Natalie Berner^{1,2}; William Vabrinkas^{2,1}; Adina Kalet²; Scott Sherman^{1,2}; Melanie Jay^{1,2}. ¹VA NY Harbor Healthcare System, New York, NY; ²NYU School of Medicine, New York, NY. (Tracking ID #2197556)

BACKGROUND: Obesity is highly prevalent at Veterans Affairs (VA) Medical Centers, but healthcare teams often fail to counsel patients to lose weight due to competing demands. Tools are needed to facilitate obesity counseling in the primary care (PC) setting. Goal setting can promote weight loss, and expert system software programs may be able to facilitate goal setting. Based on formative data, we created an interactive online tool to facilitate goal setting for lifestyle behavior change in PC at the VA. We then conducted usability testing to further refine this tool and understand best strategies for its use among Veterans.

METHODS: We used principles of User-Centered Design with stakeholder input from 6 focus groups with Veterans, 25 key informant interviews with healthcare team members, and 6 usability studies of the VA's MOVE! online questionnaire to create an interactive online tool to help overweight/obese Veterans create initial weight management goals and facilitate obesity-related counseling by a health coach and/or healthcare team. We then conducted usability testing using a "Think Aloud" protocol where a moderator observed each participant using the tool on a tablet computer as they verbalized thoughts/reactions. This was followed by a 15-min health coaching session and a semi-structured interview to elicit reflections on the experience. Sessions were digitally recorded, professionally transcribed, and analyzed to identify areas for tool improvement.

RESULTS: The resulting tool, called MOVE! Toward Your Goals (MTG), was designed at a 5th grade literacy level with low text density per page and simple navigation. The MTG tool uses the following algorithm: The patient completes a questionnaire about weight, barriers to weight loss, and lifestyle behaviors; each answer generates tailored weight loss or behavior change advice. The patient then indicates how much weight he or she wants to lose and assigns a number (1–10) indicating the perceived importance of each piece of advice. Based on this information, the tool guides the patient to choose a weight loss goal, up to 2 nutrition goals, and a physical activity goal. The tool then provides links for the coach (or healthcare team member) to print out an individualized patient summary (health advice and initial goals), SMART goal setting worksheet, VA weight management resources, tailored educational handouts, and a report for the coach. The role of the coach is to help the patient make the goals "SMART" (specific, measurable, attainable, relevant, and time-based), address potential barriers, and link the patient to more intensive VA and community resources. Usability testing of the MTG tool with 5 Veteran participants (3 male, 2 female) revealed that they appreciated the clean visual layout, the in-person support while using the tool, and had a strong positive reaction to the health coaching session and personalized binder of printouts. They left the session feeling motivated to work on their goals. Identified barriers to tool use included problems with tool navigation, tablet use, and unclear wording of some questions.

CONCLUSIONS: Initial usability testing suggests that the MTG tool can facilitate collaborative goal setting. Findings will inform iterative changes and usability testing is ongoing. The MTG tool will then be tested as part of a pilot randomized controlled trial of a primary care-based weight management intervention at the VA.

DEVELOPMENT OF OBESITY AND RELATED DISEASES IN A PROSPECTIVE LONGITUDINAL COHORT OF AFRICAN REFUGEES COMPARED TO MATCHED REGIONAL CONTROLS Corinne Rhodes; Sanja Percac-Lima. Massa-

chusetts General Hospital, Harvard Medical School, Jamaica Plain, MA. (Tracking ID #2190044)

BACKGROUND: Refugees qualify for 8 months of Medicaid on arrival to the United States, but few resources are available to track and study longitudinal health of this population. This study's objective was to explore development of obesity and related disease in refugees from Africa after resettlement in the US. We hypothesized African refugees' body mass index (BMI) would significantly increase after resettlement.

METHODS: We obtained a comprehensive list of 938 refugees who arrived in Rhode Island (RI) between 2004 and 2007 from the Department of Health. We followed the medical records of 354 refugees ≥ 18 years old cared for in the largest RI state hospital system to obtain BMI closest to 3 time points (initial system interaction, 1 year, and 5 years) as well as obesity related diagnoses (hypertension (HTN), hyperlipidemia (HL), and diabetes mellitus (DM)) at arrival and at 5 years. One hundred seventy-five Refugees were excluded due to pregnancy or limited BMI information. Changes in continuous data were analyzed with student t-tests or ANOVA and categorical data was analyzed with Fisher's exact tests. Refugee BMI time trends for longitudinal person-clustered refugee data were analyzed using mixed regression models. To account for regional trends in BMI and rates of obesity-related diseases we constructed comparison U.S. populations from the National Ambulatory Medical Clinic and National Hospital Ambulatory Medical Clinic Surveys (NAMCS/NHAMCS). We matched each refugee visit in a 1:1 ratio to a randomly selected NAMCS/NHAMCS visit by gender, race, age (± 1 year), and clinic visit year (± 2 years). Regional BMI trend for NAMCS/NHAMCS cross-sectional visits was analyzed using linear regression.

RESULTS: Of 178 adult refugees from the largest RI hospital system with multiple BMIs recorded, 164 (92.1 %) were African, and 156 were matched to the NAMCS/NHAMCS population. Refugees were primarily women (60.9 %), mean age 38.4 (SD 14.5), and predominantly Liberian (110, 70.5 %). At baseline, African refugees had a mean BMI of 24.8 (4.9), 4.5 % were underweight (BMI < 18.5), and 11.5 % were obese (BMI > 30). Rates of DM, HTN, and HL were 0.6, 16.7, and 2.6 %, respectively. One hundred seventy-five non-pregnant adult refugees with limited BMI data had similar demographics, baseline BMI, and rates of obesity related diseases. In the NAMCS/NHAMCS population BMI was significantly higher at 29.5 (SD 8.0, $p < 0.0001$), 1.8 % were underweight ($p = 0.03$), and 36.2 % were obese, ($p < 0.0001$). Rates of DM, HTN, and HL compared to refugee rates were 11.7 % ($p < 0.0001$), 19.1 % ($p = 0.22$), and 11.9 % ($p = 0.0003$) respectively. BMI trend over time was significant for refugees ($p < 0.0001$) with mean BMI trending from 24.8 (SE 0.44) at initial time point to 26.1 (0.44) at 1 year, and 27.6 (0.44) at 5 years. For the NAMCS/NHAMCS population, the BMI time trend was not significant ($p = 0.94$) with a mean BMI of 29.6 (SE 0.99) at the initial time point, 29.3 (0.99) at 1 year, and 29.6 (0.71) at 5 years, (Figure 1, with 95 % confidence intervals). Rates of DM2 and HL increased in refugees from initial time point to 5 years ($p = 0.0007$, 0.006) but not in the NAMCS/NHAMCS population ($p = 0.64$, 0.35). Rates of hypertension were not significantly different in either population. A sensitivity analyses in Liberians vs. non-Liberian Africans showed similar baseline BMIs (24.7 vs. 24.3 $p = 0.14$), rates of obesity and obesity related diseases, and similar regression model trends.

CONCLUSIONS: Our results reveal that African refugees gain weight after arrival to the US with mean BMI crossing from the normal to overweight category within the first year. This increase in BMI is not explained by regional U.S. trends as reflected by our NAMCS/NHAMCS comparison population. Early education about obesity, nutrition, and health during the resettlement process is essential to prevent development of obesity and obesity related diseases in this vulnerable population.

BMI trends in African refugees compared to matched controls

DIABETES AND RISK OF INCIDENT DEPRESSIVE SYMPTOMS AMONG OLDER LATINOS IN A POPULATION-BASED COHORT Maria E. Garcia¹; Anne Lee¹; Hector Gonzalez²; Tu My To¹; Mary N. Haan¹. ¹University of California, San Francisco, San Francisco, CA; ²Michigan State University, East Lansing, MI. (Tracking ID #2195208)

BACKGROUND: Compared to non-Hispanic Whites, older Latinos are disproportionately affected by depression and diabetes. Both diabetes and depression are associated with poorer health outcomes, yet there have been few longitudinal studies of comorbid depression and diabetes among Latinos. The purpose of this study was to determine whether having a diabetes diagnosis increased the incidence of poorly controlled depressive symptoms among older Latinos in a population-based cohort.

METHODS: Study participants were enrolled in the Sacramento Area Latino Study on Aging (SALSA), a population-based cohort ($n=1789$) of Latino individuals aged 60 years-101 years in 1998-99. Diabetes and depressive symptoms were measured during 7 annual home visits to year 2008. Diabetes was defined as self-reported diagnosis, elevated fasting blood sugar and/or use of a diabetic medication. Depressive symptoms were defined as Center for Epidemiological Studies-Depression (CES-D) score ≥ 16 , or use of an anti-depressant drug derived from a medicine cabinet inventory. One thousand two hundred twenty-one individuals were included in the analysis after exclusion of baseline depression cases. There were three possible outcomes: 1) CES-D <16 +no treatment, 2) CES-D ≥ 16 +no treatment, or 3) CES-D <16 or CES-D ≥ 16 +treatment. CES-D <16 +no treatment was the comparison group in multinomial logistic regression models used to examine differences among patients with and without diabetes in incident depressive symptoms. Bivariate analyses identified covariates that were significantly associated with at least one outcome. These included gender, education, and baseline diastolic blood pressure.

RESULTS: There were 374 participants with diabetes at baseline and 449 with incident depression during study follow-up. Of these, only 81 were on an anti-depressant (for presumed treatment of depressive symptoms). Table shows that only the elevated CES-D+ no treatment group is significantly different from the low CES-D and untreated combination in the unadjusted multinomial logistic regression model. Additional adjustment for age, gender, education and diastolic blood pressure influenced the association between diabetes and depressive symptoms only slightly. The risk of elevated depressive symptoms remains highest in diabetics compared to non-diabetics for those with elevated CES-D without treatment. Although the association between diabetes and treated CES-D is not statistically significant, the magnitude of the association is similar to the result for untreated elevated CES-D.

CONCLUSIONS: In a population-based study of older Latinos, we found a modest but robust association between diabetes and the incidence of poorly-controlled depressive symptoms. Treatment with an anti-depressant was rare and did not influence associations. This study suggests the need to increase screening and treatment of depression among older Latinos diagnosed with diabetes.

Multinomial logistic regression of association between diabetes and incident depressive symptoms

Category	N	Unadjusted	Adjusted for all covariates
		OR (95 % CI)	OR (95 % CI)
CES-D <16 , no treatment	772	1.0	1.0
CES-D ≥ 16 , no treatment	368	1.32 (1.01–1.73)	1.34 (1.01–1.76)
CES-D <16 or CES-D ≥ 16 , treated with anti-depressant	81	1.26 (0.77–2.04)	1.24 (0.75–2.04)
-2 log likelihood		2025.6	1879.0

DIABETES RISK AND MEDIATORS AMONG REFUGEES AND IMMIGRANTS: A LONGITUDINAL ANALYSIS Seth A. Berkowitz¹; Gabriel E. Fabreau⁴; Sridharan Raghavan²; Katherine Kentoffio⁵; Wei He¹; Steven J. Atlas²; Sanja Percac-Lima³. ¹MGH, Boston, MA; ²Massachusetts General Hospital, Boston, MA; ³Massachusetts General Hospital, Chelsea, MA; ⁴University of Calgary, Calgary, AB, Canada; ⁵Harvard Medical School, Boston, MA. (Tracking ID #2191910)

BACKGROUND: How diabetes risk for refugees and immigrants compares with that of American-born patients living in the same communities is unclear, but has important implications for diabetes prevention efforts. Better understanding of mechanisms that may mediate diabetes risk would further enhance these efforts.

METHODS: We constructed a longitudinal cohort of patients aged ≥ 18 years who came to the US as refugees. These patients were matched in a 1:3 ratio by age, gender, and date of initiation of care to 1) Spanish-speaking non-refugee immigrants, and 2) US born, English-speaking controls. All patients received primary care in the same community health center, which is a state refugee clinic and serves a low-income, ethnically diverse community in Eastern Massachusetts. Using data from an electronic repository, patients were followed longitudinally for development of diabetes, determined with a validated algorithm. We also abstracted age at cohort entry, gender, educational attainment ($<$ vs. \geq high school diploma), insurance type, median household income at the census tract level, and baseline body mass index (BMI). We used Cox regression to estimate the risk of incident diabetes for refugees and immigrants compared with controls. We also tested whether differences in educational attainment or baseline obesity ($\text{BMI} > 30 \text{ kg/m}^2$) mediate diabetes risk, using counterfactual mediation analysis. Finally, because there may be differences in reproductive patterns between groups, which could influence diabetes risk, we tested whether number of pregnancies mediated diabetes risk in women.

RESULTS: We included 3174 patients in our study. Patients with diabetes at baseline, including 2.5 % (15/604) of refugees, 6.0 % (79/1310) of immigrants, and 4.1 % (51/1260) of control patients ($p=0.001$), were excluded from analyses of incident diabetes risk. Among refugee patients, the most common countries of origin were Somalia (17.8 %), Iraq (16.7 %) and Bhutan (8.8 %). Of refugees and immigrants, 41.5 %, and 55.6 %, respectively, had $<$ high school diploma educational attainment, compared with 11.0 % of controls ($p<0.001$). Mean (SD) baseline BMI was 26.4 (5.8), 29.1 (5.7), and 29.2 (7.3) kg/m^2 , for refugees, immigrants, and controls, respectively. Over a median follow-up of 3.7 years (interquartile range 1.3–7.4 years), 7.0 % of refugees, 8.3 % of immigrants, and 6.0 % of controls developed diabetes. In unadjusted Cox regression models, both refugee (Hazard Ratio [HR] 1.59, 95 % Confidence Interval [95%CI] 1.08–2.35) and immigrant (HR 1.60 95%CI 1.18–2.17) statuses were associated with increased diabetes risk compared with controls. In Cox models adjusted for the above covariates, both refugee (HR 2.08 95%CI 1.32–3.29) and immigrant (HR 1.52 95%CI 1.02–2.27) statuses remained associated with increased diabetes risk compared with controls. The difference in risk between refugees and immigrants, in adjusted models, was not statistically significant (HR for refugees 1.37 95%CI 0.91–2.06). In mediation analyses, educational attainment mediated 36 % ($p=0.007$) of the difference in diabetes risk between refugees/immigrants and controls. By contrast, baseline obesity did not mediate difference in diabetes risk (proportion mediated 1 %, $p=0.84$). In women, number of pregnancies did not mediate diabetes risk (proportion mediated 0 %, $p=0.99$).

CONCLUSIONS: Refugees and immigrants in this study had significantly increased risk for developing diabetes compared with age and gender matched controls from the same community. This risk was mediated by differences in education. Adult education programs, or education-based lifestyle interventions to reduce diabetes incidence, such as the Diabetes Prevention Program curriculum adapted for the specific needs of refugees and immigrants, may be a promising strategy to improve health for these vulnerable patients.

DIAGNOSTIC CARDIAC FELLOWS: DO THEY INCREASE RADIATION EXPOSURE AND PROCEDURAL TIMES Ankita Sharma; Ramsey Joudeh; Molly Perini; George Fernaine. Lutheran Medical Center, Bayside, NY. (Tracking ID #2194758)

BACKGROUND: Prior studies have shown increased radiation exposure on diagnostic cardiac procedures performed by cardiology fellows. We sought to quantify and compare radiation exposure parameters during cardiac catheterization (CC) procedures performed by fellows and attendings in a community hospital without surgical backup.

METHODS: We retrospectively reviewed medical records of 661 patients who underwent cardiac catheterization from January 2012 to February 2013. Fluoroscopy time, total kerma area product (KAP), cumulative dose area product (DAP) and diagnostic start and end times were compared between second and third-year fellows and attendings. Mean differences in exposure parameters were compared using independent t-tests.

RESULTS: The attendings had lower exposure parameters except in mean fluoroscopy time. The mean total kerma area product and cumulative DAP were found to be statistically significantly different when comparing fellows to attendings. Table 1 contains the results of the independent samples t-tests.

CONCLUSIONS: There was no statistically significant difference in procedural times between fellows and attendings. However, we found a significant increase in total kerma area product (KAP) and cumulative dose area product (DAP) during a cardiac catheterization procedure performed by a diagnostic fellow. Concordant with current literature, the participation of diagnostic fellows during CC procedures adds additional risk of radiation exposure to the patient.

Independent Samples T-Test

	Number of Patients	Mean \pm Std. Deviation	P
Fluoroscopy Time (minutes)	661		0.204
Fellow	330	7.07 \pm 5.056	
Attending	331	7.65 \pm 6.623	
Total Kerma Area Product (Gy)	661		0.003
Fellow	330	1.93 \pm 2.175	
Attending	331	1.48 \pm 1.647	
Cumulative DAP (Gy.Cm2)	661		0.002

Fellow	330	36.95 \pm 27.458	
Attending	331	33.48 \pm 27.995	

DIAGNOSTIC PITFALLS: A NEW CONCEPTUAL APPROACH TO UNDERSTAND DIAGNOSTIC ERROR Gordon D. Schiff^{1, 2}; Mayya Volodarskaya¹; Harry Reyes Nieva^{1, 2}; Hardeep Singh^{3, 4}; Adam Wright^{1, 2}. ¹Brigham and Women's Hospital, Boston, MA; ²Harvard Medical School, Boston, MA; ³Houston Veterans Affairs Health Services, Houston, TX; ⁴Baylor College of Medicine, Houston, TX. (Tracking ID #2199986)

BACKGROUND: Studies have shown that diagnostic errors (DEs) are a leading patient safety problem, particularly in primary care settings, yet progress in understanding and preventing such errors has been modest. While debate exists over definitions of DEs and the extent to which they are rooted in cognitive vs. system failures, most agree they are multi-factorial and require fresh approaches. We systematically reviewed multiple data sources to develop a new conceptual approach to understand DEs by delineating their respective high-risk clinical circumstances.

METHODS: We used a mixed-methods approach to develop a new construct—"diagnostic pitfalls"—which we define as specific clinical situations where there are patterns of, or vulnerabilities to, errors that lead to missed, delayed or wrong diagnosis. We conducted a multi-pronged search using the following data sources: a) systematic literature review (using the search terms *diagnosis*, *error*, *pitfall* and *primary care*) with a predefined snowball strategy to identify additional relevant literature; b) AHRQ Web M&M (Morbidity and Mortality Rounds) cases/discussions from 2003 to 2014; c) Institutional ambulatory M&Ms of a large integrated academic network from 2006 to 2014; d) Institutional risk management patient safety event reports from 2010 to 2014 coded as diagnosis/treatment related. For each relevant case identified in the literature or via local quality/safety databases, we extracted the diagnoses (correct and erroneous) and presenting signs and symptoms. Breakdown(s) in diagnostic process were classified using two previously published taxonomies, Diagnosis Error Evaluation and Research (DEER) and Timely and Reliable Diagnosis Challenges (TARDC). From this compilation, we identified disease-specific clinical challenges and used the emerging themes to derive specific diagnostic pitfalls and concepts.

RESULTS: From 106 articles, 81 Web M&Ms, 24 institutional network ambulatory M&Ms and 1005 diagnosis/treatment risk management reports, we identified 195 disease-specific pitfalls across 127 unique diseases/diagnoses. Common missed/delayed diagnoses included cancers, cerebral hemorrhage, and pulmonary embolism; the most frequent presenting symptoms were pain, fever and emesis. Using the DEER taxonomy we identified failure/delay in considering the diagnosis ($n=34$), failure/delay in ordering needed tests ($n=25$) and failure/delay in eliciting critical history information ($n=16$) as the most frequent problematic steps in the diagnostic process. The TARDC classification system highlighted consistent issues with the performance/interpretation of laboratory tests ($n=29$), challenges related to non-specific symptoms and signs ($n=20$) and failure to diagnose underlying cause ($n=19$). A number of generic diagnostic pitfall paradigms emerged including: a) disease A repeatedly mistaken/misdiagnosed for disease B (e.g. colon cancer mistaken for celiac disease); b) failure to appreciate the limitations of a test or exam; c) atypical presentation; d) chronic disease assumed to account for a symptom rather than suspecting new diagnosis; e) failure to monitor evolving symptom.

CONCLUSIONS: "Diagnostic pitfalls" represent a new and useful construct to engage the interface between system and cognitive failure modes in diagnosis. We were able to identify and classify such pitfalls from published and locally reported cases. Recurring patterns of diagnostic pitfalls were seen that illustrate both generic and disease-specific

types of errors. Identifying such pitfalls offers potential advantages for understanding, preventing, and increasing awareness of diagnostic errors in medicine.

DIFFERENCES IN NURSING HOME QUALITY BETWEEN MEDICARE ADVANTAGE AND TRADITIONAL MEDICARE PATIENTS Emily Chang¹; Teague Ruder²; Claude Setodji²; Debra Saliba^{5, 3}; Mark Hanson³; David Zingmond¹; Neil Wenger^{1, 3}; David Ganz^{4, 1}. ¹UCLA, Los Angeles, CA; ²RAND, Pittsburgh, PA; ³RAND, Santa Monica, CA; ⁴VA GRECC, Los Angeles, CA; ⁵UCLA Borun Center, VA GRECC, Los Angeles, CA. (Tracking ID #2199859)

BACKGROUND: Medicare Advantage (MA) enrollment is steadily growing, but little is known about the quality of nursing home (NH) care provided to MA enrollees compared to enrollees in traditional fee-for-service (FFS) Medicare. Our study objective is to compare MA and FFS enrollees' quality of NH care.

METHODS: We conducted a cross-sectional study of 2.17 million Medicare enrollees receiving care at a U.S. nursing home during 2011. Medicare enrollment file extracts provided by the Centers for Medicare & Medicaid Services (CMS) were merged with data from the quarterly 2011 Long-Term Care Minimum Data Set 3.0. CMS methodology was used to calculate the 18 Nursing Home Compare quality measures as applicable for each enrollee. We then calculated the relative risks (RR) of complication/adverse outcome/quality measures between MA versus FFS enrollment, using four different regression models predicting complication (or quality of care) that progressively adjusted for increasing numbers of characteristics.

RESULTS: Among Medicare enrollees in 2011, 17 % were in MA plans. Most NH quality measure scores were similar between MA and FFS Medicare enrollees. Relative risks (RR) for MA versus FFS enrollment for the NH quality measures were unchanged when progressively adjusted for facility, beneficiary age and gender, CMS Hierarchical Condition Category score, and geographic region. Short-stay MA patients had lower rates of pressure ulcers (RR=0.76) and new antipsychotic use (RR=0.82) but higher rates of moderate to severe pain (RR=1.09). MA long-stay patients also had lower rates of antipsychotic use (RR=0.94) but had higher rates of incontinence (RR=1.08) and urinary catheterization (RR=1.10).

CONCLUSIONS: Overall, we found few differences in NH quality scores between MA and FFS Medicare enrollees. MA enrollment was associated with better scores for pressure ulcers and antipsychotic receipt but worse scores for pain control, incontinence, and urinary catheterization. Results may be limited by residual case-mix differences between MA and FFS patients or by the small number of short-stay measures reported. Future studies may be able to better distinguish NH quality performance between MA patients and FFS by including MA encounter data to improve matching between MA and FFS patients, when such data becomes generally available.

DIVISION OF LABOR IN PRIMARY CARE MANAGEMENT AMONG FEDERALLY QUALIFIED HEALTH CENTERS, 2009–2013 Jamie Ryan; Samantha Mackie; Maureen Deboo. The Commonwealth Fund, New York, NY. (Tracking ID #2198583)

BACKGROUND: Federally Qualified Health Centers (FQHCs) are community-based clinics that provide comprehensive primary care and behavioral and mental health services regardless of patients' ability to pay. There is much debate surrounding how the implementation of the Affordable Care Act (ACA) is affecting these health centers' ability to accommodate increased demand. One strategy to continue to provide quality care to a growing patient population without dramatically increasing costs is to better utilize non-physician clinicians in primary care. This analysis examines staffing patterns among various provider types working in FQHCs from 2009 to 2013.

METHODS: Data come from the 2009 and 2013 Commonwealth Fund Surveys of Federally Qualified Health Centers that were conducted among a nationally representative sample of FQHCs. The 2009 survey was completed by mail, online or by phone by 795 FQHCs (response rate of 79 %), March-May 2009; the 2013 survey was completed by mail or online by 679 FQHCs (response rate of 60 %), June-October 2013. We examine the division of labor among physicians, advanced practice providers (including nurse practitioners and physician assistants), registered nurses, and other clinical staff (e.g., medical assistants) working in FQHCs in regards to the following typical primary care management tasks: calling patients to check on medications, symptoms, or to help coordinate care between visits; executing standing orders for medication refills or ordering tests; educating patients about managing their own care; and coordinating care with providers outside the health center.

RESULTS: Health centers reported that physicians and advanced practice providers educated patients, executed standing orders for medication refills and tests, and coordinated care with outside providers at similar rates in both 2009 and 2013. All staff types were utilized more in 2013 than in 2009 for all four tasks we examined. While the increase

from 2009 to 2013 in the use of other clinical staff has outpaced that of physicians, advanced practice providers, and registered nurses with the tasks of calling patients between visits (52 % in 2009 to 76 % in 2013) and educating patients (50 to 77 %), the opposite was true for executing standing orders for medication refills or tests and coordinating care with outside providers. A greater percentage of centers reported that nurses (77 %) and other clinical staff (77 %) were involved in coordinating care with outside providers than physicians (57 %) and advanced practice providers (58 %). However, the percentage of physicians and advanced practice providers coordinating care increased more from 2009 to 2013 than that of registered nurses and other clinical staff. The number of centers reporting physician and advanced practice provider involvement in coordinating care with outside providers increased by 68 and 57 % respectively, compared to a 22 % increase for nurses and a 24 % increase for clinical staff. Additionally, the percentage of centers reporting physician and advanced practice provider involvement in patient education has increased from three-quarters in 2009 to 93 % in 2013.

CONCLUSIONS: Many health centers are already utilizing physicians and advanced practice providers in similar ways. However, there is potential to increase the use of registered nurses and other clinical staff such as medical assistants in educating patients about care management, calling patients to check on medications or symptoms, and coordinating care between visits and with external providers. However, to function efficiently and be responsive to patients' needs, care teams need to divide tasks logically. Physicians could ease off of tasks that can be completed by other clinical staff, such as coordinating care with outside providers and executing standing orders for refills and tests, to free up more time for face-to-face patient care. It is clear that increasing clinical staff would result in improved timeliness and access to health services. A practical way to increase the clinical staff available for primary care and non-complex chronic disease management without drastically increasing operating costs is to allow non-physician clinicians to practice to the full extent of their training and education. The wide variation among states' scope of practice laws limits the ability of the federal government to make staffing recommendations or scale up innovative care models such as nurse-led medical homes. Prior studies have shown that physicians agree that nurses should be able to practice to the full extent of their licenses. A national standard regarding scopes of practice could revitalize the organization of care and chronic disease management in this country.

DO EARLY PHASE DNR ORDERS APPROPRIATELY WORK FOR EMERGENTLY ADMITTED PATIENTS? Seiji Bito¹; Tomoari Mori². ¹NHO Tokyo Medical Center, Tokyo, Japan; ²The University of Tokyo, Setagaya, Japan. (Tracking ID #2193695)

BACKGROUND: Discussions about resuscitation are often harmful for emergency patients and their family. "Do not resuscitate (DNR) orders", however, are enforced immediately after hospitalization in reality. We investigated associations between patient factors and early phase DNR orders after admissions. We also investigated if early DNR orders predict patients' death as accurate as those at a later date.

METHODS: We conducted secondary data analysis using a dataset extracted from electrical medical records saved from January, 2009 to December, 2012 in an educational hospital. We sampled patients who were hospitalized as emergency admissions and stayed more than 3 days. Those who had cancer, who received surgical services, and who admitted with cardiopulmonary arrests were excluded from the analysis. We identified "early DNR orders" as those are forced on the same or the following day of the hospitalizations. We compared associations between patients' characteristics and early DNR orders first. Then we compared death rates between those with early DNR orders and those with later DNR orders.

RESULTS: Twelve thousand seven hundred fifty emergency patients' data were included in the analysis. Eleven percent of the patients were forced DNR orders and 52 % of them had early DNR orders. Only 1 % were changed their resuscitation status on discharge. While early DNR orders were examined to only 1 % of the patients under 75 years old and 5 % of those from 75 to 84 years old, 17 % of the patients 85 years old or over had early DNR orders. Logistic regression analysis showed that higher age group, cardiac diseases and neurologic diseases had significant associations with early DNR orders (OR 3.6 [95% C.I. 3.3–3.8], OR 0.5 [95% C.I. 0.4–0.6], OR 0.5 [95% C.I. 0.3–0.7], respectively). While 54 % of the patients with later DNR orders died in the hospitalization period, 28 % of those with early DNR orders died.

CONCLUSIONS: Age was a major determinant factor of early DNR orders. Early DNR orders can't accurately predict looming patients' death. Health care staff should prudently about decisions of DNR in very early phase on admissions.

DO INTERNAL MEDICINE RESIDENTS PERFORM PATIENT CENTERED MEDICAL HOME EPAS? A MIXED-METHODS STUDY Lauren Block; Nancy A. LaVine; Jennifer Verbsky; Joseph Conigliaro; Saima Chaudhry. North Shore-LIJ Health System, Lake Success, NY. (Tracking ID #2200037)

BACKGROUND: Increasingly, residents are being trained in NCQA-certified Patient Centered Medical Homes (PCMH). The Society of General Internal Medicine has defined a set of 25 PCMH Entrustable Professional Activities (EPAs) for residents. It is unknown how frequently residents are engaging in these EPAs. We sought to understand whether residents assigned to PCMH sites reported higher likelihood of engaging in EPAs than those assigned to non-PCMH sites. To improve our understanding of the facilitators and barriers to patient-centered care, we included a qualitative analysis of resident, faculty, and staff perceptions at one PCMH and one non-PCMH site.

METHODS: This was a mixed-methods study incorporating resident survey data and nominal group data from residents, faculty, and staff. Internal medicine residents at three residency programs encompassing eight ambulatory clinic sites in New York were included. At two of these programs, residents had been assigned to either a PCMH or ambulatory clinic site upon entering the program. Non-PCMH sites included a hospital-based clinic, VA, university-owned GIM practice, and private practices. The primary outcome was resident-reported performance of PCMH EPAs. Secondary outcomes included self reported learning and teaching, inter-professional collaboration, and satisfaction with clinic. The survey was conducted electronically and a nominal group technique was used to elicit qualitative data.

RESULTS: A total of 179 residents responded to the survey for an overall response rate of 80 %. Fifty two percent of residents saw patients in PCMH sites. There was no difference in year in residency or gender between residents that worked at PCMH and non-PCMH sites. Residents at PCMH sites were more likely to report engaging in EPAs in four of six NCQA domains. These included enhancing access and continuity (using phone and electronic health record accessed remotely, accommodating care for patient with language and cultural barriers), identifying and managing patient populations (intervening for patients with high risk medications, chronic diseases, and substance abuse), planning and managing care (using EMR, using guidelines, performing medication reconciliation), and providing self-care and community support (counseling patients on self management and health behaviors, using community resources). Residents at PCMH sites were not more likely to report tracking and coordinating care (helping patients transition, help patients attend visits) or measuring and improving performance (engaging in quality improvement, accessing clinic performance data) compared to residents at non-PCMH sites. Residents at PCMH sites were more likely to report working with NPs and medical assistants, but not other healthcare professionals. There were no differences in satisfaction with the ambulatory experience or in ratings on teaching, learning, or staff collaboration scales between PCMH and non-PCMH sites. From qualitative data, residents, faculty, and staff at both sites reported staff teamwork and continuity of care as facilitators of patient-centered care, and technological problems and office inefficiencies as barriers to care.

CONCLUSIONS: An increasing number of residents are training in PCMH sites. Residents at PCMH sites were more likely to engage in EPAs in several NCQA domains, but there is room for improvement in care coordination and quality assessment. Residents at PCMH sites were more likely to work with NPs and medical assistants but reported working with other professionals infrequently even though these professionals worked at the PCMH sites. This signals an opportunity to expand collaboration, define roles of the multi-disciplinary team, and implement workflows to promote communication. One potential reason residents do not engage in all aspects of patient-centered care may be limited insight into the functioning of the PCMH or awareness of PCMH principles. Qualitative data confirmed that continuity and teamwork were goals at all sites and that technological and office efficiency problems hindered provision of patient-centered care, signaling an opportunity to improve communication in resident practices.

DO KNOWLEDGE GAINS TRANSLATE INTO BEHAVIOR CHANGE? PAIRING PHYSICIAN-DIRECTED AND POINT-OF-CARE PATIENT EDUCATION STRATEGIES TO INCREASE COLORECTAL CANCER KNOWLEDGE AND SCREENING COMPLETION Kenzie A. Cameron²; Vanessa Ramirez-Zohfeld²; Nancy C. Dolan²; M. Rosario Ferreira²; Jonathan M. Radosta³; William L. Galanter⁴; Milton "Mickey" Eder¹; Michael S. Wolf²; Dachao Liu²; Alfred Rademaker². ¹Access Community Health Network, Minneapolis, MN; ²Northwestern University, Chicago, IL; ³University of Illinois Hospital and Health Sciences System, Chicago, IL; ⁴University of Illinois at Chicago, Chicago, IL. (Tracking ID #2199043)

BACKGROUND: Colorectal cancer (CRC) remains a leading cause of death in the United States; yet screening rates remain suboptimal. Most interventions to increase CRC screening target either physicians or patients, with limited success. We implemented both physician-only and combined physician-patient strategies and assessed their effectiveness on (1) patient knowledge related to CRC and CRC screening completion, (2) physician recommendation of screening, and (3) patient CRC completion. The physician strategy (MD) involved multiple physician training sessions and continuous quality improvement feedback; patients in the combined physician-patient (MD+DVD) strategy arm were also shown a patient education DVD.

METHODS: We conducted a three-arm quasi-experimental design [MD, MD+DVD, usual care (UC)] among patients at eight health centers in an urban area. Participants were English- or Spanish-speaking, age 50–75, who were not up to date with CRC screening. Clinics were allocated to receipt of physician intervention; patients at intervention clinics were randomized to the DVD. Knowledge was measured via face-to-face interviews at baseline (immediately prior to MD visit) and at post-test (immediately following MD visit) using 8 items. Differences in knowledge change (post-test - pre-test) among arms and across literacy levels were assessed using linear model analysis accounting for health center differences. Bonferroni corrected post hoc analyses were conducted with $p < 0.017$. Physician screening recommendation and patient completion of CRC screening were calculated using a risk ratio; screening recommendation and screening completion comparisons between control and intervention groups were also adjusted for clustering by clinic, analyses among the two intervention (MD, MD+DVD) arms for screening completion were adjusted for stratification by clinic and age.

RESULTS: Among 538 participants, the mean age was 57.8 (SD=6.2); 73.8 % female; 42.9 % Hispanic/Latino and 53.2 % Non-Hispanic Black; 29.7 % reported being uninsured. Among the 437 participants for whom we had complete knowledge data, mean knowledge change (increase) was 1.63 (SEM=0.09), 0.54 (SEM=0.09), and 0.17 (SEM=0.10) among the MD+DVD, MD, and UC, respectively. Knowledge change was significant for MD+DVD and MD ($p < 0.0001$). There was no effect of literacy on knowledge change for any of the arms. Knowledge change among participants in the MD+DVD arm was significantly higher than in the MD or UC arms ($p < 0.0001$), with the MD arm significantly higher than the UC arm ($p = 0.007$). Among the full sample ($n = 538$), there was no significant difference among physician recommendation of CRC screening in the control (42.9 %) versus combined intervention groups (57.6 %; Risk ratio (RR)=1.43, $p = 0.42$, 95 % CI: 0.60–3.43); due in large part to the large interclass correlation coefficient (ICC)=0.295. Results also indicated no significant effect between UC and intervention groups for CRC screening completion (RR=1.65, $p = 0.32$, 95%CI: 0.62–4.38, ICC=0.081), nor between MD and MD+DVD arms (RR=0.80, $p = 0.28$, 95%CI: 0.53–1.20).

CONCLUSIONS: Providing patients a point-of-care educational DVD on CRC and CRC screening resulted in the greatest amount of knowledge change. However, even with the provision of such foundational information, and resultant increase in patient knowledge, no comparable difference was seen in physician recommendation nor patient CRC screening completion. These results suggest that to improve CRC screening among this underserved population, there is a critical need for involvement across multiple levels of patient care—with complementary and reinforcing messages, comprehensive interventions, and system redesign to reach the patient, the physician, the clinic, and the system.

DO PRESCRIBED OPIOIDS IMPACT CD4 COUNT RESTORATION AMONG HIV+ PATIENTS INITIATING ANTIRETROVIRAL THERAPY? E. J. Edelman¹; Janet P. Tate¹; Kirsha S. A. Fiellin¹. ¹Yale University School of Medicine, New Haven, CT; ²VA Connecticut Healthcare System, West Haven, CT; ³National Institutes of Health (NIH), Bethesda, MD; ⁴University of Washington, Seattle, WA; ⁵Yale University, New Haven, CT; ⁶DC VAMC and George Washington University, Washington, DC; ⁷University of Pittsburgh and VA Pittsburgh Healthcare System, Pittsburgh, PA; ⁸Brown University, Providence, RI; ⁹Michael E. DeBakey VAMC and Baylor College of Medicine, Houston, TX; ¹⁰Boston University School of Medicine, Boston, MA. (Tracking ID #2199293)

BACKGROUND: As some opioids are immunosuppressive, we sought to determine the effect of prescribed opioids on CD4 count restoration among HIV+ patients initiating antiretroviral therapy (ART).

METHODS: HIV+ patients from the Veterans Aging Cohort Study initiating ART between 2002 and 2012 were included and followed for 2 years. We excluded those who lacked a CD4 count or had an undetectable viral load at ART initiation. Using pharmacy data, prescribed opioid exposure was categorized as none, short-term (<90 days), and long-term (≥90 days). CD4 counts were repeatedly measured and used in a mixed model to assess the unadjusted and adjusted association between prescribed opioid exposure and CD4 count (square root transformation) over time. Covariates included age, race/ethnicity, hepatitis C status, diabetes mellitus, substance use disorder, smoking status, major depression, pain diagnoses, protease inhibitor vs. NNRTI-based regimen, year of ART initiation (2002–2004, 2005–2007, 2008–2010), months on ART, and interaction terms for opioid exposure and months on ART. We also stratified analyses by baseline CD4 count (<200, 200–349, 350–499, ≥500 cells/mm³).

RESULTS: Among 4352 HIV+ eligible participants, the mean age was 48 years; 97 % were men; and the sample was racially/ethnically diverse (white 33 %, black 55 %, hispanic 6 %, other 5 %). Prescribed opioid exposure was common: 36 % short-term and 12 % long-term. CD4 count at baseline and at 24 months was lowest among those with short-term prescribed opioid exposure (Figure). In both the unadjusted and adjusted analyses, compared to none, those with short-term prescribed opioid exposure had a statistically non-significant slower rise in CD4 count; those with long-term prescribed opioid exposure had a similar rise in CD4 count compared to those with no prescribed opioid exposure (Table). In the stratified analysis, among those with a baseline CD4 count >500 cells/mm³, compared to none (increase per year: 53 cells/mm³), those with short-term prescribed opioid exposure had a statistically significant slower rise in CD4 count (increase per year: 21 cells/mm³, $p = 0.04$); those with long-term prescribed opioid exposure had a similar rise (increase per year: 51 cells/mm³, $p = 0.93$). Results were otherwise unchanged.

CONCLUSIONS: Among HIV-infected patients initiating ART, short-term prescribed opioid exposure may have mild effects on CD4 count restoration, especially among those with CD4 counts ≥500 cells/mm³. Future studies will examine whether these effects vary based on dose and prescribed opioid type.

Table. Association between Prescribed Opioids and Predicted CD4 Count, Mixed Models ($n = 4358$)

DOCTORS DON'T DIE DIFFERENTLY: DOCTORS USE OF HIGH COST LOW VALUE CARE AT END OF LIFE NO DIFFERENT FROM NON-DOCTORS Stacy M. Fischer³; Sung-joon Min³; Alexander K. Smith¹; Amy Kelley⁴; Traci E. Yamashita²; Daniel Matlock². ¹University of California, San Francisco, San Francisco, CA; ²University of Colorado, Aurora, CO; ³University of Colorado School of Medicine, Aurora, CO; ⁴Mount Sinai School of Medicine, New York, NY. (Tracking ID #2196860)

BACKGROUND: The prevailing view of the main stream media and a large body of hypothetical physician survey data suggest that physicians prefer a less invasive, more comfort-based approach to their care when facing life limiting illness. There have been no

studies to our knowledge comparing actual utilization at the end of life between physicians and non-physicians. We aimed to compare health care utilization in the last months of life between physicians and non-physicians. We hypothesize that physicians use fewer high cost, low value resources at the end of life compared to non-physician decedents.

METHODS: This is a retrospective observational cohort study. Using Medicare Part A claims data from 2009 and 2010 for decedent physicians (identified by American Medical Association's file of deceased physicians matched to their Medicare claims data, $n = 9947$) and a random sample of Medicare decedents ($n = 192006$), we compared health care utilization in the last months of life. Using logistic and linear regression modeling, we adjusted for sociodemographic characteristics and regional variations in health care. Sociodemographic information available from the Medicare claims includes birth date,

Figure. Observed CD4 Count Trajectory by Prescribed Opioid Exposure

sex, race/ethnicity, and annual household income calculated based on 2010 U.S. Census zip code data. We adjusted for comorbidity using the modified Charlson comorbidity index based on diagnoses in the Medicare claims during the final 6 months of life. To account for regional variations in health care at the end of life, we linked decedents to their hospital referral region (HRR) using zip code. For each HRR, we included a measure of supply: the number of acute care hospital beds per 1000 residents in 2006 and a measure of practice: the hospital care intensity (HCI) index in 2010. The HCI is a standardized regional composite measure that incorporates the numbers of days patients spend in the hospital and the number of physician encounters during the hospitalization measured as a ratio compared to the national average. Differences between physicians and non-physicians stratified by age group (<75, 85+ vs. 75 to 84), and age group by cohort (physician vs. non-physician) interaction in the regression models were examined for the hospital and hospice utilization to determine if the differences were consistent across age groups. Differences between medical subspecialties were also investigated by comparing one group with all other subspecialty fields. Significance was defined as $P < 0.05$ (or 95 % confidence).

RESULTS: Physician and non-physician decedents had a mean age of 82 years. Physicians were more likely to be Caucasian (92 % v 88 %) and male (94 % v 44 %). After adjusting for sociodemographic characteristics and regional variations in health care, we found both inpatient hospital and hospice utilization in the last 6 months of life remained nearly identical between physicians versus non-physicians: 1) Physician likelihood of utilizing the hospital (OR=0.98 CI 0.93–1.04); 2) Difference in mean hospital days (beta=0.14, $p=0.3$); 3) Physician likelihood of dying in the hospital (OR=0.99 CI 0.95–1.04) 5) Difference in mean ICU/CCU days (0.18, $p < 0.0001$); 6) Proportion using hospice (OR=1.23 CI 1.18–1.29); 7) Difference in mean number of days in hospice (2.06 $p < 0.0001$). We did not find meaningful differences between physicians and non-physicians when we looked at the same utilization measures in the last month of life. After stratifying by age and adjusting for covariates, the difference between physicians and non-physicians was not significantly different in 65–74 or 75–84 age categories, compared to the 85+ category (table). Utilization between medical subspecialties for hospital and hospice utilization was very similar. Compared to all other specialty fields, psychiatry appeared to have the lowest hospice use (39 % vs. 47 %, $P < 0.001$) and adult medical subspecialty appeared to have higher hospital use (13.9 vs. 12.3 mean number of days, $P=0.04$).

CONCLUSIONS: In contrast to the prevailing view of the main stream media and a large body of hypothetical physician survey data, physicians and non-physicians have very similar health care utilization at the end of life. Doctors do not die any “better” than non-doctors.

Utilization of hospital and hospice in the last 6 months of life, adjusted and stratified by age

Mean Days in Hospital (±SD)			
Age at death	Physicians (n=9914)	Non-Physicians (191,419)	p value
65–74	14.8 (±23.4)	15.4 (±21.6)	0.31
75–84	13.5 (±19.6)	14.0 (±19.0)	0.16
85+	10.0 (±15.2)	9.5 (±13.8)	0.04
Percentage utilizing hospice during last 6 months of life			
Age at death	Physicians (n=9947)	Non-Physicians (n=191,980)	p value
65–74	34.6 %	35.8 %	0.30
75–84	44.6 %	42.4 %	0.01
85+	52.5 %	47.6 %	<0.0001

DOES SOCIAL SUPPORT MODERATE THE ASSOCIATION OF SOCIOECONOMIC STATUS AND SUBCLINICAL ATHEROSCLEROSIS IN THE MULTI ETHNIC STUDY OF ATHEROSCLEROSIS (MESA)? zameer abedin^{1,2}; Ana Diez-Roux³; Kiarri Kershaw²; Anita Panjwani²; Norrina Allen². ¹Texas Tech University Health Science Center, El Paso, TX; ²Northwestern University, Chicago, IL; ³Drexel University, Philadelphia, PA. (Tracking ID #2191922)

BACKGROUND: Cardiovascular disease remains a leading cause of morbidity and mortality in the United States, claiming an estimated 2200 lives each day. Socioeconomic Status, often defined and measured as a person's income and level of education, is associated with the development of subclinical cardiovascular disease. The aim of this study was to determine whether the relationship between SES and subclinical cardiovascular disease differs by an individual's level of social support.

METHODS: This cross-sectional study utilized data on 6517 participants from the Multi-Ethnic Study of Atherosclerosis (MESA) baseline exam (2000–2002). Exposures of interest included social support and SES (calculated using household income and highest level of education). Analyses were conducted using risk-adjusted logistic and Poisson regression models, and primary outcomes measured were coronary artery calcification (CAC), ankle brachial index (ABI), and carotid intima media thickness (CIMT). Models were adjusted sequentially for demographics (age, sex, race/ethnicity), then additionally for CVD risk factors (diabetes, hypertension, hyperlipidemia, obesity, and smoking). Modification of SES by social support was tested using an interaction term, and then by stratifying regression models by participant SES and social support.

RESULTS: Overall, nearly half the sample (49.59 %) exhibited CAC greater than 0, 3.48 % exhibited an ABI below 0.9, and 0.64 % exhibited a CIMT of greater than 1.5 mm. We found that, after adjustment for potential confounders, there was significant interaction between SES and social support for the outcomes of ABI and CIMT ($P=0.008$ and 0.015 , respectively). Participants with low SES and low social support had significantly higher odds of low ABI (OR=1.86 (95 % CI=1.18 to 2.95)) and high CIMT (OR=3.40 (95 % CI=1.27 to 9.14)) as compared to individuals with high SES and high levels of social support.

CONCLUSIONS: For the outcomes of ABI and CIMT, the combination of low socioeconomic status and low social support was associated with the highest risk of subclinical atherosclerosis. Particularly for the outcome of CIMT, the presence of social support may serve to mitigate the effects of low SES, while the effects of SES and social support on ABI appear to be driven largely by SES. The lack of association seen in CAC after adjustment may be a testament to its marked association with demographic factors such as age and race, while ABI and CIMT could conceivably be more highly influenced by social and socioeconomic factors.

Fully Adjusted Odds Ratios for High CAC, Low ABI, and High CIMT (CIMT ≥ 1.5 mm)

	High CAC: Agatston Score >0 [PR (95 % CI)]; N=(%)	Low ABI: ABI ≤ 0.9 [OR (95 % CI)]; N=(%)	High CIMT: CIMT ≥ 1.5 mm [OR (95 % CI)]; N=(%)
High SES and High Social Support	1:Ref N=1420 (48.50)	1:Ref N=63 (2.17)	1:Ref N=9 (0.31)
High SES and Low Social Support	0.95 (0.79–1.13) N=368 (43.35)	1.16 (0.67–2.02) N=22 (2.62)	3.02 (1.05–8.71) N=6 (0.71)

DON'T WASTE YOUR BREATH: A STUDY OF INHALER DISPOSAL AT HOSPITAL DISCHARGE FOR COPD PATIENTS WITH ACUTE EXACERBATIONS Joyce Pang¹; Jonah Feldman^{1,2}; Vladimir Liberman¹; Stephanie Mawhirt¹; Farah Daccueil¹. ¹Winthrop University Hospital, Mineola, NY; ²Stony Brook School of Medicine, Stony Brook, NY. (Tracking ID #2198005)

BACKGROUND: Under the current fee-for-service system, no provider or group of providers is accountable for managing the quality and costs of a patient's care throughout the course of treatment. Fee for service payment often promotes fragmented and duplicative care that would be discouraged by other payment methods. Until recently internal medicine trainees have not received any formal training in identifying these types of care inefficiencies. In January 2013, after completing the ACP-AAIM curriculum on High Value Cost Conscious Care, residents in our hospital were asked to identify unrecognized sources of inefficiency or waste, and attempt to calculate the impact of these wasteful

practices. A group of residents, along with a supervising faculty member, identified routine disposal of unfinished MDI inhalers upon hospital discharge as a wasteful practice that warranted further study. This report aims to quantify the impact of this specific practice on patients with COPD exacerbations in a large university hospital.

METHODS: In our 591 bed tertiary referral center we reviewed the medication administration record for all patients hospitalized for COPD exacerbation who had MDI inhalers dispensed during hospitalizations from July to November 2012 ($N=192$). In the hospital's formulary fluticasone propionate/salmeterol came in three dosages, each with 14 inhalations. Budesonide/formoterol came in two dosages each with 60 inhalations. As per hospital protocol all MDI inhalers were disposed at discharge no matter how many dosages remained unused. To calculate the total waste generated by disposal of unfinished inhalers on discharge the number of dispensed doses was subtracted from the total number of inhalations in each medication. This was then multiplied by the cost of each dose as provided by the hospital's pharmacy staff.

RESULTS: For Fluticasone propionate/salmeterol 100/50 mcg, 250/50 mcg, and 500/50 mcg, there were 29, 462, and 144 wasted inhalations respectively. For the first two dosages, the estimated cost was \$7.4/inhalation leading to a total of \$3632.8 wasted. For Fluticasone propionate/salmeterol 500/50 mcg, there were 144 wasted inhalation with an estimated cost of \$12/inhalation leading to a total of \$1728.0 wasted. For Budesonide/formoterol there were a total of 1855 wasted inhalations; with an estimated cost of \$1.9/inhalation leading to \$3486.5 wasted. The total calculated waste during the 5 month study period was \$8847.3. This amounts to a projected waste of \$21,233.5 just for patients admitted for COPD exacerbation over a 12 month period.

CONCLUSIONS: In a fee for service payment system providers are often incentivized to provide duplicative care, but the impact of this inefficiency often goes unrealized until it is formally studied. In our hospital system, we found that a significant amount of resources were being wasted because partially used inhalers were being disposed of on discharge. This represents the first known report to evaluate the financial impact of inhaler disposal, and provides a point of reference for other institutions that currently have similar policies. Based upon these findings, starting in January 2014 our hospital began to provide patients with these unfinished inhalers. This hospital wide change occurred in large part as a result of this resident initiated report. The real world effect of this change on cost and quality remains an important avenue for future study.

DOSE INCREASES FOR PATIENTS STARTING LONG-TERM OPIOID THERAPY FOR PAIN: WHERE AND WHY DO THEY HAPPEN? Christopher A. Bautista¹; Ana-Maria Iosif²; Barth Wilsey^{1,2}; Althea Crichtlow⁴; Joy Melnikov^{4,1}; Stephen G. Henry^{1,4}. ¹University of California Davis, Sacramento, CA; ²VA Northern California Healthcare System, Mather, CA; ³University of California Davis, Davis, CA; ⁴UC Davis Center for Healthcare Policy and Research, Sacramento, CA. (Tracking ID #2197900)

BACKGROUND: Patients on high-dose opioid therapy for chronic pain are at greater risk of opioid-related overdose and death, yet we know little about the circumstances under which physicians increase patients' opioid doses. This study characterized clinical documentation for all opioid prescriptions during patients' first year of long-term opioid therapy and compared clinical documentation for patients with versus without overall opioid dose escalation.

METHODS: We performed a retrospective, nested case-control study using data from the University of California Davis electronic health record for all opioid-naïve adults with musculoskeletal pain who started opioids between July 1, 2011 and June 30, 2012 and who remained on opioids for 1 year. Cases were patients who experienced overall opioid dose escalation (defined as an increase of ≥ 30 mg morphine/day over 1 year); cases were matched with 2 randomly selected control patients without dose escalation. Two coders independently reviewed all encounters with opioid prescriptions during each patient's first year on opioids and classified each prescription as either a dose increase, dose decrease, or no change based on physician documentation. Coders abstracted encounter type, 10 pain management practices recommended by VA and American Pain Society guidelines, and physicians' clinical reasoning for each prescription. Disagreements were resolved by discussion. Descriptive statistics were used to analyze prescriptions, clinical reasoning, and guideline-concordant pain management. Mixed-effects logistic regression was used to compare patients with versus without overall opioid dose escalation.

RESULTS: We coded 675 encounters involving opioid prescriptions for 66 patients; 22 with overall opioid dose escalation and 44 without dose escalation. Inter-coder agreement (kappa) for prescription classification variables ranged from 0.73 to 0.91. Thirty-four percent of prescriptions were classified as opioid dose increases, 8 % as dose decreases, and 59 % as no change. Sixty-seven percent of all prescriptions and 38 % of opioid dose increases took place via email or telephone encounters without face-to-face patient contact. Forty-two percent of all prescriptions and 31 % of opioid dose increases had no reason documented for the opioid prescription. When physicians documented reasoning for an opioid dose increase, the most common reasons were inadequate pain relief (23 %), increased pain severity (15 %), and patient request (11 %). Patient self-escalation was documented for 11 % of opioid dose increases involving case patients,

compared to 2 % involving controls. Physicians documented significantly more guideline-concordant pain management practices for patients with overall dose escalation compared to controls (3.9 versus 2.4, $P<0.001$). There was no significant difference between cases and controls for prescription classification, proportion of encounters without face-to-face patient contact, or proportion of prescriptions without documented reasoning.

CONCLUSIONS: During patients' first year of long-term opioid therapy for pain, the majority of opioid prescriptions and over one-third of opioid dose increases were written without face-to-face patient contact. Many opioid prescriptions and dose increases contained no explanation for the prescription. We found few significant differences in documentation between patients with versus without overall dose escalation. These findings suggest that physicians may pay relatively little attention to patients' opioid dose or to the rationale for continuing opioids during the first year of treatment. The frequency of prescriptions written without face-to-face patient contact likely contributes to this phenomenon.

DUAL THERAPY FOR PSEUDOMONAS AND OUTCOMES IN HEALTHCARE ASSOCIATED PNEUMONIA Michael B. Rothberg²; Marya Zilberberg³; Penelope S. Pekow¹; Aruna Priya¹; Sarah Haessler¹; Tara Lagu¹; Thomas Higgins¹; Peter K. Lindenauer^{1, 1}. ¹Baystate Medical Center, Springfield, MA; ²Cleveland Clinic, Cleveland, OH; ³University of Massachusetts, Amherst, MA. (Tracking ID #2197976)

BACKGROUND: Guidelines for treatment of healthcare-associated pneumonia (HCAP) recommend that empiric therapy include 2 agents with activity against *Pseudomonas* for all patients. The recommendation is based primarily on studies of ventilator associated pneumonia. The objective of this study was to examine the association between dual therapy for *Pseudomonas* (DT) and outcomes for patients with HCAP.

METHODS: We conducted a retrospective cohort study at 338 US hospitals that participate in the Premier data consortium. We included all adults hospitalized for HCAP between July 2007 and June 2010. All patients received empiric therapy for Methicillin resistant *Staphylococcus aureus* (as per HCAP guidelines) and either one or two agents with activity against *Pseudomonas*. Patients who received DT begun on hospital day 1 or 2 were compared with those who received single therapy (ST). The primary outcome was in-hospital mortality. Secondary outcomes included late deterioration (admission to intensive care unit (ICU), mechanical ventilation, or pressors on day 3 or later), 30-day readmissions, acute kidney injury, *C. difficile* infection, length of stay, and costs. We developed a hierarchical logistic regression model for treatment to produce propensity scores for DT vs. ST. Stabilized inverse probability of treatment weighting was used to model outcomes. Multivariable hierarchical generalized linear models were developed to assess the independent association between exposure to DT for each outcome adjusted for patient characteristics, other early treatments, propensity for dual therapy, predicted mortality, and hospital characteristics. We also conducted a stratified analysis to determine the presence of treatment effect heterogeneity based on severity of illness. We considered the following strata: ICU patients treated with mechanical ventilation or pressor medications, other ICU patients, and non-ICU patients. SAS software procedure GLIMMIX was used to account for the hierarchical nature of the data (patients clustered within hospital and with hospital as a random effect).

RESULTS: Of 31,949 patients at 338 hospitals, 14809 (46.4 %) received DT, and 17140 (53.6 %) received ST. Compared to patients who received ST, those who received DT were similar in age and co-morbidity profile but were more likely to be admitted initially to an ICU (45.4 % vs 36.0 %, $p<0.001$), and had higher observed mortality (17.6 % vs. 16.7 %, $p<0.001$). After adjustment for demographics, comorbidities, propensity for dual therapy, and initial severity of disease, receipt of DT was associated with lower risk of mortality (OR 0.93, 95 % CI 0.87–0.99), but the number-needed-to-treat to prevent one inpatient death was 146. Effectiveness of dual coverage did not vary by severity of illness. In covariate adjusted models there were no differences between DT and ST in rate of late deterioration, readmissions, acute kidney injury, *C. difficile* infection, cost, or length of stay.

CONCLUSIONS: Among HCAP patients receiving antibiotics for MRSA and *Pseudomonas*, dual coverage for *Pseudomonas* was associated with slightly better short term survival but a large number-needed-to-treat. Better tools are needed to identify patients who might benefit from dual coverage.

EARLY CLINICAL EDUCATION CAN IMPROVE MEDICAL STUDENTS' CLINICAL REASONING BEFORE CLERKSHIPS Heather L. Heiman²; Celia O'Brien³; Toshiko Uchida²; John Butter¹; Marsha E. Yelen³; Patricia M. Garcia¹. ¹Northwestern Feinberg School of Medicine, Chicago, IL; ²Northwestern University Feinberg School of Medicine, Chicago, IL; ³Northwestern University Feinberg School of Medicine, Chicago, IL. (Tracking ID #2198569)

BACKGROUND: Responding to calls for educational reform, medical schools have increasingly introduced authentic clinical experiences into students' first 2 years. Early clinical exposure has been reported to improve professionalism, student satisfaction, and history-taking. Clinical reasoning is rarely a stated objective of early clinical exposure, but experts have called for earlier introduction of diagnostic reasoning in medical education. In restructuring our 4-year curriculum, we strengthened clinical medicine instruction for pre-clerkship students. We examined the impact of this change on students' self-assessed diagnostic reasoning and other synthetic clinical skills shortly after entering clerkships.

METHODS: In the prior curriculum, students received two hours per week of clinical medicine instruction. In year 1, standardized communication and physical exam instruction occurred in the clinical education center (CEC). In year 2, students worked with a clinical preceptor every other week, returning to the CEC to reinforce skills on alternate weeks. They also submitted 5 history and physicals for hospitalized patients. Starting in 2012, students received three hours of clinical medicine each week in the pre-clerkship phase. Key tenets of the new curriculum included integration of clinical content with basic sciences, continuity of mentorship, and augmented student assessment. Students met patients in weekly "clinical correlations"; the patients had illnesses students were studying in science. In each interactive lecture, students learned a clinical skill relevant to the care of that patient, and in the ensuing weeks they practiced it. Students worked with two clinical mentors at all times. A small-group mentor provided standardized skills training, and a clinical mentor oversaw authentic patient experiences. To promote learning, we diversified and increased assessments. Observed structured clinical examinations increased from two to three per year. In addition to receiving eight preceptor evaluations, students had semi-annual direct observations, and multiple choice examinations began including clinical medicine content. Students completed written assignments for 9 hospitalized patients. The Clinical Skills Preparation Survey was administered from 2007 to 2014 to all students following the first month of clinical clerkships. Students rated how their clinical skills courses prepared them for their first clinical rotation using a 5-point scale. Here we focus on student ratings of 7 skills related to clinical reasoning and on the overall clinical preparation score. We omitted 107 students who did not enroll in a clerkship at the start of the academic year. We achieved an 87 % response rate to obtain a final sample of 1036 medical students, 129 of whom participated in the new curriculum. We ran Mann-Whitney *U*-tests to compare students in the two groups. Pearson's correlation coefficient (*r*) was calculated to test the magnitude of significant findings.

RESULTS: Students who participated in the new clinical skills curriculum reported feeling significantly more prepared in all 7 specific reasoning skills and overall (Table). Old curriculum students rated themselves as prepared (above a 3) for two of seven skills: evaluating outpatients and writing a history and physical. New curriculum students rated themselves as prepared in five of seven skills: evaluating outpatients, writing a history and physical, constructing a problem list, formulating a differential diagnosis, and giving oral presentations. The largest effect size ($r=0.30$) was seen in formulating a differential diagnosis.

CONCLUSIONS: A revised clinical skills curriculum was associated with improvements in student confidence in abilities that reflect clinical reasoning, including generation of a differential diagnosis and a problem list. The AAMC has stated that these skills are required at entry to clerkships and are an entrustable professional activity for entering residency. We believe improved integration of content, precepting, and assessment account for this improvement. The transition to clinical years has been described as stressful, and the need for clinical reasoning can be an abrupt change from pre-clinical years. Lowering the stress of this transition by preparing students to reason clinically may create more opportunities for learning early in clerkships.

Comparison of student preparedness levels between old (2007–2013) and new (2014) curriculum

*1=not prepared at all, 3=prepared, 5=extremely well prepared

EARLY EFFECTS OF LORCASERIN ON GLYCEMIC PARAMETERS IN OBESE AND OVERWEIGHT PATIENTS WITH TYPE 2 DIABETES MELLITUS: A RETROSPECTIVE ANALYSIS OF BLOOM-DM Elisa Fabbrini³; Randi Fain¹; Alan Glicklich²; Yuhua Li¹; William Shanahan²; William Soliman¹. ¹Eisai Inc, Woodcliff Lake, NJ; ²Arena Pharmaceuticals, San Diego, CA; ³Washington University School of Medicine, St Louis, MO. (Tracking ID #2198474)

BACKGROUND: Pre-clinical data show that 5-HT_{2C} activation may improve insulin resistance. Lorcaserin (LOR) is a selective 5-HT_{2C} agonist that has been shown to significantly reduce weight, fasting plasma glucose (FPG), and hemoglobin A1c (HbA1c) in overweight/obese patients with type 2 diabetes mellitus (T2DM) over 1 year. This retrospective analysis studied the glycemic effects of LOR at earlier time points.

METHODS: The BLOOM-DM trial enrolled patients with BMI 27–45 kg/m² and T2DM uncontrolled by oral antidiabetic drugs. Patients were randomized to LOR 10 mg twice daily (BID) (*n*=256) or placebo (PBO) (*n*=253). All patients received a standard diet and exercise program. Primary endpoints were the percent of patients achieving ≥5 % and ≥10 % weight loss, and the mean change in weight at week 52. This analysis retrospectively evaluated the effects of LOR on changes in FPG, fasting insulin, HbA1c, and body weight (BW) after 2 (FPG, fasting insulin, and BW only), 24, and 52 weeks of therapy in the modified intent-to-treat (MITT) population (last observation carried forward).

RESULTS: LOR significantly reduced FPG beginning at week 2 (−27.8 [LOR] vs −15.4 mg/dL [PBO], *p*<0.001), prior to substantial changes in BW (−1.0 [LOR] vs −0.7 kg [PBO], *p*=not significant). Reductions in FPG with LOR were maintained (week 24: −29.3 [LOR] vs −16.4 mg/dL [PBO], *p*=0.001; week 52: −29.2 [LOR] vs −11.4 [PBO], *p*<0.001), with no significant effect on fasting insulin observed at any time point (week 2: −2.04 [LOR] vs −2.55 [PBO]; week 24: −2.46 [LOR] vs −1.12 [PBO]; week 52: −2.68 [LOR] vs −1.91 [PBO] μIU/mL). Significant reductions in HbA1c with LOR were observed at week 12 (−1.0 [LOR] vs −0.6 [PBO], *p*<0.0001), week 24 (−1.0 [LOR] vs −0.6 [PBO], *p*<0.0001), and week 52 (−0.9 [LOR] vs −0.4 [PBO], *p*<0.0001).

CONCLUSIONS: LOR reduced FPG as early as week 2 before substantial weight loss. These data suggest that LOR may play a role in regulating glucose homeostasis, independent of weight loss.

EARLY-ONSET FUNCTIONAL DIFFICULTY AND ITS RELATIONSHIP TO FUNCTIONAL DEPENDENCE Rebecca Brown; Yinghui Miao; Michael Steinman. Division of Geriatrics, University of California, San Francisco, San Francisco, CA. (Tracking ID #2196446)

BACKGROUND: Older adults are the age group most likely to experience functional dependence, meaning the need for help performing basic daily activities. However, functional difficulty—i.e., experiencing difficulty performing a task, though still performing it without help—may precede dependence by decades. Little is known about how functional difficulties arise at younger ages and how these difficulties relate to the emergence of functional dependence.

METHODS: We analyzed longitudinal data from 8680 participants in the nationally-representative Health and Retirement Study. Participants were age 50–56 at enrollment and free of impairment in activities of daily living (ADLs) and instrumental activities of daily living (IADLs). We analyzed data from these individuals at 2 year intervals for up to 20 years for new-onset functional difficulty and dependence. We defined ADL difficulty as self-reported difficulty performing 1 or more ADLs and ADL dependence as self-reported need for help performing 1 or more ADLs. We defined difficulty and dependence in IADLs similarly. The incidence of new-onset ADL and IADL difficulty and dependence at different ages were evaluated using flexible parametric survival analysis. Reported values incorporate survey weights to account for the complex survey design.

RESULTS: Overall, 54 % of participants were male and 80 % were white. The incidence of new-onset ADL difficulty increased rapidly as participants progressed from their early to mid-50s: at age 52, the incidence of new-onset ADL difficulty was 9 per 1000 person-years, rising to 17 per 1000 person-years at age 57. However, starting at age 58 the incidence rates rose much less steeply for each additional year of life, from 18 per 1000 person-years at age 58 to 21 per 1000 person-years at age 78. In contrast, the incidence of ADL dependence increased at a relatively constant rate with increasing age, from 1 per 1000 person-years at age 52 to 18 per 1000 person-years at age 78. The incidence of IADL difficulty and dependence by age showed a similar pattern.

CONCLUSIONS: Although functional dependence is usually thought of as a problem of older adults, its antecedents develop much earlier. Identifying functional difficulty and intervening when it first arises, in late middle age, may have the potential to prevent or slow the progression from functional difficulty to dependence.

EFFECT OF A COLORECTAL CANCER SCREENING DECISION AID ON DECISION MAKING OUTCOMES IN A LOW-INCOME, MAJORITY LATINO PATIENT POPULATION Alison Brenner¹; Danelle Callan²; Miriam Espaillet³; Khalil Harbi¹; Richard Hoffman⁴; Andrew McWilliams³; Michael Pignone⁵; Robert Rhyne²; Hazel Tapp³; Brisa Urquiza de Hernandez³; Mark Weaver⁵; Daniel S. Reuland⁵. ¹Cecil G. Sheps Center for Health Services Research, Chapel Hill, NC; ²University of New Mexico, Albuquerque, NM; ³Carolinas HealthCare System, Charlotte, NC; ⁴Albuquerque VAMC/University of New Mexico School of Medicine, Albuquerque, NM; ⁵University of North Carolina, Chapel Hill, NC. (Tracking ID #2196755)

BACKGROUND: Decision aids for colorectal cancer (CRC) screening have been shown to improve CRC screening-related decision making and test completion in highly-insured, English-speaking populations. However, the effects of such decision aids in diverse, vulnerable patient populations remain unclear, and they have not been tested in Latino patient populations in a clinic setting. We are currently conducting a pragmatic, randomized controlled trial of a two-component intervention that includes a CRC screening decision aid delivered before a provider visit and patient navigation delivered after the visit in safety net clinics. The full trial will eventually assess screening test completion as the distal outcome; this analysis examines the effect of the decision aid component of the intervention on intermediate decision-making outcomes.

METHODS: We enrolled primary care patients ages 50–75 at average CRC risk who were not current with recommended screening from two clinic sites that serve racially and ethnically diverse, low-income communities in North Carolina and New Mexico. After a baseline survey, participants were randomized to an intervention group who viewed a 14-min CRC screening decision aid video (in Spanish or English) before their provider visit, or a control group who viewed a food safety video. Immediately after their provider visit, participants completed an oral follow-up survey administered by a bilingual research assistant. Decision making outcomes included screening-related knowledge (on 6 item scale), discussions with the provider, test preferences, and test ordering. We also assessed intention to complete screening (on a 5-point Likert scale, dichotomized as “low intention” and “high intention” for analysis). We used Mantel-Haenszel row mean score tests to compare outcomes across study arms, controlling for baseline value where possible.

RESULTS: Participants (*n*=171) had mean age of 58 years and were 61 % female, 57 % Latino, 22 % non-Latino White, and 18 % African American. Most (69 %) had a household income of less than \$20,000; 48 % had limited health-literacy, 39 % were uninsured, and 43 % were Spanish-speaking. On the follow-up survey, intervention participants answered an average of 4.5 of the 6 knowledge questions correctly (vs. 2.4 at baseline), while control participants answered an average of 2.5 questions correctly (vs. 2.5 at baseline), difference in differences 2.1; (95 % CI 1.8, 2.5), *p*<0.001. Compared with controls, intervention participants were more likely to report having a screening discussion with their provider (71 % vs. 42 %, *p*<0.001); indicate having “enough information to decide” (96 % vs 69 %, *p*<0.001); indicate a specific testing preference (89 % vs 61 %, *p*<0.001), report high intention to complete screening (95 % vs 86 %, *p*=0.04), and have a screening test ordered (55 % vs. 33 %; *p*=0.003). Similar effects were observed for these outcomes when restricting the analysis to the Latino subsample.

CONCLUSIONS: In a low-income, racially and ethnically diverse patient population, a decision aid offered in a participant’s preferred language increases screening-related knowledge, clinical discussions, intent to complete screening, and test ordering, and is effective in both Latino and non-Latino patients.

EFFECT OF BASELINE TIMEFRAME ON POTENTIAL BIAS IN RISK FACTOR ASSESSMENT IN AN EHR-BASED COHORT Jason L. Vassy¹; Yuk-Lam Ho¹; David R. Gagnon¹; J. M. Gaziano¹; Jacqueline Honerlaw¹; Sanjay Raju¹; Peter W. Wilson²; Kelly Cho¹. ¹VA Boston Healthcare System, Boston, MA; ²Atlanta VA Medical Center, Atlanta, GA. (Tracking ID #2181953)

BACKGROUND: Prospective cohort studies in classical epidemiology begin with a baseline exam when risk factors are measured, after which participants are observed over time for health outcomes. Longitudinal patient data from electronic health records (EHR) hold potential for large-scale clinical epidemiology. However, they may necessitate flexibility in defining the timeframe of baseline risk factor assessment, since patients in a health system access care at varying frequencies. This variable schedule of contact with the health system may introduce information bias or selection bias to any study using such an EHR-defined cohort. In creating the first cardiovascular disease (CVD) cohort study using patient data from a large health system, we tested the hypothesis that widening the timeframe used to measure baseline CVD risk factors increases the yield of eligible patient data without introducing bias.

METHODS: To define a veteran cohort study, we used EHR data from the New England (VISN 1) and Southeast (VISN 7) Networks of the Veterans Health Administration. We identified 589,361 eligible VISN 1 and 7 patients, defined as having valid demographic data and ≥ 1 set of blood lipid results between 2000 and 2007. We anchored the index date

to the date of the first eligible lipid results. We then expanded the definition of the baseline timeframe by 1-week intervals before or after this date, assessing the proportion of eligible patients with blood pressure (BP) measurements with each successive widening of the baseline timeframe. We compared 3 mutually exclusive groups of patients: 1) those with BP from the exact index date, 2) those with BP not on the index date but within the VISN-specific 90th percentile to either side of the index date, and 3) those with no BP within the VISN-specific 90th percentile. We identified baseline CVD, diabetes, and mental health conditions from ICD-9 codes and aspirin use from pharmacy records. Driving time to facility was estimated from each patient's home zip code.

RESULTS: Group 1 contained 146,636 (61.0 %) and 289,906 (83.1 %) of the eligible patients in VISN 1 and 7, respectively. This proportion reached 90 % within +91 or -154 days from the index date in VISN 1 and within only +7 or -14 days in VISN 7. For each VISN, the 3 groups did not differ substantially in BP or LDL-C levels, but Group 3 had less available race data, lower prevalence of baseline comorbidities, and fewer outpatient contacts with the health system.

CONCLUSIONS: Creating a prospective CVD cohort from EHR data is feasible but may require special handling of patients with infrequent visits to minimize information and selection bias. The potential for bias may vary considerably across different regions within the same large integrated health system. Use of these methods can identify biases and allow modification of study design to eliminate them.

Time to nearest blood pressure (BP) measurement from index date of lipid results among New England (VISN 1) and Southeast (VISN 7) Network patients in the Veterans Health Administration

Characteristics of New England (VISN 1) and Southeast (VISN 7) VA patients: Group 1) those with blood pressure (BP) measured on the exact index date of lipid results; Group 2) those with BP not on the index date but within the VISN-specific 90th percentile to either side of the index date, and Group 3) those with no BP within the VISN-specific 90th percentile. Data are means (standard deviations, SD), medians (interquartile ranges, IQR), or percentages, as appropriate. CVD, cardiovascular disease; LDL-C, low-density lipoprotein cholesterol; PTSD, post-traumatic stress disorder; SBP, systolic blood pressure.

EFFECT OF EMPLOYEE HEALTH PLAN FINANCIAL INCENTIVES ON DIABETES AND CARDIOVASCULAR RISK FACTOR CONTROL

Anita D. Misra-Hebert; Bo Hu; Glen B. Taksler; Bruce Rogen; Robert Zimmerman; Michael B. Rothberg. Cleveland Clinic, Cleveland, OH. (Tracking ID #2195973)

BACKGROUND: Worksite wellness programs emphasize lifestyle changes and disease management in the work setting. Financial incentives associated with wellness program participation have the potential to change health behaviors and reduce downstream health care costs. However, it is unknown whether financial incentives improve disease management in participants when compared to those who voluntarily obtain care (without financial incentives). The purpose of the present study is to assess the impact of the introduction of employee health plan financial incentives on control of diabetes as well as control of other cardiovascular risk factors in employees with diabetes.

METHODS: We conducted a retrospective cohort study using insurance claims data linked with electronic medical records from January 2008–December 2012 in one health system. Study participants included Cleveland Clinic employees with diabetes covered by the organization's self-funded insurance plan which covers over 38,000 employees and over 82,000 lives with 3700 covered members with diabetes. We created a comparison group comprised of non-employee patients with diabetes and commercial health insurance, who were cared for in the same primary physician practices, and obtained care without financial incentives. Exposures included the introduction of an employer-sponsored disease management program, including an initial fixed financial incentive (\$100 in 2009, increasing to \$300 in 2010) that was tied to participation only, and a subsequent 30 % health insurance premium discount (\$600–\$1200 depending on plan chosen in 2011 and 2012) that was tied to both participation and achievement of specific clinical goals. Employees were matched in 2 year cohorts to correspond with the introduction of different levels of financial incentives. Each cohort included all employees with diabetes (both disease management program participants and non-participants) with at least one glycosylated hemoglobin (HbA1C) in both years. Employees were matched to non-employees using propensity scores from a model that included age, sex, body mass index (BMI), insulin use, initial HbA1C, and primary care site. Following the introduction of each incentive, in each cohort, we measured the change for employees vs. the matched non-employee comparison group in the following outcomes: HbA1C, low density lipoprotein (LDL), systolic blood pressure, and weight.

RESULTS: A total of 1092 employee patients with diabetes were matched to a comparison group of 1092 non-employee patients. With increasing incentives for participation in disease management programs, the proportion of eligible employees enrolled in the programs increased from 9 % in 2009 to 53 % in 2012 ($p < 0.001$); 9.8 % of all employees with baseline HbA1c > 9 enrolled in 2009 and 35.3 % in 2012 ($p < 0.001$). The baseline mean HbA1c of participants joining the program in 2009 was 7.52 and in 2012 was 7.35. In their first year in the diabetes management program, participants' HbA1C declined by 0.32 points (95 % Confidence Interval (CI) 0.21–0.43) and weight by 2.31 kg (95 % CI 1.45–3.17). The comparison group had similar HbA1C improvements (0.21 points, 95 % CI 0.08–0.34, difference in differences $p = 0.13$). The weight in the non-employee group declined 0.41 kg (95 % CI –0.14–0.96, $p = 0.01$ for the difference in differences). Offers of small, fixed financial incentives for program participation were temporally associated with small, non-significant decreases of HbA1C in all employees with diabetes (0.07–0.13 points, $p > 0.05$) while financial incentives tied to treatment targets were temporally associated with a HbA1C decline of 0.18, $p = 0.000$. However, similar changes were observed in the comparison group, implying that other secular factors may have been responsible for the decline. Weight decreased more significantly in the employee cohort than in the comparison group in 2012 (1.32 kg vs. 0.52 kg, $p = 0.02$). For the subgroup of employees with HbA1c > 9, the HbA1c continued to decline throughout the study but changes were similar in the comparison group. Mean LDL cholesterol also decreased for all employees throughout the study period, with similar reductions seen among the comparison group.

CONCLUSIONS: Compared to patients who sought care voluntarily, employees offered financial incentives to participate in disease management programs and achieve health targets had greater reductions in weight but not diabetic control or LDL cholesterol. Financial incentives encourage employees to enter diabetes management and may improve outcomes. Future research will consider the association of these financial incentives on long-term diabetes management, as well as overall health care utilization and expenditure.

EFFECT OF THE TAILORED ICD FACILITATED DISCUSSION ON PATIENT AND FAMILY DECISION-MAKING ABOUT CIED DEACTIVATION AT THE END OF LIFE: A PILOT RANDOMIZED CONTROLLED TRIAL Mark Hughes^{3,4}; Gayane Yenokyan⁵; Daniel Sulmasy¹; Lisa S. Lehmann²; Julie Johnson¹; Joan Kub⁶; Marie Nolan⁶; ¹University of Chicago, Chicago, IL; ²Brigham and Women's Hospital, Boston, MA; ³Johns Hopkins University School of Medicine, Baltimore, MD; ⁴Johns Hopkins University Berman Institute of Bioethics, Baltimore, MD; ⁵Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD; ⁶Johns Hopkins University School of Nursing, Baltimore, MD. (Tracking ID #2200035)

BACKGROUND: Guidelines on cardiovascular implantable electronic device (CIED) management recommend informing patients and families about CIED deactivation to prevent unnecessary shocks near death. An American Heart Association report calls for research on the timing, manner, and psychological impact of discussing CIED deactivation with patients and families. The purpose of this study was to pilot test the TAILORED (Trial to Advance Individual Loved Ones' Roles in End-of-Life Decisions) intervention on patient and family CIED decision-making outcomes.

METHODS: The study was conducted at two academic medical centers with diverse patient populations. Study subjects were dyads of adult patients with CIED and New York Heart Association (NYHA) Level II or III heart failure (HF) and an adult family member whom they might involve in health care decision making. Patients or family members with cognitive impairment were excluded. Dyads were randomized into intervention (INT) and control groups (CON). The TAILORED Intervention is a brief, nurse-facilitated, patient-family discussion involving assessment of patient preference for family involvement in health care decisions and support for family members involved in proxy decision making. As part of the discussions, the nurse provided a take-home handout to the dyad, which used illustrations to represent the decision-making role the patient preferred and the role that the family member thought the patient preferred. The patient and family member were encouraged to talk further about the patient's decision making style preferences. Four weeks after baseline, family members were telephoned to "booster" the intervention, in which they were asked if they had any questions about the intervention and if they had reviewed the take-home handout with the patient or other family members. If they had not yet developed a plan regarding CIED deactivation with the patient, they were encouraged to do so. Dyad members separately completed surveys at baseline (T1) and 8 weeks after the intervention (T2). The main outcomes were the creation of a plan regarding CIED deactivation at the end of life (ICD PLAN), decision making distress (measured with 22-item, 5-point Likert Impact of Event Scale (IES)), and decision making self-efficacy (measured with 7-item, 5-point Likert Family Decision-Making Self-Efficacy Scale). Descriptive statistics were used to summarize the demographic characteristics of the sample. Outcomes were compared between study arms at baseline and at 8 weeks using generalized linear regression models with adjustment for study site and robust variance to account for patient-level correlation over time.

RESULTS: The sample consisted of 56 dyads (27 INT, 29 CON); 43 (74 %) completed T2 surveys. Ten patients (5 in each group) died during study follow up. Mean age of patients was 61, 71 % were male, 61 % received CIED for prevention, and 48 % had received CIED shock before. Family members' mean age was 54 and 52 % were spouse or partner. Both CON and INT had increased ICD PLAN at T2 (CON: T1 11 % and T2 36 %, $p = .04$; INT: T1 24 % and T2 62 %, $p = .02$). Distress decreased in INT (IES: T1 20.9 ± 14.7 and T2 13.8 ± 14.1, $p = .01$), but increased for CON (IES: T1 17.9 ± 13.8 and T2 20.3 ± 21.7, $p = .45$). Total IES severity scores at T2 did not differ between groups ($p = .24$). Those with ICD PLAN at T2 ($N = 21$) tended to have lower levels of distress at T1 than those without a plan, but the relationship between distress and ICD PLAN at T2 did not differ between INT and CON ($p = .69$). Overall decision-making self-efficacy was high and did not change significantly from T1 to T2 (CON: T1 30.5 ± 4.5 to T2 30.9 ± 3.8, $p = .67$; INT: T1 29.4 ± 5.2 to T2 29.0 ± 6.9, $p = .82$), nor was self-efficacy different between CON and INT at T2 ($p = .29$). At T2, family members' confidence in decisions about deactivating CIED if the patient were conscious was 36 % for CON and 48 % for INT ($p = .63$), and if the patient were unconscious, confidence was 50 % for CON and 57 % for INT ($p = .61$). A negative relationship between self-efficacy scores and IES scores was suggested in conscious (–0.17, CI –0.89–0.55, $p = 0.64$) and unconscious scenarios (–0.29, CI –1.13–0.54, $p = 0.48$) after adjustment for time, study group, and study site. Imputing for missing data did not change study outcomes.

CONCLUSIONS: The majority of surrogates receiving the TAILORED intervention had a plan regarding CIED deactivation by the end of the study, but still less than the 100 % one would hope for. There tended to be more confidence in making a decision about CIED deactivation among intervention participants, but overall self-efficacy in end of life decisions was high in both groups. The data suggest that those who were less distressed at baseline were more likely to develop a plan about the CIED. Surrogates receiving the intervention showed decreased distress over time. Nurse-led interventions like TAILORED may help the process of CIED management by supporting family members in the decision making process.

ELECTRONICALLY MEASURING ADHERENCE TO ANTIHYPERTENSIVE MEDICATIONS IMPROVES CLINICIAN MANAGEMENT OF UNCONTROLLED HYPERTENSION: THE MATCH CLUSTER RANDOMIZED CLINICAL TRIAL Ian M. Kronish¹; Nathalie Moise¹; Thomas McGinn²; Yan Quan¹; William Chaplin³; Benjamin D. Gallagher¹. ¹Columbia University Medical Center, New York, NY; ²Hofstra North Shore-LIJ, Manhasset, NY; ³St Johns University, Jamaica, NY. (Tracking ID #2192543)

BACKGROUND: Up to 50 % of hypertensive patients are non-adherent to their blood pressure (BP) regimen. Thus, to appropriately manage uncontrolled hypertension, clinicians should ideally determine whether BP is not at goal due to a need for additional medication or due to insufficient adherence to medication. Yet, in practice, clinicians often fail to assess adherence. Even when assessed, clinicians are poor at accurately determining who is non-adherent and are often uncertain as to the true level of adherence. Our goal was to determine whether providing clinicians with electronically-measured medication adherence data at the time of visits with patients with uncontrolled hypertension would improve the management of uncontrolled hypertension.

METHODS: Between 2010 and 2014, we conducted a parallel two-arm cluster randomized trial at two hospital-based primary care clinics in New York City. Twelve primary care providers were randomly assigned to the intervention and 12 to usual care. Patients were assigned to the group in which their provider was randomized. One hundred patients (65 Intervention; 35 Control) with persistently uncontrolled hypertension (BP \geq 140/90 mmHg or \geq 130/80 mmHg if diabetes or chronic kidney disease) were asked to take their BP medications from an electronic pillbox (MedSignals) during the interval between two scheduled primary care visits. At the time of the second clinic visit, providers in the intervention group received a brief report that summarized the percent of doses that were taken as prescribed during the entire monitoring period and during the prior 7 days. Providers in the control group did not receive an adherence report. The primary outcome was the proportion of second visits with appropriate clinical management for uncontrolled hypertension. Clinical management was defined as appropriate if clinicians intensified the BP regimen or ordered testing for identifiable hypertension in adherent patients (\geq 80 % of doses taken as prescribed) or if they counseled about medication non-adherence in non-adherent patients ($<$ 80 % of doses taken as prescribed). Chart abstraction performed by two medically-trained study personnel blinded to group assignment was used to categorize clinical management. Key secondary outcomes including quality of care and clinician communication during the second visit were assessed by interviewing patients after the visit using standardized questionnaires. General estimating equation models (logit link) fitted with clinician as the cluster variable, "appropriateness of management" as outcome, and group assignment as the explanatory variable were used to determine the effect of the intervention.

RESULTS: The mean age of patients was 64 years, 72 % were women, 75 % were Hispanic, and 83 % had Medicaid. Mean BP at the time of the second visit was 155/83 mmHg, and 41 % were non-adherent during the monitoring period. There were no significant differences in sociodemographic or medical characteristics between patients in the intervention and control groups. The proportion of second visits with appropriate management was higher in the intervention group than in the control group (69 % versus 34 %; $p=0.001$). This corresponded to a greater proportion of adherent patients in the intervention group having their regimen intensified (56 % versus 21 %, $p=0.01$) and a greater proportion of non-adherent patients in the intervention group having adherence addressed by their provider (84 % versus 39 %, $p=0.005$). Patients in the intervention group were more likely to give their clinicians high ratings on overall quality of care ($p=0.05$), as well as on measures of patient-centered and collaborative communication about hypertension ($p=0.001$ and $p=0.02$, respectively). The majority of patients (64 %) found the electronic pillbox "very easy" to use, and almost all (94 %) said they would use the electronic pillbox again if asked by their clinician.

CONCLUSIONS: The integration of electronic adherence monitoring into clinical settings is a promising approach for improving the management of uncontrolled hypertension. This approach may be useful for improving the management of other health conditions such as diabetes or asthma for which an accurate assessment of medication adherence is essential to management decisions. Future studies should test the effectiveness of this intervention at improving medication adherence and BP control.

ELEPHANT IN THE ROOM? GENERAL MEDICINE FACULTY PERCEPTIONS OF THE IMPACT OF ELECTRONIC MEDICAL RECORD (EMR) ON PATIENT-DOCTOR COMMUNICATION Wei Wei Lee; Lollita Alkureishi; Jeanne M. Farman; Vineet M. Arora. University of Chicago, Chicago, IL. (Tracking ID #2196315)

BACKGROUND: Studies demonstrate that EMR use in exam rooms can prevent providers from focusing on patients. Despite widespread adoption of EMR in academic institutions in ambulatory settings, little is known about how general medicine faculty

providers perceive EMR adoption and their ability to integrate the EMR in a patient-centered manner. While there are known EMR-related skills that enhance the clinical interaction, few providers receive formal training. We aim to survey General Internal Medicine (GIM) faculty at the University of Chicago on their perceptions of EMR use and the impact on patient-doctor communication.

METHODS: After reviewing the literature, we developed a 34 item survey with five-point Likert-scale responses on knowledge, attitude and skills pertaining to EMR-related communication in the outpatient setting. One year after the University of Chicago implemented the EPIC ©EMR system in the outpatient clinic, we surveyed GIM faculty members at a monthly section meeting. The following is a sample question from the survey: How much do you agree with the statement 'I focus too much on the EMR and not enough on what the patient is saying.' Likert responses at the high end of the scale were grouped to dichotomize data (i.e. agree/strongly agree) and descriptive statistics were summarized.

RESULTS: Thirty one (31/32, 97 %) GIM faculty surveys were analyzed. The majority [58 % (18/31)] of respondents were female and the mean age was 47 (range 33–59). Fewer than a third [28 % (9/31)] rated their knowledge of 'Patient-Centered EMR Use' as good or excellent, with just over a third [35 % (10/31)] reporting their skill level as proficient or expert. Despite this, nearly two thirds of respondents (64 %, 20/31) reported they often or always integrated EMR-use with patients in the clinic room. However, respondents also reported agreeing with many statements about the pitfalls of EMR in the room. For example, 42 % (13/31) agreed that 'EMR use negatively impacts my ability to communicate with patients' and just over a third [35 % (11/31)] reported that 'the EMR negatively impacts the patient-doctor relationship.' Unfortunately, 42 % (13/31) agreed that they 'focus too much on the EMR and not enough on what the patient is saying,' with the majority [68 % (21/31)] reporting agreement with 'I do not maintain adequate eye contact with the patient while using the EMR.' Forty two percent (13/31) agreed that 'using the EMR during the clinic visit is stressful' and only half [52 % (9/31)] were 'confident in their ability to use the EMR in a patient-centered manner.' Roughly one third [28 % (9/31)] of respondents agreed that 'prior to the EMR, I provided better patient-centered care.' While 45 % (14/31) reported the 'training on patient-centered EMR use' was very or extremely important to their clinical practice, only 1 person (3 %) rated their training as good or excellent. The majority of respondents (71 %, 22/31) agreed that 'training on patient-centered EMR use should be required for all attendings.'

CONCLUSIONS: Faculty members in an academic general medicine practice report that EMR use can negatively impact patient-doctor communication in the outpatient setting, and that they struggle with eye contact and using the EMR in a patient-centered manner. Despite available best practices on EMR-related communication skills, few faculty members receive formal training. Faculty development courses should be implemented to address this gap in continuing medical education.

END OF LIFE DISCUSSIONS AMONG MEDICARE BENEFICIARIES Minal Kale²; Katherine Ornstein¹. ¹Mount Sinai, New York, NY; ²Mount Sinai School of Medicine, New York, NY. (Tracking ID #2197878)

BACKGROUND: Delivering high-quality care at the end of life has been a growing focus in health care, particularly as people live longer and age with multiple chronic diseases. Clear communication and elicitation of people's preferences regarding end-of-life is considered a central component to providing patient-centered care. However, attempts to make health policies that would promote these discussions, through new reimbursement structures for advance care planning have been mischaracterized as "death panels" and have delayed the wide-spread acceptance of advance care planning. Using a nationally representative survey of Medicare beneficiaries, we examined the characteristics and predictors of individuals having end-of-life discussions.

METHODS: We used data from the National Health and Aging Trends Study (NHATS), a nationally representative longitudinal survey of Medicare beneficiaries over age 65 that has been conducted annually since 2011. NHATS includes detailed information on self-reported activities of daily life, health conditions, living arrangements, well-being, sociodemographic characteristics, and physical measures of health. Round 2 of the survey includes a module of questions regarding end of life plans and care that was administered to a random sample of the survey respondents. We examined the sociodemographic and clinical characteristics of Medicare beneficiaries, and performed a multivariate logistic regression model to determine predictors of having engaged in end-of-life care discussions.

RESULTS: One thousand nine hundred sixty-four individuals completed the end-of-life module, representing a weighted sample of 9,219,720 individuals. In multivariate logistic regression analysis the following variables were associated with not having end of life discussions: females (Odds Ratio [OR]: 0.79, (95 % Confidence Interval [CI]: 0.65–0.98), black race (OR: 0.41, 95 % CI: 0.30–0.56), and other race OR 0.50, 95 % CI 0.29–0.85). Those who had completed high school/GED (OR: 1.59, 95 % CI: 1.16–2.17), some

college (OR 2.67, 95 % CI: 1.90–3.74), had larger social network size (OR: 1.21, 95 % CI: 1.08–1.35), and English language speakers (OR: 3.03, 95 % CI: 1.25–7.35) were more likely to have completed the discussion. We found that increasing age, marital status, Medicaid insurance, multimorbidity, frailty, having a regular doctor, self-reported bad health, and having been hospitalized were not significant predictors ($p>0.05$ for all comparisons).

CONCLUSIONS: In our analysis of a nationally representative survey of Medicare beneficiaries, we found that sociodemographic characteristics including race, education status, English language use, and social network size were significantly associated with having had a discussion about end-of-life care. Surprisingly, several markers of poor health, including self-reported poor health, frailty, multimorbidity, and hospitalization in the previous year were not associated with having this discussion. Our results suggest that efforts to promote end of life discussions might benefit from structural changes that could target those with high health care needs.

ENGAGING STAKEHOLDERS IN DEFINING FACTORS OF BUILDING AND SUSTAINING TRUST IN COMMUNITY-ENGAGED RESEARCH PARTNERSHIPS

Gaurav Dave²; Giselle M. Corbie-Smith^{1, 2}; Crystal W. Cene^{1, 2}. ¹University of North Carolina, Chapel Hill, NC; ²University of North Carolina at Chapel Hill, Chapel Hill, NC. (Tracking ID #2200167)

BACKGROUND: Collaboration between communities and academic institutions are receiving increasing attention as a strategy to address health disparities. Building and maintaining trust is critical in the development of effective collaborations and a key outcome of successful community-engaged partnerships. The primary objective of this multisite pilot study was to engage stakeholders in defining determinants of trust in community-engaged research (CEnR) and as a result develop a framework for measuring trust in CEnR, a vital long-term outcome highlighted in the national Clinical and Translational Science Award (CTSA) community engagement model

METHODS: Conceptually guided by Carpio's model linking Putnam's seminal work and Bourdieu's conceptualization of social capital, the study was conducted at four CTSA sites—University of North Carolina at Chapel Hill, University of Arkansas Medical Sciences, University of California at Los Angeles and University of Florida, with the University of Pittsburgh serving as the coordinating center for data collection, analyses and reporting. Three stakeholder groups who had some experience with CEnR—community members, healthcare providers and academicians, participated in three sessions: brainstorming, rating and sorting and, interpretation. During the brainstorming session, participants provided input to the following prompt “Based on your experience(s), list all the things that you think contribute to trust between community and academic partners in research?” All statements, consolidated into a master list, were then rated and sorted on: Importance for creating trust between community and academic partners in research; influence on the general public's trust of research; and, importance for maintaining trust between community and academic partners in research. We used concept mapping, a structured, respondent-driven, mixed-methods approach, which produces a visual

framework for how study participants conceptualize key determinants of trust in CEnR and describe ways in which those factors relate to each other. Using the Concept Systems Global Max © software, we conducted hierarchical cluster analysis and explored the relative importance of the statements to developing and maintaining public trust in CEnR.

RESULTS: A total of 186 participants provided input during the brainstorming session across four sites generating 2172 individual items that were consolidated into 125 unique items. During the second session, 156 participants rated and sorted the 125 items. A point-series map was created, each point/number representing 125 unique items, the points that are closest to each other are items that were group together most frequently whereas items that were further away from each other are considered less similar. During the interpretation session, 143 participants used the point series map to determine how many “clusters” or themes the data should be organized into, and to give each cluster a name. Participants divided the final 125 items master list into five clusters (figure 1): authentic, effective and transparent communication; mutually respectful and reciprocal relationships; sustainability; committed partnerships; and, communication, credibility and methodology to anticipate and resolve problems.

CONCLUSIONS: This study increases our understanding and improves our assessment of the underlying factors contributing to building and sustaining CEnR partnerships and public trust in research from diverse stakeholder perspectives. This study is an important first step in identifying an initial set of determinants of trust that can be applied and measured across CTSA or CEnR partnerships to: 1) understand differences and similarities in trust across sites; 2) identify both positive and negative determinants of trust; 3) identify characteristics that maintain trust; and 4) inform the direction future research to assess the fidelity of related conceptual frameworks for building trust in CEnR.

EPIDEMIOLOGY OF VENTILATOR ASSOCIATED PNEUMONIA AND TIME TRENDS OF MULTIDRUG RESISTANT BACTERIA IN THE GERIATRIC POPULATION

Theodora Anagnostou¹; Marios Arvanitis²; Themistoklis Kourkoumpetis²; Panayiotis Ziakas³; Athanasios Desalemos²; Eleftherios Mylonakis³. ¹Mount Auburn Hospital, Boston, MA; ²Boston Medical Center, Boston, MA; ³Rhode Island Hospital, Brown University, Providence, RI. (Tracking ID #2156055)

BACKGROUND: Ventilator Associated Pneumonia (VAP) is associated with high morbidity and mortality and annual costs of \$3.5 billion. The increased rate of comorbidities in the elderly and their frequent hospitalizations can alter the microbial colonization rates. To contribute to our understanding of the pathogenesis of this infection in the geriatric patients, we ventured to elucidate the differences of VAP in the elderly population.

METHODS: We conducted a retrospective analysis of the medical charts of all 208 patients admitted to the adult medical and surgical intensive care units of the Massachusetts General Hospital that developed VAP during a 5 year period. In order to evaluate the specific characteristics and outcomes of VAP in the elderly, we separated our population in two groups using the cutoff of 65 years. Group comparison was made using the Mann-Whitney non-parametric test. Count data were reported as % frequencies and compared

FINAL Cluster Map with Names

using the Fisher's exact test. Between-group differences were adjusted by performing a multivariable logistic regression analysis, for parameters with $p < 0.10$ at the group analysis. Adjusted effects were reported as Odds Ratio (OR) with their 95 % confidence interval. Survival analysis was performed using the Kaplan-Meier method and the log-rank p statistic was reported. All tests were two-tailed, with significance level set to < 0.05 . Stata v11 (College Station, TX), was used for data analysis.

RESULTS: Two hundred patients were included in the study of which 72 (36 %) were above 65 years old. Interestingly, the two populations had comparable disease severity on ICU admission (median SAPS II score 37.5 vs. 37, $p = 0.48$) and did not differ on other markers of illness severity such as *Candida* colonization (33 % vs. 35 %, $p = 0.82$). However, the older population had higher prevalence of pulmonary comorbidities (37 % vs. 13 %, $p = 0.005$) and marginally higher prevalence of diabetes mellitus (24 % vs. 13 %, $p = 0.08$). Age (HR 1.04 95 % CI 1.01–1.07, $p = 0.003$) was an independent predictor of mortality and age ≥ 65 years was associated with increased incidence of VAP due to multidrug resistant bacteria (MDRB) (44 % vs. 28 %, $p = 0.07$). However, in multivariate analysis, multidrug resistant infection (HR 1.50, 95 % CI 0.54–4.17, $p = 0.44$) was not an independent risk factors for 28-day mortality in this population. Finally, MDR VAP rates in our hospital decreased over the study period, likely as a result of the World Health Organization Guidelines regarding Hygiene measures.

CONCLUSIONS: Patients above 65 years old have 3 times higher mortality compared to younger adults and increased incidence of multidrug resistant bacteria.

Factors associated with 28-day mortality in VAP in multivariate analysis

	Hazard Ratio	95 % Confidence Intervals	p -value
Age ≥ 65 years	2.82	1.12–7.11	0.03
Male gender	1.30	0.49–3.49	0.60
SAPS II	1.05	1.01–1.08	0.01
MRSA	1.50	0.54–4.17	0.44
Pulmonary comorbidities	0.88	0.31–2.50	0.81

MDR: multidrug resistant; SAPS II: simplified acute physiology score II; VAP: Ventilator associated pneumonia.

Twenty eight-day mortality in VAP in relation with age, failure rate estimates. Elderly patients (≥ 65 years old) displayed significantly higher mortality (log-rank $p = 0.01$).

ESTABLISHING AND TEACHING A STANDARD FOR TEST RESULT MANAGEMENT: RESIDENT REVIEW QUEUE COVERAGE PILOT kara greenwald³; Jennifer Rockfeld²; Barbara Porter¹. ¹NYU SOM, New York, NY; ²NYU School of Medicine, New York, NY; ³new york university school of medicine at bellevue hospital center, New York, NY. (Tracking ID #2152764)

BACKGROUND: Seven to thirty percent of abnormal test results are not managed in a timely fashion in outpatient settings nationally. (1) No standard exists for outpatient test

result management. In a December 2013 needs assessment, there were a total of 569 unsigned abnormal test values among 23 s and third year residents who had not been in clinic more than once in the preceding 2 weeks in the Bellevue Adult Primary Care Center (APCC). The objective of this study was to develop a standard for residents to act on abnormal test results in a timely fashion in the Bellevue APCC by creating a supportive infrastructure.

METHODS: We designed and taught a resident curriculum on panel management and electronic medical record (EMR) test result features. Residents provided feedback on the curriculum and coverage system which informed modifications to the curriculum and system. We set a standard of reviewing test results weekly. In January 2014 we started a coverage system where residents on ambulatory care block cover test results for residents on rotations with infrequent clinic and residents are given scheduled time to do coverage. Volume of unsigned test results for all residents receiving coverage was counted every 2 weeks. When a resident was found to have over 50 unsigned abnormal test results they received a personalized intervention. Abnormal test result volume was monitored every 2 weeks for residents who received personalized intervention.

RESULTS: All Bellevue APCC residents completed the curriculum; approximately 150 residents. At baseline in December 2013 there was an average of 24 unsigned abnormal results per second and third year residents on a rotation with infrequent clinic in the preceding 2 weeks. Five of six residents with high volume review queues (up to 244 abnormal results) showed improvement in test result volume. We observed a 42 % reduction in unsigned abnormal results by week 8, 80 % reduction by week 14, and from week 14 on have had sustained reduction as low as 90 % reduction, last in August 2014 down to 6 results per resident from 24 at baseline. Residents reported having enough time for coverage, satisfaction with coverage system and reduced anxiety about test results. Approximately 25 % of second and third year residents were not aware of EMR result features.

CONCLUSIONS: We created a standard for test result management, a curriculum to teach the standard, basics of panel management and EMR results features, incorporated learner feedback into the curriculum and implemented a resident to resident coverage system for abnormal test results. With these interventions we standardized test result management, created a supportive infrastructure, and increased awareness about the review queue and panel management. We overcame key barriers to timely follow up of abnormal results: resident time, location and knowledge gaps. We also identified deficits in resident education and engaged residents to improve the residency curriculum. The observed sustained reduction in unsigned abnormal results demonstrates the success of our interventions.

ETIOLOGIES AND SHORT-TERM MORTALITY AMONG PATIENTS WITH ULTRA-ELEVATED SERUM FERRITIN LEVELS Timothy C. Beer; Joseph Vadakara. Geisinger Medical Center, Danville, PA. (Tracking ID #2192812)

BACKGROUND: Higher serum ferritin levels (SF) have been demonstrated to be associated with poorer outcomes in several disease states, including cirrhosis, renal disease and several types of cancer. Several studies have evaluated the distribution of etiologies among patients with highly elevated SF. However, few of these studies seem to report on mortality. The purpose of this study is to evaluate the distribution of etiologies and short-term mortality of patients with SF above 5000 ng/mL.

METHODS: We queried our institutional EMR database for adults with SF above 5000 ng/mL measured between July 2004 and August 2014. For patients with multiple SF above 5000 ng/mL, only the first measured level was considered. All eligible patients had their age, gender, SF, contributing etiologies (up to three) and status ("alive" versus "deceased" and length of time between SF measurement and death) extracted for use in this study. Contributing etiologies for hyperferritinemia were determined by review of laboratory, radiographic and pathologic data as well as clinical notes. Based on previous publications, the following diagnoses were considered as potential etiologies for hyperferritinemia: acute liver injury (including fulminant liver failure, shock liver and acute hepatitis), cancer, blood transfusions, myelodysplastic syndrome (MDS), end stage renal disease (ESRD), hereditary hemochromatosis, systemic juvenile idiopathic arthritis (sJIA), hemophagocytic lymphohistiocytosis (HLH) and macrophage activation syndrome (MAS). Etiologies for patients who did not have one of these diagnoses were classified as "unknown." Mortality rates were calculated for 30 days and 6 months following the date of index SF measurement.

RESULTS: A total of 405 patients with SF above 5000 ng/mL were identified. The mean age was 60 years (range 18–90), 63 % were male, mean SF was 12,280 ng/mL (range 5010–97,372 ng/mL), mean 30-day mortality was 32 % and mean 6-month mortality was 50 %. Roughly half of patients (51 %) had multiple identifiable etiologies for their hyperferritinemia, 44 % had only one etiology and 5 % had no identifiable etiology. Among all patients, the three most commonly identified contributing etiologies were blood transfusions (48 %), liver injury (44 %) and cancer (33 %). Among patients with only one etiology for their hyperferritinemia, liver injury (73 %) was most common, followed by blood transfusions (9 %) and cancer (8 %). No patient had ESRD or MDS as a

sole etiology. Among all patients, mean SF was highest among those who had MAS (60,681 ng/mL), HLH (40,645 ng/mL) or liver injury (16,444 ng/mL) as a contributing etiology. Among patients with only one identified etiology, mean SF was again highest among those with MAS (60,681 ng/mL), HLH (34,389 ng/mL) and liver injury (14,894 ng/mL). Among patients with only one identified etiology, only those with liver injury (22/131), HLH (1/2) or MAS (1/1) had any SF above 20,000 ng/mL. Among all patients, 30-day mortality was highest among those with HLH (50 %), cancer (39 %) or liver injury (39 %) and 6-month mortality was highest among those with HLH (75 %), cancer (70 %) or MDS (56 %). Among patients with only one identified etiology, 30-day mortality was highest among those with HLH (100 %), cancer (64 %) and liver injury (33 %) and at 6 months remained highest among those with HLH (100 %), cancer (93 %) and liver injury (39 %).

CONCLUSIONS: The majority of patients with SF above 5000 ng/mL had multiple contributing etiologies for their extreme hyperferritinemia. Neither ESRD nor MDS was the sole etiology for a single case of SF above 5000 ng/mL. These two findings contrast with those of some previous reports, likely due to our approach of allowing for multiple contributing etiologies for SF elevations. Among patients with a single identified etiology for hyperferritinemia, liver injury (73 %) was by far most commonly responsible, followed distantly by blood transfusions (9 %) and cancer (8 %). HLH and MAS were associated with the highest mean SF, however, because these syndromes are so rare, even the most astronomically elevated SF levels are more likely to be due to liver injury. Indeed, in this study, liver injury accounted for 92 % of single-etiology cases of SF above 20,000 ng/mL. Among patients with cancer as their only etiology for hyperferritinemia, mortality was quite high at 30 days (64 %) and rose significantly by 6 months (93 %). In contrast, among patients with liver injury as their only etiology, mortality only increased by 6 % between 30 days (33 %) and 6 months (39 %). It is possible that highly elevated SF levels portend particularly high immediate and sub-acute mortality rates among patients with cancer, while they portend a high risk of death in only the immediate timeframe for patients with acute liver injury. This issue could be explored further in future research.

EVALUATION OF A DIAGNOSTIC CHECKLIST FOR USE IN INTERNAL MEDICINE RESIDENT EDUCATION Deborah DiNardo³; Sarah A. Tilstra⁴; Melissa McNeil²; William Follansbee²; Shanta M. Zimmer¹; Coreen Farris⁵; Silvia Mamede⁵; Henk Schmidt⁵; Amber E. Barnato¹. ¹University of Pittsburgh, Pittsburgh, PA; ²University of Pittsburgh Medical Center, Pittsburgh, PA; ³University of Pittsburgh School of Medicine, Pittsburgh, PA; ⁴University of Pittsburgh School of Medicine/Medical Center, Pittsburgh, PA; ⁵Erasmus University, Rotterdam, Netherlands; ⁶University of Pittsburgh Institute for Clinical Research Education, Pittsburgh, PA. (Tracking ID #2196645)

BACKGROUND: Flawed clinical reasoning and cognitive bias contribute to diagnostic errors. We developed a “diagnostic checklist” to promote cognitive de-biasing in internal medicine resident education using principles of reflective reasoning. The purpose of this study was to test the effect of this checklist on diagnostic accuracy and to obtain feedback from users.

METHODS: We performed a within-subjects controlled experimental evaluation of the checklist on written cases, followed by focus group interview. We invited all post-graduate 3 (PGY-3) residents at the University of Pittsburgh Medical Center (UPMC) to complete 10 clinical cases in a proctored setting in June 2014. First, we instructed residents to record the first diagnosis that came to mind after reading the case. Second, we asked them to evaluate 5 of the initial 10 cases again, using prompts from the diagnostic checklist prior to making a final diagnosis. We counterbalanced control (non-checklist) and intervention (checklist) cases using a block design. Two independent investigators scored diagnostic accuracy on the cases. We used repeated measures regression to assess the effect of checklist use on diagnostic accuracy, controlling for case complexity. Two investigators reviewed audiotapes of the structured debriefing focus groups and identified key themes related to usability and acceptability of the checklist for clinical teaching and decision making.

RESULTS: A total of 34 of 51 eligible PGY-3 residents (67 %) participated. One requested that his/her responses not be used for research; responses from the remaining 33 residents were included in the analysis. Inter-rater reliability of scoring suggested near-perfect agreement ($k=0.93$). Average diagnostic accuracy increased from 72 to 86 % with the checklist for simple cases and from 34 to 37 % for complex cases. In a random effects regression, checklist use was statistically significantly associated with improved diagnostic accuracy overall ($p=0.05$). This effect did not vary within strata of case complexity (simple vs. complex; $p=0.29$ for interaction). The dominant themes from the focus group interviews included: 1. The checklist was acceptable and understandable for use in evaluating clinical cases, 2. The tool would be most useful in real clinical settings when evaluating complicated cases, when teaching early learners, or when evaluating patients who have been handed off from other providers, and 3. Specific questions from the checklist were deemed to be particularly useful when evaluating clinical cases.

CONCLUSIONS: In this single-center study of PGY-3 internal medicine residents in the US, the use of a diagnostic checklist led to a statistically significant improvement in diagnostic accuracy on written clinical cases. Residents found the checklist to be acceptable for use, and offered valuable insights into the potential applications of the checklist in real clinical scenarios.

Diagnostic Checklist

1. What is your leading diagnosis?
 - a. What elements of the case support this diagnosis?
 - b. What elements of the case contradict this diagnosis? (Is there any discordant information?)
 - c. What elements are missing that you would expect to be present if your leading diagnosis were true?
2. What else could it be? (List alternative diagnoses, answer questions a, b, and c as you did above.)
3. How do you explain the findings of the case in terms of pathophysiology?
4. Now what is your final ranked differential diagnosis?

EVALUATION OF A PATIENT DECISION AID FOR ACUTE LOW BACK PAIN

Leigh H. Simmons²; Sarah Hewitt²; Lauren Leavitt¹; Karen R. Sepucha². ¹MGH, Boston, MA; ²Massachusetts General Hospital, Boston, MA. (Tracking ID #2200232)

BACKGROUND: Making decisions about treatment of acute low back pain (ALBP) can be challenging for clinicians and patients. Many patients have misperceptions about the utility of imaging and procedures for acute low back pain treatment. Patient decision aids (PtDAs) can help inform patients about treatment options and engage them in decisions about their health care; however, these tools have not been well-studied in acute care settings. This project evaluated an acute low back pain PtDA in three urgent care clinics.

METHODS: The before-after study had an observation or usual care phase and an intervention phase where all eligible participants received a decision aid and worksheet before seeing the provider. All patients seen at three urgent care clinics who had a complaint of low back pain were screened for eligibility. Eligible participants were surveyed 1 week and 8 weeks following their urgent care visit. The 1 week survey included items to assess patient knowledge, patient expectations for the visit, involvement in decision making, self-efficacy to manage ALBP (0–10 scale), pain (0–10 scale), and satisfaction with visit. Here, we examine whether patients in the intervention group had higher knowledge, more involvement in decision making, and higher self efficacy about management of back pain 1 week post visit.

RESULTS: For the observation group, 40/82 (RR=49 %) patients completed the 1 week survey and 34/40 (RR=85 %) completed the 8 week survey. For the intervention group, 32/80 (RR=40 %) completed the 1 week survey and 19/32 (RR=59 %) completed the 8 week survey. In the intervention group, 88 % (28/32) reported receiving the PtDA and 50 % (16/32) reported reviewing “most” or “all” of the DVD and/or booklet. The groups did not differ significantly in any demographic characteristic, on average the sample was 44 years old, gender (54 % female), race (58 % White), and employment (76 % fulltime). The majority of patients in both groups had tried “bed rest” (83 %) and OTC pain medicine (75 %) before their visit. When asked about their expectations for the initial visit, the majority of patients in both groups indicated it was very or extremely important to understand what is happening with the back (95 and 91 %, $p=0.21$), to receive a clear diagnosis for the pain (88 and 88 %, $p=0.70$) and to get reassurance that pain was not caused by something serious (85 and 88 %, $p=0.33$). Fewer patients in the observation group indicated it was very or extremely important to get a referral to a specialist (20 % vs. 47 %, $p=0.03$) or have imaging (20 % vs. 44 %, $p=0.05$) compared to the intervention group. There were no statistically significant differences between the observation and control groups on the main outcomes. The mean knowledge scores were 55.5 % for observation and 52 % for intervention ($p=0.85$). Across both groups, only about half of patients (57 %) understood that doing normal activities is not likely to hurt their back. About half (49 %) also understood that it was very unlikely that there was a serious cause (such as cancer) for most acute low back pain. Most patients received a diagnosis during the visit (88 % of observation group and 69 % of intervention group, $p=0.46$). Most patients also reported that their health care provider explained options to manage back pain (83 and 75 %, $p=0.26$). More than half of the patients reported that the health care provider asked for their preference about management of back pain (58 % of observation and 69 % of intervention, $p=0.34$). At 1 week, mean self-efficacy scores were 7.3/10 and 7/10 ($p=0.49$) and mean pain scale scores were 4.5/10 and 4.85/10 ($p=0.55$) for the observation and intervention groups, respectively. Many

patients were “very satisfied” with the care they received at the visit (63 % observation and 47 % intervention, $p=0.2$).

CONCLUSIONS: Patients seeking urgent care for ALBP had considerable gaps in their knowledge, but did report high self-efficacy. Contrary to the hypotheses, the PtDA did not have an impact on knowledge or self efficacy. Though the PtDA distribution intervention was well-received by office staff, the PtDA was only reviewed by half of the patients. Different approaches may be needed to ensure informed decisions for ALBP in the urgent care setting.

EVALUATION OF DISCORDANT UPPER ENDOSCOPY IN OUTPATIENTS WITH GASTROESOPHAGEAL REFLUX DISORDER Jennifer X. Cai¹; Emily J. Campbell²; James M. Richter². ¹Johns Hopkins Hospital, Baltimore, MD; ²Massachusetts General Hospital, Boston, MA. (Tracking ID #2199270)

BACKGROUND: Upper endoscopy has become widely used for the diagnosis and management of gastroesophageal reflux (GERD) and low-risk dyspepsia. In a recent study that sampled 5 % of Medicare beneficiaries, one in three individuals who received an esophagogastroduodenoscopy (EGD) had a repeated procedure within 3 years and 43 % of repeated EGDs were done in patients who did not have a diagnosis at index or on repeat exam that justified the additional procedure. Both the Choosing Wisely campaign and the American College of Physicians (ACP) advocate for appropriate use of upper endoscopy in the setting of GERD and low-risk dyspepsia. No studies to date have examined rates of concordance with current best practice guidelines in the treatment of these two common indications. We aim to measure the appropriate use of upper endoscopy in patients with GERD, low-risk dyspepsia and related diagnoses and to compare these rates across types of providers and indications.

METHODS: A retrospective chart review was performed of all consecutive outpatients who underwent an upper endoscopy between September and December 2013 for GERD, dyspepsia, esophagitis, and Barrett's esophagus. Based on ACP best practice guidelines, appropriate indications for endoscopy included patients with 1) non-dysplastic Barrett's esophagus who did not receive an EGD within the last 3 years for surveillance, 2) acute symptoms (<5 years) that persist despite a therapeutic trial of 4-8 weeks of twice-daily proton-pump inhibitor (PPI) therapy, 3) chronic symptoms (>5 years) who are male and greater than 50 years of age, 4) alarm symptoms (dysphagia, bleeding, anemia, weight loss, or recurrent vomiting), and 5) severe erosive esophagitis (grade B or worse) after 2 months of PPI therapy.

RESULTS: A total of 550 upper endoscopies were identified and included in the study, of which 37.8 % ($n=208$) were discordant with current guidelines. Among procedures referred by primary care, 39.4 % ($n=161$) were discordant with guidelines whereas among those endoscopies initiated by gastroenterologists, 33.3 % ($n=47$) were discordant ($P=0.20$). Nearly 50 % of all procedures referred for Barrett's esophagus and chronic reflux symptoms were found to be discordant with guidelines (Table 1). In contrast, less than 2 % of procedures referred for alarm symptoms were discordant. Reasons for discordance included an inadequate trial of PPI therapy prior to endoscopy (30.3 %, $n=63$), frequent surveillance for non-dysplastic Barrett's esophagus within 3 years (28.4 %, $n=59$), chronic reflux symptoms in females (19.2 %, $n=40$), and chronic symptoms in patients under 50 years of age (9.6 %, $n=20$). Among all patients in the study, 22.5 % ($n=124$) had more than one upper endoscopy within the last 3 years.

CONCLUSIONS: A large proportion of EGDs performed for GERD and low-risk dyspepsia in the outpatient setting are discordant with current best practice guidelines, with nearly one-fourth receiving a repeat upper endoscopy within the last 3 years. An inadequate PPI trial, premature Barrett's esophagus surveillance, age less than 50, and female gender were the most common reasons for discordance. This study highlights an opportunity for a multidisciplinary approach to quality improvement including physician and patient education and specialist pre-review of primary care referrals.

Table 1. Overall frequency and proportion of procedures found to be discordant with guidelines by indication

Indication	Frequency (N)	Discordance rate (N)	P-value
Barrett's esophagus	21.1 (116)	49.1 (57)	0.005
Acute symptoms	44.2 (243)	25.5 (62)	<0.0001
Chronic symptoms	41.8 (230)	47.0 (108)	<0.0001
Alarm symptoms	30.7 (169)	1.78 (3)	<0.0001
Severe esophagitis	2.91 (16)	37.5 (6)	0.979

EVIDENCE-BASED QUALITY IMPROVEMENT IN A VA WOMEN'S HEALTH PRACTICE BASED RESEARCH NETWORK Karen M. Goldstein¹; Susan M. Frayne^{5, 6}; Jennifer Gierisch¹; Jill Blakeney¹³; Elizabeth M. (Tracking ID #2194776)

BACKGROUND: Most research evidence fails to change clinical care, in part due to the gap between strictly standardized research settings and the variable conditions at the bedside. Practice based research networks (PBRNs) were developed as a mechanism for conducting research in ‘real world’ settings and to bring research findings to busy clinicians. Evidence-based quality improvement (EBQI) can be an effective strategy to accelerate implementation of clinical trial findings into routine clinical practice through use of existing research findings, employment of multi-level clinical and administrative engagement, and capitalizing on productive research-clinical partnerships. Practice based research networks (PBRNs) are a promising setting for EBQI because they amplify the impact of successful outcomes by multiplying efforts across different sites and afford an opportunity to study implementation variations by serving as a “community laboratory”. To date, little has been described about the experience of EBQI in the PBRN setting. We conducted a multi-site cluster randomized trial in the recently created VA-based Women's Health PBRN (WH-PBRN) to test EBQI as a strategy to identify site specific implementation approaches of an enhanced gender awareness training targeted to VA providers and staff. We describe the barriers to and facilitators of the EBQI approach in this nascent PBRN setting.

METHODS: This EBQI project was conducted at the four geographically diverse, inaugural sites in the WH-PBRN. The training implemented was *Caring for Women Veterans (CWV)*, a 30 min on-line, interactive, evidence-based training program designed to target gender awareness among VA employees. The EBQI approach included local expert panels to identify site-specific needs, tailoring of the local training delivery plan, and identification of local “owners” to carry out the adapted training plan to selected clinical workgroups at each facility. We used the Replicating Effective Programs (REP) conceptual framework, previously described in the context of implementation, to identify PBRN-specific barriers and facilitators of the EBQI approach. We collected information about perceived barriers and facilitators in two ways. First, themes were informally noted during the course of the EBQI activities and again during post-EBQI intervention debriefing calls. Then, after the completion of EBQI activities, each site was asked to identify barriers to and facilitators of EBQI activities across the four phases of the REP framework (i.e. *pre-conditions, pre-implementation, implementation, and maintenance/evolution*). Notes from the debriefing calls and the targeted REP phase-based survey were reviewed and consolidated into summary findings, which were then shared with the four Site Leads for further revision and clarification.

RESULTS: Four hundred, forty-two employees received the gender sensitivity training across the four sites. The PBRN impacted the EBQI process in multiple ways. Specific facilitators were noted, such as marked facility leadership support across sites reinforced by common institutional values, opportunities to capitalize on common resources and efforts across sites, the ability for timely sharing of project experiences among site participants, and the use of the PBRN coordinating center support for managing multi-site EBQI complexities. Noted barriers included differences in site timelines due to staffing turnover and variable local resources for completing project activities.

CONCLUSIONS: PBRNs offer specific advantages for multi-site EBQI projects and represent a promising pathway for speeding the translation of research findings into everyday practice through the approximation of primary care teams and their research partners. Lessons learned from our multi-site cluster randomized trial of EBQI will impact strategies for the wider dissemination of the CWV gender awareness curriculum within the VA setting and inform future PBRN-based EBQI projects.

EXAMINING GENDER DIFFERENCES IN CARDIOVASCULAR DISEASE RISK FACTORS AMONG LOW-INCOME DIABETIC PATIENTS Rosette J. Chakkalakal²; Russell L. Rothman¹. ¹Vanderbilt, Nashville, TN; ²Vanderbilt University, Nashville, TN. (Tracking ID #2199275)

BACKGROUND: A diagnosis of diabetes increases the risk of cardiovascular disease (CVD) to a greater extent in women than in men. Prior research suggests this disparity is

largely mediated by gender differences in the prevalence and/or management of major CVD risk factors, such as body mass index (BMI), systolic blood pressure (SBP), and LDL cholesterol. It is unknown if gender differences in these CVD risk factors are also present in low-income diabetic populations. The purpose of this project was to compare demographic characteristics, type 2 diabetes (T2DM) related characteristics, and major CVD risk factors between low-income men and women with T2DM.

METHODS: The PRIDE study (Public Private Partnership Addressing Literacy-Numeracy to Improve Diabetes Care) is a cluster-randomized trial designed to assess the efficacy of a low-literacy/numeracy-oriented intervention to improve T2DM care in Tennessee Department of Health “safety-net” primary care clinics. Using PRIDE enrollment data, we conducted a cross-sectional observational study to compare demographic characteristics, T2DM-related characteristics, and major CVD risk factors between male and female study participants. Categorical variables were analyzed using Chi-square test or Fisher’s exact test; continuous variables were analyzed using *t*-test. Demographic characteristics included age, race, ethnicity, and income. T2DM-related characteristics included duration of T2DM, use of oral antidiabetic medications, use of insulin, hemoglobin A1C, health numeracy, and diabetes self-efficacy. Numeracy was assessed using the 5-item Diabetes Numeracy Test (DNT-5) and reported as the percentage of correct answers. Diabetes self-efficacy was assessed using the Perceived Diabetes Self-Management Scale (PDSMS). Major CVD risk factors included tobacco use, SBP, LDL cholesterol, and BMI.

RESULTS: The study sample included 248 women (60.49 %) and 162 men (39.51 %). Female participants reported a significantly longer duration of T2DM (9.62 ± 7.14 years versus 7.87 ± 6.76 years, $p=0.01$) and significantly lower diabetes self-efficacy (PDSMS score of 24.08 ± 5.63 versus 25.50 ± 5.84 , $p=0.01$) compared to male participants. There were no other significant gender differences in demographic characteristics, T2DM-related characteristics, or major CVD risk factors in the study sample (Table 1).

CONCLUSIONS: In this low-income sample of men and women with T2DM, there were no significant gender differences in major CVD risk factors but women had significantly lower diabetes self-efficacy relative to men. Greater diabetes self-efficacy has previously been found to be associated with improved glycemic control. Thus, our findings suggest that diabetes self-efficacy may be an additional contributing factor to gender disparities in CVD among diabetics, particularly for low-income populations, and should be included in future evaluations of this topic.

Gender Differences in Demographic Characteristics, T2DM-Related Characteristics, and Major CVD Risk Factors among PRIDE Participants

	Women (n=248) Mean±SD or % (n)	Men (n=162) Mean±SD or % (n)	p-value*

EXAMINING THE DIFFERENCE BETWEEN INTERACTIVE VOICE RESPONSE SYSTEM VS. PHARMACIST-CAPTURED PATIENT SYMPTOMS FOR ADVERSE DRUG EVENTS SCREENING Jeffrey Medoff³, Japneet Kwatra³, Elissa V. Klinger², Alejandra Salazar³, Lucas Marinacci³, Jennifer Haas¹, Patricia C. Dkyes⁴, David W. Bates², Gordon D. Schiff³. ¹BWH, Boston, MA; ²Brigham and Women, Boston, MA; ³Brigham and Women’s Hospital, Boston, MA; ⁴bwh, Sudbury, MA. (Tracking ID #2200259)

BACKGROUND: Interactive Voice Recognition Systems (IVRS) offer the potential for providing automated, efficient feedback from patients. IVRS platforms are capable of reaching out in a cost-efficient manner to large numbers of patients and can query patients via telephone to collect responses that can be used to assess the quality of care and identify potential problems. IVRS may be especially useful when coupled with real-time handoffs to a live person who can respond to problems identified, assist with treatment, and refer cases in need of further attention to appropriate care or follow-up. Ideally, both IVRS and live clinicians should obtain congruent information from the patient. However discrepancies may exist between patient-reported symptoms to an IVRS versus what is reported in live conversation. Such discrepancies raise questions about the limitations of the effectiveness of an IVRS platform in evaluating patient health. This analysis examines the most commonly reported symptoms captured via IVRS versus those reported to a pharmacist subsequently conversing with the patient via phone screening for detection of potential adverse drug reaction (ADR) symptoms.

METHODS: We recruited patients identified as newly starting oral medications to treat one of four common conditions (depression, insomnia, hypertension and diabetes) in a primary care clinic. Eligible patients were mailed advance information letters, with an option to opt-out from receiving the IVRS call. Eligible patients were then called using IVRS and asked questions regarding adherence and a series of 25 symptoms possibly associated with their new medication. All calls in which symptoms were reported were on completion of the IVRS screen immediately transferred to a clinical pharmacist. Participants could also choose to be transferred without a positive screen if they had any questions or concerns about their medication. The patient-pharmacist phone encounter assessed reported or any other medication related symptoms, and was documented in a clinical note in the patient’s electronic health record (EHR). If a positive IVRS screen participant was not successfully transferred from the IVRS to the pharmacist, study staff attempted to manually contact the participant and review their survey results.

RESULTS: Of a total of 4847 patients called, 609 patients (12.6 %) completed the IVRS calls. Of that number, 306 (50.2 %) reported at least 1 possible side effect on the IVRS call. In total, 808 symptoms were reported to the IVRS and 704 symptoms were reported to the pharmacist. The pharmacist noted 41 symptoms (5.8 % of total number of symptoms reported to the pharmacist) that were not solicited by the IVRS tool. Table 1 compares the most commonly reported symptoms on IVRS and with the live pharmacist.

CONCLUSIONS: While the frequency of symptoms reported to the IVRS versus to a live pharmacist was similar, notable differences included frequency of gastrointestinal problems including stomach problems, diarrhea, and weight gain. Interestingly, sexual function problems and memory issues/confusion were also reported roughly 2 % less to the (female) pharmacist than to the IVRS. On the other hand, other symptoms were captured only by the pharmacist encounter, largely because they were not included as structured fields in the IVRS survey. Ideally, a standalone IVRS platform could be sufficiently reliable to screen for symptoms without requiring unnecessary redundant confirmation by a live pharmacist. However a parsimonious, limited number of questions may miss significant patient complaints not covered in the structured screening questions. The trade-off of a short, streamlined survey is that that it may diminish ability to detect less common symptoms. In this study, live pharmacist involvement resulted in detection of additional issues that patients felt needed to be addressed.

Most Frequent Reported Symptoms (IVR and Pharmacist)

Top Symptoms IVR	Times Reported IVR (N=808)	Top Symptoms Pharmacist	Times Reported Pharmacist (N=704)
Fatigue/Tiredness	85 (10.5 %)	Fatigue/Tiredness	84 (11.9 %)

Difficulty Sleeping	27 (3.3 %)	Sexual Function	24 (3.4 %)

EXPERIENCES OF PRIMARY CARE PHYSICIANS RESPONDING TO POINT-OF-CARE PRICE INFORMATION Katherine Schiavoni¹; Lisa S. Lehmann²; Wen Guan¹; Meredith Rosenthal⁵; Thomas D. Sequist³; Alyna T. Chien^{1,4}. ¹Boston Children's Hospital, Boston, MA; ²Brigham and Women, Boston, MA; ³Partners Healthcare System, Boston, MA; ⁴Harvard Medical School, Boston, MA; ⁵Harvard School of Public Health, Boston, MA. (Tracking ID #2197741)

BACKGROUND: Physicians are targets of price transparency initiatives because they play a central role in ordering tests and lack knowledge regarding health care prices. Prior investigations tend to study trainees in inpatient settings after short-term price information exposure; very little is known about how ongoing price information affects frontline primary care physicians (PCPs) in outpatient practice. We qualitatively study PCPs who began receiving median paid price information for commonly-ordered outpatient imaging tests (e.g., colonoscopies, MRIs) in January 2014. As part of a larger study, a random two-thirds of these PCPs additionally received this price information whenever placing orders within their electronic health record.

METHODS: After 9 months of price information exposure, we recruited on average 3 PCPs from 15 practice locations within a single large multi-specialty group in Massachusetts. Forty-six PCPs participated in 30-min audio-recorded semi-structured interviews in which they were asked to describe: (a) their gut reaction to having price information, (b) how having price information affected the nature of their clinical decision-making or conversations with patients, and (c) the degree to which they felt professionally obligated to deliver care that was aligned with patient, organizational, or societal goals. We used the constant comparative method of qualitative analysis; two primary readers independently coded interview transcripts using Dedoose software; we adjudicated differences through discussion.

RESULTS: Data analysis is ongoing. Among our interviewees, 27 (57 %) were female, had completed residency an average of 22 years ago (SD 10, range 3–43), and 31 (67 %) were engaged in direct patient care for 3–5 days per week. Two-thirds viewed the introduction of price information as a positive change for their clinical practice, while most of the remaining one-third were ambivalent. The few who viewed the change negatively mainly described feeling ill-trained to use the information. For clinical decision-making, more than half reported using price information as a reminder to check themselves about whether an order was truly clinically indicated; few reported actually changing ordering practices (e.g., no alternative test available, clinical decision had been made prior to receiving price information). For patient conversations, three-quarters described price information being useful for responding to patient inquiries about price, but most stated that the initiative did not go far enough because it did not provide individual patients' out-of-pocket price. The two most frequently described sources of conflicting professional obligations arose from patients requesting tests that were not clinically indicated and from patients not being able to afford clinically indicated tests; having price information was not considered to be useful in the former scenario, but occasionally helpful in the latter.

CONCLUSIONS: Seasoned primary care physicians active in outpatient care can welcome the availability of price information. However, their reports suggest that this information is more helpful in assisting patients with their out-of-pocket spending needs than in clinical decision-making. More deliberate guidance for physicians on how to use price information may be needed to avoid or mitigate negative physician experiences or change ordering practices; additional training may be particularly helpful for negotiating situations in which professional obligations compete.

EXPLORING BEHAVIOURS OF JOURNAL AUTHORS AND EDITORS Jason R. Kerr¹; David Moher³; Sharon Straus². ¹University of Toronto, Toronto, ON, Canada; ²Li Ka Shing knowledge institute of St Michael's, University of Toronto, Toronto, ON, Canada; ³Ottawa Hospital Research Institute, Ottawa, ON, Canada. (Tracking ID #2189999)

BACKGROUND: Adhering to appropriate ethical and professional standards when conducting research is essential for researchers. Similarly, those responsible for disseminating the results of research, including authors and journal editors, should maintain the highest ethical standards to ensure that the published record is an accurate, transparent, and reproducible account of what was done (methods) and found (results). While a body of literature exists on the nature and frequency of professional misconduct by authors, less information is available on the ethical behaviours of journals and journal editors. Our investigation is aimed at addressing this gap in the literature, specifically by exploring the experience, prevalence, and perception of unprofessional conduct in publication from the authors' perspective.

METHODS: Corresponding authors on articles published between January 1st, 2013 and June 30th, 2013 from the five peer-reviewed general medical journals with the highest Thomson impact factors were identified. Corresponding authors from articles published during the same time frame from randomly selected medical journals on Beall's list of 'predatory journals' were also identified. An online survey consisting of 30 questions about perceived unethical behaviour on the part of both journals and authors was sent to each of the authors via e-mail, with subsequent e-mail and fax reminders.

RESULTS: Four hundred thirty-two authors were identified from the five medical journals with the highest Thomson impact factors. One hundred ninety-nine authors were identified from the five predatory journals. The survey response rate from the impact factor (IF) journal authors was 19.7 % (85/432). The survey response rate for the predatory journal (PRED) authors was 8.0 % (16/199). 78.8 and 50.0 % of the IF authors and PRED authors, respectively, had published at least 11 manuscripts in peer-reviewed journals over the past 3 years. The most prevalent behaviours from the IF authors' perspective can be found in Table 1. From the PRED journal authors' perspective, the most common journal behaviour was taking too much time between submission of the manuscript and decision on acceptance or rejection (81.3 %, 13/16 authors) and the most common author behaviour was submitting the same manuscript with minimal changes to another journal after a rejection (75.0 %, 12/16 authors). The largest differences in journal-based behaviour between the IF and PRED groups were for having a journal accept a manuscript, only to state later on that it would be published in a lesser known sister journal (7.1 % vs. 37.5 %, respectively) and having a manuscript reviewed by someone without expertise in the field of study (57.65 % vs. 12.5 %, respectively). The largest differences in author-based behaviour between the IF and PRED groups were including authors on a manuscript even though they did not contribute significantly to the work in exchange for inclusion on one of their manuscripts (7.1 % vs. 37.5 %, respectively) and adding references to a manuscript that were not relevant in order to improve the chances of acceptance (14.1 % vs. 6.3 %, respectively).

CONCLUSIONS: This study is the first to identify the experience of authors in the peer-review process with respect to perceived unethical behaviours on the parts of both authors and journal editors. This study shows that unethical behaviour in the medical literature is perceived to be common by authors who have published in highly-regarded journals as well as authors who have published in predatory journals, with the most prevalent issues arising during the peer-review process. These findings illustrate the need for more stringent regulations around peer-review to ensure that the process is fair and equitable for authors, editors, and peer reviewers.

Most prevalent findings for impact factor journal authors

Behaviour / situation	Number of authors indicating behaviour (out of 85)	Percentage of authors indicating behaviour	Mean number of instances per author
Excessive time taken between manuscript submission and decision to publish or not	65	76.5 %	8.4
Reviewer of manuscript did not fully understand the content	64	75.3 %	7.3
Reviewer did not have sufficient expertise in subject matter of manuscript	49	57.6 %	9.5
Manuscript was accepted or rejected contrary to all comments from peer reviewers	25	29.4 %	6.9
Manuscript rejected by a journal followed by a manuscript with very similar content published soon after in the same journal	24	28.2 %	1.79
Perceived selection of peer reviewers by a journal based on their bias either for or against an author	19	22.3 %	3.37
Suspicion that a reviewer has stolen a manuscript idea after reviewing it negatively for a journal	14	16.5 %	2.46

EXPLORING MEDICAL STUDENT'S PERSPECTIVES REGARDING INSTRUCTION ON THE RECOGNITION AND MANAGEMENT OF RACIAL AND ETHNIC IMPLICIT BIAS Cristina M. Gonzalez¹; Maria L. Deno³; Emily Kintzer³; Diane McKee¹; Paul R. Marantz². ¹Albert Einstein College of Medicine/Montefiore Medical Center, Bronx, NY; ²Albert Einstein College of Medicine, Bronx, NY; ³Albert Einstein College of Medicine, Bronx, NY. (Tracking ID #2194180)

BACKGROUND: Evidence suggests that individual physicians' actions contribute to disparities in health. Some disparities in clinical practice may be due to implicit (subconscious) bias rather than explicit (conscious) bias. Implicit bias can impact clinical decision-making and could therefore contribute to healthcare disparities. A curriculum on recognition and management of implicit bias may mitigate individual provider contributions to healthcare disparities. To our knowledge, no curricula are published for medical students, our future physicians. A curriculum addressing racial and ethnic implicit bias will require discussions that are potentially emotionally charged. To enhance student engagement in the eventual curriculum, our study explores medical students' perceptions of challenges and opportunities when participating in instruction in implicit bias recognition and management in clinical encounters.

METHODS: We conducted focus group interviews with students at Albert Einstein College of Medicine, in Bronx NY, using convenience and snowball sampling. Focus groups were conducted until saturation of themes was achieved. Research assistants conducted the focus groups using a semi-structured interview guide. They were digitally recorded and professionally transcribed. Qualitative analysis was performed using grounded theory. Two investigators independently analyzed two transcripts and created a list of codes, which were applied to two other transcripts to refine and finalize the codebook. Any disputes in coding were resolved through consensus, with a third party available when needed.

RESULTS: Eleven focus groups were conducted with a total of 56 participants representing every class. Some students had participated in implicit bias exercises previously. Three major themes emerged in the data analysis: obstacles to engagement in instruction, challenges in the clinical years, and facilitation of the instructional sessions. OBSTACLES TO ENGAGEMENT were identified even by the students who believed learning about implicit bias is important. Students feared the consequences of discovering that some of their behaviors may not coincide with the egalitarian values they espouse. *"I think I'd be frustrated with myself, ... and I think I would also just feel horrible for the people that are affected...So I think that would be like an internal battle for me."* Many did not trust that conversations would remain confidential. *"There definitely needs to be an element of confidentiality because, I mean, we're all going to be each other's colleagues. I don't want to be the neighborhood ophthalmologist who's the racist the everybody remembers from med school."* Socially desirable answers might result, with no real personal growth. *"In my class, people expounded more on what they thought people wanted to hear, which was oh, I did really well on the [implicit bias] test...here's one example of when my patients was like this and the attending said one thing, and I said 'No, that's wrong.' So I think people wanted to reinforce with each other that they were not being racist or biased."* Students often agreed that instruction needed to move beyond awareness of implicit bias into skill building to manage their biases when providing patient care. Developing these skills could lead to unanticipated challenges in the clinical years. *"I think the worst feeling is hearing someone else say something racist or biased and not feeling like you can tell them that wasn't OK ...and feeling trapped in that position is really tough."* *"I think the challenge is that it's difficult to bring it up to the attending because you don't know if this is wrong or if this is the way that it is in a teaching hospital."* Students identified opportunities to improve the quality of the FACILITATION OF THE INSTRUCTIONAL SESSIONS and provided several suggestions for innovative teaching strategies. *"Fourth years are very close to the way we feel, but then they've had really rich experiences in their third years and through their sub-Is. So they have this wealth of knowledge that we don't have yet, but at the same time, they still feel very relatable, and I don't feel scared being like, 'Oh, is this person going to affect my grade somehow?'... Something feels more comfortable with that."* Students suggested easing into racial bias as a teaching strategy to encourage buy-in from more resistant students. *"So using those things, which are not charged and sensitive would be a good way to be like, 'oh wow I do have these biases' and slowly transition over to more charged subjects like these [racial and ethnic bias]."*

CONCLUSIONS: Medical student volunteers identified obstacles to instruction on implicit bias recognition and management, and potential challenges in applying skills. Their concerns must be addressed in the curriculum to ensure safety, confidentiality, and foster open and honest student engagement. Their insights will inform future curriculum development and recruitment and training of facilitators.

EXPLORING PATIENT'S PERCEPTIONS OF RACIAL AND ETHNIC BIAS IN MEDICAL ENCOUNTERS Cristina M. Gonzalez¹; Maria L. Deno²; Emily Kintzer²;

Diane McKee¹; Paul R. Marantz². ¹Albert Einstein College of Medicine/Montefiore Medical Center, Bronx, NY; ²Albert Einstein College of Medicine, Bronx, NY. (Tracking ID #2194173)

BACKGROUND: Evidence suggests that some physicians' clinical choices vary based on their patient's race or ethnicity. Such differences are referred to as within provider disparities and have been documented in clinical settings. These differences are less often the result of overt racism (explicit bias) than of subconscious assumptions (implicit bias). Evidence suggests that implicit bias impacts clinical decision-making and could therefore contribute to healthcare disparities. A curriculum on recognition and management of implicit bias may mitigate individual provider's contributions to healthcare disparities. As part of a targeted needs assessment to inform the eventual curriculum, the objective of our study is to explore patients' perspectives of bias in medical encounters and their lived experiences of discrimination, and solicit their suggestions for steps to eliminate this perceived bias in medical encounters.

METHODS: Eligible participants had sought medical care as a patient themselves or for their children at least once in the last year and lived in or worked in New York. Purposive sampling was employed to enroll Latino (US and non-US born) and Black (African American, African, and Caribbean) participants spanning the socioeconomic spectrum (SES) spectrum in New York City. Focus groups were conducted in English and Spanish using a semi-structured interview guide, were digitally recorded, and professionally transcribed. Standard qualitative analysis of the transcripts was performed using grounded theory. Two investigators independently analyzed two transcripts and generated a list of codes, which were applied to two other transcripts to refine and finalize the codebook. The remaining transcripts were analyzed independently by two members of the investigative team. Any disputes in coding were resolved through discussion, with a third party available when consensus could not be reached. Demographic data were collected. Focus groups were conducted until qualitative analysis revealed that saturation of themes had been reached.

RESULTS: We conducted 10 patient focus groups, 6 in English and 4 in Spanish, with a total of 74 participants. Demographic data demonstrated successful sampling across the SES. Four major themes emerged from the data analysis: participants' perceptions of 1) feeling dismissed; 2) feeling empowered versus feeling powerless; 3) the consequences of privilege and the lack of privilege; and 4) the effects of being the recipient of discrimination. Patients recounted several instances of feeling dismissed ranging from the staff at the front desk, through their encounter with their physician. *"She was a doctor- and... she yanked off the first snap on the left leg. So I'm thinking, like I'm human. She was courteous to that [White] lady and I've got just as much age as her. I qualify on the level and scale of human being as her, but I didn't feel that from that doctor."* Patients' levels of feeling empowered versus feeling powerless varied according to personal characteristics, such as immigration status. *"This is the doctor and I am African, I would be like, 'Okay, do not ask him that question or he will not treat your child well.' I be like swallow. I go with it."* Patients discussed the consequences of privilege and the lack of privilege. Several participants recounted the feeling of losing privilege when judged solely on their external appearance. *"They put me sort of in the corner and I can't talk very well because I can't breathe so well. The nurse comes over to me and actually says, 'Tu tiene tu Medicaid?' I whispered out, 'I'm a doctor' in perfect English. Within two minutes there was an entire orthopedic team around me...I kept wondering about what if I hadn't been a doctor, you know? Pretty eye opening and very sad."* Participants commonly experienced discrimination in their daily lives and developed mechanisms to compensate for it when seeking medical care. *"You need a doctor. That's why you tolerate it. As I told you, I go in a very nice way in order to get the same response from them [as compared to a White patient]. And I practically make a face, like a sad face, to get them to feel pity for me and to get treated well and to avoid conflict. Because if not, I will lose."*

CONCLUSIONS: The potential implicit biases of providers interact with racial or ethnic minority patients' sensitivity to possible cues of bias to jointly influence the outcomes of clinical care. Patients identified several provider behaviors that led them to perceive bias in their medical encounters. Patients enter these encounters in the context of their daily lived experience, including experiencing discrimination that may influence their perceptions of clinical care. Our patients' insights as well as their suggestions on how to mitigate the effects of bias will inform a curriculum in the recognition and management of implicit bias in medical encounters for medical students and practicing physicians, and may potentially be applicable to all staff.

EXPOSURE TO FICTIONAL MEDICAL TELEVISION AND HEALTH: A SYSTEMATIC REVIEW Beth Hoffman; Ariel Shensa; Charles B. Wessel; Brian A. Primack. University of Pittsburgh, Pittsburgh, PA. (Tracking ID #2198783)

BACKGROUND: This year marks the 20th anniversary of the premiere of *ER* and *Chicago Hope*, which ushered in a distinct, new era of fictional medical television. At

its peak, *ER* attracted over 30 million viewers per week, and current fictional medical television programs such as *Grey's Anatomy* continue to draw over 10 million viewers each week. The average American adult spends only an hour in an actual physician's office each year, but he or she watches about 2000 h of television each year. Therefore, these programs may impart knowledge about public health topics, shape patients' perceptions of health and health care, and even alter health behaviors known to be related to leading causes of death and disease. As a result, some researchers have assessed associations between exposure to fictional medical television and health related factors. However, there has yet to be a systematic review of this literature in order to synthesize extant research and make recommendations for future study. This review aims to fill that gap.

METHODS: We conducted systematic literature searches in three databases: Medline, Ovid CINAHL and Ovid PsychINFO. Search strategies were developed under the guidance of a professional research librarian. Reference lists of articles found through the database searches were examined to identify additional relevant articles. Selected studies had (1) to be published in a peer-reviewed journal, (2) to be related to a fictionalized medical television program taking place primarily in a health-related setting, and (3) to assess viewers' health related knowledge, perceptions, and/or behaviors. In light of critical consensus supporting the 1994 premiere of *ER* and *Chicago Hope* as marking a new era of fictional medical television, we also restricted selected studies to those published in the past 20 years. Studies were classified according to (1) participant factors such as age and sex, (2) exposure-related factors such as the specific program studied and the dose of exposure, (3) outcome-related factors such as whether perceptions, knowledge, and/or behaviors were assessed, and (4) study quality.

RESULTS: Of 1422 articles identified, 24 articles met criteria for selection. One-third (33 %) studied participants in the 18–24 age range (college undergraduates). No studies assessed participants ages 65 and up. Only one study assessed differences among individuals of different racial and ethnic backgrounds (e.g., Caucasian, Latino, African-American). The most commonly assessed programs were *ER* (54 %), *Grey's Anatomy* (42 %), and *House M.D.* (25 %). Studies examined the association of program exposure with health-related perceptions (71 %), knowledge (42 %), and behaviors (42 %). Of studies examining knowledge or perceptions, the most popular health topics were organ donation (33 %), cancer (17 %), alcohol (11 %), and sexually transmitted infections (11 %). The most common behaviors studied were having discussions about health with friends or family (40 %), and/or consulting a physician (40 %). The majority of these behavior studies (70 %) found a positive association between viewership and health behavior. No studies assessed longitudinal associations more than 2 months. Most studies were of fair to poor quality in terms of rigor of study design.

CONCLUSIONS: Fictional medical television may provide a variety of health-related knowledge. These programs may also influence health-related perceptions, knowledge, and/or behaviors. However, the vast majority of work previously conducted in this area has been cross-sectional or very short-term and thereby limited in its ability to assess influence. Considering the importance of health disparities and the lack of studies in this area focusing on minority populations, this would also be an important area for future work. While most work in this area has focused on associations between programming and high-interest topics such as organ donation and sexually-transmitted infections, a small minority addressed the potential for this medium to influence health behaviors more closely related to morbidity and mortality such as tobacco use and diet and exercise patterns. It would be valuable for future work to utilize more rigorous study designs and to assess the potential to leverage this large exposure to influence health behaviors other than discussion of information and/or consultation with a physician.

FACILITATORS OF TEAM FUNCTIONING DURING THE EARLY STAGES OF PCMH IMPLEMENTATION Karleen Giannitrapani⁴; Alexis K. Huynh⁶; Andrew Lanto⁵; Susan E. Stockdale²; Lisa S. Meredith³; Lisa V. Rubenstein¹. ¹GLA VA, North Hills, CA; ²Greater Los Angeles VA Healthcare System, Sepulveda, CA; ³RAND Corporation, Santa Monica, CA; ⁴UCLA / VA GLA, Los Angeles, CA; ⁵VA Greater LA Healthcare System, Sepulveda CA, CA; ⁶Veterans Affairs, Sepulveda, CA. (Tracking ID #2196640)

BACKGROUND: The Veteran Health Administration (VA) has implemented a version of the Patient Centered Medical Home model called PACT—Patient Aligned Care Teams—one goal of which is to employ a team-based approach to achieve high quality, patient centered, continuous care. Under PACT, clinicians and staff are organized into small working groups called “teamlets” each of which, in the ideal implementation, consists of a Primary Care Provider (PCP), a Registered Nurse Care Manager (RN), a clinical assistant and an administrative assistant. This study was undertaken as part of the “Veterans Assessment and Improvement Laboratory (VAIL), an initiative which aimed to support and evaluate the transition to a PACT in Southern California and Western Nevada. VAIL developed a logic model to provide a framework when evaluating elements of the implementation. Effective team-based care is an important element of this support. The

objective of this study is to identify the modifiable factors that act as facilitators of team functioning during primary care practice transformation.

METHODS: Research Design: The data for the study come from a cross-sectional online survey of 818 providers and staff working in 23 VA primary care clinics, fielded in early stages of PCMH implementation (November 2011–March 2012). The overall response rate was 63 % ($n=515$). Measures: The dependent variable is a 100 point scale developed from 5 items capturing components of team functioning. The independent variables map to the VAIL logic model and include perceived support from facility leadership, attending local trainings, attending trainings with team members, job type (Primary Care Provider, Registered Nurse, clinical associate, and clerk), facility size, tenure at the VA, satisfaction with the team, and readiness for change. Associations with age, race/ethnicity, and gender were also explored but not included in the final model. Analysis: Multilevel mixed effects linear regression model with the clinic treated as the random effect.

RESULTS: Perceived support from leadership ($\beta=.139$, $z=3.34$, $p<.001$) and satisfaction with the team ($\beta=.1128$, $z=15.16$, $p<.001$) were significantly associated with team functioning. Attending local trainings, attending trainings with team members, facility size, tenure at the VA, and readiness for change were not. Associations with team functioning and age, race/ethnicity, and gender were explored but not included in the final model. Job type (Primary Care Provider (PCP), Registered Nurse (RN), Licensed Practical Nurse (LPN), and clerk) was not associated with team functioning, with the exception of one pairwise comparison. After accounting for other covariates, LPNs reported higher levels of team functioning than did PCPs ($\beta=4.65$, $z=-2.32$, $p<.05$).

CONCLUSIONS: Identifying the factors that act as facilitators to team functioning during the early implementation of a PCMH model allows us to provide the following insight to future PCMH implementation efforts: highly functioning teams have members who feel supported by their clinic and facility leaders and satisfied with the working relationships on their teams. By identifying potential facilitating factors we hope to provide guidance on where to invest resources during times of transition.

FACTORS ASSOCIATED WITH 30-DAY COPD READMISSIONS Jenny J. Lin²; Katherine Krauskopf¹; Juan Wisnivesky³. ¹Icahn School of Medicine at Mount Sinai, New York, NY; ²Mount Sinai, New York, NY; ³Mount Sinai School of Medicine, New York, NY. (Tracking ID #2198988)

BACKGROUND: Preventing hospital readmissions, particularly among COPD patients is a major public health priority. Moreover, beginning in 2015, the Centers for Medicare and Medicaid Services (CMS) Hospital Readmissions Reduction Program, which requires CMS to reduce payments to hospitals with excess 30-day readmissions, will be expanded to include COPD. In order to reduce COPD readmissions, it is important to determine risk factors.

METHODS: We used administrative hospital discharge data from the 2011 New York State Inpatient Database (SID) of the Healthcare Cost and Utilization Project (HCUP). The study was limited to individuals ≥ 18 years of age for whom COPD was the primary admitting diagnosis. The outcome was defined as an inpatient admission ≤ 30 days after hospital discharge. Predictors of readmission included patient demographics (age, sex, race, insurance), ICD-9-derived physical and mental health comorbidities, length of stay (LOS) of COPD admission, and COPD disease severity (defined as ICD-9 evidence of pulmonary hypertension and respiratory failure). We used unadjusted and adjusted analyses with adjusting for clustering using generalized estimating equations (GEE) to assess for associations of predictors with 30-day readmission.

RESULTS: We identified 50,861 admissions where COPD was the primary diagnosis. Of these, 5839 (12 %) were followed by a 30-day readmission. Unadjusted analyses showed that patients who had a 30-day readmission were more likely to be older (mean age 71.4 vs. 70.4 years), white, have Medicare as primary insurance, and to have had a longer median LOS for the initial admission (5 vs. 4 days; $p<0.03$ for all comparisons). In adjusted analyses, readmissions were also associated with comorbid mood diagnoses ($p=0.006$), pulmonary hypertension ($p=0.03$), and respiratory failure ($p<0.002$).

CONCLUSIONS: In a large administrative dataset representing inpatient discharge records from New York State, we found that patients with COPD-related 30-day readmissions were more likely to be older, insured by Medicare, to have comorbid mood disorders, and markers of severe COPD. These findings suggest that these factors should be considered in the design of interventions to prevent readmissions in this population. Further work should assess these factors in other regions of the US to determine the breadth of their applicability as targets for interventions.

FACTORS ASSOCIATED WITH A HISTORY OF SEXUAL ASSAULT AMONG US MEN AND WOMEN

Holly N. Thomas¹; Sonya Borrero²; Rebecca C. Thurston¹.
¹University of Pittsburgh, Pittsburgh, PA; ²University of Pittsburgh and VA Pittsburgh, Pittsburgh, PA. (Tracking ID #2199934)

BACKGROUND: A history of sexual assault is associated with poorer health and quality of life. Characterizing the factors that are associated with a history of sexual assault can help healthcare providers identify and care for individuals who have experienced it. The aim of this study was to determine the factors associated with a history of sexual assault among US adults.

METHODS: This was a cross-sectional analysis using the second wave of a US-population-based sample of individuals aged 28 to 84. Participants were initially identified by random digit dialing. The second wave of the study re-contacted the original participants from 2004 to 2006, and data were collected using telephone interviews and self-administered questionnaires. History of sexual assault, sexual orientation, and history of mood disorder were each assessed by a single question. Due to low numbers, homosexual and bisexual individuals were considered in one group. Percentages, means, and standard deviations were calculated to describe the sample. Post-stratification weights based on race, age, and education status were used to calculate percentages for the general US population. Univariable logistic regression was used to assess factors that may be related to a history of sexual assault, including demographic variables (age, race, ethnicity, education status, etc.), psychosocial variables (psychological history, marital status, drug and alcohol use, etc.), sexual orientation, and veteran status. Variables with $p < 0.10$ were entered into a multivariable model.

RESULTS: Of 2453 individuals who answered the question regarding sexual assault, 50 (4.9 %, 6.0 % weighted) men and 315 (22.1 %, 23.5 % weighted) women reported a history of sexual assault. Of those who had experienced sexual assault, 237 (70.0 %) were under 18 years old at the time of the assault, and 78.5 % of individuals were negatively affected by the assault in the long term. Among men, homosexual and bisexual individuals had 10 times higher odds of a history of sexual assault (Table 1). Veteran status was associated with 4 times higher odds of a sexual assault history. Younger age, history of a mood disorder, and religion were also associated with a history of sexual assault. Among women, veteran status was associated with 8 times higher odds of a sexual assault history (Table 2). Younger age, Hispanic ethnicity, divorced marital status, and history of mood disorder were also associated with sexual assault history.

CONCLUSIONS: Sexual assault is common, with about 5 % of men and 24 % of women reporting a history of sexual assault. Sexual minority men are more likely to report a history of sexual assault than heterosexual men; this has been demonstrated in prior studies. It should be noted that because this data is cross-sectional, causality cannot be determined. It is more likely that sexual minority men are targeted for sexual assault and *not* that a history of sexual assault leads to a homosexual or bisexual orientation. Veterans, both men and women, were more likely to report a history of sexual assault than non-veterans. Prior literature has demonstrated that a history of sexual violence is common among female veterans, but few studies have examined this issue among male veterans. Healthcare providers should be aware of these factors that are associated with a history of sexual assault; this will allow providers to perform targeted screening and identify and treat individuals who have experienced prior assault.

Table 1. Multivariable factors associated with sexual assault among men in MIDUS 2, N=1030

Variable	OR for history of sexual assault (95 % CI)	P value	Overall P value
Sexual orientation			0.002
Heterosexual	1 [ref]		
Homosexual or bisexual	10.01 (2.31, 43.30)		
Age	0.94 (0.90, 0.99)		0.009
Mood disorder (versus no)	3.03 (1.13, 8.013)		0.028
Religion			0.032
None	1.58 (0.57, 4.38)	0.38	
Protestant	1 [ref]		
Catholic	0.35 (0.07, 1.66)	0.186	
Other	3.75 (1.19, 11.78)	0.024	
Veteran (versus no)	3.54 (1.38, 9.38)		0.001

Adjusted for marital status, alcohol problem, and drug use

Table 2. Multivariable factors associated with sexual assault among women in MIDUS 2, N=1423

Variable	OR for history of sexual assault (95 % CI)	P value	Overall P value
Age	0.97 (0.96, 0.99)		0.004
Hispanic (versus no)	2.99 (1.03, 8.71)		0.044
Marital status			0.002
Married	1 [ref]		
Cohabiting	1.89 (0.83, 4.28)	0.128	
Divorced	2.46 (1.51, 4.00)	<0.001	
Widowed	0.74 (0.31, 1.74)	0.49	
Never married / not cohabiting	1.23 (0.60, 2.51)	0.57	
Mood disorder (versus no)	2.15 (1.44, 2.51)		<0.001
Veteran status (versus no)	7.80 (2.81, 21.63)		<0.001

Adjusted for sexual orientation, alcohol problem, drug use, number of sex partners, disability, homelessness

FACTORS ASSOCIATED WITH ACHIEVING CLINICALLY SIGNIFICANT WEIGHT LOSS IN A NATIONAL, NONPROFIT WEIGHT LOSS PROGRAM

Nia S. Mitchell. University of Colorado, Aurora, CO. (Tracking ID #2199211)

BACKGROUND: Overweight and obesity continue to affect almost 70 % of people in the United States, and it is important to help them lose weight because the excess weight adversely affects their health. The Institute of Medicine defines clinically significant weight loss as weight loss of ≥ 5 % of initial weight because it is associated with improvements in weight-related comorbidities, including diabetes, hypertension, and obstructive sleep apnea. Take Off Pounds Sensibly (TOPS) is a national, nonprofit weight loss group, and almost 95 % of its members are women. Observational data of 69,489 women who participated in the program for at least 1 year showed that their average weight loss was 6 % of their initial weight. However, only 50 % of those participants lost ≥ 5 % of initial weight; 32 % lost between 0 and < 5 %; and almost 18 % gained weight. The purpose of this study is to examine factors associated with achieving clinically significant weight loss at 1 year amongst TOPS female participants.

METHODS: Participants were females who joined TOPS from 2005 to 2011 and had a birthdate recorded in the TOPS national database. The initial dataset contained 52,322 women. Unadjusted analyses were performed to determine the variables used in the final multivariable log-binomial regression model. These included participant age, initial weight, number of members per chapter, and chapter age. Participant age (years) was divided into the following categories: 18 to < 45 ; 45 to < 55 ; 55 to < 60 ; 60 to < 65 ; 65 to < 70 ; and 70 and older; this allowed for similar numbers of participants in each group. Chapter size was divided into < 25 members and ≥ 25 members, and approximately half of the chapters fell into each group. Initial weight and chapter age were modeled as continuous variables.

RESULTS: Results of the model are shown in **Table 1**. Increasing age was significantly associated with achieving clinically significant weight loss. Participants in chapters with 25 members or more were 9 % more likely to achieve clinically significant weight loss than those in chapters with less than 25 members. For every 5 kg increment in initial weight, women were 1 % more likely to achieve clinically significant weight loss. For every 10 year increment of chapter age, participants were 1 % less likely to achieve clinically significant weight loss.

CONCLUSIONS: Of the categories in the model, participant age had the largest influence on achieving clinically significant weight loss. Older women may be more successful at losing weight because they have less competing demands than younger women. The number of participants in each chapter also had a significant effect on weight loss. Women in chapters with at least 25 members were more likely to achieve significant weight loss than those in chapters with less than 25 members. Chapters with more participants might be more motivating and engaging than those with less. Although initial weight and chapter age had less impact than age and chapter size, women with higher initial weights and those in newer chapters were more likely to achieve significant weight loss. Heavier women may be more successful because the suggested lifestyle changes may be a greater departure from their initial habits than their lighter counterparts; and newer chapters may represent less stagnation among members. Weight loss can be influenced by many modifiable and non-modifiable factors. It is important to know which factors influence weight loss to maximize the success of those trying to lose weight.

Adjusted Relative Risk for Achieving Clinically Significant Weight Loss at 1 Year by Category

Category	Sub-category	Adjusted Relative-Risk (95 % confidence interval)	P value
Age (years)	18 to <45 (ref.)	—	—
	45 to <55	1.11 (1.07, 1.15)	<.0001
	55 to <60	1.18 (1.13, 1.22)	<.0001
	60 to <65	1.20 (1.16, 1.24)	<.0001
	65 to <70	1.23 (1.19, 1.28)	<.0001
	≥70	1.31 (1.26, 1.35)	<.0001
Chapter size	<25 members (ref.)	—	—
	≥25 members	1.09 (1.07, 1.11)	<.0001
Starting weight (kg)	Weight (per 5 kg)	1.01 (1.00, 1.01)*	<.0001
Chapter age (years)	Chapters age (per 10 years)	0.99 (0.98, 1.00)*	.001

*The 95 % CI appears to contain 1.00 due to rounding.

FACTORS ASSOCIATED WITH BORDERLINE VERSUS DEFINITE PERIPHERAL ARTERY DISEASE AMONG AFRICAN AMERICANS

Tracie C. Collins¹; Spencer Post¹; Rachel Marsh¹; Harpreet M. Singh¹; Rosalee Zackula². ¹KU School of Medicine - Wichita, Wichita, MN; ²University of Kansas School of Medicine-Wichita, Wichita, KS. (Tracking ID #2199254)

Research reported in this publication was supported by the National Heart, Lung, and Blood Institute of the National Institutes of Health under Award Number R01HL098909. The content is solely the responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health.

BACKGROUND: Peripheral artery disease (PAD), defined as atherosclerosis of the abdominal aorta and arteries of the lower extremities, is a common disease affecting 8 to 12 million Americans. PAD disproportionately affects African Americans as compared to non-Hispanic whites. Prior studies have focused on defining risk factors for PAD but less is known about factors associated with PAD versus borderline disease among African Americans. We sought to determine those factors associated with definite versus borderline disease among African Americans.

METHODS: Currently, we are conducting a 5-year study, 12-month trial, funded by the NIH in which we seek to determine the efficacy of a behavioral intervention to improve walking distance among African American adults with PAD. Participants complete three visits which include baseline, 6, and 12 months. We analyzed baseline data from this clinical trial. Trial eligibility includes self-identifying as African American and screening positive for PAD based on an objective assessment, the ankle-brachial index (ABI; ratio of systolic blood pressure in the ankle to that in the arm). Participants must have PAD (ABI < 0.9) or borderline disease (ABI 0.91–0.99). Participants are excluded if they have undergone lower extremity amputation, leg revascularization (open or endovascular) within the preceding 3 months, contraindications to walking for exercise, and a treadmill test positive for coronary ischemia. For the latter, participants can be eligible following treatment for coronary ischemia. Variables collected are; laboratory data (lipid profile and glycosylated hemoglobin) and vital signs including BMI. Participants also complete interviewer-administered, validated surveys to ascertain medical history (Lifestyle and Clinical Survey), dietary habits (Food Frequency Questionnaire), quality of life (Vascular Quality of Life Questionnaire), and leg symptom subtypes (San Diego Claudication Questionnaire). For the bivariate analysis, we used chi-square and t-tests for categorical and continuous variables, respectively. For the multivariate model, we used generalized linear modeling with the dependent variable of ABI < 0.9. Independent variables considered for each model included laboratory results, leg symptom subtypes of intermittent claudication or atypical leg symptoms versus asymptomatic disease, medical history (categorical variables), and dietary habits.

RESULTS: Among 107 African Americans enrolled, 75 % are women. The mean age of the cohort is 64 years (SD 12). Within the cohort, 92 (86 %) have hypertension, 38 (36 %) have diabetes mellitus, 26 (24 %) are current smokers, 59 (55 %) have hyperlipidemia, 58 (54 %) are past smokers, and 41 (38 %) have osteoarthritis. Factors significantly associated with definite versus borderline PAD were consumption of bad fats 5 or more times per week adjusted OR 3.97 (95 % CI 1.16, 13.65) and systolic blood pressure adjusted OR 1.06 (95 % CI 1.01, 1.10).

CONCLUSIONS: Factors associated with definite versus borderline PAD among African Americans included diets high in bad fats and systolic blood pressure. This is one of the first studies to identify an association between dietary habits and PAD. Future work should address the role of a dietary intervention and the impact of systolic blood pressure control to reduce the risk of progressing from borderline to definite PAD among African Americans.

FACTORS ASSOCIATED WITH DISTINCT RESIDENTIAL PATTERNS IN OLDER HOMELESS ADULTS Christopher T. Lee¹; David Guzman²; Claudia Ponath²; Lina Tieu¹; Elise Riley¹; Margot Kushel^{1, 2}. ¹University of California, San Francisco, San Francisco, CA; ²San Francisco General Hospital, San Francisco, CA. (Tracking ID #2191845)

BACKGROUND: Subpopulations of homeless individuals reside in different environments which haven't been described in the existing literature. These individuals have different risk profiles and residential venues themselves may mediate exposure to trauma, access to services, and opportunities for rehousing. We used a cluster analysis to create a classification of residential venues among a sample of older homeless adults and identified factors associated with these venues. Defining residential patterns and determining factors correlated with them may allow for more targeted service delivery and further elucidate the role of the lived environment in mediating the morbidity and chronicity of homelessness.

METHODS: We conducted structured interviews with 350 individuals aged 50 and older experiencing homelessness, as defined by the HEARTH Act (2009). We recruited participants using population-based sampling from encampments, recycling centers, homeless shelters, and low-cost meal programs in Oakland, CA as a baseline study of the Health Outcomes of People Experiencing Homeless in Older Middle Age (HOPE-HOME) cohort. Participants used a residential time-line inventory to characterize where they lived in the 180 days preceding the interview. With these data, we used cluster analysis to generate four patterns of residential venues. We assessed demographics and lifetime histories of substance use and mental health problems prior to losing stable housing and physical and sexual abuse during the last year of stable housing. We measured social supports using an index comprised of whether the individual had a confidant and someone to lend them money and created an institutional support index using principal component analysis of variables for having case managers, primary care clinics, and receiving government assistance in the last year of stable housing. We used nonparametric ANOVA to identify differences in risk factors between housing clusters and multinomial logistic regression to generate adjusted relative risk ratios (RRR) for predictors of each group, using the largest (unsheltered cluster) as the baseline.

RESULTS: The sample was 77.1 % men with a mean age of 58.1 years. Cluster analysis revealed four housing groups: "unsheltered" individuals ($n=162$) spent an average of 85.6 % of days living on streets or encampments, "cohabiters" ($n=57$) spent 71.2 % of days living with friends or family, "renters" ($n=43$) spent 80.2 % of days in their own rented rooms or apartments, and "shelter users" ($n=88$) spent time in shelters (39.4 % of days) and transitional housing or hotels (22.7 % of days). Women were overrepresented in the cohabiters (45.6 %) and renters (32.6 %) compared to the unsheltered (14.2 %) and shelter users (19.3 %) ($P<0.001$). The number of days homeless this episode were significantly higher in the unsheltered (1739.9) and shelter users (1167.1) than in the cohabiters (498.3) and renters (294.7) ($P<0.001$). Pre-homeless institutional supports were significantly higher in the renters compared to the unsheltered cluster ($P=0.006$). There were no significant differences in age, race, education, veteran status or history of mental health problems between groups. After adjustment, compared to the unsheltered cluster, predictors for membership in the cohabiters cluster were being a woman (RRR 4.4, $P=0.002$), older age of first homelessness (RRR 1.04 per year, $P=0.04$), history of abuse (RRR 2.9, $P=0.03$) and greater social support (RRR 2.3, $P=0.004$). Predictors for membership in the renters cluster were being a woman (RRR 3.7, $P=0.02$) and shorter duration of homelessness (RRR 0.8, $P=0.045$). The shelter user cluster was associated with greater social support (RRR 1.6, $P=0.03$) and negatively associated with prior regular cocaine use (RRR 0.4, $P=0.004$).

CONCLUSIONS: We identified four distinct residential patterns among older homeless persons, each associated with unique social factors. Those with more recent onset of homelessness, particularly women, are significantly less likely to reside in shelters or streets. Identifying renters and cohabiters who are hidden from traditional enumeration methods may allow for targeted interventions for those imminently at risk of losing housing. The unsheltered and shelter users represent two distinct populations; lower levels of drug use and greater social supports may have enabled shelter users to avoid living on streets. Social support was significantly protective against street homelessness; our findings add to the existing literature on the broadly protective role of social support in homeless populations by elucidating effects specifically among older homeless individuals. We find that using a broader sampling frame for homelessness allows for the identification of distinct subpopulations that are underrepresented in the literature.

FACTORS ASSOCIATED WITH FOLLOW-UP VISIT PATTERNS AT A UNIVERSITY CARDIOLOGY PRACTICE Caterina Y. Liu; Michael Wang; Ralph Gonzales. UCSF, San Francisco, CA. (Tracking ID #2194757)

BACKGROUND: Follow-up care is an essential component of outpatient medicine, but few guidelines address appropriate frequency. In specialty care, follow-up visits comprise over 75 % of total visits in US ambulatory care practices. Excess follow-up visits consume available appointment supply and contribute to long wait times and delays in care. We studied follow-up visit patterns for new patients to a university-based cardiology practice, and how patterns vary by patient, provider and system factors.

METHODS: This is a retrospective cohort study of patients who completed a new patient visit at an urban university-based cardiology practice during fiscal years 2012–2014. Data was extracted from the electronic medical record database. The primary outcomes were time and frequency of follow-up visits to a physician or nurse practitioner in the cardiology practice during the observation period; visits for procedures and tests were excluded. Predictor variables included patient factors (age, gender, race, diagnosis); provider factors (gender, type); and system factors (insurance type, primary care within the university health system). Providers with fewer than 100 new patients were excluded to improve reliability of point estimates and increase generalizability. Both first follow-up and second-follow-up visits were examined as outcomes with two or more follow-up visits representing a population of patients for whom ongoing care in the specialty clinic is more likely. In bivariate analyses, the log-rank test was performed to test for statistical significance of differences in time to first and second follow-up across patient, provider, and system variables. Cox proportional hazards regression analysis was performed to examine predictors of time to first and second follow-up. All analyses were conducted using Stata 13 (StataCorp, TX).

RESULTS: During the 3-year study period, this cardiology practice provided 89,492 patient care visits, of which 9032 were new patient visits. The mean age was 56 years,

52 % were male, 54 % were Caucasian, 40 % had private insurance, and 25 % had a primary care provider within the same university system. Cardiac dysrhythmia was the most common diagnosis (25.5 %). Overall, half of patients had at least one follow-up visit and a quarter had at least two follow-up visits within 1 year of their initial visit. The 15 % of patients with 3 or more follow-up visits accounted for 58 % of the follow-up visit volume generated by new patients. In bivariate analyses, the proportion with at least one follow-up varied statistically significantly by provider (**Figure 1**), practice year, gender, race, insurance, primary care location, and diagnosis. Results were similar for time to second follow-up, although practice year was no longer statistically significant. In Cox regression analyses, independent predictors of time to first follow-up included patient age (HR 1.03 (1.00–1.06) for 10 year increase), gender (HR 0.91 (0.85, 0.98) for females), race (HR 1.18 (1.07, 1.30) for Asian relative to Caucasian), insurance (HR 1.22 (1.07, 1.39) for Medi-Cal compared to private insurance), practice year (HR 0.68 for FY13 compared to FY12), primary care within the same system (HR 1.11 (1.02, 1.19)) and diagnosis (HR 1.42 (1.18, 1.70) for congestive heart failure compared to coronary artery disease). Estimates were similar for time to second follow-up. In both models, the individual physician variable remained significantly associated with follow-up after adjustment.

CONCLUSIONS: There is large variation in follow-up practices by patient, provider, and system factors within this university-based cardiology practice. Individual provider variation in follow-up visit patterns persisted after adjusting for patient and system factors. A small proportion of new patients generated most of the follow-up volume, while a majority of patients never had any follow-up. These results suggest an opportunity to standardize how follow-up visit decisions are made in cardiology clinic, with the potential goal of increasing specialty care access.

Time to follow-up by provider: each line represents an individual provider's practice behavior.

FACTORS ASSOCIATED WITH RESIDENT CONTINUITY IN AMBULATORY TRAINING PRACTICES Megan Ditty; Julia West; Brett Robbins; Lynn C. Garfunkel; Karen Nead; Michael Mendoza; Robert J. Fortuna. University of Rochester, Rochester, NY. (Tracking ID #2194668)

BACKGROUND: Continuity and longitudinal care of patients are cornerstones of primary care and have been associated with improved outcomes in care. Providing a longitudinal primary care experience between residents and patients is a key goal of residency training. Our objective was to identify factors that are associated with increased

continuity in residency teaching practices and to examine how continuity is associated with quality measures.

METHODS: We analyzed 120,400 patient visits to four resident continuity programs in Upstate New York between 7/1/2013 and 6/30/14. We defined continuity from both the resident and patient perspective. Resident continuity was defined as the percent of patients seen by a resident who are their primary patient. Patient continuity was defined as the percent of all patient visits seen by either their primary resident or team attending. We surveyed program directors, clinic directors, office managers, and chief residents to determine what factors each site used to promote continuity. Data were analyzed using chi square tests for proportions and Cochran-Armitage tests for trends. Logistic regression models were used to examine the independent influence of factors on continuity.

RESULTS: Resident continuity ranged from 33.1 to 83.7 % between sites. Patient continuity ranged from 20.6 to 71.5 %. Factors associated with improved resident continuity included absence of physician extenders (nurse practitioners or physician assistants) (71.5 % vs 51.7 %; $P < 0.001$), advancing post-graduate year (PGY) of resident

(54.9 to 69.9 %; $P < 0.001$), offering morning clinic sessions (59.5 % vs 33.1 %; $P < 0.001$), increased mean clinical faculty FTE (33.1 to 71.5 %; $P < 0.001$), scheduling protocol for acute visits (41.1 % vs 77.5 %; $P < 0.001$), and having a policy for patient dismissal for missed appointments (51.7 % vs 71.5 %; $P < 0.001$). Similarly, factors associated with improved patient continuity include included absence of physician extenders, advancing PGY, offering morning clinic sessions, providing more than one clinical session per week with the primary resident, increased mean clinical faculty FTE, scheduling protocols, and having a patient dismissal policy ($P < 0.001$ for all). Increased patient continuity was associated with improved rates of diabetic control (54.6 to 62.8 %; $P < 0.001$), hypertension control (57.5 to 82.8 %; $P < 0.001$), screening colonoscopy (31.9 to 69.2 %; $P < 0.001$), and screening mammography (38.2 to 74.8 %; $P < 0.001$).

CONCLUSIONS: Variations in resident and patient continuity are associated with a number of modifiable clinic factors. Increased clinical faculty time, scheduling protocols, and the absence of physician extenders were most strongly associated with increasing continuity. Improving continuity may help improve important quality measures, including diabetic control, hypertension control, and cancer screening rates.

FACTORS ASSOCIATED WITH THE DIAGNOSIS OF OBESITY IN ADOLESCENTS AND YOUNG ADULTS Erica O. Miller; Bryan Stanistreet; Robert J. Fortuna. University of Rochester, Rochester, NY. (Tracking ID #2194781)

BACKGROUND: In the United States, 17 % of children and 36 % of adults are obese based on BMI standards, yet few patients receive a clinical diagnosis of obesity or are counseled about lifestyle modification. We examined the rates of diagnosis of obesity and evaluated socioeconomic and demographic factors associated with the accurate diagnosis of obesity in obese individuals.

METHODS: We assessed the rates of diagnosis of obesity using the National Ambulatory and National Hospital Ambulatory Medical Care Surveys (NAMCS and NHAMCS). Obesity was defined by Body Mass Index (BMI) according to nationally accepted standards. We determined if a patient with obesity based on BMI had been clinically diagnosed with obesity via either of the following (1) a diagnosis listed in the patient's chart; or (2) the provider's answer to the direct question "despite the diagnoses listed, does this patient have obesity?" In obese individuals, we examined the association between the accurate diagnosis of obesity and socioeconomic status, age, gender, race, ethnicity, insurance status, and geographic region. We determined level of education based on the percent of patients with a college education within a specific geocode. We used bivariate comparisons for socioeconomic status with multivariate regression models to adjust for age, gender, race, and ethnicity.

RESULTS: We examined 180,211,878 weighted office visits from obese children, adolescents, and young adults aged 5–34 years between 2006 and 2010. Obese young adults (aged 22–34 years) were more likely to be accurately diagnosed with obesity compared to obese adolescents (aged 13–21 years) or obese children (45.4 % vs 39.7 % vs. 23.4 %; $P < 0.001$). Overall, obese individuals residing in more highly educated areas were more likely to be diagnosed with obesity than those living in less highly educated areas (43.1 % vs. 36.9 %; Adjusted Odds Ratio (AOR) 1.5; 95 % CI 1.1–2.0). Among obese young adults, individuals were more likely to be diagnosed if they resided in more highly educated areas (AOR 1.6; 95 % CI 1.1–2.3) or were female (AOR 2.2; 95 % CI 1.5–3.2). Similarly, adolescents were more likely to be diagnosed if they resided in more highly educated areas (AOR 1.6; 95 % CI 1.0–2.5), were female (AOR 1.9; 95 % CI 1.5–3.4), or were non-white (AOR 1.9; 95 % CI 1.0–3.4). Patients in the Northeast were more likely to be diagnosed with obesity than those in the Midwest, South, and West.

CONCLUSIONS: Risk for underdiagnosis of obesity is highest in less educated areas and males. These trends reflect the complex interactions of many factors affecting the diagnosis of obesity. Identification of at-risk groups helps clinicians understand biases to increase accurate diagnosis of obesity, which can improve access to appropriate counseling, screening, and management.

FACTORS ASSOCIATED WITH WALKING ABILITY AMONG AFRICAN AMERICANS WITH PERIPHERAL ARTERY DISEASE Tracie C. Collins¹; Rosalee Zackula²; Nikki Nollen⁴; Nicole Rogers³; Jasjit Ahluwalia². ¹KU School of Medicine - Wichita, Wichita, MN; ²University of Kansas School of Medicine-Wichita, Wichita, KS; ³Wichita State University, Wichita, KS; ⁴University of Kansas School of Medicine, Kansas City, KS; ⁵University of Minnesota, Minneapolis, KS. (Tracking ID #2199126)

Research reported in this publication was supported by the National Heart, Lung, and Blood Institute of the National Institutes of Health under Award Number R01HL098909. The content is solely the responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health.

BACKGROUND: African Americans are two times more likely than non-Hispanic whites to have peripheral artery disease (PAD)—atherosclerosis of the abdominal aorta and arteries of the lower extremities. Walking distance is a commonly measured outcome among patients with PAD but less is known about the factors associated with this outcome among African Americans with PAD. We sought to determine the risk factors associated with walking distance among a cohort of African Americans with PAD.

METHODS: We analyzed baseline data from an ongoing 5-year NIH funded clinical trial in which we seek to determine the efficacy of a behavioral intervention to improve walking distance among African Americans with PAD. Trial eligibility includes self-identifying as African American and screening positive for PAD as defined by an ankle-brachial index (ABI) ≤ 0.99 . Participants are excluded if they have undergone lower extremity amputation, leg revascularization (open or endovascular) within the preceding 3 months, contraindications to walking for exercise, and a positive screen for coronary ischemia as determined by a treadmill test. Participants complete a baseline visit and two follow-up visits at 6-, and 12 months. Variables collected include walking distance (6-min walking test), functional status (Short Physical Performance Battery Testing [SPPB]), laboratory data (lipid profile and glycosylated hemoglobin) and vital signs including BMI. Participants also complete interviewer-administered, validated surveys to ascertain medical history (Lifestyle and Clinical Survey), quality of life (Vascular Quality of Life Questionnaire), and leg symptom subtypes (San Diego Claudication Questionnaire). For this sub-analysis, we used generalized linear modeling with the dependent variable of walking distance (continuous variable). Independent variables considered for each model included ABI < 0.9 versus higher), functional status (SPPB score 1 to 10), leg symptom subtypes (intermittent claudication or atypical leg symptoms versus asymptomatic disease), glycosylated hemoglobin (7 or higher), and medical history.

RESULTS: Among the 107 African Americans enrolled, 75 % are women and the mean age of the cohort is 64 (SD 12). Mean baseline walking distance among the cohort was 1152 ft (SD=240). Within the cohort, 92 (86 %) have hypertension, 38 (36 %) have diabetes mellitus, 26 (24 %) are current smokers, 59 (55 %) have hyperlipidemia, 58 (54 %) are former smokers, and 41 (38 %) have osteoarthritis. Factors associated with greater walking distance included quality of life score [β coefficient 64.358 ($P=.003$)], glycosylated hemoglobin [β coefficient 163.402 ($P=.002$)], diastolic blood pressure [β coefficient 5.614 ($P=.019$)], and SPPB scores [β coefficient 63.722 ($P<.001$)]. In contrast, systolic blood pressure was associated with a lower walking distance [β coefficient -3.285 ($P=.027$)]. No statistically significant associations were found between ABI, gender, BMI, leg symptom subtypes, LDL, or triglycerides and walking distance.

CONCLUSIONS: Factors associated with walking ability among African Americans with PAD included quality of life, systolic blood pressure, diastolic blood pressure, and SPPB. Future research should identify the role of controlling systolic blood pressure and improving SPPB scores to increase walking in this population. Further, more studies are needed to assess the association of diastolic blood pressure with PAD and to identify the causal association between quality of life and walking distance among African Americans with PAD.

FACTORS IMPACTING THE LENGTH OF ROUNDS ON AN INPATIENT MEDICINE TEACHING SERVICE Justin M. Glasgow; Himani Divatia; Joseph M. Deutsch. Christiana Care Health System, Newark, DE. (Tracking ID #2195389)

BACKGROUND: Medical residency programs use inpatient rounds as a time to review clinical data, discuss plans of care, communicate with patients, family, and other care providers, and to teach the science and art of medicine. With these many varied goals, our program struggles to keep inpatient rounds to a maximum of 180 min (lasting 9 am to noon) so as to limit impact on other clinical and educational activities. In response to this challenge, a group of hospitalists and residents at our institution restructured our inpatient teams and began conducting daily surveys with the goal of identifying how various factors impact the length of teaching rounds.

METHODS: After restructuring the residency program has 4 teaching teams in a large suburban hospital, divided equally among two hospitalist groups, one a hospital owned group and the other a private group. The teams have one of two structures, either a single resident with two interns or a single resident with one intern. Additionally, there is a two resident, two intern team at a smaller urban hospital within the program. Using a mobile

survey platform a six question survey was “texted” to one resident per team prior to weekday afternoon sign-out rounds. The survey questions were: a) Team name, b) Rounding start time, c) Rounding end time, d) Number of patients, e) Number of patients new to the attending, and f) Number of team members participating in rounds. Results from these surveys were used to create generalized linear models that predicted length of rounds based on number of patients seen, number of team members, and number of new patients as fixed effects with separate models for attending, teaching team, and hospitalist company as random effects.

RESULTS: The surveys have a 53 % response rate (285/535). During this period, rounds averaged 185 min, ranging 60–390 min, and 36 % (103/285) of responses recorded a length of rounds that exceeded 180 min. Teams saw an average of 12 patients, ranging 3–20, with a median of 3 new patients each day. The final factors impacting the length of inpatient rounds were 1) Number of patients seen, 2) Number of new patients, and 3) Individual attending. After accounting for those factors, the number of members rounding with the team, the team structure, nor the hospitalist program appeared to significantly impact the length of rounds. The final model was Length of Rounds (in minutes) = $77 + 6.5\alpha + 2.3\beta + \gamma$, where α = Number of patients seen, β = Number of new patients, and γ is the random effect for each of the 36 attendings in the sample. Values for attending impact (γ) ranged from -73 min–102 min. While interpretation of the data is limited given the minimal information collected during the survey, the model suggests that teams spend on average 6.5 min presenting a patient, an additional 2.3 min presenting a new patient, and 77 min with other tasks such as multi-disciplinary rounds, walking between rooms, and educational activities. The time spent on these additional activities, however varied significantly across individual attendings as exhibited by the wide range of γ values.

CONCLUSIONS: The survey demonstrated that approximately a third of medicine teaching rounds exceeded our program goal of 180 min. While the number of patients seen played an expected role in the length of rounds, our data showed that variation across attendings had a significant impact. The results of the analysis are currently being used to drive the next round of systems redesign in two key manners. First, attendings are being provided with their individual results while a faculty committee is creating a teaching attending development program to address individual variance. Second, we are developing a time observation study to better understand how time is spent on activities during rounds and how much of that time would be considered non-value added.

FAMILIAL CLUSTERING OF DIABETES INFLUENCES TYPE 2 DIABETES RISK MORE STRONGLY THAN SOCIAL CLUSTERING OF OBESITY: A SOCIAL NETWORK ANALYSIS IN THE FRAMINGHAM OFFSPRING STUDY Sridharan Raghavan¹; Mark C. Pachucki³; Yuchiao Chang²; Josée Dupuis¹; James B. Meigs³. ¹Boston University SPH, Boston, MA; ²Harvard Medical School, Boston, MA; ³Massachusetts General Hospital, Boston, MA. (Tracking ID #2199071)

BACKGROUND: Social network analysis allows examination of shared characteristics, including health behaviors and diseases, between individuals who are socially connected to one another. Obesity and family history of diabetes are the two strongest risk factors for type 2 diabetes (T2D). Prior work in the Framingham Heart Study has shown that an individual's risk of obesity is influenced by his/her social contacts—both non-familial contacts and family members; however, whether shared obesity risk across social ties translates to shared diabetes risk remains unexplored. We examined T2D clustering in a social network to estimate the influence of familial and non-familial social ties on diabetes risk. We hypothesized that type 2 diabetes risk is associated with social ties to other people with diabetes and with body mass index (BMI) of social contacts.

METHODS: Administrative data identified interpersonal ties between Framingham Offspring Study participants at each of 8 exam visits between 1971 and 2008 ($N=4872$ participants). Diabetes status of each person (ego) and each social contact (alter) was defined as fasting glucose >125 mg/dl or taking diabetes medications. We used generalized estimating equations clustered by ego to estimate associations between prevalent ego diabetes and alter diabetes and BMI across 8 exams, adjusting for ego's sex, age, BMI, self-reported T2D family history, count of 19 common diabetes genetic variants, social network size, and exam visit. Analyses were repeated in networks stratified by familial versus non-familial ties.

RESULTS: Ego T2D was associated with alter T2D (OR 1.38, $p=0.005$) but not alter BMI (OR 1.01, $p=0.30$). When stratified by ego-alter relationship, ego T2D was associated with familial alter T2D (OR 1.57, $p=0.003$) but the effect was weaker for non-familial alter T2D (OR 1.30, $p=0.07$). Adjusting for genetic risk attenuated the familial ego-alter T2D association (OR 1.43, $p=0.02$) but marginally strengthened the non-familial ego-alter T2D association (OR 1.33, $p=0.04$). Though ego BMI was strongly associated with alter BMI, ego T2D was not associated with alter BMI in either familial or non-familial contacts.

CONCLUSIONS: We found that T2D risk was shared across social ties, with a greater effect across familial than non-familial ties. Though obesity is known to be shared among social contacts, shared T2D risk was independent of shared obesity. That familial T2D clustering is not explained fully by family T2D history and T2D genetic risk suggests additional shared risk factors among related individuals. Further analyses that account for ego education and interactions of genetic risk with relationship type are needed to fully characterize T2D risk in social networks.

FAMILY CAREGIVERS AND THEIR ROLES IN THE TRANSITION FROM HOSPITAL TO HOME FOR LIMITED ENGLISH PROFICIENT PATIENTS

Leah S. Karliner; Eliseo J. Perez-Stable; Sunita Mutha; Anna M. Napoles. UCSF, San Francisco, CA. (Tracking ID #2199304)

BACKGROUND: Older patients often rely on family caregivers for help with their medical needs and communication with their medical care team, particularly when hospitalized. Involvement of a family caregiver during hospitalization is especially common among patients with limited English proficiency (LEP). Yet, little is known about family caregivers or their roles at the time of hospitalization and during the immediate post-discharge transition period.

METHODS: As part of a larger study of discharge communication with hospitalized LEP patients, we interviewed Chinese and Spanish speaking patients hospitalized on the cardiology, general surgery, and orthopedic floors of an urban academic medical center. Patients were asked about their family caregivers and to identify the caregiver who was present to receive medical information at the time of discharge. We then interviewed that caregiver by telephone about their relationship with the patient, general caregiver roles, roles since hospitalization, and their own health status and demographics.

RESULTS: We interviewed 214 hospitalized LEP patients; 138 (64 %) were Chinese-speakers and the remainder Spanish-speakers; 120 (56 %) were women; mean age was 69. Two-thirds (68 %) reported having someone to help them make important medical decisions. The vast majority reported that they had someone to help talk with the doctor about their medical care (85 %) and communicate with hospital staff (81 %). For approximately two-thirds, the caregiver was an adult child/grandchild. Most (89 %) said someone would be helping them at home after discharge, this was most often an adult child/grandchild (42 %) or a spouse/partner (25 %). We interviewed caregivers for 160 of the patients (12 patients reported having no caregiver present at the time of discharge, 11 died before follow-up and no caregiver was interviewed, we were unable to contact 21 caregivers, and 10 caregivers refused participation). Among the 160 caregivers, 66 % were women and mean age was 47. Most (81 %) were born outside the U.S., only 41 % reported English as their preferred language for healthcare, 24 % had not completed high school, and 30 % had inadequate health literacy based on a 3-item scale. A third reported their own health to be less than ‘good’, and a quarter reported financial hardships in the past year. The majority (69 %) were the patient's adult child/grandchild, while 21 % were spouses/partners, 9 % other relatives and 1 % friends. While 41 % lived in the same home as the patient, a third lived in another nearby city. Three-quarters reported seeing the patient every day since discharge. Although 38 % reported feeling no stress in the past week about caring for the patient, 18 % reported feeling stress all or most of the time, 22 % some and 22 % a little of the time.

CONCLUSIONS: Family caregivers perform multiple vital roles for LEP patients in the transition from hospital to home, including assisting with communication and decision-making. However, many of these caregivers are themselves non-English speakers with inadequate health literacy, and a substantial proportion also report financial and caregiver stress. Future investigations should identify the unique communication and support needs of caregivers of LEP patients and examine the relationship between providing support and health outcomes for both LEP patients and their caregivers.

FEASIBILITY AND EVALUATION OF ON-SITE DIABETES SCREENING, MONITORING, SELF-MANAGEMENT SUPPORT, AND FOOD FROM LOCAL FOOD PANTRIES Hilary Seligman^{1,3}; Courtney Lyles^{1,3}; Kim Prendergast²; Michelle Berger-Marshall²; Elaine Waxman². ¹University of California, San Francisco, San Francisco, CA; ²Feeding America, Chicago, IL; ³Center for Vulnerable Populations, San Francisco, CA. (Tracking ID #2196377)

BACKGROUND: Health clinics have a challenging time reaching many of the most marginalized patients with diabetes, particularly for the frequent visits necessary to provide self-management support. Food pantries are easily accessible, engage the same clients repeatedly over time, reach a highly vulnerable segment of the population, and offer food. We explored the feasibility and effectiveness of providing diabetes self-management support and monitoring in the food pantry setting.

METHODS: We screened a convenience sample of Spanish- and English-speaking food pantry clients affiliated with three food bank networks in California, Texas, and Ohio. Clients with a new or confirmed diagnosis of diabetes (using point-of-care HbA1c testing at the food pantry) were invited to participate in an on-site diabetes intervention that varied across sites but included, at a minimum, bi-monthly boxes of diabetes-appropriate foods, self-management education, on-site monitoring of HbA1c, and referral to a primary care home (if none existed). We conducted surveys at baseline and 4-month follow up and examined pre-post changes in HbA1c and diabetes self-management support using paired t-tests and McNemar's tests.

RESULTS: We identified 768 participants with diabetes, 89 % of whom completed pre-post evaluation surveys (mean age 57 years; 74 % female; 53 % Latino; 62 % with high school degree or less; 39 % low food secure and 44 % very low food secure). Mean HbA1c was 8.1 % at baseline and fell to 7.9 % at follow up ($p < 0.01$, with reductions at the three sites of 0.14, 0.19, and 0.39 %). Reports of severe hypoglycemic events fell from 15 to 11 % ($p = 0.05$). We also observed statistically significant improvements in fruit and vegetable intake, medication adherence, self-efficacy, diabetes distress, depressive symptoms, and medication affordability. Participant satisfaction was high.

CONCLUSIONS: It is feasible to use point-of-care HbA1c testing in the food pantry setting to screen clients for diabetes/pre-diabetes and monitor glycemic control of clients with known diabetes. This intervention appeared to significantly and positively impact HbA1c and diabetes self-management. Although food pantries are a non-traditional setting for addressing diabetes, this pre-post data gives evidence that, at a minimum, such translation of self-management support into community-based settings without robust health expertise may be a promising model for future health promotion.

Pre-Post Changes in Outcomes

	Pre-Intervention	Post-Intervention	p-value
HbA1c, mean	8.1 %	7.9 %	<0.01
HbA1c >9 %, %	28 %	25 %	0.09
Severe hypoglycemic events, %	15 %	11 %	0.05
Fruit and vegetable intake, mean servings/day	2.8	3.1	<0.01
Medication non-adherence, mean (0-4)	1.2	1.1	<0.01
Self-efficacy, mean (1-10)	6.8	7.3	<0.01
Diabetes distress, mean (1-6)	3.1	2.7	<0.01
Food vs. medicine/ supplies trade-offs, %	47 %	36 %	<0.01

FEEDBACK AS A TOOL FOR PROMOTING HIGH QUALITY DOCUMENTATION AMONG INTERNAL MEDICINE RESIDENTS Amalia Wegner¹; Lorna Campbell¹; Yushu Shi³; Kathryn Fletcher². ¹MCW, Milwaukee, WI; ²Milwaukee VAMC/Medical College of Wisconsin, Milwaukee, WI; ³PCOR, Milwaukee, WI. (Tracking ID #2194883)

BACKGROUND: Inpatient progress notes are a key component of care for hospitalized patients. However, notes written by residents are far removed from this ideal, with most notes being too long while still missing key pieces of information (e.g. accurate plans). This issue spans residency programs throughout the country; as a result, the Internal Medicine Resident Review Committee (under the ACGME) instituted Milestone 22 to focus on competence of written documentation. Our study aimed to improve the overall quality of inpatient progress notes using an audit and feedback intervention.

METHODS: Our study design is a prospective, pre-post intervention at a large teaching hospital. Between September 2014-December 2014, we assessed the quality of inpatient notes written by residents on the General Internal Medicine ward teams. We assessed quality by using the PDQI-9, a validated tool that allows a reviewer to score 9 attributes on a 5-point Likert-type scale: up-to-date, accurate, thorough, useful, organized, comprehensible, succinct, synthesized, and internally consistent. We scored one note per resident during the second week of the month (pre-intervention), followed by feedback to the resident which was specific to that scored note. We then scored another note in the third week of the same month (post-intervention) to assess the impact of the feedback. We collected additional data for each reviewed note: year of training of the writer, training program of the writer (e.g. categorical medicine versus preliminary), if this was the writer's first inpatient medicine ward month, team census, patient hospital day, number of problems on the problem list, patient age and sex. We used paired t-tests for univariate analysis and a mixed model regression for the multivariable analysis.

RESULTS: We reviewed 94 notes, with 61 % of notes written by PGY 1's and 61 % notes were from the categorical medicine program. The average team census was 11 patients. Mean patient age was 61 years old. Patient had an average of 7.3 problems on the problem list. All attributes improved from week 2 (pre-intervention) to week 3 (post-intervention) but the following attributes significantly improved: total score, synthesized, succinct, and thorough (table). In multivariable analysis, PGY 3's had significantly higher total PDQI-9 scores than PGY 1's. There were no other significant predictors of PDQI-9 score.

CONCLUSIONS: Many medical educators believe that progress notes provide an opportunity for residents to actively synthesize patient issues and demonstrate knowledge. Of course, progress notes are also an extremely important communication tool. Therefore, high quality notes are of importance for education and patient care. We have demonstrated that a simple audit and feedback intervention can improve the overall quality of inpatient progress notes, with the most significant improvement demonstrated in the attributes of synthesized, succinct, and thorough. Limitations of this study include that sustainability of these results has not yet been assessed and that the intervention requires faculty time and effort. Other programs may benefit from introducing a similar intervention.

Significantly Improved Progress Notes Attributes

Attributes	Pre-Intervention (Mean, SD)	Post-Intervention (Mean, SD)	Change in Mean (Post-Pre)	P-value
Total score (9–45)	34.98 (5.42)	36.95 (5.28)	1.979	0.0022
Thorough (1–5, 5=Extremely)	3.63 (0.95)	3.94 (0.90)	0.306	0.038
Succinct (1–5, 5=Extremely)	3.75 (0.93)	4.24 (0.69)	0.490	0.0005
Synthesized (1–5, 5=Extremely)	3.42 (1.02)	3.78 (1.10)	0.347	0.0136

FEEDBACK TO ACHIEVE SAFE SIGN-OUT TECHNIQUE (FASST)

Jessica Kuester^{1, 3}; Matthew Doers¹; Tessa Damm¹; Erica M. Wozniak¹; Kinsey A. Nattinger¹; Kathlyn Fletcher². ¹Medical College of Wisconsin, Milwaukee, WI; ²Milwaukee VAMC/Medical College of Wisconsin, Milwaukee, WI; ³Clement J Zablocki VA Medical Center, Milwaukee, WI. (Tracking ID #2197422)

BACKGROUND: Hand-offs occur when patient information and responsibility for care are passed from one clinician to another. Due to transition to a hospitalist-based system of inpatient care and recent reductions in house staff work hours, there has been an resultant increase in the number of hand-offs that most inpatients experience. Patient hand-offs typically include a written and verbal component. Based on a previous study, we identified suboptimal written sign-out documents as a potential patient safety problem. We aimed to improve the quality of the written sign-out documents using an audit and feedback intervention.

METHODS: This was a prospective, pre-post quality improvement study. The setting was a large academic hospital. Participants were recruited from the six general internal medicine teaching service teams. Data was collected by downloading sign-out documents of the general medicine ward teams from the electronic medical record for three consecutive weeks during the months of September, October, and November 2013. A previously developed 11-item checklist was used to evaluate the quality of each patient entry on the sign-out document. The first week sign-outs provided the baseline data. During the second week, teams were provided written and verbal feedback on their sign-out document. The third week sign-out documents provided outcome data. Sign-outs were also downloaded and analyzed for one week during December 2013 and June 2014 to evaluate for duration of intervention effect. Non-routine events (NREs) were identified by facilitated survey of the cross-covering house staff and utilized as a patient safety marker. Pre- and post-intervention sign-out score data for each month were pooled and compared by checklist item using a chi-square test, or Fisher's exact test where sample sizes were small. A logistic regression was used to evaluate the pre-post effect of intervention on the presence or absence of an NRE, controlling for sign-out score and the number of patients on each sign-out. A kappa statistic was computed for each checklist item to assess inter-rater agreement between the investigators scoring sign-outs.

RESULTS: A checklist was utilized to score 2321 individual written sign-out entries (552 pre-intervention and 615 post-intervention) in order to evaluate the inclusion of 11 components essential to an effective sign-out. The direct feedback intervention method resulted in highly significant ($p \leq 0.01$) improvement in the percent of sign-outs documenting five of the checklist items (pre, post): mental status (67.0, 80.0 %), decisionality (51.1, 67.5 %), degree of sick (59.1, 68.5 %), absence of confusing or conflicting information (90.9, 95.3 %), and absence of vague language (61.2, 68.1 %). For most checklist items, improvements in sign-out quality were lost by December 2013, and by June 2014, some scores were actually lower than the pre-intervention values. No significant associations were found between occurrences of NREs and written sign-out quality, intervention period, or the number of patients on sign-outs. Nearly all kappa statistics comparing sign-out raters reflected very strong agreement on checklist items, validating the use of multiple raters to evaluate sign-out quality.

CONCLUSIONS: Timely, direct feedback on the written sign-out can improve the quality of the written component of patient hand-offs in the short term. More research is warranted to investigate how frequently such feedback is required to maintain sign-out quality and what factors may have contributed to the demonstrated "June effect." Improvement in the quality of written sign-outs was not found to be associated with an increase in patient safety, but sample size limitations for patient safety outcomes in the current study, as well as the complexity of the patient hand-off process as a whole, support the need for further investigation.

FLAGGING ELEVATED GLUCOSE VALUES IN THE ELECTRONIC MEDICAL RECORD: DOES IT IMPROVE RECOGNITION AND FOLLOWUP OF ABNORMAL VALUES? Zahra Merchant; Kazeen Abdullah; Riya Joshi; Deepa Bhat; Jason Fish; Ethan Halm; Michael E. Bowen. UT Southwestern Medical Center, Dallas, TX. (Tracking ID #2198672)

BACKGROUND: Laboratory values are commonly flagged as abnormal in the electronic medical record (EMR) when they are outside of designated reference ranges. However, the impact of this approach on provider practice and results management is not well understood. Using elevated random blood glucose (RBG) values in routine clinical practice in an academic medical center, we examined follow-up rates of elevated RBG values and hypothesized that providers were more likely to follow-up results that were flagged as abnormal.

METHODS: We conducted a retrospective chart review of non-pregnant adults ≥ 18 years without diagnosed DM who had at least one ambulatory visit between 2011 and 2013. Eligible patients had at least one ambulatory RBG ≥ 125 mg/dL and no resulted hemoglobin A1C test in the 2 years before the RBG value. The RBG ≥ 125 mg/dL threshold was selected based on evidence that RBG values over this threshold can identify DM. Of 367 patients meeting this criteria, we randomly selected 150 charts for in-depth review. Two trained abstractors reviewed half of the charts each using a structured data collection form based on a conceptual model of ambulatory clinical errors. A 10 % random sample ($n=15$) of charts was reviewed by both abstractors and a Kappa statistic was calculated. All data were abstracted from our comprehensive EMR (Epic), which contains data across all care settings. The EMR automatically flags RBG values ≥ 140 mg/dL as abnormal for being outside of the reference range. Lab results are automatically released via the MyChart patient portal to patients 4 days after completion in accordance with the Meaningful Use guidelines. The primary outcome was successful follow-up of RBG values ≥ 140 mg/dL. Success was defined as 1) ordering an A1C within 30 days; 2) a resulted A1C within 12 months; 3) comment on the elevated value by the ordering provider within 30 days; or 4) communication of test results to the patient within 30 days. The primary predictor was the elevated RBG value, divided into 2 groups: < 140 mg/dL (reference group) and ≥ 140 mg/dL. Non-parametric, descriptive analyses were conducted. Multivariate, exact logistic regression was used to evaluate the association between flagged results and successful follow-up, adjusting for the total number of clinic visits and a completed follow-up encounter with the ordering provider within the 12 months after the elevated RBG.

RESULTS: Of 150 charts reviewed, we excluded 53 that did not meet study criteria or had cancer diagnosed within 3 years before the elevated RBG. A total of 97 charts were included in this analysis. The interrater reliability was Kappa=0.73 ($P < 0.002$). The median age was 68.4 years. (53.6–75.4), 29 % had a family history of DM, and 58 % had hypertension. Only 3 % had a diagnosis of pre-DM. Eighty-eight percent had a primary care provider at the academic medical center. In the 12 months following the elevated RBG, the median number of visits was 7 (IQR: 4–11), and 83 % of patients completed a visit with the ordering provider within 12 months after the RBG value was resulted. All results were reviewed by ordering providers a median of 4 (1–17) days after they were resulted. Only about one-third (36 %) of elevated RBGs were followed-up. Twenty percent of patients had more than one elevated RBG. No significant differences in age, sex, race, BMI, or type of ordering provider were observed between the reference group and the ≥ 140 mg/dL group. In unadjusted analysis, follow-up success of the ≥ 140 mg/dL group was not significantly different than that of the reference group (OR=2.2, CI=0.82–5.8, $P=0.13$). In adjusted analyses, those with RBG ≥ 140 mg/dL were more not more likely (OR=2.6, CI=0.91–7.4, $P=0.08$) to have the value followed-up; however, there was a trend towards statistical significance. Although 75 % of patients used the electronic patient portal, automated flagging of RBG values ≥ 140 mg/dL for providers and the release of these flagged, abnormal values to patients via the electronic patient portal was not associated with increased follow-up.

CONCLUSIONS: Overall, follow-up of elevated glucose values is low regardless of whether values are flagged as abnormal or not. In all cases, providers viewed the elevated labs electronically. However, flagging elevated glucose results does not lead to increased follow-up action, and labs were automatically released to patients even if abnormal. Additional studies are needed to understand the results management practices of providers, and improved systems-based interventions are needed to facilitate follow-up of abnormal glucose values.

FOLLOW-UP OF ABNORMAL CHEST CT IN SMOKERS AT HIGH RISK FOR DEVELOPING LUNG CANCER Sanja Percac-Lima²; Jeffrey M. Ashburner²; Dorothy Rimmelin¹; Steven J. Atlas². ¹Harvard Medical School, Boston, MA; ²Massachusetts General Hospital, Boston, MA. (Tracking ID #2198516)

BACKGROUND: Lung cancer is the leading cause of cancer death in the US. Although recommended, lung cancer screening is still not covered by most insurers. However many

high-risk smokers receive chest CTs as part of symptom evaluation. The objective of this study was to assess indication for, and rates of abnormal chest CTs and follow-up of abnormal findings in smokers at high risk for developing lung cancer.

METHODS: In this retrospective study, we reviewed electronic medical records of patients at increased risk for lung cancer (current smokers, aged 55–79 years) who received a chest CT during 2012 in a large, diverse academic primary care network. Data collected included: the order site, indication, results of the CT scan, and the recommendation for follow-up. We excluded patients who had a prior diagnosis of lung cancer, died, or if the end of data collection (June 1, 2014) was prior to the date of recommended follow-up. Our primary outcome was the proportion of patients with timely follow-up of their initial abnormal CT, defined as receiving the recommended test within 30 days of the time period recommended by radiologist. In secondary analyses we compared the follow-up by indication, results, patient characteristics (language, race, insurance), primary care practice type (community health center or not), recommended time to follow up and CT order site and adjusted for age, gender, number of clinic visits over the prior 3-years, and outpatient Charlson comorbidity score in logistic regression models.

RESULTS: Of 3256 smokers at high risk for developing lung cancer, 446 (14 %) had a chest CT during 2012. We excluded 70 patients because they died, were already diagnosed with lung cancer, had their CT scan done elsewhere, or left the primary care network. Among the remaining 376 patients, 90 % (337) had an abnormality noted on chest CT and 55 % (184) had a specific recommendation for follow-up. The recommended follow-up time ranged from 30–365 days with a mean of 177 days (median: 90 days). Among patients with a follow-up recommendation, the mean age was 65.6 years, 55 % were female, 94 % spoke English, 90 % were white, and 16 % had Medicaid or lacked insurance. Fifty-seven percent (105 of 184) of patients received timely follow-up. Patients were more likely to have timely follow-up if the indication for CT was pulmonary disease (28 % of patients with timely follow-up vs. 9 % among those without timely follow-up, $p=0.002$). Patients receiving care in community health centers were more likely than those from non-community health centers to have a timely recommended follow-up (65.6 % vs. 46.0 %, adjusted p -value=0.04). Twenty (11 %) patients never received any follow-up, most commonly due to the presence of serious co-morbid conditions. Of 184 patients with an abnormality and a specific recommendation, 24 had a ‘suspicious malignancy’ CT result and of these all had a follow-up, however in 3 (5 %) it was not within the recommended time. There were no differences in follow-up by order site, insurance, race, language or the time frame recommended for follow up.

CONCLUSIONS: In a time period before screening was recommended for lung cancer using low-dose CT scans, we observed that patients at high risk of developing lung cancer

often did not receive the follow-up of an abnormal chest CT findings within the recommended time frame. Lung cancer screening is a complex process and will often require follow-up testing. In addition to identifying those individuals who are most likely to benefit from lung cancer screening, these results highlight the need for developing systems to identify, track, and support patients to obtain recommended follow-up to ensure that the benefits of screening identified in clinical trials are translated to usual clinical practice.

FOOD ENVIRONMENT, DIET BEHAVIOR AND WEIGHT GAIN IN A MULTI-ETHNIC URBAN COHORT Pooja A. Lagisetty¹; Rebecca Piccolo³; May Yang³; Lisa D. Marceau³; Richard W. Grant¹; John B. McKinlay³; James B. Meigs². ¹Kaiser Permanente Northern California, Oakland, CA; ²Massachusetts General Hospital, Boston, MA; ³NERI, Watertown, MA; ⁴University of Michigan, Ann Arbor, MI. (Tracking ID #2198103)

BACKGROUND: The relationship between lack of neighborhood healthy food access and increased obesity has led to a sharp increase in policy initiatives focused on improving local access to healthier food sources in poorer communities. We tested the hypothesis that geographic proximity to healthier food stores is associated with healthy diet behavior and a decrease in weight gain over time.

METHODS: Body weight and diet behavior were measured on 3136 participants in the Boston Area Community Health (BACH) Survey at baseline (2002–2005) and follow-up in (2010–2012). Boston city food environment was mapped using ArcGIS software. Food access with relationship to subjects’ home address was defined as low (>0.5mi) and high access (<0.25mi). Diet behavior was measured with a Block food frequency questionnaire and assessed with a diet score derived from AHA and ADA guidelines. Linear regression models predicted percent weight change over time associated with proximity to food environment, access and dietary behavior.

RESULTS: The mean weight was 82.8 kg at baseline and the mean percentage weight change from 2002 to 2010 was +2.44 % (SE=0.36 %). There was no statistically significant ($P<0.05$) relationship of low or high healthy eating scores or percent weight gain over a mean 7.3 years with low or high low access to fast food stores, convenience stores, or grocery stores and supermarkets. Accounting for car ownership did not alter the results.

CONCLUSIONS: Efforts to reduce obesity in poorer communities may need to focus on other aspects of healthy eating in addition to food store access.

Beta coefficient and 95 % confidence intervals for continuous measures of percent weight change for each level of access to food environment

FOOD INSECURITY IS ASSOCIATED WITH PERIPHERAL ARTERIAL DISEASE IN OLDER ADULT POPULATIONS Michelle L. Redmond¹; Fanglong Dong¹; Jeannine Goetz, PhD²; Lisette T. Jacobson¹; Tracie C. Collins¹. ¹KU School of Medicine - Wichita, Wichita, KS; ²University of Kansas Medical Center, Kansas City, KS. (Tracking ID #2197858)

BACKGROUND: Food insecurity, defined as the limited or uncertain availability of nutritious and safe foods, is linked to poor nutrition and diet-sensitive chronic diseases. Food insecure individuals often have dietary patterns that include less nutrient-rich foods, increased consumption of saturated fats and meat products which are potential risk factors for the progression of peripheral arterial disease (PAD). Food insecurity among older

adults with diet-sensitive chronic disease impacts health negatively because lack of availability to nutritious and safe foods can exacerbate health conditions such as diabetes and hypertension, which are risk factors for PAD. Because PAD prevalence increases with age, this study explored whether a relationship exists between food insecurity and PAD among a national sample of older adults.

METHODS: The authors conducted a cross-sectional data analysis using data from the 1999–2004 National Health and Nutrition Examination Survey. All participants with PAD were included (ankle brachial index [ABI] score ≤ 0.90) as well as those with borderline disease (ABI 0.91 to 0.99). Participants were excluded from the analysis if they: were less than 60 years of age, did not report both the left and right ABI score, did not report family poverty income ratio, and did not complete the food security survey module. The US

Household Food Security Survey Module, an 18-item validated instrument, was used to measure household food security level during the previous 12-month period. Similar to other studies on food insecurity, our study utilized the first 10-items, which addressed adult food security. Bivariate analyses were conducted using the Rao-Scott Chi-square test to examine associations between PAD and sociodemographic variables. Multivariable survey logistic regression was employed to assess the effect of food insecurity on the presence of PAD, with adjustment for respondent's sociodemographic characteristics. Survey weights were utilized to account for survey non-response, over-sampling, post-stratification, and sampling error.

RESULTS: A total of 2017 older adult respondents from 1999–2004 NHANES were included in the final analysis. A majority of respondents (84.8 %) were food secure, thus experiencing no problems or anxiety with accessing adequate and safe foods. More than half (60.7 %) of respondents were female, 75 % were non-Hispanic white, 14.4 % were current smokers, 55.1 % had hypertension, 17.5 % had diabetes mellitus, 44.6 % had high cholesterol, 30.3 % had PAD and the average age was 71.9 years. Our study found food insecurity was associated with PAD among older adults (adjusted odds ratio, 1.97, 95 % CI=1.11–2.03). Additionally, adults ≥ 70 years of age with PAD (ABI ≤ 0.90) or borderline disease (ABI 0.91 to 0.99), had a higher percentage of food insecurity than those with no PAD ($p=0.027$). The fully adjusted model suggests that respondents were more likely to develop PAD if they were non-Hispanic black (OR=1.5, 95 % CI=1.11–2.03), a current smoker (OR=2.81 95 %, CI 2.01–3.93), a previous smoker (OR=1.60, 95 % CI=1.23–2.07), had hypertension (OR=1.73, 95 % CI=1.34–2.22), had diabetes mellitus (OR=1.73, 95 % CI=1.31–2.28), and/or high cholesterol (OR=1.22, 95 % CI=1.00–1.49).

CONCLUSIONS: Older adults with definite as well as borderline PAD experience food insecurity. While the association between nutrition and PAD is not well-defined, there is some literature to suggest an association between food insecurity and diet-sensitive chronic diseases (diabetes and hypertension) which are risk factors for PAD. Future work should address the role of addressing food insecurity among older adults to reduce the risk for and/or progression of PAD. Supported by Grant No.3R01HL098909-04S1

FOOD INSECURITY, FOOD DESERTS, AND GLYCEMIC CONTROL: A MULTI-LEVEL LONGITUDINAL ANALYSIS Seth A. Berkowitz¹; Steven J. Atlas²; Lily Barnard³; Carine Y. Traore²; James B. Meigs²; Deborah J. Wexler². ¹MGH, Boston, MA; ²Massachusetts General Hospital, Boston, MA; ³Tufts University, Medford, MA. (Tracking ID #2191915)

BACKGROUND: Food insecurity, defined as limited access to food owing to cost, and residence in a food 'desert', an area with limited options to purchase fresh foods, have both been associated with adverse diabetes outcomes. Recently, there have been significant investments in interventions that expand neighborhood food access, while nutritional assistance programs have seen spending cuts. To determine possible implications of this for diabetes management, we sought to determine the variation in glycemic control explained by both patient-level and area-level factors.

METHODS: We conducted a longitudinal cohort study from June 1, 2013 to December 1, 2014. A random sample of diabetes patients who were empanelled in the same primary care network completed the 6-item Food Security Survey Module in English or Spanish. Patients with ≥ 2 affirmative responses were considered to have food insecurity. We analyzed food insecurity as a patient level variable, as is common in this type of research, although it affects the entire household. We abstracted sociodemographic and clinical information from the electronic health record. Patient addresses were geocoded to census tracts using the U.S. Census' MAF/TIGER database. We used the 2014 U.S. Department of Agriculture's Food Access Research Atlas to determine if a patient's residence was in a food desert census tract. Our primary outcome was hemoglobin A1c (HbA1c). We performed descriptive statistics using chi-squared and t-tests. We then assessed the association between food insecurity, residence in a food desert, and baseline glycemic control using hierarchical linear models (SAS PROC MIXED) with census tract-level random effects. We calculated intraclass correlation coefficients (ICC) to partition the variation in glycemic control between patient-level and census tract-level factors. Finally, we used longitudinal hierarchical models, with patient-level and census tract-level random effects, to determine the association between food insecurity, residence in a food desert, and subsequent glycemic control.

RESULTS: We enrolled 411 patients: mean age was 62 (SD: 12) years, 47 % were women, 79 % were non-Hispanic white, and 14 % had not graduated high school. Twenty percent reported food insecurity, and 29 % lived in a food desert. Patients who reported food insecurity were more likely to live in a food desert than those who did not (36 % vs. 27 %, $p=.04$). At baseline, food insecurity was associated with greater HbA1c (7.8 % vs. 7.2 %, $p=.02$); living in a food desert was not (7.3 % vs. 7.2 %, $p=.69$). Based on the ICC, census tract-level variables, such as residence in a food desert, explained only 4 % of the variation in HbA1c. In hierarchical models adjusted for age, gender, race/ethnicity,

education, insurance, Charlson comorbidity score, duration of diabetes, health literacy, nativity, survey language, diabetes medications, and residence in a food desert, food insecurity remained associated with greater HbA1c (0.5 % greater, 95 % CI 0.1 to 0.9 %). Residence in a food desert was not associated with greater HbA1c (0.0 % difference, 95 % CI -0.4 to 0.3 %). In longitudinal analyses, based on the ICC, census tract characteristics explained only 6 % of the variation in HbA1c over time, while patient-level characteristics explained 74 %. In longitudinal hierarchical models adjusted for the same covariates as the baseline models, food insecurity was associated with greater increase in HbA1c over time (0.24 %/year greater increase in those with food insecurity, 95%CI 0.05 to 0.48 %, $p=.02$), while residence in a food desert was not (-0.12 %/year change in HbA1c, 95%CI -0.24 to 0.12 %).

CONCLUSIONS: Variation in glycemic control was largely explained by patient-level factors. While food insecurity was significantly associated with both greater HbA1c at baseline and increase in HbA1c over time, residence in a food desert was not. Interventions that seek to increase neighborhood food access may have limited impact on glycemic control if they are not coupled with efforts to reduce food insecurity.

FREQUENCY AND CAUSES OF DELAYS IN HOSPITAL DISCHARGE FROM A SAFETY-NET HOSPITAL AFTER MASSACHUSETTS' NEAR UNIVERSAL COVERAGE REFORM Judy Y. Kwok; Paula Lueras; Dylan Bothamley; Jennifer Huang; Carolyn Koulouris; Amy Pasternack; Christina Phillips; Rebecca Rogers; Neil N. Shah; Gaurab Basu; Danny McCormick. Harvard Medical School / Cambridge Health Alliance, Cambridge, MA. (Tracking ID #2171529)

BACKGROUND: Patients often stay in acute care hospitals longer than medically necessary. Non-medically justified days of hospitalization, often un-reimbursed, can create economic pressure on financially struggling hospitals such as safety net hospitals. These days can also decrease bed availability for the acutely ill and increase the risk of iatrogenic illness. Prior research has shown that a common cause of discharge delay is the lack of insurance, particularly among patients requiring post-discharge home- or facility-based care (HFC) such as a skilled nursing facility (SNF), rehabilitation hospital, psychiatric facility, or home care services. However, anecdotal evidence has suggested that even patients having insurance may face discharge delays if they require HFC that is not fully covered or they have complex clinical or social challenges (opiate use, homelessness, behavioral problems, e.g.) less desirable to non-acute care facilities. Massachusetts' 2006 health reform law provided "near-universal" coverage to state residents. No prior studies have examined the frequency or cause of delays in hospital discharge at safety net hospitals, particularly in the setting of "near universal" coverage that could diminish such delays.

METHODS: Data were prospectively collected on 850 consecutive hospital discharges (accounting for 2309 hospital days) from the adult general medicine service at the second largest acute care safety-net hospital in Massachusetts during the period of October 2013 to February 2014. For each day of hospitalization, a research team member recorded if the day was medically necessary, as determined by the treating physician during daily morning multidisciplinary rounds that employed a robust discharge planning process involving social workers and case managers. Patients designated as medically cleared for discharge but who were not discharged on that day were considered to have a non-medical delay; for each such day, the consensus reason for delay articulated by team members in multidisciplinary rounds was recorded. Demographic information including insurance type was extracted from the medical record. We calculated the frequency of delays in discharge, tabulated the reasons for delays, and examined the insurance status of patients requiring post-discharge HFC.

RESULTS: Of 850 patient discharges, 487 were age < 65 and 363 were 65 or older. The majority of patients were insured (96.2 %) with most having Medicare (46.3 %) or Medicaid (29.3 %); only 12.1 % of patients were privately insured. Most patients were discharged to home (65.3 %) but discharge to settings for HFC was common (29.6 %). Of all study patients, 15.1 % experienced a delay in discharge, with delay days accounting for 11.7 % of all hospital days. Among patients discharged to HCF ($n=252$), 30.1 % experienced a delay, nearly all of whom had Medicare or Medicaid (94.1 %). Among patients age < 65 , most common reasons for delayed discharge were unavailability of inpatient psychiatric beds (29.8 %), unavailability of SNF beds (26.6 %), or an unsafe home environment (8.9 %). Among patients age ≥ 65 , the most common reasons for delayed discharge were unavailability of SNF beds (42.1 %), Medicare's 3-day stay requirement (10.3 %), and lack of guardianship determination (10.3 %). Few, if any, reasons were under the control of the hospital; most were related to external health care system factors and, to a lesser extent, patient factors.

CONCLUSIONS: In this acute care safety-net hospital, many patients experience non-medically justifiable delays in hospital discharge, with a significant proportion of all hospital days being attributable to such delays. In the post-reform era, lack of health

insurance played little role in delays; the most commonly identified reasons for delays were the unavailability of post-discharge care facilities even though the vast majority had Medicare or Medicaid. Further research should explore barriers to hospital discharge of publicly insured patients to post-acute care facilities and to home with services.

FREQUENCY OF FOLLOW UP IMAGING RECOMMENDED BY RADIOLOGISTS AND THE IMPACT ON CLINICAL TREATMENT PLANS Owen W. Hanley¹; Tiara Sanborn¹; Amir Lotfi²; Poornima Manikantan¹; Janice Fitzgerald¹; Linda J. Canty³; Mihaela S. Stefan¹. ¹Baystate Medical Center, Springfield, MA; ²Baystate Medical center, Springfield, MA; ³Tufts University School of Medicine / Baystate Medical Center, Springfield, MA. (Tracking ID #2198910)

BACKGROUND: The increase in overall healthcare expenditure in the U.S. has recently been addressed in the *Choosing Wisely* campaign amongst a variety of subspecialties in an effort to decrease overall healthcare costs and minimize patient morbidity, while maintaining high quality care. There has been little research on the prevalence of radiology follow-up studies recommended by radiologists and the impact these have on clinical decision making and patient outcomes. Objective: To assess the rate and impact of follow up imaging on final diagnosis and treatment plan.

METHODS: We performed a retrospective study of all abdominal, pelvic and chest CT scans performed in patients >18 years of age between September 1, 2010 to December 31, 2010 at one academic tertiary care hospital with 750 bed capacity. The dictated radiology interpretation from an index CT scan was appraised by 3 clinical investigators. We recorded radiological findings pertaining to the ordering physicians' clinical question, other incidental radiologic findings as well as recommendation for further imaging or procedure. If further imaging was recommended, the electronic medical record was reviewed to assess if the additional imaging was performed during that hospital course. If further imaging was pursued, we reviewed clinicians' notes to assess the impact on diagnosis, treatment or clinical decision making. A standardized assessment form was piloted for approximately 10 % of the total CT scans reviewed until there was a perfect agreement between the investigators. Statistical methodology included a description of the findings.

RESULTS: Of the 441 CT scans reviewed, 58 % were of the abdomen/pelvis and 42 % of the chest. Potentially relevant findings were reported by radiologists in 79 % of the scans. Of the scans surveyed, a follow up radiological image or procedure was recommended in 15 % of cases. Of the 67 cases where follow up imaging was recommended, 50 % were for incidental findings rather than the primary indication for the scan. Follow up was performed in 24 (36 %). Of these scans: – 25.0 % confirmed the initial diagnosis and did not change the treatment plan – 20.8 % confirmed a questionable diagnosis and did change the treatment plan – 12.5 % identified alternative pathology that altered the treatment plan – 41.7 % imaging was both therapeutic and diagnostic. There were 43 scans (64 %) in which the recommended follow up imaging was not performed: – 13.6 % were felt to not be clinically relevant by primary clinical team – 34.1 % were deferred for outpatient follow up – 13.6 % an alternate clinical decision or intervention was pursued – 40.9 % there was insufficient information about why the recommended scans were not performed.

CONCLUSIONS: Compared to findings in prior studies where radiologists recommended further imaging in approximately one third of radiology reports, the radiologists in our institution seemed to recommend further imaging less frequently. We found that the recommended imaging was only performed in one third of the cases, though when it was performed it changed management or resulted in a therapeutic procedure in three fourths of cases. The rate of follow-up scans performed in our study does not account for those performed later by outpatient clinicians, therefore is likely an underestimate.

FREQUENT USERS OF THE EMERGENCY DEPARTMENT IN A UNIVERSAL HEALTH COVERAGE SYSTEM: A RANDOMIZED CONTROLLED TRIAL OF A CASE-MANAGEMENT INTERVENTION Patrick Bodenmann^{1, 2}; Dr. Venetia-Sofia Velonaki^{3, 4}; Stéphanie Baggio⁵; Dr. Katia Iglesias^{6, 7}; Dr. Karine Moschetti^{8, 9}; Ornella Ruggeri³; Dr. Olivier Hugli¹⁰; Prof. Bernard Burnand⁷; Prof. Jean-Blaise Wasserfallen^{8, 9}; Francis Vu¹; Prof. Jean-Bernard Daeppen¹¹. ¹Vulnerable Population Center, Lausanne, Switzerland; ²University of Lausanne, Lausanne, Switzerland; ³Department of Community Medicine and Public Health, Lausanne, Switzerland; ⁴Lausanne University Hospital, Lausanne, Switzerland; ⁵Life Course and Social Inequality Research Center, Faculty of Social and political Sciences, University of Lausanne, Lausanne, Switzerland; ⁶Center for the Understanding of Social processes, University of Neuchâtel, Neuchâtel, Switzerland; ⁷Institute of Social and Preventive Medicine, Lausanne University Hospital, Lausanne, Switzerland; ⁸Health Technology Assessment Unit, University of Lausanne, Lausanne, Switzerland; ⁹Institute of Health Economics and Management, University of Lausanne, Lausanne, Switzerland; ¹⁰Emergency Department,

Lausanne University Hospital, Lausanne, Switzerland; ¹¹Alcohol Treatment Center, Lausanne University Hospital, Lausanne, Switzerland. (Tracking ID #2197285)

BACKGROUND: Frequent emergency department users in developed countries represent a relatively small group of patients (4 to 8 %) but account for a disproportionately high number of all emergency department attendances (21 to 28 %), contributing to overcrowding, generating high health-care costs, and calling into question the appropriateness of their visits. Few interventions aimed at improving the management of such users have been proved effective in reducing emergency department use. Our study tested the hypothesis that an interdisciplinary case-management intervention—compared to standard emergency care—reduces emergency department attendance through a better orientation in the Swiss universal health coverage system.

METHODS: In this randomized controlled trial, adult frequent emergency department users (5 or more visits during the previous 12 months) who visited the emergency department of the University Hospital of Lausanne, Switzerland between May 2012 and July 2013 were allocated either to the case-management intervention ($N=125$) or to standard emergency care ($N=125$) and were monitored for 12 months (at 2, 5.5, 9, and 12 months). Randomization was computer generated and concealed, and patients and the research staff were blinded to the patient's allocation, while the case-managers were obviously not blinded. Participants in the intervention group, additional to standard emergency care, received a case management intervention including: – counseling, based on principles of motivational interviewing, focused on social determinants of health and the use of medical care services; – assistance in obtaining income entitlements, better health insurance coverage, stable housing, and schooling for children, and in preventing potential violence in the home; – referral to mental health services, substance abuse services, and primary care providers. This intervention was carried out by an interdisciplinary (four nurse practitioners and a general practitioner/supervisor), mobile team at baseline, and at 1, 3, and 5 months later, in the ambulatory care setting, the hospital, or at patients' place of residence. In between the consultations, the patients had the opportunity to contact—at any moment—the case management team. Participants in the control group received standard emergency care. A generalized, linear, mixed-effects model for count data (Poisson distribution) was applied to compare the participants' number of visits to the emergency department during the 12 months (Period 1) preceding recruitment to the number of visits during the 12 months of monitoring (Period 2). The participants' groups (intervention or control), the period (Periods 1 or 2), and the interaction of these two variables were used as independent variables; age, gender, education level, fluency in French, income, social determinants, somatic and mental indicators, and risk behaviors were used as controlled variables. Results are reported according to an intention-to-treat analysis.

RESULTS: At 12 months of follow-up, data were completed for 115 participants in the intervention group and 115 in the control group ($N=230$, deaths: 10 in each group). The mean age of participants was 45.1 (± 17.9), 50 % were Swiss, and the majority were male (57 %), French speaking (80 %), and with low educational level (70 %); 43 % were dependent on social welfare; the majority suffered from somatic (69 %) or mental (50 %) health issues; and 33 % presented risk behaviors (tobacco, alcohol, drugs, sexual risks, or violence). The number of emergency department visits was lower during Period 2 compared to Period 1 for both groups ($b=-0.56$, $p<0.001$) but the decrease was significantly more important for the intervention group ($b=-0.025$, $p=0.012$). Whether a participant was in the control or intervention group was not, itself, found to have an impact on the number of visits ($b=-0.02$, $p=0.821$), which means both groups were comparable with regards to the number of emergency department visits during the 12 months preceding recruitment (Period 1).

CONCLUSIONS: This study strengthens the evidence that a case-management intervention leads to a reduction in emergency department use by frequent emergency department users, through their improved orientation in a universal health coverage system. Because, as in other developed countries, total numbers of emergency department visits in Switzerland (around 1.6 million per year) have been steadily growing, our findings should have policy implications for the generalization of such teams on a larger scale nationally, and in other countries with universal health coverage, taking into account the impact on patients (in terms of trust, perceived discrimination, quality of life, and health indicators) and the financial resources required.

FRIEND OR FOE: FACULTY, RESIDENT AND PATIENT PERCEPTIONS OF IPAD USE IN THE INPATIENT SETTING Wei Wei Lee²; Lollita Alkureishi²; Valerie G. Press²; Micah Prochaska²; Paul Bergl¹; David Meltzer²; Vineet M. Arora². ¹Medical College of Wisconsin, Milwaukee, WI; ²University of Chicago, Chicago, IL. (Tracking ID #2196130)

BACKGROUND: Use of tablet computers in the hospital is becoming more common. Unfortunately, studies show interns spend much more time in front of a screen than in

direct patient care. Further, while iPad use in residency programs is increasing, it is unclear how physicians and patients perceive iPad use affecting doctor-patient communication.

METHODS: We surveyed internal medicine residents (IMR) and attendings (general internists and hospitalists) on perceptions of iPad use and the impact on patient-doctor communication at various conferences. Patient perceptions were assessed in an ongoing survey study of resource-allocation and quality of care among inpatients. Likert responses at the high end of the scale were grouped to dichotomize data (i.e. agree/strongly agree). Descriptive statistics were used to summarize the data and 2 sample tests of proportion were used to explore resident-faculty differences in perceptions.

RESULTS: Thirty-nine faculty [GIM: 30/32 (94 %); HM: 9/11 (82 %)] and 90 resident (90/101, 89 %) surveys were analyzed. Almost all faculty [95 % (36/38)] reported residents used iPads, but only 18 % (7/39) reported using iPads in the hospital themselves. Both faculty and residents agreed that resident iPad use improved patient care (87 % (33/38); 60 % (54/90) respectively) and efficiency (97 % (37/38); 86 % (77/90) respectively). Faculty were more likely to perceive that residents spend more time with this technology than with patients [76 % (29/38) vs. 29 % (26/90), $p < 0.001$]. While 40 % (36/90) of residents agreed that iPad use 'allows them to spend more time at the patient's bedside providing patient education', less than a third [27 % (24/90)] reported frequent (≥ 4 /month) use of iPads to 'educate patients about medical conditions.' About 1/3 [29 % (26/90)] of residents reported that iPad use negatively impacts their ability to communicate with patients. Few [39 % (35/90)] residents 'were confident in their ability to use the iPad in a patient centered manner.' Eighty-four patient surveys (94 %, 84/89) were analyzed. Only 1 patient (1 %, 1/84) agreed that 'doctors spent more time with computers or mobile devices than with me'. Only a quarter of patients (23 %, 19/84) agreed that their 'physicians used the computer or mobile devices to provide education.'

CONCLUSIONS: While both faculty and residents agreed that resident iPad use improves patient care and efficiency, faculty were more likely to perceive that iPads took residents away from the bedside. Interestingly, patients did not perceive that physicians spent more time with devices than with them. One-third of residents felt iPad use hampers their ability to communicate with patients and few were using the iPad to educate patients. Only a minority of residents were confident in their ability to use the iPad in a patient-centered manner. Our findings highlight the need to train providers to optimize use of iPads to engage patients at the bedside.

FROM PAST TO PRESENT: CONTINUITY OF CARE IN A RESIDENT CLINIC AFTER A 4+1 BLOCK SCHEDULE IMPLEMENTATION Halle G. Sobel; Charita Vadlamudi. FAHC, Burlington, VT. (Tracking ID #2159920)

BACKGROUND: Continuity of care is considered to be an important aspect to providing good clinical care in the outpatient setting. During residency training, there are many barriers that challenge resident and patient continuity in ambulatory clinics. Leaders in Internal Medicine have called for ambulatory redesign with block scheduling models and clinics are now in a position to evaluate the impact of these innovations. This was the case in the Internal Medicine program at the University of Vermont Medical Center (UVMC) which followed a traditional ½ day a week ambulatory clinic model until July 2012. The program was restructured in July 2012 to a 4+1 system in which resident physicians alternated with 4-week blocks of inpatient and elective rotations and a 1-week block of dedicated ambulatory care. This allowed residents to be in clinic consistently every 5 weeks. Our study will determine if continuity of care has improved, stayed the same or declined between resident physician and patient with the new block model.

METHODS: The UVMC Internal Medicine Residency program consists of 35–41 categorical residents each year who were all included in this study. Residents attend one continuity clinic site at the University Health Center Given Clinic. The traditional ½ day per week of outpatient clinic for each resident was in place until July 2012 after which the new 4+1 system was implemented. Each resident had an assigned panel of patients that averaged from 50 to 80 patients. During the clinic week, time was divided into continuity clinic, didactic, and subspecialty clinic sessions. During the continuity clinic sessions, residents saw patients from their own panel as well as acute visits for patients assigned to a different resident or attending primary care physician (PCP). In this study, continuity of care was measured for each patient who attended the resident clinic with an assigned resident PCP. Data regarding patient visits was gathered using EPIC and the GE scheduling system. This project was approved by the University of Vermont institutional review board (IRB) as Not Human Subject Research. Data were collected on patient visits only if the patient had an assigned resident physician as their PCP. For each of the patients, the total numbers of visits to the clinic were collected for the three periods of time: July 2011-June 2012, July 2012-June 2013, and July 2013-June 2014. From these visits, we delineated the number of visits the patient had with their assigned

resident PCP. Patients who had no visits during any given year were excluded from the study.

RESULTS: A total of 199 patients met criteria for the study. There were 838, 817, 791 total patient visits during July 2011-June 2012, July 2012-June 2013, and July 2013-June 2014 respectively. The Usual Provider of Continuity Index (UPC) is a measure of continuity that is calculated by dividing the number of visits to the same provider by the total number of visits to the clinic. For July 2011-June 2012: UPC 0.0059, July 2012-June 2013: UPC 0.0942, and July 2013-June 2014: UPC 0.4045

CONCLUSIONS: The results from our study show that the continuity of care improved in the 4+1 system when compared to the traditional system. Furthermore, there was large improvement in continuity during the July 2013-June 2014 period (year 2 of 4+1 system) from July 2012-June 2013 (year 1 of 4+1). In addition to the block model, this improvement in year 2 could also be attributed to increased education for staff on the importance of scheduling patients with the resident physician and also improvements in EPIC that allowed for easier identification of the PCP resident on the patient banner of each chart. Furthermore, residents were consistently encouraged to make follow-up appointments with their own patients. These results are exciting as the structure of the ambulatory week evolves and allows faculty to train residents in ambulatory population management and other emerging topics. It is hopeful that residents may find continuity clinic a more satisfying experience as they develop the resident-patient relationship and have more time to reflect on this partnership. The future is rich for areas to study including whether or not such improved continuity improves patient care outcomes and improves residents entering the field of ambulatory general internal medicine.

FUNCTIONAL STATUS, SOCIAL SUPPORT AND WEALTH IMPACT READMISSIONS FOR PNEUMONIA AND HEART FAILURE BEYOND STANDARD MEDICARE RISK-ADJUSTORS Jennifer Meddings¹; Heidi Reichert¹; Shawna N. Smith¹; Theodore Iwashyna^{2, 1}; Kenneth M. Langa^{1, 2}; Timothy Hofer^{2, 1}; Helen McGuirk¹; Laurence F. McMahon^{1, 3}. ¹University of Michigan, Ann Arbor, MI; ²Ann Arbor VA Medical Center, Ann Arbor, MI; ³University of Michigan School of Public Health, Ann Arbor, MI. (Tracking ID #2198274)

BACKGROUND: Hospital rates of unplanned Medicare readmissions within 30 days of discharge for pneumonia and heart failure are publicly reported on 'Hospital Compare' by the Centers for Medicare and Medicaid Services (CMS) and used to assess value-based purchasing hospital payments and penalties for hospitals. These readmission rates are "risk-adjusted," accounting for age, gender and medical comorbidities available within Medicare claims data. We hypothesized that patient functional status, social support and wealth also impact unplanned readmission rates beyond standard CMS risk-adjustors.

METHODS: Two data sets were used and linked for this analysis to study adults aged 65 years and older with Fee-for-Service Medicare and available data over the period 1995 to 2012. Patient-level Medicare claims data described inpatient, outpatient and home health care services and diagnoses. The nationally representative Health and Retirement Study (HRS) is an ongoing biennial prospective cohort study of more than 35,000 older adults' physical health and functioning, finances and social support. We developed logistic regression random-intercept models to assess the impact of functional status, social support and wealth (as assessed in the HRS survey most recent to the index admission) upon readmissions for any cause after an index admission for pneumonia or heart failure, beyond the patient characteristics (age, gender, comorbid diagnoses) and inclusion/exclusion criteria in current CMS readmission models. Functional status was assessed by number of limitations with activities of daily living (ADLs), categorized as 1–2 ADL difficulties, or 3+ ADL difficulties compared to no difficulties. Categorical social support measures included spousal support (comparing spouses with <3 ADL difficulties or 3+ difficulties with no spouse) and having children. Other controls and measures in the model included whether the patient was a nursing home resident at the time of the HRS survey prior to admission and whether home health care was used within the 2 years prior to the HRS survey. A measure of total wealth was also studied. Time, patient race and comorbid conditions (including age and gender) were also included. Hospital-level characteristics were not available. Likelihood ratio tests were used to compare nested models. A significance level of 0.05 was used.

RESULTS: Among 1782 index admissions for pneumonia, there were 272 (15.3 %) unplanned readmissions within 30 days of discharge after the index admission. HRS interview data had been collected a mean of 509 days (median 431) prior to the index pneumonia admission. Pneumonia patients with 3+ ADL difficulties were found to have significantly greater odds of readmission (OR=1.5; 95 % CI: 1.0–2.1), as were African American patients (OR=1.7; CI: 1.1–2.6), and patients that used home health care in the past 2 years (OR=1.6; CI: 1.1–2.2). Unexpectedly, pneumonia patients with a spouse having <3 ADL difficulties (OR=1.4; CI: 1.0–1.9) or with children (OR 2.1; CI: 1.1–4.1) also had significantly greater odds of readmission. A likelihood ratio test comparing our

full model to the current CMS pneumonia readmission model showed a significant improvement in fit ($p < 0.0001$). The full model's performance (c-statistic 0.78) was improved compared to the current CMS pneumonia readmission model (c-statistic of 0.64). Among 2271 index admissions for heart failure, there were 530 (23.3 %) unplanned readmissions within 30 days of discharge. Readmission rates after index admissions for heart failure decreased significantly over the study period. HRS interview data had been collected a mean of 510 days (median 430) prior to the index heart failure admission. Functional status, spouse characteristics, having children and previously requiring nursing home or home health care services were not associated with rates of readmissions after a heart failure admission. Greater wealth (square root of \$000 s, OR 0.988; CI: 0.977–0.999) was associated with lower odds of readmission. A likelihood ratio test comparing our full model to the current CMS health failure readmission model showed a significant improvement in fit ($p = 0.03$). The full model's performance (c-statistic 0.69) was improved compared to the current CMS heart failure readmission model (c-statistic of 0.61).

CONCLUSIONS: Patient functional status, spouse functional status, having children and prior needs for home health care were each associated with greater odds of readmission in the pneumonia cohort, but not for the heart failure cohort. Greater wealth was associated with lower odds of readmission for the heart failure cohort. Our findings suggest that CMS should consider accounting for functional status, social support and wealth in models used to compare hospital performance by readmission rates since they are associated with the outcome of interest, are often factors outside the control of the hospital, and are well known to be unevenly distributed across hospitals.

GENDER DIFFERENCES IN COPING MECHANISMS IN INTERNAL MEDICINE RESIDENTS Brielle Spataro¹; Sarah A. Tilstra³; Melissa McNeil². ¹UPMC Presbyterian Hospital, Pittsburgh, PA; ²University of Pittsburgh Medical Center, Pittsburgh, PA; ³University of Pittsburgh School of Medicine/Medical Center, Pittsburgh, PA. (Tracking ID #2192407)

BACKGROUND: Physician burnout is a syndrome characterized by emotional exhaustion, depersonalization and a low sense of personal accomplishment. It affects physicians in all levels of training. Burnout can erode professionalism, influence quality of care and increase risk for medical errors. Burnout is thought to affect genders differently. Studies have shown no gender differences in frequency of burnout but higher rates of emotional exhaustion in women and depersonalization in men. Burnout results from recurrent exposure to stressful experiences. Coping mechanisms are behavioral and psychological efforts that people use to deal with stress. The relationship between burnout and coping mechanisms is unknown, and little data exist regarding gender differences in the use of coping mechanisms. Objective: Evaluate for gender differences in burnout and use of coping mechanisms among internal medicine residents.

METHODS: Cross-sectional survey data was analyzed from 100 male and 98 female internal medicine residents at a large academic center in June 2014. This sample included all PGY-1, 2 and 3 internal medicine, transitional, and medicine-pediatrics residents. Residents completed the Maslach Burnout Inventory-General Survey (MBI-GS) and the Brief Cope as part of a series of mandatory residency program requirements. The MBI-GS measures burnout in three scales: emotional exhaustion, cynicism and professional efficacy. It's validated in healthcare professionals. The results are divided into high, moderate and low levels of burnout based on the normative distribution of doctors and nurses. The Brief Cope is a 28-item instrument measuring the frequency of 14 different coping mechanisms on a 4-point Likert-type scale. It is widely used in the literature and has good reliability in many different populations. Descriptive statistics were used to determine the percentage of residents that met criteria for "high" levels on each of the MBI-GS subscales. Score cutoff levels were for emotional exhaustion ≥ 3.2 , cynicism ≥ 2.2 and professional efficacy ≤ 4.00 (reverse scale). The Brief Cope results were analyzed by mean frequencies of each of the 14 coping mechanisms measured in female and male residents (range 2–8). Two sided t-tests were used to calculate p values. There was a 100 % completion rate of both instruments.

RESULTS: Overall 16 % of residents had high levels of emotional exhaustion, 18 % with high levels of cynicism and 22 % had low professional efficacy. Compared to males, females experienced a significantly higher incidence of emotional exhaustion (22 % vs 9 %, $p < 0.005$), and a reported higher levels of cynicism, (22 % v. 13 %, $p = 0.13$), although this was not significant. There was no gender difference in sense of professional efficacy (22 % vs. 22 %, $p = 0.50$). As for coping mechanisms, the use of emotional support, the use of instrumental support and self-blame were more frequent in female residents. The use of humor was more frequent in male residents. There were no statistically significant differences in the frequency of use of other coping mechanisms (Table).

CONCLUSIONS: Female internal medicine residents report higher levels of emotional exhaustion, and use emotional support ("seeking comfort and understanding"),

instrumental support ("seeking advice"), and self-blame ("criticizing and blaming oneself") more frequently than their male colleagues. While using emotional and instrumental support coping mechanisms are often thought of as protective, self-blame can be a maladaptive pattern of coping. It is important to understand the coping mechanisms utilized by residents to help deal with the stress of training, as the use of various coping techniques may affect the development of or recovery from burnout. Further studies are needed to determine which coping mechanisms are associated with lower levels of burnout so that their use can be encouraged in our trainees.

Frequency of Use of Coping Mechanism by Gender

Coping Mechanism	Male Mean (sd)	Female Mean (sd)	p-value
Acceptance	4.65 (1.93)	5.09 (1.70)	0.089
Active Coping	5.20 (1.79)	5.29 (1.75)	0.734
Behavioral Disengagement	2.36 (0.88)	2.43 (0.87)	0.583
Denial	2.15 (0.52)	2.21 (0.71)	0.466
Humor	4.43 (1.78)	3.82 (1.55)	<0.05
Planning	4.96 (1.98)	5.18 (1.70)	0.395
Positive Reframing	4.76 (1.78)	5.19 (1.72)	0.083
Religion	3.39 (1.73)	3.67 (1.74)	0.252
Self blame	3.10 (1.41)	3.59 (1.59)	<0.05
Self Distraction	4.42 (1.56)	4.68 (1.59)	0.240
Substance Abuse	2.17 (0.55)	2.06 (0.32)	0.091
Use of emotional support	5.29 (1.77)	6.06 (1.58)	<0.005
Use of Instrumental Support	4.91 (1.82)	5.53 (1.85)	<0.05
Venting	3.66 (1.39)	3.89 (1.41)	0.253

Frequency can range from 2–8, higher value indicates more frequent use of the mechanism

GENDER DIFFERENCES IN INPATIENT END-OF-LIFE DISCUSSIONS FOR PATIENTS WITH ADVANCED CANCER Rashmi K. Sharma; Sasha Jones; Frank Penedo; Kenzie A. Cameron. Northwestern University, Chicago, IL. (Tracking ID #2198519)

BACKGROUND: Men with advanced cancer are more likely than women to receive aggressive, non-beneficial care at the end of life (EOL). We have previously shown that when EOL discussions occur, they facilitate decreased receipt of aggressive care for men but not for women. However, little is known about how gender may influence the content of EOL discussions. We sought to evaluate gender differences in the content of inpatient EOL discussions for patients with advanced cancer.

METHODS: Via daily contact with oncology, hospitalist, and palliative care services, we identified 40 hospitalized metastatic cancer patients with a known upcoming EOL discussion. As part of a larger study, patients and physicians completed surveys that included assessment of treatment preferences and key topics discussed. We used chi-square tests to evaluate gender differences in topics discussed (yes/no). We calculated both percent agreement and Cohen's kappa to assess physician-patient concordance regarding treatment preferences and topics discussed; percent agreement is reported.

RESULTS: Sixty percent of the 20 male patients were Non-Hispanic White (NHW), 70 % were married, and mean age was 59.6 \pm 15.4 years. Seventy-five percent of the 20 female patients were NHW, 25 % were married, and mean age was 61.4 \pm 8.5 years. All patients had at least a high school education. Thirteen male patients and 16 female patients completed the post-discussion survey. Physicians completed surveys for all 40 discussions. A significant difference was observed in the percentage of male (100 %) and female (75 %) patients reporting discussion of goals of care ($p = 0.03$). For other key topics no significant differences emerged: incurability (54 % men vs. 31 % women reported discussion), treatment options (54 vs. 31 %), prognosis (77 vs. 56 %), resuscitation preferences (46 vs. 69 %), and hospice (62 vs. 81 %). Physicians reported discussing incurability in 80 % of discussions with male patients vs. 85 % for female patients, goals of care (95 % vs. 90 %), treatment options (95 vs. 70 %, $p = 0.04$), prognosis (60 vs. 65 %), resuscitation preferences (30 vs. 60 %, $p = 0.03$) and hospice (65 vs. 85 %). Physician-patient concordance regarding topics of discussion was generally poor. In all but one key topic (resuscitation preferences), agreement between patient and physician that a topic was discussed was higher among male as compared to female patients. Specifically, physician patient-concordance (percent agreement) for male patients regarding incurability was 54 vs. 35 % agreement for female patients; goals of care (92 vs. 77 %), treatment options (77 vs. 59 %), prognosis (65 vs. 65 %), hospice (92 vs. 88 %), and resuscitation preferences (69 vs. 82 %). Regarding EOL treatment preferences, 23 % of male patients reported a preference to focus on extending life, 62 % preferred to focus on comfort, and

15 % were unsure, compared to 13 % of female patients who preferred to extend life, 81 % who preferred comfort, and 6 % unsure. Physician-patient concordance regarding treatment preferences was especially poor for female patients (kappa -0.01 vs. 0.45 for male patients); physicians overestimated the percentage of patients preferring care focused on extending life for 15 % of male and 25 % of female patients.

CONCLUSIONS: We found gender differences in the content of EOL discussions. We also found poor physician-patient agreement regarding treatment preferences and discussion of incurability for male and female patients. While our findings are limited by a small sample size, they suggest that additional research is needed to explore how gender differences in EOL communication may account for observed differences in receipt of care at the EOL.

HEALTH DISPARITIES IN THE TREATMENT OF POOR PROGNOSIS CANCER: AGE AND RACE IN THE RECEIPT OF CANCER DIRECTED SURGERY

Will Chapman²; Rodrigo Aguilar C¹; Allen Chen¹; Alex R. Montero¹.
¹Georgetown University Hospital, Washington, DC; ²Georgetown University School of Medicine, Washington, DC. (Tracking ID #2199515)

BACKGROUND: Poor prognosis cancers such as pancreatic and lung cancer disproportionately affect blacks. The incidence is higher and survival poorer for these cancers in black patients when compared to white patients. Despite a higher incidence, black patients are less likely to undergo cancer directed surgery for these cancers when compared to white patients. Factors underlying these disparities are likely multidimensional, but some research indicates that blacks are offered resection at similar rates as white patients. Our aim was to explore the possible role of age on this racial disparity in the surgical treatment of pancreatic and lung cancer utilizing the Nationwide Inpatient Sample (NIS), a national database of discharge data from a sample of all US nonfederal hospitals.

METHODS: Utilizing NIS data from 2007 to 2009, all adult patients undergoing pancreatic resection for pancreatic cancer were identified via a primary procedure code for Whipple surgery (ICD9=52.7). Patients with a primary diagnosis of acute or chronic pancreatitis were excluded. All adult patients undergoing lung resection were identified via a primary procedure code for pneumonectomy or lobectomy as defined by the Agency for Healthcare Research and Quality (AHRQ)'s Clinical Classification Software for pneumonectomy or lobectomy. For the respective cancer, our outcome variable was patient age. Our independent variable was race/ethnicity. Our covariates were sex, Charlson Comorbidity Index (CCI), insurance status, and income (quartile at the zipcode level). Univariate analyses utilized the Student T test and Chi square test. Multivariable analyses utilized general linear models. All analyses were carried out in SAS (version 9.3).

RESULTS: Of all patients undergoing pancreatic and lung resection respectively, 76.1 and 82.5 % were white and 7.3 and 7.6 % were black. In univariate analysis, race/ethnicity was significantly associated with age for both pancreatic and lung resection patients ($p < .001$). In younger patients (age <65) within each race/ethnicity category, the proportion undergoing resection for these cancers was higher in blacks when compared to whites. In contrast, in the very old (age >80) the proportion undergoing resection for these cancers was much higher in white patients (i.e. of all white patients undergoing pancreatic resection 10.3 % were over 80 whereas only 3.4 % of black patients were over 80). Multivariable adjustment for sex, CCI, insurance status, and income did not significantly alter these findings.

CONCLUSIONS: Consistent with prior data, our study found that black patients receiving cancer directed surgery for poor prognosis cancers were underrepresented when compared to their overall proportion of the US population (12.6 %). Additionally, receipt of these surgeries was highly associated with age—very old minority patients were much less likely to undergo surgery than younger minority patients even after adjustment for comorbidity and SES. When counseling patients diagnosed with poor prognosis cancers, clinicians should be aware of the particularly low prevalence of receipt of possibly life prolonging cancer directed surgery in the very old, minority patient. Additionally, system interventions intended to address this health disparity should consider an age-specific design that targets older minority patients.

HEALTH IMPACT OF ALTERNATIVE SCENARIOS OF EXPANDING ELECTRONIC CIGARETTE SALES: A MONTE CARLO ANALYSIS Sara Kalkhoran; Stanton A. Glantz. University of California, San Francisco, San Francisco, CA. (*Tracking ID #2194974*)

BACKGROUND: The prevalence of electronic cigarette (e-cigarette) use is increasing. Population health impacts will depend on effects on cigarette smoking behaviors, levels of dual use with conventional cigarettes, and product toxicity. We evaluated the potential health effects of various scenarios of increasing promotion and use of e-cigarettes in the United States.

METHODS: A Monte Carlo simulation was developed from an initial state of no cigarette or e-cigarette use to one of five final states: never use of cigarettes or e-cigarettes, cigarette use, e-cigarette use, dual use of cigarettes and e-cigarettes, or quit. A base case (simulating the status quo) and nine different scenarios were analyzed. Health "costs" were assigned to each final state on a unitless scale from 0 to 100, with 0 for never smoking cigarettes and 100 for continued smoking. Scenarios were analyzed assuming e-cigarette health costs from 1 to 50 % of the health cost of cigarettes.

RESULTS: Compared to the base case, a harm reduction scenario where more smokers are interested in quitting and more use e-cigarettes for quit attempts instead of unassisted attempts, or one where e-cigarettes are taken up only by youth who would have smoked cigarettes, had population-level health benefit regardless of e-cigarette health cost. Conversely, in scenarios where either e-cigarette promotion leads to renormalization of cigarette smoking or e-cigarettes are used primarily by youth who never would have smoked, there is net health harm across all e-cigarette health costs. In other scenarios, the net health effect varies based on what the health cost of e-cigarettes will turn out to be, with most showing net harm if e-cigarettes are 5–30 % as harmful as cigarettes (Figure).

CONCLUSIONS: Population health effects of widespread promotion and distribution of e-cigarettes will greatly depend on how harmful e-cigarettes turn out to be. Projections based on current youth uptake and use patterns in smokers suggest net health harms are likely in many scenarios.

Probability of each scenario having net health benefit versus the base case as a function of e-cigarette health cost. The top two scenarios always have population health benefit and the bottom two scenarios always have population health deficit (lines slightly shifted for display, are actually 100 %). The lines correspond to the following scenarios (from top to bottom): (1) 10 % absolute increase in e-cigarette use from cigarette initiators, (2) harm reduction, (3) decreased quit intentions with more e-cigarette use for cessation from those not attempting to quit, (4) aggressive promotion, (5) fivefold increase in e-cigarette initiation, (6) e-cigarette as nicotine replacement therapy substitute, (7) decreased quit intentions with more e-cigarette use for cessation, (8) renormalization of smoking, and (9) 10 % absolute increase in e-cigarette use from never users

HEALTH LITERACY LIMITATIONS IN ACCESSING & USING A PATIENT PORTAL: IMPLICATIONS FOR DISPARITIES IN CARE

Chandra Y. Osborn^{1, 1}; Samuel K. Nwosu¹; Kathryn Goggins²; Jonathan S. Schildcrout¹; Sunil Kripalani^{1, 2}. ¹Vanderbilt University, Nashville, TN; ²Vanderbilt University Medical Center, Nashville, TN. (Tracking ID #2198269)

BACKGROUND: Internet patient portals satisfy meaningful use requirements by exposing personal health information (PHI) in a secure manner to patients and caregiver delegates. Most portals also allow patients or delegates to securely message healthcare providers to ask clinical questions and receive responses, thus, obtaining care outside face-to-face clinic visits. Therefore, not using these systems may create disparities in access to care, and might ultimately contribute to disparities in health. We examined the relationship between patient characteristics, including sociodemographics, and patients' health literacy and numeracy skills with access and usage of an online patient portal.

METHODS: Patients hospitalized with acute cardiovascular conditions at Vanderbilt University Medical Center or Williamson Medical Center in Tennessee were enrolled in the Vanderbilt Inpatient Cohort Study (VICS). Using baseline data, we performed a cross-sectional analysis to determine the patient characteristics associated with having a patient portal account, how often the account was used for messaging providers, and how often the account was used to access PHI. For each of these outcome variables, we examined bivariate relationships (using chi-square, Kruskal-Wallis, and Wilcoxon tests). We also ran a multivariable logistic regression model for the binary outcome (having a portal account or not) and proportional odds regression models for ordinal outcomes (how often the portal was used for messaging and for accessing PHI). Models controlled for age, gender, minority status, education, income, insurance status, health literacy assessed with the Brief Health Literacy Screen (BHLS) and the Short Test of Functional Health Literacy in Adults (sTOFHLA), and numeracy assessed with the Subjective Numeracy Scale.

RESULTS: The average age of all patients ($n=860$) was 61 years; 55.5 % of patients were male; and 18.2 % were minorities. The average education was 13 years and average sTOFHLA score was 33 (out of 36). Of the 860 patients who had heard of the institution's patient portal, 510 patients had an account (59.3 %). We found that having a patient account was associated with minority status, insurance status, age, education, income, subjective numeracy, brief health literacy screen score, and sTOFHLA score ($p<0.05$ for each comparison). These same variables were significantly associated with how often patients used the patient portal for messaging providers and accessing PHI. In adjusted analyses, the odds of having a patient portal account were 63 % lower for patients with Private-Pay/No-insurance when compared to patients with commercial insurance ($p=0.005$); and were lower for patients with lower income ($p=0.001$). Additionally, use of the portal to message providers increased by 29 % per 4 point increase in health literacy as assessed by the BHLS ($p=0.046$), and was also significantly associated with more education, higher income, and higher sTOFHLA score ($p=0.024$, $p<0.001$, $p=0.030$). For patients with Private-Pay/No-insurance, Other, and TNCare/Medicaid the odds of using the portal for messaging decreased by 65 % ($p=0.005$), 68 % ($p=0.023$) and 61 % ($p=0.044$) respectively when compared to patients with commercial insurance. Use of the portal to access PHI decreased by 63 % for patients with Private-Pay/No-insurance when compared to patients with commercial insurance ($p=0.008$), and was increased among patients with higher income ($p=0.049$).

CONCLUSIONS: As usage of patient portals and secure messaging increases, health literacy disparities in usage are likely, potentially creating disparities in access to healthcare and health outcomes.

HEALTH-SPECIFIC INFORMATION AND COMMUNICATION TECHNOLOGY USE AND ITS RELATIONSHIP TO CHRONIC DISEASE STATUS IN COMMUNITIES ON THE SOUTH SIDE OF CHICAGO

Anjali Gopalan^{1, 2}; Loretta R. Cain⁴; Jennifer A. Makelarski⁴; Lori B. Garibay⁵; Raina M. Merchant³; Stacy T. Lindau⁴. ¹Philadelphia VA Medical Center, Philadelphia, PA; ²Robert Wood Johnson Clinical Scholars Program, Philadelphia PA, PA; ³Perelman School of Medicine at the University

of Pennsylvania, Philadelphia, PA; ⁴The University of Chicago, Chicago, IL; ⁵Rescue Social Change Group, Washington, DC. (Tracking ID #2192280)

BACKGROUND: Preventable chronic diseases are a leading driver of rising US health care costs. Many patient-facing information and communication technologies (ICT) aim to aid in the prevention and management of these costly conditions. These technologies include mobile apps for disease monitoring and management, text messages for appointment and self-care reminders and web-based information and decision support tools. While efficacy studies have demonstrated a variety of improved clinical outcomes with ICT-based interventions, the ability of health-specific ICT resources to more broadly impact health outcomes will depend on accessibility and use in populations with high rates of these health conditions. The South Side Health and Vitality Studies, a collaboration between University of Chicago researchers and community residents, seeks to identify mechanisms through which ICT can be used by people living in high poverty communities to enhance wellness, self-care and disease management. We first describe patterns of ICT use on Chicago's South Side and compare them to national estimates. We then examine the relationship between common chronic conditions, specifically obesity, hypertension, and diabetes and health-specific ICT use.

METHODS: A population-based biosocial survey was conducted between November 2012 and July 2013 with a probability sample of 267 adults ages 35 years and older randomly selected from households on Chicago's South Side. After applying appropriate survey weights, descriptive statistics were used to examine the prevalence of general ICT use (texting, emailing, going online or app use), as well as health-specific ICT use (looking up health information, health-related app use, purchasing medications, communicating with providers, participating in online health support groups and managing records or benefits). These estimates were then compared to national-level estimates of these ICT activities from the 2012 PewResearch Internet Project. Chi-square tests were used to examine the relationship between sociodemographic characteristics and chronic disease status, specifically obesity (measured BMI ≥ 30 kg/m²), hypertension (self-reported or SBP ≥ 140 or DBP ≥ 90), and diabetes (self-reported or hemoglobin A1c ≥ 6.5 %) and the likelihood of health-specific ICT use. Multivariable logistic regression, adjusting for age and insurance type, was used to describe the relationship between chronic disease status and the odds of health-specific ICT use.

RESULTS: The weighted survey response rate for this probability sample was 62 %. In this sample, 24 % were unemployed or unable to work, 25 % were uninsured, and 36 % reported an annual household income less than \$25,000. General (75 %) and health-specific (52 %) ICT use were prevalent and more common among younger, more educated, and insured individuals. No differences in health-specific use were noted by race or ethnicity. Rates of all ICT activities were similar when comparing the South Side population with national estimates. The prevalence of chronic conditions among the South Side population was high: hypertension (63 % overall, 49 % diagnosed and 14 % undiagnosed), obesity (53 % overall, 37 % diagnosed and 16 % undiagnosed) and diabetes (25 % overall, 18 % diagnosed and 7 % undiagnosed). Among individuals with at least one chronic disease (76 %), the highest prevalence of health-specific ICT use was among people with diagnosed obesity (67 %) and the lowest prevalence of use was among people with diagnosed hypertension (39 %). In bivariate analysis, there was a statistically significant difference in health-specific ICT use by obesity status, with those of normal weight (29 %) having a lower prevalence of use than overweight (48 %), undiagnosed obese (50 %) and diagnosed obese individuals (66 %, $p<0.01$). Also, those with diagnosed hypertension had a significantly lower prevalence of use (39 %) than those who were normotensive (68 %, $p=0.01$). After controlling for age and insurance type, diagnosed obesity (AOR=4.2 [95 % CI:1.5-11.5]) and undiagnosed diabetes (AOR=4.2 [95 % CI:1.1-15.5]) were associated with increased odds of health-specific ICT use when compared to those without these conditions.

CONCLUSIONS: The burden of chronic and undiagnosed disease was very high in this urban population; only 24 % had none of the examined chronic conditions. Health-specific ICT use was also prevalent but varied by socioeconomic characteristics and disease status. The study findings suggest that obesity may be an especially ideal target for health-specific ICT-based interventions in this population. The high prevalence of obesity among residents on Chicago's South Side and in other high poverty, minority communities, along with the finding of increased odds of health-specific use ICT in this group reveals an already online population with high health needs and risks. This is a group that could be significantly impacted by thoughtfully designed and effectively implemented ICT-based health interventions and resources.

HEALTHY LIVING PARTNERSHIPS TO PREVENT DIABETES (HELP PD): A RANDOMIZED CONTROLLED TRIAL TO PREVENT DIABETES THROUGH DIET AND EXERCISE: 2 YEAR EFFECTS ON THE METABOLIC SYNDROME Carolyn F. Pedley²; Caroline Blackwell³; Doug Case²; Jeffrey A. Katula^{3, 4}; Mara Z. Vitolins¹; David C. Goff⁶. ¹Wake Forest School of Medicine, Winston Salem, NC; ²Wake Forest Medical Center, Winston-Salem, NC; ³Wake Forest School of Medicine, Winston-Salem, NC; ⁴Wake Forest, Winston-Salem, NC; ⁵University of Colorado, Denver, CO. (Tracking ID #2196912)

BACKGROUND: The metabolic syndrome is a constellation of clinical features which in combination identifies individuals who are at increased risk of developing diabetes and cardiovascular disease including stroke. Cardiovascular events remain the leading cause of death in the United States and interventions to reduce risks are an important function of internal medicine practices. The Healthy Living Partnerships to Prevent Diabetes (HELP PD) lifestyle intervention was designed to promote modest weight loss (5–7 %) and was conducted as a single center RCT to prevent the development of diabetes in high risk individuals. The effects on the metabolic syndrome in participants were analyzed at 12 and 24 months.

METHODS: Single center RCT was conducted via a local diabetes education center which oversaw the conduct of the lifestyle intervention. Overweight and obese participants (BMI 25–39.9) with elevated fasting glucose (95–125 mg/dl) were randomly assigned to either a group-based lifestyle weight loss (LWL) intervention or enhanced usual care (EUC). Three hundred one individuals were enrolled in the trial and data was collected during 2007–2011. LWL groups of 8–12 met in community settings weekly for 6 months with the sessions conducted by trained community health workers (CHWs). These sessions focused on creating negative energy balance by negative calorie balance and increased physical activity and was modeled after the interventions of DPP. During months 7–24 the focus shifted to weight maintenance. EUC participants met with a dietician for 2 individual sessions and then received monthly mailings of a newsletter. Outcomes were assessed every 6 months and included fasting glucose, waist circumference, triglycerides, blood pressure, LDL and HDL cholesterol. Participants were assessed for the presence of the metabolic syndrome which as proposed by the Adult Treatment Panel III (ATP III) and revised by the National Cholesterol Education Program (NCEP) is defined by the combination of any 3 of the following 5 traits: (1) waist circumference ≥ 40 in. for males and ≥ 35 in. for females, (2) fasting triglycerides ≥ 150 mg/dl or drug treatment for triglycerides, (3) HDL cholesterol male < 40 mg/dl and female < 50 mg/dl or drug treatment for low HDL, (4) blood pressure ≥ 130 mm Hg systolic or ≥ 85 mm Hg diastolic or drug treatment for elevated blood pressure and (5) fasting glucose (FPG) ≥ 100 mg/dl or drug treatment to lower blood glucose. Chi-square and Wilcoxon rank-sum tests were used to assess baseline differences between the intervention and control groups in categorical and continuous variables, respectively. Repeated measures analysis of variance, constrained to have equal means at baseline was used to assess the effect of the HELP PD intervention on the parameters of the metabolic syndrome. An unstructured covariance matrix was used to model the within patient correlations over time. Linear contrasts were used to assess the intervention effect at each time as well as the average post-randomization effect. SAS v9.3 was used to perform the analyses.

RESULTS: At baseline there were no significant differences in the presence of the metabolic syndrome between the LWL group 108/151 (72 %) vs 104/150 (69 %) in the EUC group. At 6, 12 and 24 months there were significant reductions in waist circumference and fasting glucose in the LWL compared to the EUC participants. Systolic blood pressure was significantly less at 6 months (120.5 vs 124.9 but not at 12, 18 and 24 months. Diastolic blood pressure differences were significant at 6 and 24 months favoring LWL. HDL cholesterol was significantly greater in the LWL compared to EUC at 12 and 24 months. Fasting triglycerides were significantly less at 12 months in LWL but not at 24 months. At 12 months there were significantly fewer with the metabolic syndrome in the LWL 71/135 (53 %) vs EUC 95/138 (69 %). The pattern persisted at 24 months with 77/127 (61 %) having the metabolic syndrome in the LWL compared to 103/134 (77 %) in the control group.

CONCLUSIONS: The HELP PD lifestyle intervention was successful in achieving modest weight loss comparable to the DPP trial. This population of overweight/ obese individuals with elevated fasting glucose 95–125 mg/dl had a high prevalence of the metabolic syndrome (72 % LWL) and (69 % EUC). The benefits of the program in reducing the metabolic syndrome in the LWL intervention group were highly significant and these benefits were still present at 24 months. Such interventions could be incorporated into internal medicine practices as a powerful tool in preventing cardiovascular disease in high risk individuals.

HELPING WOMEN UNDERSTAND THEIR BREAST DENSITY RESULTS THROUGH A PATIENT-CENTERED VIDEO Erin N. Marcus^{3, 2}; Monica M. Yepes^{1, 2}; Noella Dietz^{4, 2}; Debra Annane². ¹University of Miami Miller School of Medicine, Miami, FL; ²Sylvester Comprehensive Cancer Center, Miami, FL; ³University of Miami Miller School of Medicine, Miami, FL; ⁴University of Miami Miller School of Medicine, Miami, DC. (Tracking ID #2198096)

BACKGROUND: Breast density decreases the sensitivity of screening mammography. At the behest of patient advocates, several states have passed legislation requiring breast imaging centers to inform women in writing of their density results, so that women with elevated breast density can consider supplemental screening with ultrasound or newer imaging modalities such as breast tomosynthesis. It is unclear how to communicate this information in a way that minimizes patients' anxiety and improves their understanding.

METHODS: We conducted five focus groups in English and Spanish with 25 women who had been diagnosed with dense breasts. Qualitative analyses were done to capture women's understanding of dense breasts and how they thought density information should be explained. Based on the focus group data, investigators created scripts for two seven minute videos in English and Spanish. The first half of the videos consist of a breast imaging physician explaining density, ultrasound, and tomosynthesis and the likelihood of false positive results. The second half of the videos consist of on-camera interviews with women who have dense breasts.

RESULTS: The investigators conducted six interviews with focus group participants. Two of the women had also undergone tomosynthesis; all had undergone ultrasound in addition to mammography screening. Recurring themes included the women's fears about their prognosis when told they had dense breasts, the lessening of their anxiety after they understood the meaning of density, and their recommendation for other women to be proactive and ask their doctor for more information. The videos are being edited and will be shown to all focus group participants to assess acceptability when completed.

CONCLUSIONS: Video is a useful tool to communicate breast density information and provide patient-centered information about tomosynthesis and other breast imaging techniques. Once completed, the video we developed will be available for dissemination in breast center waiting rooms. Future investigations should assess the effectiveness of this method in improving patient understanding of breast density and breast imaging generally.

HIGH PERCEIVED SOCIAL SUPPORT PROTECTS AGAINST 30 DAY HOSPITAL READMISSION IN A MULTI-ETHNIC, LIMITED ENGLISH PROFICIENCY, SAFETY-NET POPULATION Brian Chan; Lauren Goldman; Urmimala Sarkar; David Guzman; Edgar Pierluissi; Michelle Schneidermann; Jeff Critchfield; Margot Kuschel. San Francisco General Hospital, University of California, San Francisco, San Francisco, CA. (Tracking ID #2195414)

BACKGROUND: The Center for Medicare and Medicaid Services (CMS) Hospital Readmissions Reduction Program focused attention to preventing 30-day hospital readmissions. Readmission prevention programs in safety-net hospitals have met with mixed success, increasing concern for the financial risks readmission policies have on these institutions and the populations served. Low social support is thought to be associated with poor health outcomes; however, little is known regarding the relationship between social support and hospital readmission. We examine the role of a multidimensional measure of perceived social support in 30 day readmission rates in a cohort of older adults admitted to a safety-net hospital.

METHODS: Over the course of 2 years (2010–2012), we enrolled community-dwelling English, Spanish and Chinese speaking older adults (55 years and older) admitted to non-surgical and non-psychiatric services at a University-affiliated urban safety-net hospital in San Francisco, California. We assessed social support during the baseline interview using the Multidimensional Scale of Perceived Social Support (MSPSS), a 12 item instrument that measures perception of support relationships from spouse, family, and friends. We defined high levels of social support as the highest quartile of MSPSS in the population. We ascertained 30 day readmission and mortality based upon a combination of participant self-report by telephone interview, hospital record, and death record review. We used multivariate logistic regression to adjust for patient demographics, health status, and health behaviors.

RESULTS: The study population ($n=700$) had mean age of 66.2 (SD 9.0), with 19.0 % White, 24.5 % Black, 31.6 % Asian, and 19.6 % Latino. Over half the patient population had cognitive impairment assessed by Telephone Interview for Cognitive Status (TICS score < 20) (54.2 %), and 28.1 % were noted to have a deficit in Activities of Daily Living (ADL). The overall 30 day hospital readmission rate was 14.0 %; 5 participants died prior to 30 day follow up (0.7 %). Amongst the 152 participants in the highest quartile of perceived social support, 13 experienced readmission and none died within 30 days

(8.6 %). Those with high levels of perceived social support were 2 times less likely to experience readmission or death than those with lower levels (OR=0.47, 95 % CI .26, .99). When adjusted for age, sex, race, cognitive impairment, Charlson score, prior hospitalization, substance abuse, and ADL disability, the relationship of high social support to readmission or death was attenuated but persisted (AOR=0.56, 95 % CI .29, 1.1).

CONCLUSIONS: In a cohort of hospitalized older, low-income, multi-lingual, cognitively impaired population with high medical comorbidities nearing discharge, those with high levels of perceived social support were less likely to experience 30 day readmission or mortality. Accounting for individuals' perceived social support on admission may aid targeting of transitional care resources to improve outcomes. These findings suggest interventions that provide a social support component merit increased attention.

HIGH QUALITY TRANSITIONS OF CARE REDUCE HOSPITAL READMISSIONS AMONG PATIENTS WITH PCI AND CABG

Jennifer N. Goldstein; LeRoi S. Hicks; Paul Kolm; Daniel J. Elliott. Christiana Care Health System, Newark, DE. (Tracking ID #2197758)

BACKGROUND: Under the Partnership for Patients Program, the Centers for Medicare & Medicaid have invested \$300 million in programs to improve transitions of care (TOC) from hospital to home with the goal of decreasing unnecessary hospital readmissions. However, the relationship between transitions of care and hospital readmissions remains unclear. In 2013, a new TOC quality metric, the Care Transitions Measure (CTM[®]-3) was incorporated into the Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS) survey. High scores on the CTM[®]-3 have been associated with fewer readmissions in small populations ($n=200-300$). However, this association has not been tested in larger, more diverse populations. Given the recent policy initiatives focused on TOC and readmissions, it is important to clarify the relationship between the two. The primary objective of this study was to determine whether CTM[®]-3 scores were independently associated with readmissions within a larger more representative cohort of patients that it has previously been tested.

METHODS: Analysis of data from a longitudinal, single center study of patients who received percutaneous coronary intervention (PCI) or coronary artery bypass grafting (CABG) at Christiana Care Health System from 2013 to 2014. CTM[®]-3 scores were collected by trained research staff blinded to study hypothesis, by telephone, within 30 days of discharge. Three ANOVA analyses were performed for those with PCI, CABG, and the combined group to determine the relationship between mean CTM[®]-3 scores and covariates associated with readmission (race, gender, age, insurance status, comorbidity count, and prior hospital use). Logistic regression for the combined group examined whether CTM[®]-3 scores independently predicted 30 day non-elective readmission.

RESULTS: Of 2963 total patients, 1594 (54 %) completed CTM[®]-3 surveys. Within this group, 197 (12 %) were African American, 136 (9 %) had Medicaid, 816 (51 %) had Medicare, 1434 (90 %) were over the age of 50 and 920 (58 %) had greater than 3 comorbidities. Within the PCI, CABG, and combined groups, higher mean CTM[®]-3 scores were associated with fewer comorbidities (PCI: mean 82.5, vs 75.8 $p<0.001$; CABG: mean 83.3 vs 79.1 $p<0.045$; combined: mean 82.6 vs 77.0 $p<0.001$). Within PCI and combined groups, higher mean CTM[®]-3 scores were associated with lower prior hospital use (PCI: mean 81.9 vs 75.6, $p<0.001$; combined: mean 82.1 vs. 77.2 $p<0.001$) and lower rates of readmission (PCI: mean 80.9 vs 73, $p<0.001$; combined: mean 81.06 vs 74.58, $p<0.001$). On logistic regression, higher CTM[®]-3 scores were associated with lower risk of readmission (adjusted odds ratio 0.99, 95 % Confidence Interval 0.97–0.99, $p=0.004$). Every 10-point increase in CTM[®]-3 decreased risk of readmission by 14 %.

CONCLUSIONS: This is the largest study to date to examine the relationship between CTM[®]-3 scores and readmissions, and we found that the relationship was significant, but modest. We also found that CTM[®]-3 scores were associated with immutable clinical factors related to readmissions such as number of comorbidities and prior hospital utilization, which could impact the ability to improve CTM[®]-3 scores through TOC interventions. A considerable public investment has been made based on the association between high quality TOC and readmissions. It is important for policy makers and health systems to understand that this relationship remains tenuous and that the new HCAHPS metric for TOC, the CTM[®]-3 may be difficult to improve.

HIGH-COST PATIENTS: “HOT-SPOTTERS” DON’T EXPLAIN THE HALF OF

IT Sang Been N. Hong²; Noah Whitman¹; Nirav Vakharia¹; Glen B. Taksler¹; Michael B. Rothberg¹. ¹Cleveland Clinic, Cleveland, OH; ²Cleveland Clinic, Cleveland Heights, OH. (Tracking ID #2195077)

BACKGROUND: Healthcare costs in the US are concentrated among a small fraction of the population, but knowledge regarding the characteristics of high-cost patients is limited.

Patients with frequent admission to the hospital or ED, aka “hot-spotters,” have received special media attention in recent years, but efforts to curb costs through enhanced coordination of outpatient care have not yielded cost savings. To better understand the patterns of high cost care, we examined the differences in inpatient and outpatient utilization, as well as the distribution of high-cost conditions, among sub-groups of high-cost patients over a single year.

METHODS: We performed a retrospective cross-sectional chart review of high-cost patients in one health system. Using the Quality Resource and Use Report distributed by the Centers for Medicare and Medicaid Services, we identified Medicare patients who were hospitalized exclusively at Cleveland Clinic Health System (CCHS) hospitals and received at least 90 % of their primary care services at a CCHS facility in 2012. Using data from CCHS internal cost accounting systems, we summed all direct and indirect costs associated with receiving care at a CCHS facility to estimate total costs per patient. We defined the high cost population as the 10 % of patients with the highest expenditures. This high-cost population was divided into four roughly even quartiles, from most expensive to least (i.e. the top 1–2.5, 2.5–5, 5–7.5, and 7.5–10 percentiles of the population). Total number of admissions, inpatient days, ICU days, ED visits, and outpatient visits were obtained from the electronic medical record. Hot-spotters were defined as those in the ≥95th percentile for number of hospital and/or ED admissions. We used the Agency for Healthcare Research and Quality Clinical Conditions Software to group primary and secondary ICD-9 diagnosis and procedure codes. High-cost conditions and procedures were identified through a literature search and clinical judgment. We used the non-parametric Kruskal-Wallis test to identify differences in means and a Chi-squared test or Fisher's exact test for differences in proportions among the high-cost quartiles.

RESULTS: The sample included 14,855 patients. High-cost patients (10 % of patients, $n=1486$) accounted for 60 %, the top two high-cost quartiles (5 %) accounted for 45 %, and the top 1 % of patients accounted for nearly 20 % of the entire population's costs. High-cost patients incurred almost 90 % of all inpatient costs. Mean utilization of services increased with quartile for all services, except primary care visits. However, there was a wide range of utilization patterns. Overall, one-third of high-cost patients had no admissions and few had more than 2, but in each quartile, some patients were not admitted. A similar trend was observed for inpatient days, ICU days, and ED visits. Even the top 1 % had varied utilization patterns. Hot-spotters had ≥4 admissions or ≥4 ED visits. They accounted for 11.5 % of high-cost patients ($n=171$) and 25.1 % of their costs (Figure). Most hot-spotters clustered in the top quartile ($n=115$, 67.3 %), but they represented just 7.7 % of that group. They accounted for a third (34.2 %) of the most expensive 1 % of patients. The distribution of high-cost conditions varied across quartiles. For example, chemotherapy was most common in the top quartile (32.1 % vs. 11.1 %, 5.6 %, and 1.9 % in the 2nd-4th quartiles, respectively, $p<0.001$). Osteoarthritis was most common in the third quartile. Diabetes and cardiac arrhythmia and arrest were present in >20 % of patients and evenly distributed across quartiles. High-cost procedures that concentrated in the top two quartiles included heart valve surgery (100 %), spinal fusion (100 %), and transplant surgery (100 %).

CONCLUSIONS: Patterns of resource utilization vary among high cost patients, with hot-spotters representing just a small minority of that population. Therefore, programs that focus solely on preventing admissions through care coordination are unlikely to have a large impact on overall cost.

Proportion of hot-spotters among the high-cost population and their attributable costs.

HIGH-RISK HOSPITALIZED PATIENTS HAVE LOW PERCEIVED SUSCEPTIBILITY TO CHRONIC KIDNEY DISEASE Milda R. Saunders²; Sharon D. Kim¹; David Meltzer¹; Marshall Chin¹. ¹University of Chicago, Chicago, IL; ²University of Chicago Medical Center, Chicago, IL. (Tracking ID #219733)

BACKGROUND: Over 14 % of the US population has chronic kidney disease (CKD), a disease associated with high morbidity and mortality. However, the development and progression of CKD can be delayed with aggressive risk factor control of diabetes and hypertension, the two most common risk factors for CKD. We sought to assess perceived susceptibility to CKD and to identify factors associated with perceived risk of CKD in our cohort of high risk, hospitalized patients.

METHODS: Between July and September 2014, we surveyed 717 general medicine inpatients about their perceived risk for kidney disease. As part of at the University of Chicago Hospitalist Project, a large-scale ongoing study of hospitalized patients and patient outcomes, patients completed an inpatient interview on their demographic characteristics, health status, and recent health care use. During the interview, we asked patients use a 5 point scale to report how likely they were "to develop weak or failing kidneys or chronic kidney disease in the next 10 years." We compared demographic, clinical, and health service use variables by patient report of CKD susceptibility using a chi-square test for the categorical variables and a one-way ANOVA test for the continuous variables. We used logistic regression to analyze the influence of the demographic, clinical, and health care utilization covariates on the likelihood of a patient reporting risk for CKD.

RESULTS: In this sample of urban, hospitalized patients, perceived risk for CKD was low; only 27 % of patients considered themselves likely (very likely or moderately likely) to develop CKD. The majority of patients were African American (68 %), women (55 %) with a median age of 54. Patients also had a high prevalence of self-reported CKD (19 %) or CKD risk factors included diabetes (25.6 %) and hypertension (55.4 %). In bivariable analysis, factors associated with high perceived risk of CKD include having diabetes (OR 1.7), hypertension (OR 2.1), cardiovascular disease (OR 1.8), and 4 or more doctor visits per year (OR 2.8, compared to 1 or less, all $p < 0.05$). Patients that wanted their physician to present them with choices and ask their opinions were less likely to perceive themselves at risk for CKD (OR 0.35, 95 % CI 0.03, 0.91). These factors did not remain significant in multi-variable analysis.

CONCLUSIONS: In hospitalized patients at high risk for CKD, perception of CKD risk remained low. Hospitalization provides an opportunity to identify existing CKD risk factors in order to educate patients and link them to multi-disciplinary outpatient care.

HIGHER INPATIENT ACUTE MYOCARDIAL INFARCTION MORTALITY AMONG ASIAN AMERICANS Eun Ji Kim²; Nancy R. Kressin⁴; Michael K. Pasche-Orlow³; Jennifer E. Rosen²; Meng-Yun Lin¹; Amresh D. Hanchate³. ¹Boston Medical Center, Boston, MA; ²Boston University, Cambridge, MA; ³Boston University School of Medicine, Boston, MA; ⁴Dept of Veterans Affairs and Boston University, West Roxbury, MA; ⁵Medstar Health Research Institute, Hyattsville, MD. (Tracking ID #2198396)

BACKGROUND: There are approximately 1.5 million patients who sustain acute myocardial infarction (AMI) annually in the US and about 5 % of the patients die during their inpatient stay. Asians (including Pacific Islanders) make up 5 % of the US population and are known to have the relatively low risk factors for coronary artery disease compared to other racial/ethnic groups. To date, there is no population-level study that examines racial differences among Asians in inpatient AMI outcomes.

METHODS: We obtained 2010 state inpatient discharge data from 15 states - Arizona, California, Colorado, Florida, Massachusetts, Maryland, Nevada, New Jersey, New Mexico, New York, Oregon, Pennsylvania, Texas, Virginia and Washington - with near-complete reporting of race/ethnicity and high proportions of racial/ethnic minorities. Using the Agency for Healthcare Research and Quality (AHRQ) Inpatient Quality Indicators (IQI) protocol, we identified AMI admissions among adults aged 18 and older. The main outcome was inpatient mortality. Using hierarchical logistic regression models, we estimated differences in inpatient mortality among minorities (Asians, Hispanics, non-Hispanic blacks, and others), relative to non-Hispanic whites, after adjusting for compositional differences in demographics, co-morbidities (Elixhauser categories), area-level differences in indicators of socioeconomic status (SES) (income and poverty) insurance status, rural location, availability of cardiologists, and clustering of patients within hospitals. Similar comparisons were made for ST segment elevation MI (STEMI) and non-STEMI AMIs. Finally, using census county-level data, we compared inpatient AMI mortality rate differences by ethnicity (Indian, Filipino, Vietnamese, Korean, Japanese, and others) treating Chinese as the reference group.

RESULTS: The selected 15 states contained over 75 % of the national Asian population. We identified a total of 444,431 AMIs across race/ethnicity: Asians (2.8 %), Hispanics (11.9 %), non-Hispanic blacks (9.2 %), non-Hispanic whites (70.2 %), others (3.3 %) and missing (2.6 %). Observed inpatient mortality rate was higher among Asians (7.8 %) compared to whites (6.5 %), blacks (5.5 %) and Hispanics (6.2 %) (all p values < 0.05). We examined non-ST segment elevation MI (NSTEMI) and ST segment elevation MI (STEMI) separately and found that inpatient mortality for Asians was the highest for both types (NSTEMI mortality: 5.8 % (Asian), 5.0 % (White), 4.1 % (Black), 4.8 % (Hispanic) and STEMI mortality: 11.0 % (Asian), 9.6 % (White), 9.8 % (Black), 9.0 % (Hispanic)). After adjusting for sex, age, comorbidities and state of residence, inpatient mortality was highest among Asians, but similar among blacks and Hispanics, compared to whites (Table 1). To understand possible mediators of this association, we also examined for racial/ethnic differences in area-level indicators of SES, rural location, and provider availability. It showed that a lower proportion of Asians belonged to high poverty level and a majority of the Asians resided in large metropolitan areas (1+ million population) with high number of cardiologists available (Table 2). Among different Asian ethnicity groups compared to Chinese, the differences in inpatient AMI mortality did not attain statistical significance.

CONCLUSIONS: Despite more favorable socioeconomic status and provider availability indicators among Asian Americans, they had higher AMI inpatient mortality compared to whites, blacks and Hispanics. Further study is required to better understand the underlying causes.

Estimates of Disparities in Inpatient Mortality among patients admitted for AMI: Odds ratio (with 95 % confidence interval)

	Asian or Pacific Islander	Hispanic	Non-Hispanic Black	Other
AMI	1.29 [1.12, 1.47]	1.05 [0.97, 1.14]	0.95 [0.88, 1.03]	1.14 [1.02, 1.28]
STEMI	1.20 [0.98, 1.47]	0.95 [0.84, 1.08]	1.10 [0.97, 1.25]	1.23 [1.05, 1.46]
NSTEMI	1.35 [1.12, 1.63]	1.16 [1.05, 1.29]	0.95 [0.86, 1.06]	1.11 [0.95, 1.30]

Reference=non-Hispanic whites

Table 2 Racial/ethnic Differences in Area Level Socioeconomic Status and Provider Availability Indicators

	White	Black	Hispanic	Asian	Other
% Living in high poverty level areas	19	42	51	19	33
% Living in major metropolitan areas	56	79	67	88	71
% Living in areas with 16+ cardiologists/county	63	75	79	85	76

HIGHER LEVEL OF PATIENT-CENTERED MEDICAL HOME IMPLEMENTATION ASSOCIATED WITH IMPROVEMENTS IN CLINICAL QUALITY OF CARE IN THE NATION-WIDE VHA PACT INITIATIVE Ann-Marie Rosland^{3, 5}; Edwin Wong¹; Donna M. Zulman^{6, 7}; Rebecca I. Piegari⁴; Katherine Prenovost³; Stephan D. Fihn⁴; Karin M. Nelson^{1, 2}. ¹Northwest Center for Outcomes Research in Older Adults, Seattle, WA; ²University of Washington, VA Puget Sound, Seattle, WA; ³VA Ann Arbor, Ann Arbor, MI; ⁴Department of Veterans Affairs, Seattle, WA; ⁵University of Michigan Medical School, Ann Arbor, MI; ⁶VA Palo Alto, Palo Alto, CA; ⁷Stanford University, Palo Alto, CA. (Tracking ID #2198149)

BACKGROUND: In 2010, the Veterans Health Administration (VHA) began to establish patient-centered medical homes (PCMH) at all primary care (PC) clinics nationwide as part of the Patient Aligned Care Teams (PACT) initiative. PACT focuses on whole-clinic improvements in patient-centered care delivery, such as increased continuity and access and multi-disciplinary team-based care. PACT does not explicitly focus on care for specific medical conditions or patient populations. However, effective implementation of PCMH may have beneficial effects on care for chronic illness. This study examined whether extent of PACT implementation at individual VHA PC clinics by 2012 was associated with changes in chronic illness care between 2009 (pre-PACT) and 2013.

METHODS: Pre-post observational study of VHA's 955 PC clinics (serving >5 million patients). Using multivariate linear regression, we examined the association between clinics' PACT implementation and clinic-level change in 15 individual clinical quality indicators (CQI) for patients with diabetes (DM), hypertension (HTN), ischemic heart

disease (IHD), and heart failure (HF). CQI were collected by VHA's External Peer Review Program, in which external contractors manually abstract electronic health records to assess clinical performance using standardized criteria. Each indicator is expressed as the % of a clinic's qualifying patients who received guideline adherent care. PACT implementation was measured using the previously developed PI² score, an 53 variable index representing 8 PCMH domains, ranging from -8 (least extensive implementation) to +8 (most extensive). All models were adjusted for clinics' baseline value of the CQI measure, community vs. hospital-based clinic, rural vs. urban location, and area unemployment levels. Results are reported as model-based predictions for 2009–2013 change in proportion of patients receiving guideline adherent care for clinics with the least PACT implementation (PI²<-4) vs. those with the most (PI²>+4).

RESULTS: Overall, clinical quality was high. However, more extensive PACT implementation was significantly associated with larger improvements in 5 quality measures at $p<0.05$ and in 2 measures at $p<0.06$. Specifically, compared to clinics with the least PACT implementation, clinics with the most PACT implementation had significantly greater improvements in: annual LDL measurement in IHD (2009–13 predicted change +2.4 % vs. 0 %, $p<0.01$), LDL<100 in IHD (+7.8 % vs. +2.7 %, $p<0.01$) and DM (+3.1 % vs. +0.09 %, $p=0.06$), ACE inhibitor or ARB prescription for recent IHD with EF <40 % (+0.03 % vs. -0.02 %, $p<0.01$), blood pressure <160/100 in HTN (+0.8 % vs. -0.9 %, $p<0.001$) and DM (+0.2 % vs. -1.1 %, $p=0.03$), and annual HbA1c measurement in DM (+1.3 % vs. +0.5 %, $p=0.06$). Measures for which change over time was unassociated with PI² score were: aspirin prescription in CVD or DM; HbA1c<9 in DM; regular foot, retinal or renal function checks in DM; and HF with EF<40 % with ACE inhibitor/ARB prescription.

CONCLUSIONS: Over the period of initial PACT implementation, clinics with PACT most extensively in place by 2012 had significantly larger improvements in almost half of the chronic disease process and outcome quality measures examined. This study suggests that focusing resources on PCMH-aligned changes in care delivery across all patients may result in downstream improvements in quality of care and clinical outcomes for patients with specific chronic diseases.

HIV AND ASCVD RISK: AN EVOLVING DISEASE REQUIRES EVOLVING PREVENTION STRATEGIES Cameron Lambert; Pratik Sandesara; Laurence Sperling. Emory University School of Medicine, Atlanta, GA. (Tracking ID #2196424)

BACKGROUND: Premature ASCVD amongst HIV patients is a well-known complication of the disease and will become more prevalent as the life expectancy of HIV patients increases. The higher incidence of ASCVD in the HIV population is likely due to the increasing life expectancy of infected patients and HIV related non-traditional risk factors such as endothelial dysfunction. As the ability to control HIV infection evolves, so should clinicians' approach to ASCVD prevention strategies in these patients. Currently, risk factors are not often known, inconsistently identified and opportunities to modify risk are lost. This investigation aimed to 1) Describe the prevalence of common ASCVD risk factors in the HIV population and 2) Determine if an HIV population with elevated ASCVD risk received appropriate risk optimization.

METHODS: We examined data from the NHANES (National Health and Nutrition Examination Study) database from 1999–2012. We extracted the HIV population, their ASCVD risk factors and list of medications. Using the 2013 ACC/AHA pooled cohort risk assessment tool from the Guideline on the Assessment of Cardiovascular Risk, ASCVD risk was estimated.

RESULTS: HIV patients accounted for 0.53 % of the 22,384 surveyed subjects within the NHANES database ($n=119$). Thirty-four percent of these HIV patients reported taking antiretroviral therapy (ART). The HIV population was 67 % African-American ($n=80$), 73 % male ($n=87$) and had a median age of 39. Blood pressure was not optimally controlled (systolic blood pressure<110 mmHg) in 79 % of patients ($n=77$). Total cholesterol was not optimally controlled (<170 mg/dL) in 59 % of patients ($n=68$). Fifty-seven percent reported a smoking history ($n=68$) and 6 % were diabetic ($n=7$). The four groups likely to benefit from statin therapy according to the ACC/AHA guidelines were analyzed in this study. Those with proven ASCVD were not assessed given the lack of data. Of the 10 participants with 10-year ASCVD risk predictions greater than 7.5 %, only 1 was prescribed a statin. Two of six (33 %) patients aged 40 to 75 with diabetes and LDL 70–189 mg/dL were prescribed a statin. No HIV patients had LDL levels greater than 190 mg/dL.

CONCLUSIONS: ASCVD risk factors are highly prevalent in the HIV population. This may be due to virus-related factors, ART-related off target effects or epidemiologic differences. Prevention of morbidity and mortality in the HIV population must start with early detection of the viral infection. Aggressive risk factor modification strategies must be universally applied from the time of diagnosis to mitigate the ASCVD risk in the HIV population.

HOLDOVER SIGNOUT: CHARACTERISTICS OF NEW OVERNIGHT ADMISSION HANDOFFS Jonathan Duong²; Trevor Jensen²; Sasha Morduchowicz²; Stephanie Rennke¹; Lekshmi Santhosh²; Sarah Schaeffer²; James D. Harrison²; Bradley A. Sharpe¹; Sumant Ranji². ¹UCSF, San Francisco, CA; ²University of California San Francisco, San Francisco, CA. (Tracking ID #2196931)

BACKGROUND: Resident duty hour restrictions have resulted in an increase in the number of new overnight admissions that are subsequently transferred to day teams. These "holdovers" make up about 40 % of all admissions to our teaching medicine service, however, little is known about the efficiency, safety and educational objectives of holdover signout. Our goal is to describe baseline characteristics of holdover signouts in an internal medicine residency program.

METHODS: We performed an observational cross sectional study using a convenience sample of morning holdover signouts between overnight admitting residents and receiving day teams on our inpatient medicine service. Receiving day teams consisted of medical students, interns, a resident, and an attending. Signout included the overnight resident presentation, closing the loop by the day team, and any teaching or constructive feedback by team members. Closing the loop consisted of after-presentation questions, clarifications, and to-dos, while constructive feedback included specific statements designed to acknowledge or improve overnight management. We audited the duration of each holdover signout, and the frequency of signouts with closing the loop, teaching moments, and immediate constructive feedback. A subset of holdover observations also measured the frequency of presentations with interruptions by team members and the duration of the overnight resident presentation, including patient data (history of present illness, review of systems, physical exam, social/family history, medications and laboratory data) and assessment and plan. We summarized the data using descriptive statistics.

RESULTS: We observed 61 holdover signouts performed by 47 residents, which are detailed in Table 1. The median holdover signout duration was 14.3 min. The receiving team closed the loop for all observed signouts. Teaching moments from team members occurred at a rate of 32.8 % while immediate constructive feedback did not occur. The subset data consisted of 34 holdover signouts, with the median resident presentation lasting 13.4 min. The patient data portion, all of which can be found in our electronic medical record (EMR), made up a median 62.0 % of the presentation time. Three presentations had interruptions by team members.

CONCLUSIONS: This is the first known reported data on holdover signouts. Holdover signout is a longer process than other signout and patient data available in an EMR may not need to be a substantial portion of holdover presentations. In addition, overnight admissions are a source of missed teaching and feedback opportunities for overnight residents. These findings suggest there may be a role for creating standard best practices to improve efficiency and education during the holdover signout process.

Holdover admission signout characteristics

Table 1: Holdover admission characteristics

Total observations (N=61)	% (n)	Minutes		
		Median	Min	Max
Frequency of closing the loop	100.0 (61)	—	—	—
Frequency of teaching moments	32.8 (20)	—	—	—
Frequency of feedback	0.0 (0)	—	—	—
Duration of entire holdover signout	—	14.3	7.3	43.0
Subset of observations (N=34)	% (n)	Median	Min	Max
Duration of patient data presentation	—	8.3	2.9	12.7
Duration of assessment and plan presentation	—	4.9	2.5	8.9
Total duration of resident H&P presentation	—	13.4	5.4	21.3
% of presentation consisting of patient data available elsewhere in EMR	—	62.0 %	52.0 %	72.0 %
Duration of closing the loop and teaching, if present	—	1.5	0.5	16.1
Frequency of interruptions	8.8 % (3)	—	—	—

HOSPITALIST AND SUBSPECIALIST PERSPECTIVES ON INPATIENT CONSULTATIONS Kelly Pacitti; Anne Mathew; Amanda Roysse; Dr. Kim Jordan; John Elliot, PhD. Riverside Methodist Hospital, Columbus, OH. (Tracking ID #2195936)

BACKGROUND: The growth of Hospitalist Medicine has changed the dynamic and practice of inpatient care. Early literature reported that hospitalist care reduces length of

stay (LOS) and costs; however, a recent JAMA study found both increased cost and LOS with increased hospitalist workload. Medical subspecialty consultation is a key component in the hospitalist's patient management with potential to affect both cost and quality measures. A study examining Medicare spending found increased costs in several regions in part secondary to specialist consultation. There is a paucity of literature on the interactions between the hospitalist and the medical subspecialist and effect on patient management. This study investigated perceptions on workload, perceived appropriateness of consultations, and communication between the hospitalist and the subspecialist.

METHODS: An anonymous practice pattern survey was sent to 656 hospitalists and 295 subspecialists (nephrologists and endocrinologists) across Ohio. Data on demographics, patient workload and communication methods were obtained. Responses to hyponatremia and diabetes ketoacidosis management questions were used to determine perceptions of need for consultation. Survey responses were dichotomized to "about half the time/mostly/always" vs "never/occasionally" as well as "low volume" (0–14 patients) and "high volume" (≥ 15 patients) for comparison purposes.

RESULTS: Survey combined response rate was 14.3 % (11.7 % hospitalists and 17.3 % consultants). Perceptions of communication differed: 100 % of hospitalists compared to 73.9 % (95%CI:60.7–87.1) of consultants answered that reason for consultation is stated "half the time/mostly/or always". Direct communication for urgent consults was reported by 97.3 % (95%CI:93.6–100.0) of hospitalists though 48.8 % (95%CI:32.8–64.8) of consultants reported receiving direct communication. More hospitalists with high census answered "never/occasionally" to direct communication with subspecialists than did hospitalists with low census: 71.7 % vs 37.9 %, $p=0.008$. Additionally, 38.3 % hospitalists with high census reported placing consults for medical conditions that a general internist could manage without assistance compared to 6.9 % of hospitalists with low census, $p=0.003$. Only 50.0 % (95%CI:38.5–61.5) of hospitalists reported that consultant input resulted in major management change vs 81.0 % (95%CI:68.6–93.3) of consultants. In particular, the groups differed on consultation need for hyponatremia management: 35 % (95%CI:12.6–58.0) of subspecialists felt consultation was appropriate compared to 5.3 % (95%CI:0.1–10.4) of hospitalists. Interestingly, 53 % of high census hospitalists reported that patient load interfered with management of glucose and sodium details the majority of the time compared to 24 % of low census hospitalists, $p=0.017$. Reasons listed for consultation requests per hospitalists included: medical-legal concerns (34.2 %, 95%CI:23.3–45.1) and spectrum of disease outside of clinical practice (66.2 %, 95 % CI:55.2–77.2). The majority of respondents in both groups reported that consultation did not shorten LOS.

CONCLUSIONS: Discrepancies exist in how hospitalists and subspecialists view their roles and impact on patient care. Though limited by small response rate, this survey highlights aspects of ineffective communication between these groups and their different perspectives on need for consultation, as well as the adverse impact of high census on patient management. Future work directed at improved communication and establishment of guidelines for appropriate consultation may improve and expedite the inpatient work-up and contribute to lower healthcare costs.

HOW NURSE CARE MANAGERS WORK WITH CHRONIC PAIN PATIENTS ON CHRONIC OPIOID THERAPY TO FACILITATE ADHERENCE TO CLINICAL GUIDELINES BY THE PRIMARY CARE TEAM Allison Lange^{1, 3}, Orlaith Heymann¹, Jane M. Liebschutz¹, Karen E. Lasser^{1, 4}, Christopher W. Shanahan^{2, 3}, Hannah S. Kopinski¹, Jawad M. Husain¹, Phoebe A. Cushman¹, Victoria A. Parker⁴.
¹Boston Medical Center, Boston, MA; ²Boston University School of Medicine, Boston, MA; ³Duke University School of Medicine, Durham, NC; ⁴Boston University School of Public Health, Boston, MA; ⁵Mattapan Community Health Center, Boston, MA. (Tracking ID #2198023)

BACKGROUND: Caring for patients with chronic non-cancer pain who are chronic users of prescription opioids is challenging for healthcare teams due to provider time constraints, lack of consensus about optimal treatment, high risk of misuse and diversion of prescription opioids, and frequent co-occurring illicit drug use. Previous qualitative studies suggest improvement in patient understanding and self-treatment of chronic non-cancer pain after working with a Nurse Care Manager (NCM), but little is known about how NCMs accomplish these outcomes. No study to date has examined whether NCM-patient interactions help increase PCP adherence to chronic opioid therapy guidelines. Our objective is to describe the strategies an NCM uses for effectively interacting with patients on chronic opioid therapy in the context of a multi-component intervention, the Transforming Opioid Prescribing in Primary Care (TOPCARE) cluster randomized controlled trial. TOPCARE's overall goal is to improve opioid prescribing for chronic pain in primary care.

METHODS: We studied patients under the care of PCPs who had been randomized to the intervention arm of the TOPCARE study. We observed interactions that took place

between two NCMs and these patients. A convenience sample of 29 observations was utilized based on the availability of an observer at the time of appointments. Observers took notes using structured observation guides developed after two pilot observations. The structured guide included prompts to note NCM behaviors, patient behaviors, NCM expressed perceptions of risk, NCM feedback to the patient, and NCM goals (established in pre- or post-observation debrief). Whenever possible, observers captured verbatim quotes in the observation notes. Later the same day, the observer added content and context to the notes that had been observed but not recorded. We coded the observations using conventional content analysis and developed codes that best described the interactions. Subsequently, the team refined each code, and then sorted the codes into overarching themes that described different aspects of the NCM's actions. We used Nvivo v. 10 (QSR International, Cambridge, MA) to organize and analyze the data.

RESULTS: Five major strategies emerged from the data analysis. 1) The NCM put the rationale for intensive opioid management into context for the patient. The NCM framed his/her role on the patient's healthcare team, often by offering support for the patient. S/he also explained the reason for increased monitoring of the patient's opioid use. 2) The NCM collected information about the patient's life circumstances to determine their risk for opioid misuse. The NCM used several strategies for collecting information, including asking routine questions about substance use, psychiatric history, and current use patterns of the patient's pain medication to assess risk for opioid misuse. Additionally, the NCM asked open-ended questions and clarified the patient's behavior with probing questions. 3) The NCM coached patients to help them navigate their illness, medication use, and the healthcare system by offering clinical recommendations and giving information about how opioid medications work. 4) The NCM and the patient discussed discrepancies and changes to the patient's opioid prescriptions and chronic pain management plan. The NCM made observations about inconsistencies in the patient's story, and the patient explained the discrepancy either with a reason that did not violate the opioid treatment agreement or with admission to behavior violating the treatment agreement. The patient and NCM sometimes disagreed about the NCM's assessment and the patient and NCM arrived at different conclusions. 5) The NCM initiated a therapeutic relationship with patients by attempting to connect with them, make them feel comfortable, and by providing empathetic responses. All themes were observed across multiple NCM-patient interactions.

CONCLUSIONS: As a vital component of the healthcare team, NCMs collected information and used coaching strategies to encourage chronic non-cancer pain patients on chronic opioid therapy to participate in guideline-adherent practices with their primary care provider. To our knowledge, no other study has described how the NCM's activities with patients contribute to improved PCP provision of guideline adherent care. These findings will contribute to the successful replication of NCM intensive management strategies in other primary care settings.

HOW STRONG IS THE PRIMARY CARE SAFETY NET? ASSESSING THE ABILITY OF FEDERALLY QUALIFIED HEALTH CENTERS TO SERVE AS PATIENT-CENTERED MEDICAL HOMES Jamie Ryan, Pamela Riley. The Commonwealth Fund, New York, NY. (Tracking ID #2198640)

BACKGROUND: Federally Qualified Health Centers (FQHCs) are community-based clinics that provide comprehensive primary care and behavioral and mental health services regardless of patients' ability to pay. There is much debate surrounding how the implementation of the Affordable Care Act (ACA) is affecting these health centers' ability to accommodate increased demand. After implementation of state health reform in Massachusetts in 2006, health centers observed an increased demand for services among newly insured low- and middle-income residents. The ACA has the potential to similarly increase demand for services at FQHCs nationwide, elevating the importance of these centers' ability to provide quality, cost-effective care. A prior Commonwealth Fund study found that health centers that function as medical homes—that is, primary care practices that are able to provide high-quality, comprehensive, easily accessible, patient-centered care—are associated with the reduction, and even elimination, of racial and ethnic disparities in health care delivery and health status. In light of the reduction in disparities afforded by medical homes, it is important to study the implementation of the medical home model among primary care providers for the most vulnerable populations.

METHODS: Data come from the 2009 and 2013 Commonwealth Fund Surveys of Federally Qualified Health Centers that were conducted among a nationally representative sample of FQHCs. The 2009 survey was conducted by mail, online and by phone, March–May 2009; the 2013 survey was conducted by mail and online, June–October 2013. We created a 12-point scale of medical home capacity based on R. Nocon et al.'s Short-Form Safety Net Medical Home Scale. This scale assesses six domains of the medical home: Access and Communication, Patient Tracking and Registry, Care Management, Test and Referral Tracking, Quality Improvement, and External Coordination. We considered a health center to have high medical home capacity if it can perform at least nine of the 12

core functions; medium capacity is defined as meeting six to eight functions, while low capacity is defined as meeting fewer than five functions.

RESULTS: Federally qualified health centers exhibited a marked increase in their capability to function as medical homes from 2009 to 2013. The percentage of centers exhibiting high medical home capacity more than tripled, from 5 % in 2009 to 16 % in 2013. The majority of centers (61 %) exhibited medium or high medical home capacity in 2013; this is a marked improvement over 2009, when the majority (64 %) exhibited low medical home capacity. The greatest improvements were observed in the domains of patient tracking and registry functions and care management capacity, whereas health centers' performance actually decreased in the area of coordinating with external providers. Fewer than one-quarter of all centers reported easily obtaining specialist or subspecialist appointments (22 %) and procedures (22 %) for their Medicaid patients; these figures drop to 7 and 4 %, respectively, for uninsured patients. However, among those centers possessing the attributes of a medical home, these figures nearly doubled.

CONCLUSIONS: Our findings show that on the whole FQHCs have increased their capacity to serve as medical homes, and as such are likely better prepared to meet the increased demands they will face to effectively meet patients' needs under the ACA's coverage expansions. The progress experienced by FQHCs may be attributable in part to concerted efforts by the Bureau of Primary Health Care to prioritize medical home transformation among the nation's community health centers. Despite increasing medical home capacity among FQHCs, challenges persist with obtaining specialty care access for Medicaid and uninsured patients, a difficulty that is only anticipated to increase under the Affordable Care Act. Participation in integrated delivery systems, such as accountable care organizations, is one promising avenue to improve specialty care access for Medicaid beneficiaries served by FQHCs. However, additional support is needed to help community health centers overcome the financial and infrastructural challenges to participating in integrated care delivery models.

HUMAN PAPILLOMAVIRUS TESTING BY VETERANS ADMINISTRATION WOMEN'S HEALTH PROVIDERS: A PILOT STUDY Laura D. Hallett^{1,2}; Megan R. Gerber^{1,2}. ¹Boston University, Jamaica Plain, MA; ²Boston University Medical Center, Needham, MA. (Tracking ID #2201144)

BACKGROUND: Evidence-based guidelines have been created by professional societies, including the American Society for Colposcopy and Cervical Pathology (ASCCP) and United States Preventive Services Task Force (USPSTF), for use of human papillomavirus (HPV) cotesting in cervical cancer screening. Inappropriate use of HPV testing may lead to unnecessary procedures and added cost. We investigated whether Veterans Administration (VA) providers order HPV consistently with these guidelines. As more women veterans access VA care, it is critical to ascertain whether evidence-based care is delivered.

METHODS: To evaluate HPV ordering, we undertook a pilot chart review of all patients aged 18–65 for whom an HPV test was ordered in fiscal year 2014 at VA Boston. We collected data including patient age and gynecologic history to determine whether HPV testing was ordered according to USPSTF guidelines for screening and ASCCP guidelines for follow-up of abnormal cytology. If testing was inconsistent with guidelines, we examined whether the reason for HPV testing was documented in the chart. Reflex tests, added when the cytology showed ASC-US (atypical squamous cells of undetermined significance), were excluded from analyses since they were not ordered by providers. We also ascertained whether colposcopy was ordered subsequent to HPV testing.

RESULTS: We examined 210 charts of patients for whom HPV testing was ordered. One hundred forty-two patients (67.6 %) had an HPV test inconsistent with USPSTF and ASCCP guidelines. Of these, 90 had no reason for the test documented by the provider. For the 53 patients with a documented reason for HPV testing, the most common were history of cervical dysplasia, HPV positivity, and STI testing. Three tests were ordered at patient request. Of the 142 patients tested off guidelines, 62 had a history of abnormal cytology, and six had a history of CIN2, CIN3 or adenocarcinoma in situ. Patients reporting history of an abnormal pap were nearly three times as likely (age-adjusted OR 2.66 [1.45, 4.89]) to undergo guideline-based HPV testing as those with no such history. This relationship persisted when women under 30 ($n=31$) were removed from the analyses. Thirteen patients with a negative pap smear and positive HPV test were referred for colposcopy; of these 13, 10 tests were ordered in discordance with guidelines.

CONCLUSIONS: This study demonstrated potential overuse of HPV testing among women's health providers at one VA. Patients with abnormal pap histories had higher odds of having a test ordered according to guidelines, suggesting that providers may lack an understanding of HPV testing guidelines for screening healthy asymptomatic women. This knowledge deficit is further evidenced by use of HPV testing as STD screening. Because this study only examined cases in which HPV testing was ordered, a future study evaluating all women presenting for cervical cancer screening could examine the effect of

variables such as prior history of dysplasia on providers' decisions to order HPV testing. Development of an educational intervention or decision aid may improve VA providers' use of HPV testing guidelines.

HYPERTENSION KNOWLEDGE IMPACTS ANTIHYPERTENSIVE MEDICATION ADHERENCE Leonardo Tamariz¹; Irene Kirolos²; Ana M. Palacio¹. ¹University of Miami, Miami, FL; ²University of Miami-Miller School of Medicine, Miami, FL. (Tracking ID #2198200)

BACKGROUND: One-half of patients in the United States with hypertension have poorly controlled blood pressure. A major contributor to poor blood pressure control is poor adherence to prescribed antihypertensive medication therapy. However, reasons for nonadherence and strategies to improve it remain elusive. The purpose of this study is to evaluate the effect of hypertension knowledge and minority status on self-reported medication adherence.

METHODS: We conducted a cross-sectional evaluation of hypertensive patients attending their scheduled primary care visits at the Miami VA. We measured hypertension knowledge using a validated brief 10-question survey that evaluated understanding the definition of hypertension, its long term effects and lifestyle and behavior factors that might affect blood pressure control. We defined low hypertension knowledge if participants answered 3 questions incorrectly. Our outcome variable was medication adherence measured using 8-item Morisky Medication Adherence scale (MMAS-8). We calculated the prevalence of low hypertension knowledge and reported differences by race using ANOVA. We used linear regression to determine the beta coefficient of hypertension knowledge.

RESULTS: We recruited 125 Veterans with hypertension and a mean age of 61.6+/-9.1 of whom 29 % were Hispanic and 46 % were Black. The prevalence of low hypertension knowledge was 23 %; 95 % CI (19–27). White hypertensive patients had the highest hypertensive knowledge (8.7+/-0.9) compared to Hispanics (7.8+/-1.7) and Blacks (8.1+/-1.3) ($p=0.01$). Self-reported adherence was similar between all ethnicities ($p=0.57$). The beta-coefficient of hypertension knowledge for medication adherence was -0.33; 95 % CI -0.58 to -0.07 $p=0.01$ adjusted for demographics, health literacy and pill burden. The beta coefficient of the interaction between hypertension knowledge and ethnicity was -0.09 95 % CI -0.58 to 0.40 $p=0.71$.

CONCLUSIONS: Low hypertension knowledge is common among hypertensive veterans and this impacts medication adherence independent of ethnicity, pill burden and health literacy. Future studies evaluating interventions to improve adherence to blood pressure medications should include strategies targeting hypertension knowledge.

IDENTIFYING AND DEFINING CONTENT DOMAINS FOR A SCIENCE OF HEALTHCARE DELIVERY CURRICULUM: RESULTS FROM THE AMERICAN MEDICAL ASSOCIATION ACCELERATING CHANGE IN MEDICAL EDUCATION SYSTEMS-BASED PRACTICE WORKING GROUP Jed Gonzalo¹; Stephanie Star²; Michael Dekhtyar²; Jeffrey Borkan⁴; Susan Skochelak². ¹Penn State College of Medicine, Hershey, PA; ²American Medical Association, Chicago, IL; ³Mayo Clinic, Rochester, MN; ⁴Warren Alpert Medical School of Brown University, Providence, RI. (Tracking ID #2194944)

BACKGROUND: The emerging transformation in healthcare delivery, which includes a fundamental shift in the traditional physician role, requires an increased focus on an expanded set of competencies in systems-based practice (SBP), or the Science of Healthcare Delivery (SHCD). Although educators have called for an increased focus on SHCD curriculum topics, including interprofessional collaboration, quality and safety, and population health, the integration of these topics in undergraduate (UME) and graduate medical education (GME) has been limited. The incorporation of SHCD topics requires a clear and expansive understanding of potential topics that could be included in such a curriculum, which are independent of traditional basic and clinical sciences. However, definitions of "SBP" do not explicitly delineate educational topic areas, and the literature related to SHCD topics is scattered and seemingly opportunistic rather than comprehensive and synthetic. In 2013, the American Medical Association (AMA) awarded 11 grants to US medical schools to Accelerate Change in Medical Education (ACE). By leveraging the progress of the AMA's ACE grantee schools, in this study, we explicitly sought to develop a comprehensive content framework for a SHCD curriculum.

METHODS: The AMA's ACE SBP working group embarked on a two-phase project to address deficiencies in a comprehensive SHCD curriculum by investigating content areas currently or proposed-to-be implemented within 1 year at a sampling of US medical schools. Our investigation was sensitized by Engel's biopsychosocial model, allowing for a broad-based empirical lens to identify curriculum areas beyond the biomedical

components of physician-patient interactions, including subsequent levels in the social hierarchy from psychological to systems levels. First, we analyzed full grant submissions to the AMA's ACE grant program ($n=30$) to identify preliminary SHCD content domains and develop operational definitions for each. Using the process of constant comparative analyses, two investigators generated a preliminary codebook and analyzed segments of the dataset independently, with data management support from Atlas.ti™ 6.0 and NVivo™. At regular intervals, investigators compared codes for inconsistency and agreement, and updated and modified the codebook. Next, using these curriculum domains and definitions, participating AMA ACE schools ($n=11$) performed an in-depth assessment of curriculum documents and syllabi from all 4 years in their UME program to identify specific content areas within these domains.

RESULTS: Our preliminary analyses identified two categories of domains: curriculum domains and cross-cutting domains. Curriculum domains refer to content applicable to the SHCD, including: (1) Structures and Processes, e.g. resources, interprofessional collaboration, accountable care organizations, (2) Policy and Economics, e.g. the Affordable Care Act, insurance, reimbursement, (3) Clinical Informatics and Health Information Technology, e.g. electronic health records, point-of-care decision making tools, data registries, (4) Population and Public Health, e.g. population health interventions, community resources, (5) Socio-Ecological Determinants of Health, e.g. health disparities, cultural bias, (6) Value-Based Care, e.g. cost-conscious care, patient safety, and, (7) Health System Improvement, e.g. quality improvement principles. Cross-cutting domains referred to content traditionally addressed in UME curriculum, but now newly contextualized within content areas of a SHCD Curriculum, including leadership, teamwork, systems thinking, evidence-based medicine, ethics and professionalism, and scholarship.

CONCLUSIONS: In this investigation to develop a comprehensive framework for a SHCD curriculum, we identified 7 content and 6 cross-cutting domains currently applied in US medical schools. Traditionally, the term systems-based practice (SBP) has been used to address trainee competency at the UME and GME levels, however a comprehensive understanding of content domains potentially applicable to SBP have not been identified. These results provide the foundation for a comprehensive framework for a SHCD curriculum, and expand the working definition of SBP to include other critical components of the SHCD traditionally outside of teamwork and quality improvement. The identification of cross-cutting domains contextualized in a SHCD curriculum domains highlight the overlap of proposed "new" content areas with the traditional areas of curriculum, and reflect the need to reexamine and update curriculum to better align with current educational needs. These results can inform UME and GME programs developing SHCD curricula and the milestones and competencies related to the SHCD, and can catalyze the national conversation regarding the knowledge and skills required for physician trainees to become collaboratively effective, systems-based physicians.

IDENTIFYING CHALLENGES IN IMPLEMENTING SYSTEMS-BASED CURRICULUM: A QUALITATIVE ASSESSMENT OF MEDICAL STUDENT PERSPECTIVES Jed Gonzalo; Daniel R. Wolpaw; Paul Haidet. Penn State College of Medicine, Hershey, PA. (Tracking ID #2194911)

BACKGROUND: To foster the education of collaboratively effective, systems-based physicians, educators have recommended expanding the traditional basic science model to include systems sciences, such as population health, quality improvement, and high-value care. Despite these recommendations, educational programs still primarily focus on physician-centric knowledge and skills rather than systems abilities. With recommendations to expand systems sciences into undergraduate and graduate programs, educators must address the challenges involved with successfully integrating systems courses into the curriculum. To our knowledge, no studies have explored the challenges associated with integrating systems sciences. In 2013, our medical school received a grant from the American Medical Association to implement a new Systems Curriculum, which included an 18-month long course focused on insurance, cost, care coordination, population health, value, and teamwork, along with an experiential role for students to serve as patient navigators in the healthcare system. In support of our planning and design efforts, we undertook this study to identify "special pedagogical challenges" by exploring our students' understanding of systems-based practice and attitudes toward a systems curriculum.

METHODS: From December 2013 to February 2014, we digitally-recorded 11 focus groups with a purposive sample of 1st to 4th-year medical students at the Penn State College of Medicine. Our interview guide consisted of primarily open-ended questions that explored students' understanding of systems-based practice, their perceived benefits and barriers to implementing a systems curriculum, and factors that may diminish success of this initiative. Based on our literature review, student attitudes regarding systems curriculum and experiences were not identified, therefore we used a data-driven, inductive thematic analysis. The process of constant comparative analyses was used to identify initial themes and categories, and generate a preliminary codebook. Two investigators

independently analyzed an initial transcript and compared initial codes for agreement, and jointly adjudicated and updated the codebook. Then, the remaining transcripts were coded, with regular adjudication sessions. Disagreements were discussed and additional codes created and collapsed, and the codebook was subsequently modified.

RESULTS: Eleven focus groups were completed (41 total part) with three groups of 1st-year students ($n=11$), three groups of 2nd-year students ($n=13$), three groups of 3rd-year students ($n=11$), and two groups of 4th-year students ($n=6$). In our preliminary analysis, we found that although students struggled to define the phrase "systems-based practice," group discussion revealed a strong understanding of systems concepts and healthcare delivery. Several perceived benefits to a systems curriculum included the acquisition of systems knowledge and skills, enhanced understanding of patients' perspectives, and students' re-engagement with their motivations for entering medicine. Barriers were categorized into six themes: (1) primacy of traditional examinations, (2) lack of sufficient knowledge and skills to be effective with patients, (3) culture un conducive for systems science education, (4) a notion of systems topics as "non-essential" learning, (5) concern for lack of standardization of educational experiences, and, (6) "not my job." Underlying these findings was students' recognition of competing priorities - one to perform well on examinations and enter residency, and another to develop a skill set that includes abilities not necessarily tested on standardized examinations but critical to become a "good" physician.

CONCLUSIONS: Despite demonstrating uncertainty about the definition of "systems-based practice," students demonstrated a good working knowledge of systems concepts. Students reported several foundational perceived benefits for experiencing a new systems curriculum, including a focus on patient-centered experiences and perspectives. At the same time, the principal driver of students' motivations in medical school is achieving good examination and evaluation scores to improve chances of a successful residency match. Consequently, the introduction of new systems sciences, with limited penetration into board examinations or residency acceptance, would be viewed as "peripheral" and "non-essential." Students identified their primary external drivers of influence, such as board examinations, are often "at odds" with their intrinsic desire to pursue the core skills required to become a patient-centered, systems-savvy physician. Recognizing the success of any curriculum depends on student engagement, if the goal is to transform medical education to meet the evolving demands of medical practice, then educators must do more than introduce new curriculum. We must find creative ways to move from "important" to essential, and make systems-based learning "count" in the eyes of our students.

IDENTIFYING ONE PERSONAL DOCTOR IN CARE IS ASSOCIATED WITH HEALTH CARE SATISFACTION Joshua M. Liao^{1, 3}; Mark J. Ommerborn²; Cheryl R. Clark¹. ¹Brigham and Women's Hospital, Boston, MA; ²Brigham & Women's Hospital, Boston, MA; ³Harvard Medical School, Boston, MA. (Tracking ID #2199249)

BACKGROUND: Patient satisfaction with health care is a complex but important part of evaluating health care quality, value, transparency, and patient-centeredness. In some populations, satisfaction has been correlated with aspects of "personal care," defined as the ability to choose a personal doctor, establish a personal patient-physician relationship, or maintain regular sources of care. Known determinants of both satisfaction and aspects of personal care include race/ethnicity, socioeconomic status, health status, insurance status and delayed care. As value-based reform and new delivery models alter how patients and physicians interact, it is important to understand the association between personal care and satisfaction. However, there are limited available data from general population-based samples examining the relationship between having one or more personal doctor(s) as an aspect of personal care and health care satisfaction. Our analysis examines the association between the self-reported ability to identify a personal doctor and satisfaction in a nationally representative cohort of adults in the US. Our analysis tests the hypothesis that patients who identify a personal doctor in their care will be more satisfied with health care compared to those who are unable to identify a personal provider and those who identify multiple providers in their care.

METHODS: We analyzed cross-sectional data on 225,184 adults from the 2013 Behavioral Risk Factor Surveillance System, a state administered telephone survey of non-institutionalized US households. Health care satisfaction was assessed with the question "In general, how satisfied are you with the health care you received?" We compared individuals very satisfied with the care received with individuals somewhat or not at all satisfied with the care received. Having a personal provider was assessed with the question "Do you have one person you think of as your personal doctor or health care provider?" Responses included: yes, only one; more than one; or no. Descriptive statistics were described by percentages and compared by χ^2 tests. To estimate the odds of being very satisfied with care associated with having a personal provider, we fit weighted logistic regression models adjusted for age, sex, race/ethnicity, delayed health care, time since last doctor checkup, the number of doctor visits in the past year, health insurance status,

cardiovascular disease, diabetes, self rated health status, body mass index, employment status, education and income. Wald-F tests were used for all tests of significance. Statistical analysis was performed in SAS-callable version of SUDAAN (version 9.0.1) using sampling weights to account for the complex survey design. Statistical analysis used two-tailed significance tests at the 0.05 alpha level.

RESULTS: Adults with a personal doctor were generally very satisfied with their health care (68 % very satisfied vs. 32 % somewhat or not satisfied). Adjusting for age and sex, adults with no personal doctor [OR 0.48, 95 % CI (0.46–0.51)] or more than one personal doctor [OR 0.77, 95 % CI (0.72–0.81)] were less likely to be very satisfied with care compared to adults who identified a single personal doctor (Table 1). Similarly, adjusting for other covariates—race/ethnicity, socioeconomic status, delayed care, frequency of doctor visits, health insurance status, and self-rated health and co-morbid conditions—those with no personal doctor [OR 0.65, 95 % CI (0.62–0.69)] or more than one personal doctor [OR 0.85, 95 % CI (0.80–0.91)] were less likely to be very satisfied with care.

CONCLUSIONS: In this large national cohort, satisfaction with care was associated with a number of factors, including patients' ability to identify one personal doctor in their care compared to none or more than one such doctor. As new delivery models affect patient care, our results suggest that health care satisfaction might be promoted in part through policies and changes that preserve the personal relationships between patients and physicians.

Odds Ratios for Satisfaction with Health Care Received among Adults in the United States, 2013 BRFSS

Odds Ratios^a (95 % CI)

Data from Centers for Disease Control and Prevention 2013 Behavioral Risk Factor Surveillance Survey. Analysis performed among the $N=255,184$ participants with complete data on all covariates. Notes. ^aMultivariable logistic regression models weighted with rlogit function in SUDAAN. ^bModel adjusted for age and sex. ^cModel adjusted for age, sex, delayed health care, time since last doctor checkup, the number of doctor visits in the past year and health insurance status. ^dModel adjusted for age, sex, health care access variables, cardiovascular disease, diabetes, self rated health, and body mass index. ^eModel adjusted for age, sex, health care access variables, health variables, race/ethnicity, employment status, education, income and statistically significant interaction between education and income.

IMPACT OF AN INNOVATIVE INPATIENT PATIENT NAVIGATOR PROGRAM ON LENGTH OF STAY AND 30-DAY READMISSION Janice L. Kwan¹; Matthew W. Morgan¹; Thomas E. Stewart²; Chaim Bell¹. ¹Mount Sinai Hospital, Toronto, ON, Canada; ²Niagara Health System, St. Catharines, ON, Canada. (*Tracking ID #2198799*)

BACKGROUND: Inpatient medicine is becoming increasingly complex. Efforts to minimize hospital length of stay (LOS) have resulted in patients being discharged "quicker and sicker". This has prompted the need for adaptive innovation. However, there is limited data describing hospital-based interventions targeting improvements in communication and transitional care. We created a new position, the patient navigator (PN), a dedicated patient care facilitator not responsible for clinical care. PNs were integrated into the inpatient multidisciplinary clinical team to facilitate patient and provider navigation through the complexity of a hospital admission by enhancing communication between and among patients and providers.

METHODS: We implemented the PN program in our 90-bed inpatient general medicine service in June 2010 on 2 of 4 multidisciplinary clinical teams. We expanded to all 4 teams in May 2011. PNs acted as liaisons between and among providers and patients. They attended daily care rounds, expedited consultations and tests, and were available to patients and family members via a dedicated mobile number. They answered questions related to test scheduling and consultations, and promptly relayed care questions to the clinical team. They also assisted in discharge coordination by arranging follow-up appointments, placing phone calls, and serving as primary contact following discharge. We evaluated the PN program using a retrospective cohort study that included all general medical admissions between July 2010 and March 2014 matched by case mix group, age category, and resource intensity weight. There were no exclusion criteria. Our primary outcomes were LOS and 30-day readmission rate. Patients who died, were transferred to or from an acute care facility, or signed out against medical advice were excluded from the 30-day readmission analysis. A secondary analysis restricted the timeframe from July 2010 to April 2011, when only 2 of 4 teams were exposed to PNs. Data were obtained from institutional databases. Mean values were compared using 2-sided t-tests and categorical groups using χ^2 tests. This study was approved by the hospital research ethics board.

RESULTS: Our matched cohort included 7841 admissions (3414 patients), with 5628 admissions (4593 patients) exposed and 2213 admissions (1921 patients) not exposed to PNs. The two groups were similar (Table 1). Admissions with PNs were 1.3 days (21 %

shorter (6.2 vs 7.5 days, $P<0.001$). The restricted analysis found a 1.2 day (18 %) lower LOS (6.4 vs 7.6 days, $P<0.05$). Thirty-day readmission rate was not different between the 2 groups (13.1 vs 13.8 %, $P=0.48$) or in the restricted analysis (12.0 vs 13.5 %, $P=0.40$) (Table 2).

CONCLUSIONS: We describe an innovative inpatient intervention featuring an integrated patient care facilitator not responsible for clinical care. Implementation was associated with a 21 % reduction in LOS without an increase in 30-day readmission. Ineffective communication is a common cause of poor patient outcomes in hospital-based care. This phenomenon can be amplified from external pressures to maximize productivity. PNs may offload care demands by enhancing communication for providers and patients. Our preliminary return-on-investment calculations suggest that the savings incurred from shorter LOS outweigh program costs. Our limitations include potential bias from unmeasured confounders and single-center design. Also, 30-day readmission rates were only captured for our institution, although the majority of readmissions in our region are to the index facility, and are unlikely to differ between the 2 groups. Our experience shows promise and may inform others considering similar interventions. Patient and provider experience and generalizability should be evaluated in future work.

Patient characteristics

	With PN (n=5628)	Without PN (n=2213)
Age (mean, SD)	69 (20)	68 (20)
Female sex (n, %)	3018 (53.6)	1196 (54.0)
Most responsible diagnosis (n, %)		
Chronic obstructive pulmonary disease	271 (4.8)	88 (4.0)
Pneumonia	374 (6.6)	135 (6.1)

July 2010-April 2011			
LOS (days, 95 % CI)	6.4 (5.8–7.0) (713)	7.6 (6.8–8.3) (753)	<0.05
30-day readmission rate (%)	12.0 (627)	13.5 (681)	0.40

IMPACT OF AN OVERNIGHT INTERNAL MEDICINE ACADEMIC HOSPITALIST PROGRAM ON PATIENT OUTCOMES Jed Gonzalo¹; Ethan Kuperman²; Cynthia H. Chuang¹; Erik B. Lehman²; Thomas W. Abendroth¹. ¹Penn State College of Medicine, Hershey, PA; ²Pennsylvania State University, Hershey, PA; ³University of Iowa Carver College of Medicine, Iowa City, IA. (*Tracking ID #2194871*)

BACKGROUND: Due to concerns for patient safety and quality of care, the Institute of Medicine (IOM) and Accreditation Council for Graduate Medical Education (ACGME) have increased requirements for trainee supervision, including that an attending-level supervisor be immediately available during all shifts. In response, many academic programs have implemented overnight academic hospitalists (OAH) to improve clinical care and meet these supervisory requirements. Despite the belief that on-site supervision with OAHs improves patient safety and outcomes, there is little evidence describing the impact of an OAH program on patient-level outcomes. In 2012, our hospital implemented an OAH program, with explicit patient care and resident education responsibilities. We sought to: (1) compare patient-level outcomes before and after implementation of the OAH program, and, (2) to describe OAH revenue generation and contributions to teaching and patient care during the first-year of the OAH program.

METHODS: In September 2012, our academic medical center implemented an OAH program, which included one faculty-level attending physician providing on-site, direct house staff supervision of clinical duties during the night hours (7 pm–7 am). Prior to

implementation, patients were cared for by three internal medicine house staff; attending faculty were not present on-site, but were continuously available via telephone. We compared patient outcomes before and after OAH implementation by conducting a retrospective medical record review of all patients admitted to the internal medicine service over a 37-month period; all patients aged 18 and older admitted between April 1, 2011, and August 26, 2012 (pre-implementation), and August 27, 2012, and May 31, 2014 (post-implementation) between 7:00 pm–6:59 am were eligible for inclusion. Primary outcomes included: (1) in-hospital mortality, (2) 30-day hospital readmissions, (3) hospital length of stay, (4) upgrades in care to intensive care unit during the night of admission or the hospital stay. Patient-level covariates hypothesized to influence the primary outcomes included age, gender, race, ICD9 codes, and mortality risk scores. We obtained billing records of physician charges and administered prospective daily work logs to OAHs to capture tasks performed not obtained by the electronic medical record. Comparisons between dichotomous outcomes were assessed with chi-square tests, and between the continuous outcome using student's t-tests. To adjust for underlying temporal changes, we used an interrupted time series with segmented logistic regression.

RESULTS: During the study period, 6484 patients were admitted to the internal medicine service: 2722 (42 %) and 3722 (58 %) after implementation. Patients admitted before and after implementation were similar with respect to age (63.5 vs. 63.4 years, $p=0.47$), gender (44.6 % vs. 46.2 % female, $p=0.69$), race (89 % vs. 88 % white, $p=0.11$), and APR-DRG mortality risk scores. There were no differences found in mortality (1.1 % vs. 0.9 %, $p=0.23$), 30-day readmissions (14.8 % vs. 15.6 %, $p=0.2$), length of stay (4.43 vs. 4.39 days, $p=0.38$), or upgrades in care to intensive care the night of admission (0.4 % vs. 0.7 %, $p=0.07$) or during hospitalization (3.5 % vs. 4.2 %, $p=0.19$) in patients before and after implementation. During the first year of the program, the OAHs billed 1219 patient encounters (3.1/shift) and 63 procedures (0.2/shift), and accrued \$500,000 in charges. Of 365 eligible shifts, 317 work logs were completed (87 %); OAHs reported staffing/billing 2.6 new patient admissions before midnight and 0.9 new patient admissions after midnight per shift; 156 procedures were supervised or performed independently (0.5/shift). Central venous catheters were the most common procedure performed ($n=102$, 65 % of total). The OAHs spent <10 min per shift discussing patient care issues with interprofessional providers.

CONCLUSIONS: There were no differences in mortality, 30-day readmissions, patient length of stay, and upgrades in care to the intensive care unit when comparing these outcomes before and after implementation of an OAH program. Based on billing data, the revenue generated by OAHs was modest, and insufficient to cover the positions' salaries. Although the assessed outcomes may be too infrequent or insensitive to detect an impact, the financial return on investment of the OAH role is questionable. The OAH role may fulfill requirements of the Clinical Learning Environment Review Program (CLER) to focus on quality of care and supervision, but nighttime presence of an attending physician may limit the autonomy and independence of graduate trainees required for professional development. With increasing use of OAHs, close monitoring of the degree and quality of direct on-site supervision is required to preserve the essential aspect of house staff education.

IMPACT OF HIGH DEDUCTIBLE INSURANCE ON DIABETES OUTPATIENT AND HIGH ACUITY CARE: THE NATURAL EXPERIMENTS FOR TRANSLATION IN DIABETES (NEXT-D) STUDY James F. Wharam¹; Fang Zhang³; Emma Eggleston¹; Christine Lu¹; Stephen B. Soumerai¹; Dennis Ross-Degnan². ¹Harvard

Medical School, Boston, MA; ²Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, MA; ³Harvard Pilgrim Health care Institute, Boston, MA. (Tracking ID #2199355)

BACKGROUND: High deductible health plans (HDHP) will soon be the predominant commercial insurance benefit in the US, and the Affordable Care Act will dramatically increase enrollment. HDHPs require potential annual out-of-pocket costs of \$1000–\$6000 for most services and might reduce appropriate health care, especially among the poor and sick. Almost nothing is known about the impact of modern HDHPs on chronically ill patients, and nothing is known about effects on low-income, high morbidity patients. Our objective was to examine the impact of HDHPs on diabetes outpatient and high acuity care.

METHODS: Our data source was claims data of commercially insured members of a large national health plan. We studied patients with diabetes who were continuously insured for at least 2 years between 2004–2012 and included 26,862 whose employers mandated a transition from low-deductible ($\leq \$500$) to high deductible ($\geq \1000) coverage. Our inclusion of only patients who experienced such “forced” transitions to HDHPs minimizes selection bias. We classified 9668 (36 %) of these HDHP members as lower income based on residence in neighborhoods with at least 10 % of families living below poverty. We performed employer- and member-level 1:1 propensity score matching based on multiple baseline characteristics (including age, gender, morbidity, US region of residence, income-/education-level, race/ethnicity, and costs) to contemporaneous diabetes patients whose employers offered only low-deductible coverage. We censored matched pairs simultaneously to remove attrition bias. We assessed annual rates of primary care and specialist visits, HEDIS outpatient quality measures (hemoglobin A1C, LDL, and microalbumin testing), high severity emergency department visits, and hospitalizations for 1 year before and 2 years after mandated switch from traditional to HDHPs, compared with controls. We used annual difference-in-differences Poisson regression with generalized estimating equations to calculate adjusted pre-to-post changes in the HDHP group versus the control group.

RESULTS: Among HDHP members versus controls, primary care and specialist visits declined by approximately 3 to 6 % in follow-up years 1 and 2 relative to baseline in both the overall and lower-income HDHP group (Table). We found no detectable changes in HEDIS measures of hemoglobin A1C, LDL, or microalbumin testing. The overall HDHP group experienced no changes in high severity emergency department visits (–9.8 % [–22.4 %, 2.8 %] and 0.8 % [–20.9 %, 22.5 %] in follow-up years 1 and 2, respectively) whereas the lower-income group had corresponding reductions of 17.3 % (–34.7 %, 0.2 %) and 25.2 % (–49.7 %, –0.7 %). Similarly, lower-income HDHP members with diabetes reduced hospitalizations by 13.2 % (–24.0 %, –2.4 %) and 22.3 % (–38.9 %, –5.6 %) in follow-up years 1 and 2, respectively, relative to controls. Hospitalization changes were less pronounced in the overall cohort.

CONCLUSIONS: HDHP members with diabetes reduced primary care and specialist visits to a small degree and experienced no changes in HEDIS outpatient quality measures. However, lower-income HDHP members with diabetes experienced substantial and concerning reductions in high severity emergency department visits and hospitalizations. Findings indicate a need for longer-term studies of higher risk HDHP members with low income and high morbidity. Policy interventions such as targeted cost sharing exclusions and education for vulnerable members might also be needed.

Changes in outpatient and high acuity care among HDHP members with diabetes versus controls.

	Relative Change from Baseline to Follow-up Year 1, HDHP Group vs Controls			Relative Change from Baseline to Follow-up Year 2, HDHP Group vs Controls		
	Estimate	(95 % CI)		Estimate	(95 % CI)	
Overall

IMPACT OF INTERACTIVE WORKSHOP AND WEB-BASED TOOL ON KNOWLEDGE OF CKD MANAGEMENT AMONG INTERNAL MEDICINE RESIDENTS Swati Arora; Richard Marcus; Jia Zhang; Bhavna Chopra; Khaled Nashar; Kalathil Sureshkumar. Allegheny General Hospital, Pittsburgh, PA. (Tracking ID #2191614)

BACKGROUND: Chronic Kidney Disease (CKD) is a growing epidemic affecting more than twenty million adults in United States. A large proportion of CKD population is under-recognized, especially in primary care setting and hence, sub-optimally diagnosed and managed. This is likely due to lack of emphasis on CKD management during training and inadequate availability of quick and easy decision support tools.

METHODS: In this study, we conducted a baseline assessment of Internal Medicine residents' knowledge in areas of: screening and diagnosis of CKD, anemia (A), bone-mineral disease (B), control of BP (C) and degree of proteinuria (D). We then conducted 90-min long interactive workshop on ABCD of CKD in small groups' format over a period of 5 weeks. This was followed by a post-test at the end of the workshop to evaluate the effectiveness of the intervention. The residents were subsequently provided access to a self-developed online resource on key concepts of CKD management (www.nephromania.com).

RESULTS: A total of 98 residents (PGY1-38, PGY2-30, PGY3-30) completed the workshop. About 22 % of residents were aware of KDOQI guidelines (5 % PGY1, 25 % PGY2, 43 % PGY3) before intervention versus 96 % post intervention (97 % PGY1, 97 % PGY2, 100 % PGY3), $p < .001$. While 98 % residents would screen asymptomatic diabetics or hypertensive's for CKD, only 28 % would consider screening in patients with recurrent UTIs and 60 % in patients with positive family history of CKD. This improved post-intervention to 88 and 85 %, $p < 0.01$, respectively. Results are summarized in Table 1.

CONCLUSIONS: Short term intervention with interactive workshops on ABCD of CKD management was very effective in improving recognition of CKD and identification of complications. Lack of improvement in management of hypertension in CKD patients post-intervention could be reflective of lack of consensus amongst various guidelines. A three-month follow up study is planned to evaluate long term retention with web-based tool and to assess real world impact on patient care using systematic chart review.

Table 1: Pre and Post Test Results

	Pre-test	Post-test	P-value
Awareness of KDOQI guidelines	22 %	96 %	<0.001
Accurate Recognition of CKD based on:			
Duration > 3 months	82 %	99 %	<0.0001
Degree of decline in eGFR	70 %	93 %	<0.001
Degree of ACR	28 %	58 %	<0.001
Anemia Goals:			
Hb-10-12 g/dL	92 %	99 %	NS
Interpretation of iron studies	46 %	87 %	<0.001
Bone Mineral Disease Workup:			
Hypocalcemia	66 %	75 %	NS
Hyperphosphatemia	84 %	91 %	NS
25-hydroxy Vitamin D	57 %	93 %	<0.0001
Secondary Hyperparathyroidism	88 %	96 %	<0.05
Metabolic acidosis	88 %	97 %	<0.05
Hypertension & Proteinuria Management:			
Goal Blood Pressure	49 %	58 %	NS
Screening for proteinuria	77 %	89 %	NS
First choice of anti-hypertensive	47 %	39 %	NS

IMPACT OF LABORATORY PRICE DISPLAY ON RESIDENT ATTITUDES AND KNOWLEDGE ABOUT COSTS Theodore Long²; Tasee Bongiovanni¹; Meir Dashevsky¹; Andrea Halim¹; Joseph S. Ross²; Robert L. Fogerty¹; Mark Silvestri¹. ¹Yale School of Medicine, New Haven, CT; ²Yale University School of Medicine, New Haven, CT. (Tracking ID #2192807)

BACKGROUND: Cost awareness is a common program requirement designated by the Accreditation Council for Graduate Medical Education (ACGME). However, studies to date have shown that physicians are unaware of costs in patient care, and previous educational interventions to increase cost awareness have had mixed results. We therefore sought to measure sustained change in resident physician attitude toward and knowledge of costs after a comprehensive price display intervention for all laboratory order prices in our electronic health record.

METHODS: In March 2014, we conducted an anonymous, cross sectional survey of all Internal Medicine, Pediatrics, Combined Internal Medicine and Pediatrics, Obstetrics & Gynecology, Emergency Medicine, and Orthopaedic Surgery residents at Yale-New Haven Hospital (YNHH) examining knowledge of and attitudes toward cost in health care. Participants estimated dollar value costs of selected laboratory and imaging tests. In April 2014, the Medicare allowable reimbursements for all laboratory orders were displayed in the YNHH electronic medical record. After the laboratory price display had been present for 6 months, we repeated our survey of the same target population. We performed a Wilcoxon Ranked Sum test for the unpaired attitude responses and a Wilcoxon Signed Rank test for the paired responses of participants before and after the price display intervention. The cost estimate questions were considered accurate if responses were between 50 and 200 % of the Connecticut-specific Medicare price. This range was established by prior studies of physician cost knowledge. Laboratory prices were obtained from the 2014 Medicare laboratory fee schedule. Radiology prices were obtained by summing values from the Medicare Physician Fee Schedule (professional fees) and the Medicare Outpatient Prospective Payment System Fee Schedule (facility fees). Student's t-tests were used to assess accuracy in the cost estimate portion of the survey pre- and post-intervention.

RESULTS: We received 403 completed surveys (overall response rate of 68.7 %). Prior to the intervention, 8.6 % of residents agreed or strongly agreed that they knew the costs of tests they ordered. After the intervention, this increased to 38.2 % ($p < 0.001$). The proportion of residents agreeing or strongly agreeing that they had adequate access to cost information improved from 1.0 % pre-intervention to 24.8 % post-intervention ($p < 0.001$). After the laboratory price display intervention, price estimate accuracy increased significantly for both laboratory and radiology orders. Laboratory accuracy increased from 23.7 to 52.4 % ($p < 0.001$). Radiology accuracy increased from 38.0 to 49.6 % ($p = 0.001$). For both the knowledge and attitude questions, there were no meaningful differences between specialties or between the paired and unpaired analyses.

CONCLUSIONS: We found that residents felt more comfortable with their knowledge and access to cost information after the price display intervention. Residents demonstrated significant improvement in accuracy of price estimation, which persisted 6 months after the intervention was implemented. Although prices were only displayed for laboratory orders, the improvement in estimates for both laboratory and radiology prices suggests that providing cost information for some orders may have a spillover effect for provider cost knowledge.

IMPACT OF LORCASERIN IN OBESE AND OVERWEIGHT PATIENTS WITH PREDIABETES ON WEIGHT LOSS AND REDUCING PROGRESSION TO DIABETES Richard Nesto¹; Randi Fain²; Yuhua Li²; William Shanahan³; William Soliman². ¹Lahey Hospital and Medical Center, Burlington, MA; ²Eisai Inc, Woodcliff Lake, NJ; ³Arena Pharmaceuticals, San Diego, CA. (Tracking ID #2198444)

BACKGROUND: Modest weight loss (WL; 5 %) may improve glycemic control and reduce diabetes risk. Lorcaserin (LOR), a selective 5-HT_{2C} agonist, is an approved adjunct to lifestyle intervention for chronic weight management in obese/overweight patients. This post hoc analysis evaluated if LOR (10 mg twice daily [BID]) would reduce progression from prediabetes to diabetes over 1 year compared with placebo (PBO); all patients received diet/exercise counseling.

METHODS: Data were pooled ($N = 6136$) from the BLOOM/BLOSSOM trials (body mass index of 30-45 kg/m² or 27-29.9 kg/m² with ≥ 1 weight-related comorbid condition, nondiabetic). Prediabetes was alternatively defined as hemoglobin A1c (HbA1c) 5.7-6.4 or fasting plasma glucose (FPG) 100-125 mg/dL. Diabetes was alternatively defined as HbA1c ≥ 7 at any time, ≥ 6.5 at least once post baseline and taking antidiabetic medications, or ≥ 6.5 at least twice post baseline or FPG > 125 mg/dL any time and with antidiabetic medications or at least twice post baseline.

RESULTS: Among the 1148 LOR- and 1117 PBO-treated patients with prediabetes at baseline (HbA1c criteria), more experienced 5 or 10 % WL with LOR (56, 29 %) vs PBO (28, 11 %). Three percent of LOR and 6 % of PBO patients ($p = 0.017$) developed diabetes. More patients with prediabetes experienced a reduction in HbA1c (< 5.7) with LOR than PBO (40 vs 30 %; $p < 0.001$) at week 52 without developing diabetes any time after baseline. Among 563 LOR- and 570 PBO-treated patients with prediabetes at baseline (FPG criteria), more experienced 5 % or 10 % WL with LOR (53, 27 %) than PBO (29,

10 %). Two percent of LOR and 3 % of PBO patients ($p=0.327$) developed diabetes; however, many patients experienced a reduction in FPG (<100 mg/dL; 52 % LOR, 47 % PBO; $p=0.047$).

CONCLUSIONS: Progression from prediabetes to diabetes (by HbA1c criteria) occurred in significantly fewer patients treated with LOR than PBO. A greater proportion of patients with prediabetes at baseline achieved 5 and 10 % weight loss with LOR compared with PBO over 52 weeks.

IMPACT OF MEDICAL HOME TRANSFORMATION ON BREAST CANCER SCREENING Amy Baughman¹; Phyllis Brawarsky¹; Tracy Onega²; Tor Tosteson²; Anna N. Tosteson²; Jennifer Haas¹. ¹Brigham and Womens Hospital, Boston, MA; ²Geisel School of Medicine at Dartmouth, Lebanon, NH. (Tracking ID #2198480)

BACKGROUND: Among women in the US, breast cancer is the most common cancer and is the second most common cause of cancer death. Primary care plays a critical role in breast cancer screening and detection. One primary care model that may improve the use of screening is the patient-centered medical home (PCMH), which involves physician-led multidisciplinary teams and aims to optimize care coordination, communication and access to care. Many primary care practices are adopting PCMH models of care. Understanding whether PCMH transformation is associated with changes in breast cancer screening is important given the large burden of disease and anticipated primary care shortage. We evaluated whether a higher score on a medical home assessment for primary care practices, indicating that a practice is closer to functioning like a PCMH, is associated with the use of breast cancer screening. We hypothesized that PCMH transformation would be associated with increased screening because of enhanced care coordination, care processes, and patient engagement.

METHODS: This was a retrospective cohort study that included women aged 50 to 74 in the PROSPR (Population-based Research Optimizing Screening through Personalized Regimens) registry who had at least one primary care visit to one of 13 participating Brigham and Women's Hospital (BWH)-affiliated primary care clinics between April 2012 and December 2013. Women were excluded if they had a prior history of breast cancer ($n=2085$) or died during the follow-up period ($n=279$). Beginning in 2012, BWH began measuring PCMH transformation using a framework called "Primed Status" which was modeled on the NCQA requirements for medical home recognition. The "Primed Status" score was assessed quarterly for each practice based on achieving the following elements: use of electronic health records (EHR), patient web-based portal access, team-based care, practice redesign and process improvement, and high risk patient care management. We evaluated an aggregate 0 to 100 "Primed Status" score based on the percentage of elements achieved. A score was assigned for each primary care visit for each woman. Covariates included patient age, race/ethnicity, education level, insurance status, family history of breast cancer, comorbidity, date of visit, and marital status. We examined 3 outcome measures, as medical home transformation may facilitate care between visits in addition to visit-based care, including whether or not: (1) screening was up-to-date at a visit (mammography completion within the 24 months prior to the visit); (2) screening was up-to-date at a visit OR if screening was due at a visit (no mammogram completion in prior 24 months), whether timely screening was completed within 3 months after the visit, (3) timely screening was completed within 3 months of the visit if screening was overdue at the time of the visit. We used logistic regression to examine the impact of medical home transformation on each outcome, adjusting for the above confounders. The unit of analysis was the primary care visit. Regression analyses were clustered at the level of the practice.

RESULTS: The cohort included 20,349 women. The number of primary care visits totaled 94,014; women were up-to-date at 76,332 (81 %) visits for 13,700 (67 %) women; women were due for screening at 17,682 (19 %) visits for 6649 (33 %) women. In visits where women were due for screening, screening was not completed within 3 months for a majority of the visits (13,625 (77 %) visits with no screening vs. 4057 visits with screening). All 13 practices had improvements in their "Primed Status" scores over the study period; the average practice score increased from 25 % in the first quarter to 81 % in the final quarter. At visits where screening was up-to-date, increases in Primed Status scores were associated with less screening after adjustment and this was statistically significant (Table 1, Model 1); however, this model did not account for women who went on to have timely screening within 3 months. Timely screening completion when overdue was not associated with higher scores (Table 1, Model 3) after adjustment. Finally, when evaluating the combination of visits where screening was up-to-date and completed within 3 months if overdue, screening was again not associated with better scores (Table 1, Model 2).

CONCLUSIONS: In this setting, improved medical home scores were not associated with higher rates of breast cancer screening. Medical home transformation initiatives may not adequately target prevention.

Multivariable Logistic Regression Odds Ratios for Primed Status Score (10 point change) and Breast Cancer Screening

Model	OR (95 % CI)	P Value
1) Screening up-to-date at visit	0.91 (0.87, 0.97)	<0.001
2) Screening up-to-date at visit OR Screening within 3 months if overdue at visit	0.97 (0.90, 1.04)	0.18
3) Screening within 3 months if screening was overdue at visit	1.06 (0.88, 1.27)	0.58

IMPACT OF PRIMARY CARE ON COLORECTAL CANCER SCREENING IN A SAFETY NET HEALTH SYSTEM Oanh K. Nguyen^{1,1}; Bijal A. Balasubramanian^{2,1}; Joanne Sanders¹; Jasmin Tiro¹; Wendy P. Bishop¹; Chul Ahn¹; Ethan Halm^{1,1}. ¹UT Southwestern Medical Center, Dallas, TX; ²University of Texas School of Public Health, Dallas, TX. (Tracking ID #2198257)

BACKGROUND: Colorectal cancer (CRC) is the second leading cause of cancer deaths in the US; however, only 59 % of adults are up to date with CRC screening. Screening rates are even lower among underserved populations such as the uninsured and minorities. Completion of CRC screening is particularly challenging due to the need to complete a multi-step process rather than a single test. Though health systems are promoting outreach strategies to increase initiation of CRC screening outside of an office-based visit, we hypothesized that primary care providers (PCP) nonetheless remain critical to facilitating completion of all steps of CRC screening. Thus, we sought to evaluate the association between PCP visits and delivery of CRC screening processes, from ordering and completion of initial screening tests to appropriate follow-up of abnormal initial screening with ordering and completion of further diagnostic testing.

METHODS: Retrospective cohort study of adults 50–64 years of age not up to date with CRC screening at an integrated safety net health system in Dallas, Texas. We included individuals who had an 'index' PCP visit on or after January 1, 2010, regularly received care in the system (≥ 1 outpatient visit within 12 months before or after the index visit) and had at least 12 months of follow-up time after the index visit. The date of the index visit was considered the date of cohort entry. Individuals were excluded if they were ≥ 65 years old, moved out of Dallas County, or died within 12 months of index visit due to limited follow up data. Our four outcomes corresponded to key steps in CRC screening: 1) initial order of a fecal immunochemical test or fecal occult blood test (FIT/FOBT), or screening colonoscopy; 2) completion of initial FIT/FOBT or colonoscopy; 3) order of a diagnostic colonoscopy after abnormal FIT/FOBT results; and 4) completion of diagnostic colonoscopy. For outcomes #1 and #2, we assessed the association with the number of PCP visits 12 months after the index visit; for outcomes #3 and #4, we assessed the association with the number of PCP visits 12 months after the date of abnormal FIT/FOBT. Odds ratios were estimated using multivariable logistic regression adjusted for age, sex, race/ethnicity, payer, comorbidities, and clinic type.

RESULTS: Of 32,376 individuals, the overwhelming majority were black (40 %) or Hispanic (36 %), female (64 %), and received county-sponsored charity care (68 %). Over a quarter (29 %) had multiple chronic conditions (Charlson comorbidity index ≥ 2). The mean number of PCP visits was 2.4 ± 2.2 in the 12 months after cohort entry. Of the total study population, 25,818 (79.8 %) had an initial CRC screening test ordered and 22,029 (68.0 %) completed initial testing. Only 799 (2.5 %) had an abnormal FIT/FOBT; of these, 92.3 % had orders for follow-up diagnostic colonoscopy but only 51.7 % actually had a follow-up colonoscopy. Compared to those with no PCP visits after the cohort entry, those with ≥ 1 PCP visit had significantly higher adjusted odds of receiving an order for and completing an initial screening test; a higher number of PCP visits was associated with increasing adjusted odds of initial screening test ordering and completion, demonstrating a dose-dependent relationship (Table). Among those with an abnormal FIT/FOBT, having ≥ 1 PCP visit after an abnormal FIT/FOBT was also associated with higher adjusted odds of both having a follow-up colonoscopy ordered and completed compared to having no visits during this time interval (Table).

CONCLUSIONS: Increasing primary care visits are associated with increased CRC screening initiation and completion. Though many health systems are employing outreach strategies to bolster CRC screening outside of office settings, PCPs are likely to continue to play an important role in the delivery of CRC screening.

Table. Effect of Primary Care Visits on Key Steps of Colorectal Cancer Screening ^a

	Number of primary care visits			
	0	1	2	3
Initial screen ordered ^b	[Reference]	2.53 (2.33–2.74)	3.53 (3.24–3.85)	4.08 (3.77–4.41)
Initial screen completed ^b	[Reference]	2.22 (2.06–2.40)	3.12 (2.90–3.37)	3.88 (3.61–4.16)
Follow-up ordered ^c	[Reference]	4.09 (1.96–8.54)	5.82 (2.45–13.82)	5.96 (2.76–12.84)
Follow-up completed ^c	[Reference]	3.30 (2.14–5.10)	4.29 (2.72–6.76)	5.05 (3.25–7.86)

^aAll values presented are adjusted odds ratios (95 % confidence interval) unless otherwise specified.

^bInitial screening test order and completion were assessed for the entire study population (N=32,376).

^cFollow-up testing order and completion were assessed only among individuals with an initial abnormal FIT/FOBT result (N=799).

IMPACT OF REGIONALIZED CARE ON PREVENTABLE ADVERSE EVENTS ON GENERAL MEDICINE SERVICES Stephanie Mueller¹; Kyla Giannelli²; Robert Boxer¹; Jeffrey L. Schnipper². ¹Brigham and Women, Boston, MA; ²Brigham and Women's Hospital, Boston, MA. (Tracking ID #2197622)

BACKGROUND: Failures in communication among healthcare personnel are known threats to patient safety. Inpatient medical units are particularly vulnerable to ineffective communication given the varied work structure of each care team member. The goal of this study was to examine the impact of regionalized unit-based care teams on preventable adverse events (AEs).

METHODS: We performed a retrospective cohort study of 400 randomly selected patients discharged from general medicine services before and after implementation of regionalized care (200 each), which consisted of restructuring 3 general medicine teams such that nurses and physicians cared for patients on the same unit. Patients were eligible for inclusion if they were discharged from the general medicine service from one of these units between April 1–June 19, 2013 (pre) and 2014 (post). Electronic medical records were reviewed by a trained clinician using a validated screening tool, and narrative summaries were created for any potential AE. We defined AE as an injury due to medical management (that occurred on the study unit) rather than the natural history of the illness. Two of four adjudicators separately reviewed each narrative using a validated 6-point confidence scale to determine the presence and preventability of AE (i.e., a rating of ≥ 4) classified AEs using a 4-point severity scale, and grouped AEs into 1 of 10 pre-specified categories. Disagreements in ratings were discussed by all adjudicators to reach consensus. We performed logistic regression to evaluate the impact of regionalized care on the odds of having a preventable AE, accounting for clustering by discharge unit and controlling for patients' demographics, payer, length of stay, comorbidities, and case mix. Secondary outcomes included severe preventable AEs and category of preventable AEs.

RESULTS: Of the 400 patient screens, 8 were excluded due to missing MRN (5) and discharge outside of included dates (3). Of the final 392 patient screens (198 pre, 194 post) there were 133 total AEs (66 pre, 67 post), 27 preventable AEs (13 pre, 14 post), and 9 severe preventable AEs (4 pre, 5 post). There was no significant difference in the adjusted odds of preventable AEs after implementation of regionalized care compared to before (OR 1.37, 95 % CI 0.65, 2.89). Similarly, there was no difference in severe preventable AE or in category of preventable AE.

CONCLUSIONS: We found that implementation of regionalized unit-based care teams had no significant impact on preventable AEs. Our results indicate that regionalized care alone is likely insufficient to affect major patient safety outcomes, although more subtle improvements due to better team communication may not have been captured with our methodology. However, strengthening the infrastructure to maximize opportunity for communication between all care team members can facilitate implementation of additional initiatives that may lead to more robust patient safety improvements.

IMPLEMENTATION OF A PATIENT CARE MANAGEMENT PROGRAM TO REDUCE DISPARITIES AND CONTROL HYPERTENSION IN PRIMARY CARE (RED CHIP): A PRAGMATIC TRIAL Tanvir Hussain^{2,4}; Whitney K. Franz⁴; Emily L. Brown⁴; Athena Kan⁴; Mekam T. Okoye²; Kara Taylor⁴; Katherine Dietz⁴; Jennifer Halbert⁴; Arlene Dalcin⁴; Cheryl A. Anderson^{4,3}; Romsai T. Boonyasai^{1,4}; Jill A. Marsteller⁴; Lisa A. Cooper^{2,4}. ¹Johns Hopkins University SOM, Baltimore, MD; ²Johns Hopkins University School of Medicine, Baltimore, MD; ³University of California San Diego, La Jolla, CA; ⁴Johns Hopkins Center to Eliminate Cardiovascular Health Disparities/Health Disparities, Baltimore, MD. (Tracking ID #2198962)

BACKGROUND: Despite the availability of evidence-based interventions for hypertension (HTN) treatment, data on approaches for delivering them in real-life clinical practice are sparse, particularly in nonadherent, disadvantaged, and/

or African American populations, groups which are regularly excluded in randomized, efficacy studies. Thus, we conducted a pragmatic trial to determine the feasibility, reach, and effectiveness of care management (CM) as an approach for implementing evidence-based interventions to improve blood pressure (BP) control amongst hypertensive patients, with particular attention to African Americans (AA), in a routine clinical care setting.

METHODS: In this pragmatic, non-randomized, multisite trial, we staggered implementation of a CM program, incorporating evidence-based strategies for HTN treatment, across six primary care practices in the Baltimore metropolitan area between 2010–2015. Four sites care for underserved communities with large AA populations. Any and all HTN patients ≥ 18 years with uncontrolled BP ($\geq 140/90$) within the last 6 months, receiving primary care at study sites, were eligible. Delivered completely by the clinic staff, the CM program invited eligible patients to participate in 2 h of in-person CM—three sessions, over approximately 2 months. Registered Dietitians (RDs) and Doctors of Pharmacy (PharmDs) trained in motivational interviewing and cultural competency educated patients about HTN; developed personalized action plans to encourage adherence to medications, diet, physical activity, and use of self-monitoring behaviors; and taught patients health-related problem solving. We measured program reach by tracking the flow of patients from eligibility to CM completion, including the number of eligible patients who were successfully contacted by CM, and the number attending session 1 and finally completing all three sessions. We also evaluated the effectiveness of the program in improving systolic and diastolic BP between the time of outreach/referral (pre-intervention) and the end of care management sessions (post-intervention, 3 months from session 1) employing a quasi-experimental analytic technique, which accounts for secular trends. Using a difference in differences (DID) term from a cross-sectional time series regression model, we compared patients who completed all three sessions to those who completed only one or two sessions (dropouts) and to a 10 % random sample of non-participants. All analyses were stratified by race.

RESULTS: Results are available for patients from five sites. Of the 1969 eligible patients identified from the electronic medical record, care managers were able to contact 1329 (67 %) during outreach calls, and 143 (7.3 %) of these patients attended session 1. Primary care providers, who identified additional patients during routine care, referred the additional 310 patients who attended session 1. Of the 453 patients who started CM, 156 (34 %) completed all three sessions. Among all session 1 participants, pre-intervention BP was 150/88, age 57 years, 58 % female, 66 % African American, with mean BMI of 34.5 kg/m²; there were no baseline differences between dropouts, non-participants, and those completing all sessions. However, those completing all three sessions experienced a significantly greater BP improvement at follow-up compared to non-participants [DIDs for systolic BP 14 mmHg SBP ($p=0.001$), diastolic BP 6 mmHg ($p=0.001$)] and compared to dropouts [DIDs for systolic BP 7 mmHg ($p=0.001$), diastolic BP 3 mmHg ($p=0.001$)]. Though AAs and Whites both experienced BP improvement, Whites experienced greater benefit. Compared to non-participants, Whites completing all sessions demonstrated DIDs in systolic BP of 16.1 mmHg ($p=0.001$) and in diastolic BP of 5.2 ($p=0.009$), whereas for AAs it was 7.2 mmHg ($p=0.008$) and 3.1 mmHg ($p=0.011$); interaction terms between race and DIDs were statistically significant.

CONCLUSIONS: CM comprised of RDs and PharmDs trained in motivational interviewing and cultural competency is a feasible approach for implementing evidence-based HTN treatment in a variety of primary care settings and can result in blood pressure control among HTN patients after just a few sessions. However, the very limited reach of CM and its decreased effectiveness among African Americans raise caution. For CM to improve population health and reduce disparities in HTN, methods for enhancing engagement among all patients and addressing further the barriers faced by AAs specifically must be identified.

IMPLEMENTATION OF THE PATIENT CENTERED MEDICAL HOME (PCMH) IN THE VETERANS HEALTH ADMINISTRATION (VHA): ASSOCIATIONS WITH CLINICAL OUTCOMES, PATIENT SATISFACTION, PROVIDER BURNOUT AND HEALTH CARE USE Karin M. Nelson^{4, 3}; Philip W. Sylling⁷; Edwin Wong²; Leslie Taylor⁴; Christian D. Helfrich⁵; Idamay Curtis⁷; Gordon Schectman⁶; Richard Stark¹; Stephan D. Fihn⁷. ¹Department of Veterans Affairs, Washington, DC; ²Northwest Center for Outcomes Research in Older Adults, Seattle, WA; ³University of Washington, VA Puget Sound, Seattle, WA; ⁴VA, Seattle, WA; ⁵VA Puget Sound Healthcare System, Seattle, WA; ⁶Veterans Affairs Central Office, Milwaukee, WI; ⁷Veterans Health Administration, Seattle, WA. (Tracking ID #2198377)

BACKGROUND: In 2010, the Veterans Health Administration (VHA) began implementing the patient centered medical home (PCMH). To evaluate progress and outcomes system wide, we examined the association of PCMH implementation in 2012 and 2013 with important outcomes including patient satisfaction, staff burnout, health care use and clinical quality.

METHODS: We conducted an observational study using: (1) VHA clinical and administrative data for >5.6 million Veterans who received primary care at 923 VHA hospital- and community-based outpatient clinics (CBOCs); (2) $n=279,841$ responses to the Consumer Assessment of Health Plans PCMH module administered to a weighted, random sample of Veterans who received outpatient care in 2013; and (3) 6959 responses to a survey distributed to all VHA primary care providers and staff in 2013. **Measures:** To measure PCMH implementation, we utilized a previously validated instrument, the PACT implementation progress index (PI²) comprised of 53 items from 8 core PCMH domains: access, continuity, care coordination, comprehensiveness, self-management support, patient-centered care and communication, shared decision-making and team-based care. In order to assess site PI² performance across years, we used 2012 as a reference year, and standardized 2013 items in the PI² index by the 2012 average and standard deviation of items across sites. A 2013 overall PI² score was assigned to each clinic based on the number of domains in the top and bottom 2012 quartiles for the domain scores, ranging from 8 (all domain scores in the top 2012 quartile) to -8 (all domain scores in the bottom 2012 quartile). Our main outcome measures were patient satisfaction (defined by a provider rating from 0 to 10), staff burnout (measured by a single item question), health care use (hospitalization and emergency room use), and VHA clinical quality indicators. **Statistical analysis:** We used a non-parametric test of trend for the ranks across ordered groups to test for trends in patient satisfaction and provider burnout by PI² scores. We examined 2013 utilization of emergency department and urgent care visits and total hospitalizations for high versus low implementation sites, adjusting for age, CBOC clinics and co-morbidity. To assess how trends in hospitalizations changed following the PACT initiative in 2010, we estimated time-series models of ambulatory care sensitive condition (ACSC) hospitalizations and all-cause hospitalizations from 10/1/2003 through 9/2013 for each facility. Changes in hospitalizations were calculated as the difference between the observed rate of admissions and the predicted rate of admissions that would have occurred had PACT not been implemented, during the period after PACT initiation. We tested differences in proportions of eligible patients at each VHA clinic fulfilling each of 44 quality indicators by the degree to which implementation of PACT was successful, as measured by the PI². We calculated rates of services at the facility level by dividing the number of patients who satisfied the quality measure by the number of patients who met inclusion criteria for each quality measure.

RESULTS: PCMH areas with the greatest gains from 2012 to 2013 included the percentage of Veterans using secure email messaging with their providers, the percentage of patients enrolled in home tele-monitoring, increased use of telephone clinics, and increased clinic staffing to recommended ratios. Among sites achieving the most effective implementation, we found improvements in patient satisfaction, provider burnout, and emergency room utilization. Patient satisfaction was meaningfully higher among sites that had effectively implemented PACT than those that had not (mean rating for satisfaction with provider 9.24 vs. 7.74, $p<0.001$). A similarly favorable pattern was observed for staff burnout (34 % vs. 44 % of staff reporting burnout, $p=0.011$). Emergency department and urgent care encounters were marginally lower at sites with more rather than less effective implementation (205 vs. 222 encounters per 1000 patients, $p=0.091$). No difference was noted in all-cause hospitalization. However, in the interrupted time series analysis, sites with 2013 PI² scores in the highest decile had higher rates of ACSCs and all-cause hospitalization. Seventeen of 44 clinical performance measures were significantly associated with PI² scores, with more effective PCMH implementation associated with higher quality, including LDL cholesterol of <100 for patients with IHD (64.1 % vs. 72.8 %, $p<0.001$) or diabetes (64.1 % vs. 70.8 %, $p<0.001$), influenza immunization (74.8 % vs. 78.6 %, $p=0.021$), and offering medications for tobacco cessation (94.1 vs. 96.4 %, $p=0.044$). Overall, 38 of the 44 measures were higher at sites with the highest PI² scores.

CONCLUSIONS: Sites with sustained levels of PCMH implementation had higher patient satisfaction, lower provider burnout and better clinical quality.

IMPLEMENTING A WEB-BASED INTERVENTION TO IMPROVE BREAST CANCER CARE COORDINATION IN SAFETY-NET HOSPITALS: BARRIERS, FACILITATORS & OPPORTUNITIES FOR IMPROVEMENT Nina A. Bickell³; Jenny J. Lin¹; Bonnie Bellacera²; Kelsey Murray⁴; Rebeca Franco³; Ann S. McAlearney⁴. ¹Mount Sinai, New York, NY; ²Mount Sinai School of Medicine, Hicksville, NY; ³Mount Sinai School of Medicine, New York, NY; ⁴The Ohio State University, Columbus, OH. (Tracking ID #2200263)

BACKGROUND: Minority breast cancer patients tend to have higher rates of adjuvant treatment underuse. We implemented a web-based intervention that closes referral loops between surgeons and oncologists at inner-city hospitals serving high volumes of minority breast cancer patients to assist these hospitals to improve care coordination. We then conducted follow-up interviews with key personnel to improve our understanding of the intervention implementation and to identify barriers, facilitators, and opportunities for improvement.

METHODS: We interviewed 59 administrative and clinical key informants from 11 hospitals participating in the intervention study. Interviews were recorded and transcribed verbatim. We used the constant comparative method of analysis to code interview transcripts and identify common themes regarding intervention implementation.

RESULTS: We identified implementation barriers, facilitators and opportunities at both the hospital and intervention levels. Hospital-level implementation barriers were lack of staff time, large patient panels, the diverse needs of patient populations served, and the need to incorporate the intervention into existing workflow. Intervention-related barriers included technical issues for some hospitals due to existing firewalls and limitations of the intervention itself such as use with a defined patient population (e.g., English and Spanish-speaking patients only). Implementation facilitators at the hospital-level were having staff with dedicated administrative time, involvement of the entire care team in the care coordination process, the existence of a strong policy for following up patients who missed appointments, as well as a unified electronic medical record. Intervention-level facilitators included the push notifications sending reminders about no shows, and that the intervention was implemented at different systems, so patients could be tracked regardless of the system in which they received care. An important hospital-level opportunity to improve intervention implementation would be to enable hospitals to take advantage of care coordination systems already in place so that the intervention is perceived as supplemental rather than competing with existing workflows and work-arounds. Further, the intervention itself could be enhanced by permitting care coordination of all breast cancer patients (i.e., not restricted by language or cancer stage), as well as developing functionalities such as the ability to create a master patient list, query the tracking system, and track progress on care coordination goals.

CONCLUSIONS: Coordination of care for women with breast cancer is extremely important, but safety-net hospitals face considerable resource constraints from lack of time, support, and information systems. We found substantial barriers to implementing an intervention designed to support care coordination efforts, despite initial feedback that the intervention itself was both easy to use and in line with organizational goals. As safety-net hospital networks grow expanding across numerous care sites, the challenge of care coordination will likely increase, highlighting the importance of interventions that can be successfully implemented and used to promote better care.

IMPLEMENTING INTERPROFESSIONAL, GRADUATE LEVEL, GERIATRIC PRIMARY CARE EDUCATION: REFLECTIONS ON YEAR 1 OF A NEW PROGRAM Allison Squires²; Jennifer Adams¹; Sherry A. Greenberg²; So-Young Oh¹; Lisa Altshuler¹; Tara Cortes². ¹NYU School of Medicine, New York, NY; ²New York University, New York, NY. (Tracking ID #2198520)

BACKGROUND: Preparing and deploying a primary care workforce ready to care for the aging global population requires increasing efficiency in graduate level health professions education while ensuring competence in interprofessional practice. Training programs need to meet population health needs while also addressing the challenges of coordinating training schedules of diverse professionals, many of whom are practicing professionals. This study reports on the first year program evaluation of a unique nurse practitioner and physician training program focused on improving geriatric interprofessional care in the primary care setting. The program intervention included a week long joint educational program with physicians and nurse practitioners, online learning modules, and follow up learning exercises. Faculty designing the program included experienced geriatric nurse practitioners, primary care graduate level physician educators, an instructional technologist, and a behavioral scientist.

METHODS: Evaluation data for the study drew from multiple sources including pre and post intervention focus group interviews with 10 student participants (8 MD, 2 NP), performance reports from the online learning modules, surveys about perceptions about

interprofessional teamwork and practices, course evaluations, and faculty reflections. We conducted general descriptive analyses appropriate for the data type. The small sample size limited statistical comparison for significant differences between respondents.

RESULTS: In the interviews participants emphasized how program training sites negatively limit the ability to deliver quality geriatric primary care and apply classroom content in the “real world”. Participants also reported feeling uncomfortable providing feedback about other professions when in the same room. Issues around leadership also emerged as power dynamics between professions influenced perceived roles and responsibilities. Perceptions of quality of interprofessional collaboration at the current site of clinical practice remained nearly the same before (6.56/10) and after (6.2/10) the intervention. Perceptions of team leadership and serving as an equal contributor trended upward after the intervention. Overall perceptions of interprofessional collaboration on existing teams at their training sites, however, trended largely downward. Participants, in short answer questions, felt least comfortable addressing geriatric care issues related to patient safety, end of life care situations, communication, and work allocation. Synthesizing all the results suggest that this type of program may be effective in improving geriatric content overall but in an interprofessional education context, may sensitize learners to broader issues around geriatric primary care delivery, such as appropriate use of different roles on the healthcare team.

CONCLUSIONS: Rich data from this first year of a 3 year study is informing the development of interprofessional geriatric primary care training programs, which could help health professions schools reinforce and address interprofessional care delivery issues that may predictably arise after this type of intensive educational intervention. It is also noteworthy that the role of the training site in reinforcing or undermining appropriate delivery of geriatric specific care cannot be ignored.

IMPLEMENTING PCMH ONE TEAM AT A TIME: THE USE OF COACHING SESSIONS TO CHANGE EVERYDAY CLINIC PRACTICE ^{Lauren E. Weston⁴; Claire Robinson³; Adam Tremblay^{4, 5}; Clinton L. Greenstone⁴; Molly Harrod¹; Jane Forman².}

¹Department of Veterans' Affairs Ann Arbor HealthCare System, Ann Arbor, MI; ²VA Center for Clinical Management Research, Ann Arbor, MI; ³VA Ann Arbor Health Care System, Ann Arbor, MI; ⁴Veterans Health Administration, Ann Arbor, MI; ⁵University of Michigan, Ann Arbor, MI. (Tracking ID #2200176)

BACKGROUND: Patient-centered medical homes (PCMH) are being implemented in primary care clinics throughout the United States. PCMH principles emphasize providing patients with continuous and coordinated care using a team-based approach. This approach requires a shift from the traditional, physician-centric model to one where care is shared among team members. This shift necessitates a redesign of how staff relate to and work with one another. In 2010, the Veterans Health Administration began implementing its version of the PCMH. In order to facilitate VA's PCMH, one VA primary care clinic employed a “coaching” model to aid and support their staff in the transition to a team-based model of care. Current literature tends to focus on the components necessary to conduct coaching sessions (e.g., time and space for teams to meet, education regarding the changes needed etc.) Less is known about how teams implement these changes within the clinic environment. Therefore, our objective was to understand how coaching sessions were translated into everyday practice and what, if any, impact these sessions had on PCMH implementation.

METHODS: We used qualitative methods to examine how staff who participated in coaching sessions used their experiences to design team-based processes that were then implemented within day-to-day clinic operation. We observed 19 coaching sessions over a 9 month period. We then conducted semi-structured interviews with team members (N=13) who were observed in the sessions. We analyzed both the field note and interview data using a descriptive approach comparing the planning of activities that occurred during the coaching sessions with how they described their clinic experiences in the interviews.

RESULTS: We found that clinic teams used the coaching sessions to develop processes that supported the implementation of the VA's PCMH. During the coaching sessions, some teams reviewed their access performance reports together leading them to develop strategies that would result in improved access. Some of these strategies included adding additional nurse clinics, extending established patients' non-urgent return visits and moving some appointments to non-traditional options, such as phone visits. Furthermore, because the coaching sessions were team-based, all team members were able to participate in the development of new processes by providing input and taking on new tasks. This was especially true for licensed practical nurses (LPNs) who, prior

to PCMH, were considered underutilized by all team members. LPNs began making pre-appointment phone calls to prepare patients for upcoming visits, during which they requested that patients bring medications and any outside records to their appointment, asked that they arrive early for bloodwork, and got a better overall sense of the patients' needs. During sessions, the teams would also spend time talking about individual patients who needed additional support. We heard the team members brainstorming about other healthcare professionals they could involve in patients' care, such as pharmacists to assist with medication adherence issues and telehealth to help monitor patients' conditions between visits. This helped alleviate some of the workload and, perhaps more importantly, tailored the care to the patient. Coaching sessions also provided the team an opportunity to give feedback to the coaches and one another about how they thought the processes were working. Some processes needed constant revisiting because either the team was having difficulty implementing them or the system was not set up to support them. For example, one strategy that was proposed by clinic leadership was the use of huddles so that the team could get together every day at a set time to discuss, based on the patients being seen, what was needed. However, most teams felt that they accomplished this goal throughout the day, as needed. This approach was more conducive to how they worked and communicated with one another while in clinic. Coaching sessions provided the opportunity for teams to discuss and adjust clinic processes that were not working well for the team.

CONCLUSIONS: We found that coaching sessions were an optimal way to support PCMH implementation. Although most current literature recommends a more prescribed way of conducting coaching sessions, we found that a combination of formal education about the changes necessary for PCMH implementation and the opportunity for teams to decide how those changes were to be made were an effective approach in aiding the transition to team-based care. We also found that coaching should be done over a period of time allowing teams to test out new processes and provide feedback to one another about what works, what does not work, and why. Given time, teams are able to make adjustments that fit how the team works rather than how individuals work.

IMPLICATIONS OF CHANGING TO THE CHA2DS2-VASC SCORING SYSTEM TO RISK STRATIFY PATIENTS WITH ATRIAL FIBRILLATION FOR ANTICOAGULATION THERAPY IN AN INTEGRATED SAFETY NET HEALTH SYSTEM ^{Sarah L. Anderson^{2, 1}; Carolyn A. Valdez¹; Tara B. Vlasimsky¹; Carlos Irwin Oronce¹; Joel C. Marrs^{2, 1}; Samuel D. Richesin¹; Rebecca Hanratty¹.}

¹Denver Health, Denver, CO; ²University of Colorado Skaggs School of Pharmacy & Pharmaceutical Sciences, Aurora, CO. (Tracking ID #2199251)

BACKGROUND: Due to improved risk stratification of atrial fibrillation (AF) patients, the 2014 American Heart Association/American College of Cardiology/Heart Rhythm Society Atrial Fibrillation Guidelines recommend utilizing the CHA2DS2-VASc score (1 point each for heart failure, hypertension, diabetes mellitus, vascular disease, age 65–74 years, or female gender, and 2 points each for age ≥75 years or previous stroke or transient ischemic attack [TIA]) over the previously recommended CHADS2 score (1 point each for heart failure, hypertension, diabetes mellitus, age ≥75 years, and 2 points for previous stroke or TIA) to determine those patients who would derive the most benefit from anticoagulation. A CHA2DS2-VASc score of 0 warrants no anticoagulation. Patients with a CHA2DS2-VASc score of 1 are recommended to receive no therapy, aspirin, warfarin, or a non-vitamin K antagonist oral anticoagulant (NOAC). Patients with a score of ≥2 should receive either warfarin or a NOAC. Implementation of the CHA2DS2-VASc scoring system will result in more patients qualifying for anticoagulation therapy compared to the CHADS2 score. Our objective was to determine the magnitude of the change in risk score when utilizing the CHA2DS2-VASc scoring system.

METHODS: We identified 913 patients diagnosed with AF who attended one or more primary care visits over a 2-year period within an integrated safety net health care system. We risk stratified patients using both the CHADS2 and the CHA2DS2-VASc scoring systems as low- (score of 0), moderate- (score of 1), or high-risk (score ≥2).

RESULTS: When stratified by CHADS2 score, 9.2 % (N=84) of patients were low-risk, 21.9 % (N=200) were moderate-risk, and 68.9 % (N=629) were high-risk. When stratified by CHA2DS2-VASc score, 4.2 % (N=38) of patients were low-risk, 11.0 % (N=100) were moderate-risk, and 84.1 % (N=775) were high-risk. Within the low-risk CHADS2 cohort, 45.2 % (N=38) maintained a score of 0, 47.6 % (N=40) increased to 1, and 7.1 % (N=6) increased to ≥2 when re-scored by CHA2DS2-VASc. Within the moderate-risk CHADS2 cohort, 30.5 %

($N=61$) maintained the same score and 69.5 % ($N=139$) increased to ≥ 2 when re-scored by CHA2DS2-VASc. In the low- and moderate-risk CHADS2 cohorts, the most common reason for receiving an increased score when re-scored by CHA2DS2-VASc was female gender (47.3 %), followed by similar proportions of vascular disease (25.8 %) and age 65–74 years (23.3 %), and a small proportion of patients aged ≥ 75 years (3.5 %).

CONCLUSIONS: In a safety net population of patients with AF there was a 55 % reduction in the number of patients for whom no treatment is recommended when scored using the CHA2DS2-VASc risk stratification tool. The most common reason for increased score was female gender. Increased numbers of patients indicated for anticoagulation represents an opportunity for shared decision-making between patients and providers. Increased utilization of anticoagulation should decrease incidence of thromboembolic stroke, but may increase risks of bleeding and costs associated with medication therapy and healthcare utilization. The ramifications of these potential issues on patients and the healthcare system are currently unknown.

IMPROVED PATIENT AND CAREGIVER HEALTH OUTCOMES ONE YEAR AFTER IMPLEMENTATION OF A DEMENTIA CARE MANAGEMENT PROGRAM Lee A. Jennings; Neil Wenger; Zaldy Tan; Heather McCreath; Katherine S. Serrano; Leslie C. Evertson; David B. Reuben. UCLA, Los Angeles, CA. (Tracking ID #2199481)

BACKGROUND: Caregiver strain, depressive symptoms, and low self-efficacy for managing dementia-related problems are common among those caring for patients with dementia and often poorly addressed in primary care. To better meet both patient and caregiver needs, in July 2012, UCLA launched the Alzheimer's and Dementia Care (ADC) Program, a quality improvement program that uses a co-management model with nurse practitioner Dementia Care Managers working with primary care physicians and community-based organizations to provide comprehensive dementia care.

METHODS: Design: Pre-post evaluation after 1-year of program enrollment Setting: Urban academic medical center Participants: Community-dwelling adults enrolled in a dementia care management program Measurements: Caregivers completed the Cornell Scale for Depression in Dementia and the Neuropsychiatric Inventory Questionnaire (NPI-Q) about the patient, and the Patient Health Questionnaire (PHQ-9) and Modified Caregiver Strain Index (MCSI) about themselves. Caregivers also completed a 9-item survey assessing caregiver self-efficacy for managing dementia-related problems and accessing help. Continuous variables were compared using paired *t*-test or Wilcoxon signed rank sum test for variables with non-normal distributions. Survey items were compared using McNemar's test.

RESULTS: One hundred eighty-two patient and caregiver dyads were seen for an annual follow-up visit, and 167 completed scales and surveys (55 % of program enrollees eligible for a 1-year follow-up visit). The mean patient age was 83 years, 63 % were female, and 63 % lived with the caregiver. Sixty-seven percent of caregivers were female and 91 % were spouses or children. One-year after program enrollment, more caregivers reported they had received advice about handling dementia-related problems (86 vs. 39 %); knew how to access community resources for care (57 vs. 17 %); felt confident dealing with the frustrations of caregiving (54 vs. 36 %); and felt they had a healthcare professional who helps them work through dementia care problems (72 vs. 27 %) ($p < 0.01$ for all comparisons). Patient cognitive and functional status declined during the one-year period consistent with expected rates for dementia. Despite progression of patients' dementia, caregivers reported fewer depressive symptoms for patients (Cornell) and for themselves (PHQ-9) and fewer dementia-related behavioral symptoms (NPI-Q severity score) and less caregiver distress related to these behaviors (NPI-Q distress score). (Table) Baseline caregiver strain, depressive symptoms, NPI-Q and FAQ scores, age, and gender did not differ between program enrollees who completed a one-year follow-up visit and those who did not. Enrollees who completed an annual follow-up visit had higher baseline MMSE scores (18.2 vs. 16.7, $p=0.01$).

CONCLUSIONS: One-year after enrollment in a dementia care management program, caregivers reported greater self-efficacy for managing dementia-related problems and accessing resources for care. Both patients and caregivers reported fewer depressive symptoms, and patients had fewer dementia-related behavioral symptoms despite progression of cognitive and functional impairment. Comprehensive care management for dementia using a co-management model can improve both patient and caregiver health outcomes.

UCLA Alzheimer's and Dementia Care Program Annual Outcomes, $N=182$

Caregiver Survey of Dementia Care and Self-Efficacy, selected items	Baseline N (%)	Year 1 N (%)
I have received advice about handling problems like the patient's memory loss, wandering or behavior problems.	43 (39 %)	94 (86 %)
I know how to get community services that will help me provide care.	19 (17 %)	62 (57 %)
I feel confident that I can deal with the frustrations of caregiving.	38 (36 %)	58 (54 %)
I have a healthcare professional who helps me work through dementia care problems.	28 (27 %)	74 (72 %)
Measure	M (SD)	M (SD)
Modified Caregiver Strain Index (MCSI), range 0–26	10.8 (6.1)	10.0 (6.1)
Caregiver Patient Health Questionnaire (PHQ-9), range 0–27	4.6 (4.9)	3.7 (4.1)
Neuropsychiatric Inventory Questionnaire (NPI-Q) severity score, range 0–36	10.5 (6.5)	9.3 (6.6)
Neuropsychiatric Inventory Questionnaire (NPI-Q) distress score, range 0–60	13.4 (9.6)	10.3 (8.3)
Cornell Depression Scale in Dementia, range 0–38	10.5 (6.1)	8.0 (5.9)
Mini Mental State Exam (MMSE), range 0–30	18.8 (6.0)	16.0 (6.7)
Functional Assessment Questionnaire (FAQ), range 0–30	18.1 (6.9)	21.5 (6.8)

$p < 0.05$ for all comparisons except MCSI ($p=0.11$).

For all scales a higher value indicates greater severity except for the MMSE.

IMPROVING DIABETES MANAGEMENT BY ENGAGING FAMILY SUPPORTERS IN THE PATIENT-CENTERED MEDICAL HOME: A PILOT INTERVENTION STUDY Ann-Marie Rosland^{2, 3}; Michele Heisler^{2, 3}; Ranak Trivedi^{1, 6}; Sofia Gaudioso²; Jessica Fennelly⁴; John D. Piette^{2, 5}. ¹VA Palo Alto, Palo Alto, CA; ²VA Ann Arbor, Ann Arbor, MI; ³University of Michigan Medical School, Ann Arbor, MI; ⁴University of Michigan College of Pharmacy, Ann Arbor, MI; ⁵University of Michigan School of Public Health, Ann Arbor, MI; ⁶Stanford University, Palo Alto, CA. (Tracking ID #2195938)

BACKGROUND: Patient-Centered Medical Homes (PCMH) aim to provide diabetes patients with comprehensive, team-based support for following complex care regimens. Success, however, hinges on patients' ability to be actively engaged in care. While professional staff deliver most patient engagement interventions, 50–75 % of adults with diabetes have a family member or friend (a "Care Partner") who regularly supports their diabetes management and could help them engage more effectively in care. This pilot study evaluated the feasibility and acceptability of an intervention to strengthen Care Partner capacity to help patients with high-risk diabetes engage in PCMH care and thereby improve their risk factor control.

METHODS: Participants were recruited from a VA PCMH registry of primary care diabetes patients at high risk for complications due to poor HbA1c or blood pressure (BP) control. Interested patients nominated a Care Partner. The 4-month intervention provided patient-Care Partner dyads with: one coaching session on health care engagement and evidence-based support skills; telephone coaching before patients' primary care visits; mailed after-visit summaries; weekly automated phone calls to prompt conversations about diabetes management; and tools to promote effective diabetes-related conversations. All components provided options for non-face-to-face Care Partner participation and could be delivered by PCMH team nurses. To assess feasibility and acceptability, we collected participant survey and medical record data at baseline and 4-month follow-up.

RESULTS: Nineteen patient-Care Partner dyads were recruited among 77 patients screened. Eighteen patients were men (mean age 66 years). Eleven Care Partners were co-habiting spouses. All 19 dyads completed the initial coaching session. Eighty-one percent of attempted pre-visit preparation calls and 82 % of attempted automated telephone assessments were completed. From baseline to follow-up the number of patients increased who reported that Care Partners helped them: track medications (29 to 63 %, $p=0.04$) and decide when to call their doctor/nurse with a diabetes-related problem (47 to 81 %, $p=0.04$). Care Partner self-efficacy in helping patients manage diabetes increased (8.0 to 8.6, $p=0.08$). The number of patients bringing home-glucose logs to most medical visits increased from 26 to 55 % ($p=0.07$), and patients' engagement in clinician interactions increased from 8.9 to 9.3 ($p=0.2$) on the Patient Engagement in Patient Physician Interactions scale. At follow-up, 95 % of patients and 89 % of Care Partners said they were satisfied with the program, and 84 % of both patients and Care Partners felt CO-IMPACT

helped them more effectively manage diabetes. Care Partner Caregiver Strain Index scores decreased (1.6 to 1.1, $p=0.17$). Patient and Care Partner-rated relationship quality did not change.

CONCLUSIONS: An intervention that guides high-risk diabetes patients and their Care Partners through evidence-based patient engagement and support strategies is desirable and feasible to participants, with indications that the intervention may increase Care Partner support for patient engagement and patient engagement itself, and decrease Care Partner stress. The impact of this intervention on patient engagement and diabetes management will be further evaluated in a recently funded trial that will randomize 200 dyads to a 12-month version of the intervention vs. PCMH usual care.

IMPROVING OPIOID PRESCRIBING IN THE CONTEXT OF ROUTINE PAIN SCREENING

Karleen Giannitrapani⁴; Sangeeta Ahluwalia³; Maura Pisciotto²; Risa Cromer⁶; Hannah C. Schreiber-Baum³; Steven Dobscha²; Erin E. Krebs¹; Karl Lorenz⁷. ¹Minneapolis VA Health Care System, Minneapolis, MN; ²Portland VAMC, Portland, OR; ³RAND Corporation, Encino, CA; ⁴UCLA / VA GLA, Los Angeles, CA; ⁵VA Greater Los Angeles Healthcare System, Los Angeles, CA; ⁶VA, Portland, OR; ⁷VA / UCLA/ RAND, Los Angeles, CA. (Tracking ID #2196337)

BACKGROUND: The Veteran Health Administration (VA) uses the 5th Vital Sign at each clinical encounter to assess pain using a 0–10 numeric rating scale (NRS). We asked primary care providers about their experiences with using the 5th vital sign and how it affects pain management.

METHODS: Members of primary care teams at two large academically-affiliated VA Medical Centers in two states including physicians, nurse practitioners, physician assistants, nurses, social workers, pharmacists, and support staff, participated in 9 interdisciplinary focus groups. The sites were diverse including both urban and rural primary care practices as well as both hospital and community based practices. Skilled focus group facilitators used a semi-structured interview guide to elucidate provider experiences with the 5th Vital Sign and managing pain. Qualitative analysts evaluated transcribed interviews using the method of constant comparison and produced mutually agreed upon themes.

RESULTS: Multidisciplinary primary care team members related the following themes: **Providers want to ensure high pain scores get addressed and may feel pressured to prescribe opioids** to minimize the risk of under-treating: “*You’re the bad guy if a guy comes in at ten pain and you send him out with aspirin.*” Providers also feel they lack other adequate pain management options: “*So a patient comes in and says my pain is ten out of ten. There’s some pressure on the provider about treating it. Probably with opioids because we have nothing else to offer.*” **Providers, however, prescribe with caution when their patients report high pain scores** because they believe some patients know how to game the system and quote patients as saying “*in order to get my narcotic, I have to say my pain is 10. Right? Then for sure my doctor will renew my narcotic.*” Providers also believe some patients are dishonest out of fear of losing access to opioids: “*there still is that underlying fear of being weaned.... so every time they are coming in, they are saying, ‘My pain is 10.’*” **Providers have ideas about what would help them better navigate pain management and opioid prescribing.** They want: 1) Data on function and activity not just experience of pain scores: “*what we should be focusing on...is how does the pain affect activity?*” 2) Non pharmacologic pain management approaches that provide effective alternatives to narcotics: “*If...rather than increasing narcotics or opiates it [an alternative approach] would give them options to help cope with their pain, it could help.*” 3) Coordinated multidisciplinary approaches to reducing opioid use: “*they [another clinic] used a multidisciplinary approach with lots of resources in a clinic with lots of different specialties and they were able to get I think every single patient... off of their medication.*”

CONCLUSIONS: Routine pain screening creates the expectation of better pain management among primary care providers and patients alike. Providers, however, are stymied by the numeric rating scale’s unidimensional nature as well as inadequate support for alternatives to pharmacologic management. To improve the outcomes of routine pain screening including minimizing inappropriate opioid use, primary care providers endorsed the use of simple measures that provide objective criteria (e.g. function) to support decision making, access to nonpharmacologic treatment, and integrated multidisciplinary approaches to pain management.

IMPROVING RACE/ETHNICITY DATA IN THE VETERANS HEALTH ADMINISTRATION Susan Hernandez¹; Philip W. Sylling². ¹VA, Seattle, WA; ²Veterans Health Administration, Seattle, WA. (Tracking ID #2198504)

BACKGROUND: The Department of Veteran Affairs (VA) implemented a new system for self-identified categories for race and ethnicity in 2003 that included five racial groups

(American Indian/Alaska Native, Asian, Black/African American, Native Hawaiian/Other Pacific Islander, White) and one ethnic group (Hispanic). We assessed agreement between self-reported race/ethnicity from patient satisfaction surveys and race/ethnicity data from earlier administrative data.

METHODS: The study included 8,874,659 primary care patients in the Primary Care Management Module (PCMM) and 2,004,759 completed an outpatient Survey of Healthcare Experiences of Patients (SHEP) during 2003–2013. We assessed agreement among self-reported race/ethnicity from SHEP, administrative data from the Corporate Data Warehouse (CDW), the main source of race/ethnicity data, and the Vitals Master files (extracted from Medicare files). We created the following categories for each data source: White, non-Hispanic; Black/African American, non-Hispanic; American Indian/Alaska Native (AI/AN), non-Hispanic; Asian non-Hispanic; Native Hawaiian/Other Pacific Islander (NH/PI), non-Hispanic; multiple races, non-Hispanic; other, non-Hispanic; and Hispanics. Hispanic Veterans could be of any race. Because the Vitals Statistic file lacked separate categories for Asian, Native Hawaiian, and Other Pacific Islanders we combined these categories. We also combined other and multi-race category in the SHEP for comparison with the other category in the vitals statistic file. Using SHEP data as the standard, we measured the agreement between the data sources by calculating sensitivity, specificity, positive (PPV) and negative predictive values (NPV), and Cohen’s kappa as a measure of agreement between the SHEP and administrative data. Kappa statistics of .81 represent excellent agreement.

RESULTS: The agreement between SHEP and CDW varied substantially by racial/ethnic group. PPV ranged from 96 % for whites to 13 % for multi-racial Veterans (White 96 %; Black 94 %; Hispanic 90 %; Asian 82.4 %; NH/PI 19.5 %; AI/AN 55.5 %; Multi-race 12.9). Kappa statistics ranged from .936 to .074 (White .833; Black .936; Hispanic .799; Asian .793; NH/PI .285; AI/AN .402; Multi-race .073). The agreement between self-reported SHEP and the Vitals statistic file also varied by racial/ethnic group. PPV ranged from 95 to 3.4 % (White 94.1 %; Black 93.2 %; Hispanic 95.1 %; Asian/NH/PI 77.6 %; AI/AN 59.6 %; Other/Multi-race 3.4 %). Kappa statistics ranged from .956 to .009 (White .735; Black .956; Hispanic .298; Asian/NH/PI .578; AI/AN .425; Other/Multi-race .009).

CONCLUSIONS: Overall, determination of race/ethnicity using the CDW data was relatively accurate (high PPV and kappa) for individuals who self-identified as white or black but less so for Hispanics and Asians and poor for NH/PI and AI/AN. Determination of race/ethnicity using the Vital Statistics file was also relatively accurate for individuals who self-identified as white or black but poor for Hispanics, Asian/NH/PI and AI/AN. However, the specificity (i.e., PPV) for being classified as Hispanic using Vital Statistics was high with low sensitivity. To correctly classify race and ethnicity for Veterans who use VA services, we suggest using SHEP data when available first, and then CDW data, and Vital statistic data only when necessary to adjust for missing data. Our next steps are to include race/ethnicity data from the inpatient SHEP and Department of Defense which are also self-reported data to construct a race/ethnicity variable to use for VA analyses.

IMPROVING RECOGNITION AND MANAGEMENT OF CHRONIC KIDNEY DISEASE IN PRIMARY CARE

Cara Litvin²; Steven M. Orstein¹; Madison Hyer¹. ¹Medical University of SC, Charleston, SC; ²Medical University of South Carolina, Charleston, SC. (Tracking ID #2198106)

BACKGROUND: Early detection and management of chronic kidney disease (CKD) can lead to interventions to prevent renal failure and reduce risk for cardiovascular disease. However, adherence to treatment goals is suboptimal in the primary care setting. The purpose of this study was to assess whether electronic health record (EHR)-based clinical decision support (CDS) tools can be used to improve the identification and management of CKD in primary care practices.

METHODS: This 2 year demonstration study from September 2012 to September 2014 was conducted in PPRNet, a national primary care practice-based research network whose members share a common EHR. Eleven practices in 11 states, representing 21 physicians and 11 midlevel providers, volunteered to participate. CKD CDS tools developed by the research team included a risk assessment tool that could be embedded within progress notes, EHR-based health maintenance protocols, an EHR flow chart and a patient registry generated from EHR data. To facilitate implementation of these tools, practices received quarterly CKD performance reports and hosted annual half day on-site visits for academic detailing, performance review and CDS training. CKD quality measures related to screening at-risk patients, monitoring, blood pressure management, lipid assessment, hemoglobin monitoring and avoidance of non-steroidal anti-inflammatory drugs (NSAIDs) were developed for this project using a consensus process among PPRNet providers. Linear mixed-effects regression models controlling for baseline values and number of eligible subjects were used to assess changes over time in each of these measures. Semi-structured group interviews were used to identify facilitators and barriers to CDS use.

RESULTS: There were statistically significant improvements in annual urine albumin screening for patients with diabetes or hypertension (estimated 24 month change 33.1 %, SE=0.0192, $p<0.001$) and annual urine albumin testing in patients with CKD (estimated 24 month change 21.6 %, SE=0.0312, $p<0.001$). No significant changes over time were seen in estimated glomerular filtration rate (eGFR) monitoring for patients with CKD, blood pressure monitoring, blood pressure control, lipid assessment, hemoglobin monitoring or avoidance of NSAIDs. Facilitators to CDS use included ease of use of the tools, practices' prioritization of improving CKD management, empowering staff to utilize standing orders based on EHR-based health maintenance protocols and use of the registry for patient outreach. Barriers included incorporating use into existing workflow, varied use among providers at the same practice, lack of awareness of functions by some providers and disagreement with some CDS recommendations.

CONCLUSIONS: Use of CDS tools to improve CKD identification and management in primary care practices shows promise, particularly for improving process measures such as urine albumin testing. However, other organizational, provider and patient factors must be addressed in order to effectively achieve improvements in CKD outcomes.

IMPROVING THE USE OF APPROPRIATE RADIOGRAPHS TO DIAGNOSE OSTEOARTHRITIS IN A PRIMARY CARE MEDICINE CLINIC Anielle A. Yang; Justin S. Yang; Kelly C. Cushing; Rick W. Wright; Michael A. Lane. Washington University, St. Louis, MO. (Tracking ID #2172624)

BACKGROUND: Weight bearing radiographs with Rosenberg views, the most sensitive and specific type of radiograph for detecting and assessing osteoarthritis of the knee, are underutilized by primary care physicians. Osteoarthritis severity detected radiographically can mean the difference between choices of conservative management versus assessment with magnetic resonance imaging once the patient is referred to a specialist. Improving the use of these appropriate radiographic views could improve clinical decision making while decreasing the need for repeat radiographs. The objective was to increase the utilization of appropriate radiographs through a quality improvement intervention involving physician education and changes in the electronic order entry process.

METHODS: This was a non-randomized, prospective, quality improvement study conducted at a primary care resident continuity clinic in a large academic hospital. The participants were one hundred thirty nine resident physicians. Two simultaneous interventions were implemented. The computerized provider order entry system was modified to streamline the order entry process for the appropriate radiographs and the residents

received education about appropriate imaging modalities and use of the modified order entry process. Outcomes were assessed in the 6 months pre- and post-intervention. The primary outcome was the proportion of radiographs ordered that included weight-bearing and Rosenberg views. Secondary outcomes included the number of repeat radiographs obtained for the purpose of weight-bearing or Rosenberg views, number of radiographs with merchant views, and severity of arthritis.

RESULTS: Between March 2013 and March 2014, 212 patients over the age of 40 received radiographs to evaluate for non-traumatic knee pain. Weight-bearing films increased from 28 % in the pre-implementation period to 66 % of the films in the post-implementation period ($p<0.001$). Rosenberg images were obtained in three patients (3 %) and 52 patients (49 %) during pre- and post-implementation periods ($p<0.001$), respectively. Repeat imaging decreased from 10 % in the pre-implementation period to 2 % in the post-implementation period ($p=0.009$). For the 13 patients that received repeat weight-bearing films, the severity of arthritis increased from 42 % joint space narrowing to 78 % joint space narrowing ($p<0.001$). The arthritic severity of all patients pre-implementation averaged 61 % joint space narrowing and post-implementation averaged 85 % joint space narrowing ($p=0.003$).

CONCLUSIONS: A low cost, quality improvement intervention can increase the use of appropriate imaging for patients with non-traumatic knee pain, reduce healthcare utilization by decreasing repeat imaging, and allow for a more accurate assessment of osteoarthritis severity leading to better clinical decision making.

Primary and Secondary Outcomes Pre- and Post-implementation

Imaging Type	Pre-implementation (N=105)	Post-implementation (N=107)	P-value
Weightbearing	28 % (29)	66 % (71)	<0.001
Bilateral	65 % (68)	77 % (82)	0.08
Merchant	31 % (33)	82 % (88)	<0.001
Rosenberg	3 % (3)	49 % (52)	<0.001
Repeat	10 % (11)	2 % (2)	0.009

When comparing the 6 months pre-implementation with the 6 months post-implementation, there was a statistically significant increase in the weightbearing, Rosenberg, and Merchant films ordered. There was also a statistically significant decrease in the number of repeat films that were ordered for the purpose of obtaining weightbearing or Rosenberg views.

Before the start of the intervention less than 40 % of the knee films ordered included weightbearing or Merchant views and less than 5 % included Rosenberg views. After the start of the intervention in August, there was an increase in all types of appropriate knee films that were ordered which continued through early November when the intervention ended and peaked in December. Starting in January there was a decrease in the use of appropriate films which was greater for weightbearing and Rosenberg films than for Merchant films. All three views of the knee, however, were still ordered at higher rates than before the initiation of the intervention.

INAPPROPRIATE OVERRIDES OF AGE-RELATED ALERTS IN PRESCRIBER ORDER ENTRY Olivia Dalleur^{1, 4}; Diane L. Seger^{3, 1}; Sarah P. Slight^{2, 1}; Mary Amato^{1, 5}; Tewodros Eguale^{1, 6}; Karen C. Nanji^{3, 7}; Michael Swerdloff^{3, 1}; Patricia C. Dykes^{1, 8}; Julie Fiskio^{3, 1}; David W. Bates^{1, 8, 1}Brigham and Women's Hospital, Boston, MA; ²Durham University, Stockton on Tees, United Kingdom; ³Partners Healthcare System, Wellesley, MA; ⁴Universite catholique de Louvain (UCL), Brussels, Belgium; ⁵MCPHS University, Boston, MA; ⁶Department of Medicine, McGill University, Montreal, QC, Canada; ⁷Department of Anesthesia, Critical Care and Pain Medicine,

Massachusetts General Hospital, Boston, MA; ⁸Harvard Medical School, Boston, MA. (Tracking ID #2197513)

BACKGROUND: To prevent adverse drug events from occurring in older patients, Clinical Decision Support (CDS) can suggest alternatives to drugs with an unfavourable risk/benefit ratio. In our institution, a large academic hospital in Boston, suggestions about alternatives are currently displayed as an alert in the prescriber order entry system. However, we observe that the providers overrode a large proportion of these suggestions. This study evaluated the appropriateness of these overrides.

METHODS: All alerts displayed between 2009 and 2011 were collected. We developed a set of criteria for which the overrides could be considered potentially appropriate. For example, these criteria took into account previous well-tolerated use of the same drug and the dosage used. Some drugs were considered as always inappropriate if prescribed to older patients, regardless the context (e.g. diazepam). Using this set of criteria, we measured the proportion of cases in which overriding the suggestions could be considered potentially appropriate. Two independent reviewers assessed a subsample of 208 overrides that were randomly extracted from prescribers who had a higher level of overrides and was checked for representativeness. Cases in which overriding the alert was recurrently appropriate were targeted for changes in the CDS.

RESULTS: Over 3 years, 33 141 recommendations were overridden, exposing 12 833 patients to potentially inappropriate medications. Half of these overrides were laxatives. As these were mainly prescribed for short-term treatment and bisacodyl was no longer on the latest version of the American Geriatrics Society Beers list of inappropriate drugs in elderly, all laxatives were considered as appropriate and excluded from the appropriateness analysis of the subsample. In the subsample, the reviewers classified 74 % of the overrides as inappropriate. Forty percent overrides were drugs that are always inappropriate in older patients. Other inappropriate prescribing involved drug-disease contraindications ($n=4$, anti-inflammatory drugs), side effects ($n=26$, mainly antidepressants) or inappropriate doses ($n=55$, mainly analgesics and benzodiazepines). Following this study, the alerts that were appropriately overridden were communicated to the informatics department managing the alerts as well as to the responsible committees. In addition, we organised academic detailing sessions with providers, the purpose of which was to understand the reasons behind their override decisions and to give them information about appropriate use of drugs in older patients.

CONCLUSIONS: A single improvement in the CDS—deleting alerts about laxatives—could cut the number of alerts received by providers by about half. Among the remaining alerts, although most of them were indeed inappropriate, 26 % could be considered as potentially appropriate, meaning that regular reassessment of the CDS in context of daily prescribing decisions is required to keep it relevant and reduce possible alert fatigue. Further evaluation will assess if reassessment and refinement of the alerts and the academic detailing can help decrease the override rates and improve the quality of prescribing.

INCIDENCE OF SEROTONIN SYNDROME WITH CONCOMITANT USE OF SEROTONERGIC AGENTS IN THE U.S. CLINICAL PRACTICE Zhixiao Wang¹; Lin Xie²; Stephanie Alley^{3, 4}; Onur Baser^{2, 5}; Charles Nguyen^{3, 6}. ¹Eisai, Inc, Woodcliff

Lake, NJ; ²STATinMED Research, Ann Arbor, MI; ³Long Beach VA Healthcare System, Long Beach, CA; ⁴Southern California Institute of Research, Long Beach, CA; ⁵The University of Michigan, Ann Arbor, MI; ⁶University of California Irvine School of Medicine, Irvine, CA. (Tracking ID #2198446)

BACKGROUND: Serotonin syndrome (SS) is an adverse drug reaction resulting from increased serotonin levels stimulating central and peripheral postsynaptic serotonin receptors, particularly serotonin 5-HT_{2A} receptors.¹ SS may occur in patients receiving monotherapy or combinations of serotonergic agents (SAs). Although combination of SAs is common in clinical practice, the incidence and prevalence of SS is still largely unknown. This study examined the prevalence and incidence of SS over time with concomitant use of SAs in the U.S. commercially insured population.

METHODS: Adult patients prescribed SAs were identified using the IMS PharMetrics PlusTM dataset from 01JAN2010-31DEC2013. IMS data has more than 150 million unique patients' enrollment, demographic, medical and pharmacy claims. Patients with continuous medical and pharmacy benefits for 12 months prior to the index date, defined as the first SA prescription claim date, were included and evaluated until death, disenrollment or the end of follow up. Patients were assigned to cohorts based on drug exposure: single monoamine oxidase inhibitor (MAOI) drug, MAOI drugs in combination with other SAs, single non-MAOI SA, and multiple non-MAOI SAs (2, 3, 4 and 5 or more SAs). An SS event was identified using International Classifications of Diseases, 9th Revision Clinical Modification code: 333.99. A patient may have more than one SS event during the study period and be included in multiple cohorts, depending on drug exposure patterns. Annual prevalence was calculated as the percentage of continuously enrolled patients with at least one SS claim. Annual incidence was calculated as the percentage of SS patients among enrollees with no prior SS diagnosis. Poisson regression was used to assess SS incidence trends, and adjusted incidence relative risks (IRRs) were estimated.

RESULTS: A total of 11,818,956 patients were identified and seven drug cohorts were created. The overall incidence rate in the commercially insured population decreased from 0.17 % in 2010 to 0.09 % in 2013. The highest incidence rate was observed in two cohorts: 1) patients who were prescribed MAOIs in combination with non-MAOI SAs (10.25 per 1000 person-years) and 2) patients prescribed five or more non-MAOI SAs (10.50 per 1000 person-years). The lowest incidence of SS occurred among patients prescribed a single, non-MAOI SA (1.38 per 1000 person-years). Compared to those prescribed with one non-MAOI SA, the IRR of SS was 5.49 (95 % confidence interval [CI]: 4.33–6.97) times higher among patients prescribed a MAOI in combination with non-MAOI SAs, and 5.77 (95 % CI: 5.30–6.28) times higher for those prescribed five or more non-MAOI SAs. Overall SS prevalence decreased during the 4-year study period.

CONCLUSIONS: Although the analysis indicated the relative risk of SS increased as more SAs were taken concomitantly, the overall incidence and prevalence of SS in the commercially insured population in the US were very low. This data provides physicians with additional information about SS associated with prescribing SAs. ¹Evans RW, Tepper SJ, Shapiro RE, et al. The FDA Alert on serotonin syndrome with use of triptans combined with selective serotonin reuptake inhibitors or selective serotonin-norepinephrine reuptake inhibitors: American Headache Society position paper. *Headache*. 2010;50(6):1089–99.

SA: serotonergic agents

Table 1. Serotonin Syndrome Event Rate for Patients prescribed Different Combinations of Serotonergic Agents

Cohorts	Serotonin Syndrome Event Rate per 1000 person-years	Unadjusted IRR	Adjusted IRR			
			IRR	95% CI	p-value	
One Non-MAOI Drug	1.38	1.00	Reference			
One MAOI Drug	2.97	2.16	1.63	1.13	2.34	0.0087
MAOI Combination	10.25	7.44	5.49	4.33	6.97	<0.0001
Two-drug Combination	3.37	2.45	2.20	2.15	2.25	<0.0001
Three-drug Combination	4.60	3.34	2.91	2.81	3.00	<0.0001
Four-drug Combination	6.32	4.59	3.84	3.64	4.05	<0.0001
Five or More-drug Combination	10.50	7.63	5.77	5.30	6.28	<0.0001

MAOI: monoamine oxidase inhibitor

IRR: incidence relative risk

CI: confidence interval

INCORPORATING COMMUNITY HEALTH WORKERS INTO THE VA: WHAT DO VETERANS THINK? Julie B. Silverman²; Karin M. Nelson¹; James Krieger³. ¹University of Washington, VA Puget Sound, Seattle, WA; ²VA Puget Sound, Seattle, WA; ³Public Health—Seattle King County, Seattle, WA. (Tracking ID #2191031)

BACKGROUND: Community health workers (CHWs) are lay members who work with their communities to improve access to healthcare and social services, support adoption of healthy behaviors and improve overall health and wellbeing. While use of CHWs in the U.S. is limited, the shift toward bundled payments and the growing focus on patient-centered medical homes has increased their use. Though CHW utilization within the Department of Veterans Affairs (VA) is rare, a VA-funded systematic review of healthcare disparities recommended integration of CHWs into VA settings as a promising intervention. We conducted a qualitative study to evaluate Veterans' experiences working with a CHW and assess the acceptability of CHW utilization within the VA.

METHODS: We conducted 14 semi-structured phone interviews with Veterans who had received a CHW intervention as part of a larger randomized controlled trial, Peer Support for Achieving Independence in Diabetes (Peer AID), which tested the effectiveness of a home-visit diabetes self-management support program. Peer AID participants had poorly controlled type 2 diabetes (A1c $\geq 8.0\%$), household income $<250\%$ of the federal poverty level and were 30–70 years old. The CHWs were non-Veterans and paid employees of Public Health—Seattle & King County. Phone interviews occurred after completion of study. The recorded interviews were transcribed and analyzed using inductive content analysis.

RESULTS: Veterans reported high satisfaction with the CHW intervention. Veterans appreciated the convenience of CHW making home visits, which allowed Veterans to receive diabetes self-management support without the expense and stress of traveling to the VA. They also valued the one-to-one attention and the amount of time the CHW spent with them. None of the Veterans were bothered by the non-Veteran status of the CHWs, noting that the CHWs' knowledge and training were more important than their background or Veteran status. However, several participants mentioned that having a Veteran CHW, who has a shared military background and firsthand knowledge of the VA system, could be valuable. Participants supported the idea of incorporating CHWs into the VA system.

CONCLUSIONS: Veterans had overwhelming positive experiences working with a CHW and encouraged the use of CHWs within the VA. The services provided by CHWs are well aligned with the VA's redesigned primary care model, the Patient Aligned Care Team (PACT), which emphasizes comprehensive, patient-centered, team-based care that improves access and connects Veterans to appropriate services within the VA and the communities in which they live.

INCREASED EMPATHY AS A LONG-TERM EFFECT OF A RESIDENCY WRITERS' WORKSHOP Megan S. Lemay; Anna Reisman; John Encandela; Lisa Sanders. Yale School of Medicine, New Haven, CT. (Tracking ID #2196495)

BACKGROUND: Creative writing workshops in medical training generally aim to facilitate reflection, increase empathy, and teach trainees to understand the importance of a patient's story. Over the past 11 years, 130 residents from multiple specialties have participated in the annual Yale Internal Medicine Writer's Workshop. Participants submit a narrative and then participate in an intensive two-day workshop focused on the art and

craft of writing. After the workshop, participants work on revisions with continued feedback, leading to a publication of the narratives, a public reading, and an invited grand rounds featuring a physician-writer. We hypothesized that the workshop has long-term effects on empathy, observation, and motivation to write.

METHODS: An online anonymous survey was sent to the 130 previous participants of the Yale Internal Medicine Writer's Workshop. Participants were asked to evaluate (via a 5-point Likert scale and qualitative text response) how the workshop influenced their empathy, observation skills, writing skills, and whether they were inspired to continue to write. Qualitative responses were coded by study investigators (independent coding followed by consensus) to identify themes in resident responses.

RESULTS: Ninety (69 %) former resident participants responded to the survey. The majority of residents agreed or strongly agreed that the workshop influenced their ability for careful observation (84 %), ability to be empathic (66 %), improved their writing (89 %), and inspired them to keep writing informally (such as keeping a journal) (53 %) and formally (for publication) (67 %). Respondents indicated that the workshop influenced their empathy with patients as well as colleagues. Some noted that the workshop helped them to become more empathic through recognizing that each patient has a story. One respondent noted: "By describing my patients' experiences in writing, I have increased the strength of my empathic self."

CONCLUSIONS: Residents who participated in this writing workshop described a sustained increase in their ability to be empathic with both patients and other physicians as a result of this participation. The writing workshop also taught them to observe more carefully and improved self-reported writing skills. Many former workshop participants have continued narrative writing, both formally and informally. Residency writing workshops focused on the craft of narrative writing may help to preserve and enhance empathy.

INCREASING END-OF-LIFE CARE DISCUSSIONS, INCLUDING CODE STATUS, IN A RESIDENT RUN URBAN COMMUNITY PRIMARY CARE CLINIC Andrew Ip; Rekha Thammana; Nurcan Ilksoy. Emory University, Atlanta, GA. (Tracking ID #2199949)

BACKGROUND: Many elderly patients (defined as >65 years of age) do not have advanced directives on file to address their end-of-life care. An advanced directive is an important document that respects patient wishes, guides patient care especially in regards to code status, and can save our health care system money. A large amount of Medicare billing, up to one-quarter in some studies, is for the last year of life, and only 20–30 % of the U.S. population have an advanced directive. Our resident-run clinic wished to address palliative care in our urban community in the outpatient setting, however we realized filling an advanced directive was difficult in our current system. We therefore wanted to address discussions of code-status as a starting point. Our objective is to investigate if palliative care discussions can be held during primary clinic visits. In our quality improvement study, we aim to increase the number of end-of-life care discussions, primarily code status documentations, in our urban hospital clinic patients older than 65 years.

METHODS: We aimed to study the elderly population in our urban community clinic. We used an age cut-off of 65 years to discuss code status. Resident providers were asked to implement two tests of change. The first test of change, performed in January-February of 2014 was an implementation of a computer phrase, or dot-phrase, that can be inserted into a note template for each outpatient encounter. The providers did have to copy this dot phrase into their templates in order for it to auto-populate with each new patient encounter.

The dot phrase had 2 prompts: “Is this patient over 65 years of age?” followed by a Yes or No. “Were you able to discuss code status in this outpatient visit?” followed by a Yes or No or Not Enough Time. The second test of change occurred during March of 2014, and incorporated clinic assistants handing out surveys to each patient over the age of 65 at the time of check-in. The survey had two simple questions, “Do you know what a code status is?” and “Would you be interested in discussing this today?”.

RESULTS: In the first test of change during the months of January and February, 21 % (8/38) of patients participated in code status discussions, while 32 % (12/38) of patients declined participating, and 47 % (18/38) of patients were unable to participate due to resident providers not having enough time to address code status. In our second test of change during the month of March, 48 % (14/29) of patients participated in code status discussions, while 24 % (7/29) declined participating, and 28 % (8/29) were unable to participate due to resident providers not having enough time in their clinic to address code status.

CONCLUSIONS: This study addressed how palliative care discussions can be incorporated into a busy urban community primary care clinic. Our first test of change showed that a simple dot phrase can remind providers to initiate a palliative discussion about code status, however this occurred only 20 % of the time. Our second test of change showed that a simple survey can prompt patients to bring up the topic with providers, and increased the percentage to almost 50 %. There were several barriers for our study. Our resident providers often had too little time to initiate a discussion about code status or often forgot to implement our first test of the change, the dot phrase. This was due to our patient population having multiple comorbidities as well as having a large agenda to discuss each visit. Another barrier was the lack of a standard approach to initiate a code status discussion in the outpatient setting as resident providers each had different methods on how to approach the topic with their patients.

INDIVIDUAL PCP REFERRAL BEHAVIOR FOLLOWING INTRODUCTION OF A STRUCTURED REFERRAL AND ECONSULT PROGRAM Priya A. Prasad²; Nathaniel Gleason¹; Carlin H. Senter³; Maria E. Otto²; Ariana Afshar¹; Ralph Gonzales². ¹UC San Francisco, Nathaniel Gleason, CA; ²UCSF, San Francisco, CA; ³University of California San Francisco, San Francisco, CA. (Tracking ID #2200136)

BACKGROUND: We implemented two interventions to improve access to specialty care at an academic medical center (AMC) in 2012: Structured Referrals, which provide decision-support on referral appropriateness, and eConsults, which allow the PCP to access input from a specialist, via the electronic health record (EHR), without referring the patient for in-person evaluation. We demonstrated and reported a decrease in the aggregate referral rate (referrals from across all participating primary care practices per 100 primary care visits) of 16 %. Here we analyze the impact on individual PCP referral behavior including analysis of the main General Internal Medicine practice, which is the administrative home of the above interventions, versus participating primary care practices at other locations.

METHODS: A multi-site AMC, UC San Francisco has 7 primary care practices offering care for adult patients. Approximately 100 general interests, including residents and fellows, occupy a central practice (GIM). Providers at the other 6 primary care practices include general interests, family and community medicine physicians, geriatricians, and nurse practitioners (non-GIM). PCPs in all 7 clinics employ Structured Referrals, implemented in 5/12, which include guidance on pre-referral evaluation and conservative

management. An eConsult option providing non-face-to-face evaluation by a specialist was launched in 9/2012 in all PCP practices. Related activities that took place at the GIM practice included interaction with the implementation team, who elicited feedback about referral guidelines from PCPs, and case conferences with guest subspecialists to discuss referrals and care coordination. To ensure a sample of active clinicians, PCPs who performed less than 200 visits during either the baseline and intervention periods were excluded ($n=60$ included PCPs). We compared the provider-level referral order rate (ROR) per 100 primary care office visits during the baseline period (9/11-4/12) and a seasonally matched intervention period (9/13-4/14). Referrals to all medicine subspecialty practices ($n=11$ specialties), ordered by included PCPs were analyzed. A difference score was calculated to illustrate changes in provider-level ROR between baseline and intervention periods. The mean change was compared between providers from General Internal Medicine (GIM) ($n=33$) and non-GIM ($n=27$) using a t-test. All analyses were conducted using Stata 13.

RESULTS: A decrease in the provider-level ROR among all providers, between the baseline and intervention periods, was not statistically significant (mean change in ROR, -0.68 , 95 % CI -1.9 to 0.5). Providers in the GIM clinic decreased mean ROR from 13.7 to 10.9 referral orders per 100 primary care visits, a statistically significant decrease of 20 % (mean change -2.79 , 95 % CI -4.31 to -1.27), while providers not in the GIM clinic increased mean ROR from 10.5 to 12.3 referral orders (mean change 1.9 , 95 % CI 0.44 to 3.33). There was a significant difference in the mean ROR change score when comparing providers in GIM to non-GIM (-2.8 v. 1.9 , $p<0.0001$).

CONCLUSIONS: A Structured Referral and eConsult intervention lead to a, previously reported, aggregate decrease in referrals from primary care to medicine subspecialties, but examining the mean change in individual provider referral order rate does not show a decrease overall. Instead, GIM providers located at a large, central practice significantly decreased individual ROR, while providers outside this practice increased their mean rate of referral. The finding does not appear to be a difference in referral rate by primary care specialty, i.e. between GIM providers versus FCM providers, but rather a function of location. A number of related activities took place at the GIM practice, suggesting the importance of these co-interventions. The finding has implications for the implementation of a care-delivery innovation, supporting the need to maximize familiarity with the project as well as interaction with the project team.

INDIVIDUAL VERSUS TEAM-BASED FINANCIAL INCENTIVES FOR PHYSICAL ACTIVITY—A RANDOMIZED, CONTROLLED TRIAL Mitesh Patel^{1, 2}; David A. Asch^{1, 2}; Roy Rosin¹; Dylan Small¹; Scarlett Bellamy¹; Nancy Hafl³; Samantha Lee¹; Lisa Wesby¹; Karen Hoffer¹; David Shuttleworth¹; Devon Taylor¹; Victoria Ulrich¹; Jingsan Zhu¹; Lin Yang¹; Xingmei Wang¹; Kevin G. Volpp^{1, 2}. ¹University of Pennsylvania, Philadelphia, PA; ²Philadelphia VA Medical Center, Philadelphia, PA; ³Massachusetts General Hospital, Boston, MA. (Tracking ID #2196516)

BACKGROUND: More than half of adults in the United States do not achieve the minimum recommended level of physical activity to achieve health benefits. While pedometers offer promise in encouraging more activity, their adoption is limited and the optimal way to motivate individuals or teams is unknown. More than two-thirds of adults in the United States possess a smartphone and carry it with them often. Insights from behavioral economics may offer new strategies to leverage smartphones to impact population health through the use of financial incentives. The objective of this study was to use a connected health approach with smartphones tracking step counts to compare the effectiveness of individual versus team-based financial incentives for physical activity.

METHODS: Three hundred four adult employees from a large corporation in Philadelphia formed 76 four-member teams randomized to control or one of 3 intervention arms: individual incentives, team incentives, or combined incentives (based on individual and team performance)—with reward eligibility based on achieving at least 7000 steps per day, a level endorsed by the American College of Sports Medicine as meeting federal guidelines for the minimum level of physical activity to achieve health benefits. Financial incentives were offered in the form of a \$50 drawing held every other day and had an expected economic value of \$1.40 per day. The intervention period lasted 13 weeks and participants were followed for an additional 13 weeks. Step counts were tracked by smartphone accelerometers using an application that ran passively in the background. The primary outcome measure was the proportion of participant-days that the goal was achieved during the intervention. The intent-to-treat analysis used generalized linear and mixed-models to adjust for the repeated measures of participant step counts and clustering by team. All hypothesis tests were two-sided. To maintain the type I error rate while testing 6 pairwise comparisons, we used a Bonferroni correction to define an alpha of 0.0083 as our threshold for statistical significance. We estimated that a sample of at least 280 participants would ensure 80 % power to detect a 20 % difference between arms.

RESULTS: Participants in the study sample had a mean body mass index of 29.2 (standard deviation [SD]: 6.4), mean age of 40.5 (SD 10.4), and were 77.3 % female. Compared to control during the intervention period, the proportion achieving the 7000 step goal was significantly greater for the combined incentive (0.35 vs. 0.18, Difference: 0.17, 95 % confidence interval [CI]: 0.07–0.28, $P < 0.001$) but not for the individual incentive (0.25 vs 0.18, Difference: 0.08, 95 % CI: –0.02–0.18, $P=0.13$) or the team incentive (0.17 vs 0.18, Difference: –0.003, 95 % CI: –0.11–0.10, $P=.96$). The combined incentive was significantly greater than the team incentive (0.35 vs. 0.17, Difference: 0.18, 95 % CI: 0.08–0.28, $P < 0.001$) but not the individual incentive (0.35 vs. 0.25, Difference: 0.10, 95 % CI: –0.001–0.19, $P=0.05$). Only the combined incentive had greater daily steps than control (Difference: 1446, 95 % CI: 448–2444, $P=0.005$). There were no significant differences between arms during the follow-up period.

CONCLUSIONS: Compared to control, a combination of individual and team incentives nearly doubled the proportion of days that individuals achieved physical activity goals. Incentives based on the performance of the individual alone or the entire team were not effective.

INITIATION OF CIGARETTE SMOKING AFTER ELECTRONIC CIGARETTE USE: A NATIONAL STUDY OF YOUNG ADULTS Brian A. Primack¹; Samir Soneji²; Michael Stoolmiller³; Michael J. Fine²; Jim Sargent³. ¹University of Pittsburgh, Pittsburgh, PA; ²VA Pittsburgh Healthcare System, Pittsburgh, PA; ³Dartmouth University School of Medicine, Hanover, NH; ⁴Oregon Social Learning Center, Eugene, OR. (Tracking ID #2198326)

BACKGROUND: An electronic cigarette (e-cigarette) contains a heating element that atomizes nicotine-containing liquid into an inhalable vapor. Compared with regular cigarettes, e-cigarettes seem to be lower in toxicants and associated adverse events, making them potentially valuable tools for smoking cessation. However, e-cigarette use is substantially increasing among young adults who are not users of traditional cigarettes. This large group of individuals may be at risk for sensitization to nicotine and transition to later cigarette smoking, which would have profound negative public health implications. While cross-sectional studies suggest that use of e-cigarettes is associated with intention to use regular cigarettes in the future and being open to future cigarette smoking, these important associations have not been studied longitudinally. Therefore, we conducted a longitudinal study among non-cigarette-smoking young adults to determine associations between baseline e-cigarette use and initiation of regular cigarette smoking 1 year later.

METHODS: We studied 607 non-cigarette-smoking individuals ages 16–26 years who had complete longitudinal data from two study waves collected in 2012–2014. These participants had been recruited as part of a larger nationally-representative US study that recruited via a random-digit dial telephone survey using landline and cell phone frames. At baseline for the current study, 874 non-smoking individuals had complete data, and our response rate was 69 % ($N=607$) for 1-year follow-up data. Our primary dependent variable was initiation of smoking between baseline and follow-up, and our primary independent variable was whether a participant had used e-cigarettes at baseline. We used logistic regression with sample weights to assess bivariable and multivariable associations between baseline e-cigarette use and initiation of regular cigarette smoking while controlling for multiple relevant sociodemographic, personal, and environmental variables.

RESULTS: Our sample of 607 individuals was 57 % female, 77 % Caucasian and non-Hispanic, 6 % African-American and non-Hispanic, 8 % Hispanic, and 10 % of mixed or other race. Only 9 (1.5 %) baseline participants was an e-cigarette user. Overall, 77 (12.7 %) baseline participants initiated cigarette smoking at follow-up, including 4 (44.4 %) among the baseline e-cigarette users and 73 (12.2 %) among e-cigarette non-users. In a multivariable model that included all measured relevant covariates—age, sex, race/ethnicity, maternal education, household income, sensation seeking, parental smoking, and peer smoking—baseline e-cigarette use was significantly associated with cigarette smoking initiation (AOR=4.1, $P=.028$). The other significant predictors were African-American race (AOR=2.6, $P=.041$), sensation seeking (AOR=1.86, $P=.026$) and peer smoking (AOR=1.78, $P=.001$).

CONCLUSIONS: Baseline e-cigarette smokers had substantially greater odds (about 4 times as high) of subsequently initiating cigarette smoking. This odds ratio accounted not only for socio-demographic variables but also for important covariates such as sensation seeking tendencies and peer and parental smoking. These findings highlight the concern that the thousands of adolescents and young adults who were previously tobacco-free but are now initiating e-cigarette smoking may be at substantial risk for transition to regular cigarettes. While our study was limited by relatively low power due to the small number of e-cigarette only users at baseline, it is noteworthy that results were still significant and robust in an appropriate multivariable model. In conclusion, it is an important irony that a product which is marketed as a harm reduction tool for established cigarette smokers may in fact also become an important contributor to the development of a new population of cigarette smokers.

INSULIN PRESCRIBING BY PROVIDER TYPE IN AN URBAN ACADEMIC MEDICAL CENTER Alex R. Montero²; Michelle Z. Flynn¹; Tyler Kingdon³; David An³; Jennifer Zallen³; Kerry S. Gray²; Malek Cheikh⁵; Michelle F. Magee⁴. ¹Georgetown University, Washington, DC; ²Georgetown University Hospital, Washington, DC; ³Georgetown University School of Medicine, Washington, DC; ⁴MedStar Diabetes Institute, Washington, DC; ⁵MedStar Union Memorial Hospital, Baltimore, MD. (Tracking ID #2199591)

BACKGROUND: Poor glycemic control has been linked with adverse patient outcomes in hospitalized patients. Randomized inpatient data support the use of scheduled (basal-bolus) insulin over sliding scale insulin (SSI) only regimens and national guidelines (SHM, ADA and AACE) recommend that this approach be used, along with avoidance of use of oral agents. The association between the admitting service type and adherence to these guidelines has not been characterized. Our aim was to examine to what degree trainees' inpatient insulin prescribing practices adhere to these guidelines by specialty type.

METHODS: This was a prospective cohort study. During a 6 week period (February to March 2014), the electronic charts of all consecutive adult patients (age > 18) admitted to MedStar Georgetown University Hospital non-critical care units with a documented diagnosis of diabetes mellitus (provider report or taking DM medications prior to admission) were examined. The main independent variable was admitting provider type (Medicine or Surgery service). Covariates consisted of demographics, insurance status, and Charlson Comorbidity Index (CCI). The primary outcome variable was the initial glycemic control regimen for which univariate analyses were carried out utilizing the Chi Square test; multivariable analyses utilized logistic regression. Secondary outcomes included glycemic control, with hyperglycemia defined as the proportion of patient-days with at least one FSG > 180 mg/dL; and hypoglycemia as the proportion of patient days with at least one FSG < 70.

RESULTS: Initial glycemic control regimens did not differ by admitting provider type ($p=.09$). The SSI only regimen was the most prevalent type of glycemic control regimen prescribed (48 %) compared to scheduled insulin (38 %). Few patients (0–4.3 %) were prescribed oral agents alone. Among scheduled insulin prescriptions, the majority were for long-acting basal insulin (78.72 %) and SSI (98.94 %). Both hyperglycemia ($p=.001$) and hypoglycemia ($p=.04$) were more common in patients prescribed scheduled insulin compared to SSI only. Multivariable models controlling for demographics and comorbidity did not significantly change these results.

CONCLUSIONS: Initial prescriptions of insulin was similar among house staff in Surgery and Medicine. Consistent with recommendations from national organizations, few patients were prescribed oral agents alone. Trainees on both services, however, use SSI alone commonly despite guidelines discouraging this practice. Counterintuitively, and in contrast to other reports in the literature, glycemic outcomes with scheduled insulin were worse when compared to SSI only. The major limitation is the possibility of residual confounding by relevant unmeasured factors such as severity of diabetes. Lack of familiarity with appropriate dosing of scheduled insulin containing regimens may explain this finding and suggests that housestaff education is needed. Alternatively, patients prescribed SSI only may have easier to control DM independent of the inpatient regimen prescribed to them.

Patient Characteristics

Age	62.6

INSURANCE TURNOVER, CARE FRAGMENTATION AND EMERGENCY DEPARTMENT UTILIZATION IN MASSACHUSETTS, 2011–2012 Michael Bamett^{1, 3}; Zirui Song^{2, 3}; Sherri Rose³; Asaf Bitton^{1, 3}; Michael E. Chernew³; Bruce E. Landon^{3, 4}. ¹Brigham and Women's Hospital, Brookline, MA; ²Massachusetts General Hospital, Boston, MA; ³Harvard Medical School, Boston, MA; ⁴Beth Israel Deaconess Hospital, Boston, MA. (Tracking ID #2193561)

BACKGROUND: Insurance exchanges established under the Affordable Care Act seek to promote competition among health insurance plans in order to slow the growth of premiums. In order to achieve this goal, exchanges facilitate switching among competing plans. However, plan switching may result in beneficiaries needing to switch their primary care provider due to different provider networks, causing disruptions of care. We hypothesized that insurance switching would be associated with increased rates of primary care physician changes and ED utilization.

METHODS: We used the Massachusetts all payer claims database to study changes in health care utilization associated with insurance turnover, defined as switching insurance carriers (but not switching plans within an individual carrier). We included all Massachusetts residents aged 21–64 who had at least 11 months of health insurance coverage in 2011 and 2012. Our primary exposure was insurance carrier switching, which was assigned to the month an enrollee (“switcher”) began enrollment with a new health

insurance carrier. Our primary outcomes were monthly rates of ED visits and new PCP encounters. We first examined univariate characteristics of plan switchers versus those of enrollees without an insurance change (“non-switchers”). To examine changes in monthly ED visits and new PCP visits, we used propensity score methods to match all switchers with up to 3 non-switchers who were continuously enrolled with a single insurance carrier. Matched non-switchers were assigned the same insurance switch date as the matched switcher. We compared the proportion of patients with new PCP visits 6 months before and after plan switching in the matched cohort. We then used linear regression adjusting for age, sex, hierarchical condition category score, zipcode level socioeconomic indicators and health insurance type with a difference-in-differences design to compare changes in monthly ED utilization 6 months before and after a switch.

RESULTS: Our study cohort had 1,557,954 MA residents, which included 254,874 (16.4 %) switchers during 2011–2012, of whom 139,314 (99 % of those with outcomes available 6 months before and after switching) were matched to 383,973 non-switchers. Overall, patients who switched insurance were more likely than non-switchers to be younger (mean age 40.6 vs. 43.2), have fewer comorbidities (mean HCC score 0.50 vs. 0.84), and initially have non-group commercial (11.5 vs. 5.3 %) or Medicaid managed care insurance (7.7 vs. 2.8 %, all comparisons $p<0.001$). In our propensity score matched cohort, the rate of new PCP appointments in the first 6 months after an insurance change almost doubled (6.3 % vs. 3.4 %, $p<0.001$). In unadjusted matched analysis, the period after insurance switching was associated with a sustained increase in ED visit rate (Figure). After adjustment, the month of a switch was associated with a 26 % increase (3.41 to 4.29 visits/100 persons) in the rate of ED visits for switchers vs. non-switchers. Moreover, this significant increase in ED visits sustained for at least 6 months after switching, declining from an additional 0.51 to 0.27 ED visits/100 persons (all $p<0.004$). The period from the month of a switch through 6 months afterward was associated overall with an additional 3.23 ED visits per 100 persons.

CONCLUSIONS: In a large cohort of continuously insured MA residents, we found that insurance switching is common and associated with PCP switching and increased ED utilization. Despite the lower overall health risk among switchers, we found a period of significantly increased risk for ED utilization in the 6 months after insurance switching which decreased over time. This study is limited by its observational design, however we use propensity matching and a difference-in-differences design using all available information to isolate the effect of switching. These findings suggest that insurance turnover is not frictionless and can be associated with adverse consequences.

Figure: Unadjusted monthly ED visit rates for the matched population, comparing switchers (dashed line) to non-switchers (solid line), relative to month of plan switch.

INTEGRATED CARE INCREASES EVALUATION BUT NOT TREATMENT FOR CHRONIC HEPATITIS C VIRUS INFECTION IN PRIMARY CARE Aaron D. Fox^{1, 2}; Laura C. Hawks²; Brianna L. Norton^{1, 2}; Alain H. Litvin²; Chinazo Cunningham^{1, 2}. ¹Montefiore Medical Center, Bronx, NY; ²Albert Einstein College of Medicine, Bronx, NY. (Tracking ID #2199406)

BACKGROUND: Complications from chronic Hepatitis C Virus (HCV) infection now account for more deaths in the United States than Human

Immunodeficiency Virus. New medications that directly target HCV have greater efficacy and fewer side effects than older interferon-based regimens, making HCV cure probable and HCV treatment a high priority. However, barriers to care, including fragmentation in the health care system and provider stigma toward drug users, lead to under-utilization of HCV treatment. Treating drug users in primary care settings instead of relying on outside referral to specialty centers may lead to greater rates of evaluation, treatment uptake, and cure for chronic HCV infection. We developed a model for integrated HCV care in

primary care and investigated rates of HCV evaluation and treatment before and after implementation.

METHODS: Starting in 2011 ("implementation"), primary care physicians (PCPs) at a federally qualified health center (FQHC) in New York City referred patients for integrated HCV care, which was provided onsite at the FQHC by an infectious diseases specialist. PCPs contacted an HCV patient navigator via the electronic medical record and she assisted with scheduling appointments, arranging imaging or liver biopsies, and acquiring prior authorization for medications. Before implementation, all referrals were made to an offsite hepatology clinic located at an affiliated academic hospital. For this analysis, we extracted electronic medical records (Jul 2009 to Oct 2014) for patients with HCV who received primary care at a post-incarceration transitions clinic located within the FQHC. Sociodemographic and clinical data was collected. Patients with chronic HCV infection (positive antibodies and detectable HCV RNA) were included. We compared referrals, referrals completed (≥ 1 HCV specialist visit), treatment uptake (documented prescription for HCV treatment), and HCV cure (treatment completion with post-treatment undetectable HCV RNA) before and after implementation. For subjects completing specialist referral, we also derived a reason for not initiating treatment based on documented clinical information.

RESULTS: Of 451 patients receiving primary care at the FQHC's transitions clinic, 108 were HCV positive. Of these, the median age was 50, and most were male (93 %), Hispanic non-Black (62 %), and had Medicaid insurance (97 %). Common co-morbidities included HIV infection (42 %), depression (26 %), and either current (70 %) or past (13 %) opioid use disorder. Of 89 with chronic HCV infection, 73 initiated care after implementation and 33 were referred for specialist evaluation. Sixteen initiated care before implementation and 12 were referred for specialist evaluation. After implementation, referrals completed were greater (24/33 vs 4/12, $p=0.03$), but treatment uptake (6/33 vs. 1/12, $p=NS$) and cure (3/33 vs. 1/12, $p=NS$) were no different than before implementation. Not initiating treatment was most commonly due to loss to follow-up, but 4 patients were awaiting insurance approval, and 5 patients were recommended to wait for better treatment options.

CONCLUSIONS: Rates of chronic HCV infection were high in this sample of formerly incarcerated individuals, and after implementation of integrated HCV care at the FQHC, more of those referred to an onsite HCV specialist completed the referral than before implementation. Rates of treatment initiation and cure did not differ before and after implementation, but several patients were awaiting insurance approval or availability of new medications, which prevented uptake of treatment. Integrating HCV care into FQHCs can increase access to an HCV specialists, but additional barriers to HCV treatment uptake remain and deserve further inquiry. New HCV medications offer great promise, but in order to reach those most in need of treatment, such as formerly incarcerated drug users, ongoing research into innovative HCV care delivery models that support retention in treatment will be necessary.

Sociodemographic characteristics for 89 FQHC patients with chronic HCV infection

Sociodemographic characteristics	Pre-implementation (N=16) N %	Post-implementation (N=73) N %	P-value
Age median (IQ range)	47 (42–51)	50 (46–54)	0.03

INTERDISCIPLINARY ADMISSIONS AND ROUNDING TO IMPROVE PATIENT OUTCOMES Surekha Bhamidipati¹; Seema Sonnad¹; Daniel J. Elliott²; LeRoi S. Hicks³; Janine Jordan²; Patty McGraw²; Bailey Ingraham-Lopresto²; Elizabeth Ivey³; Edmondo Robinson². ¹CCHS, Newark, DE; ²Christiana Care Health Services, Newark, DE; ³Christiana Care Health System, Newark, DE. (Tracking ID #2199217)

BACKGROUND: Interdisciplinary care teams are increasingly viewed as contributing to quality of care by coordinating care plans, potentially reducing adverse events and length of stay. Our health system has implemented an Interdisciplinary Admissions (IDA) team comprising a hospitalist, nurse, pharmacist, case manager and social worker. A similar team was created for daily Interdisciplinary Rounding (IDR). Physicians were present on this team only in cases where the hospitalist patients were geographically cohorted. The impact of IDR on outcomes is poorly understood and even less is known about the importance of physician participation in IDR. Thus, we examined whether daily IDR differentially impacted length of stay (LOS) and readmission rates dependent on physician participation. We also examined the additive effect of the IDA intervention on LOS and readmission rates.

METHODS: We prospectively enrolled hospitalist patients admitted from the emergency department between 7 am and 9 pm Monday through Thursday for 9 months. We tracked patients in four nursing units and documented whether the patient experienced interdisciplinary rounds with or without the participation of a hospitalist physician and categorized patients into 2 subgroups accordingly. These two subgroups were then stratified according to admission by an IDA team. All study patients were admitted during the times when hospitalist and interdisciplinary team staffing was similar to avoid impact of staffing on outcomes. Additionally, all study units were general medicine units admitting patients with similar acuity. Three of the study units implemented geographic cohorting, as a result the majority of their patients were staffed by a hospitalist and patients received IDR with the hospitalist. The fourth unit did not have a dedicated hospitalist to round with the IDR team. Admitted patients were posted to any of the study units based on bed availability. We obtained LOS and 7-day readmission data for all study patients. We then used non-parametric tests to compare intervention group LOS and readmission rates.

RESULTS: Of 1206 enrolled patients, 233 were in the IDR group without hospitalist and 973 were in the IDR group with a hospitalist. Patient characteristics and demographics were similar between groups. The median LOS for the two groups was 2.9 days. The median LOS in the IDR and IDR with hospitalist groups is 3.17 days 2.88 days respectively. The number of patients with LOS below this median LOS in the IDR and IDR with hospitalist groups was 96 (41.2 %) and 515 (52.9 %) patients respectively ($p=0.002$). After stratification of patients by IDA status, the effect of IDR with hospitalists on LOS remained the same. IDR patients were more likely to be readmitted than IDR with hospitalist patients (7.7 and 4.7 % respectively, $p=0.06$). For patients who did not receive IDA, IDR patients had a higher percentage of readmissions compared to those experiencing IDR with a hospitalist (9.3 % versus 4.8 %, $p=0.02$). However, in the IDA group, the percentage of readmissions was lower in the IDR group than the IDR with hospitalist group but did not reach statistical significance. (2.0 % versus 4.4 %, $p=0.7$)

CONCLUSIONS: IDR with attending physician participation appears to reduce hospital LOS and readmission rates. The IDA intervention may reduce readmission rates but this effect is likely attenuated by the IDR with hospitalist intervention. For institutions looking to develop IDR, it may be valuable to include physician participation to achieve reductions in LOS and readmissions.

INTERNAL MEDICINE RESIDENTS' PERCEIVED RESPONSIBILITY FOR TRANSITIONS OF CARE: A NEEDS ASSESSMENT Eric A. Young^{1, 6}; Chad Stickrath^{1, 6}; Aaron Calderon⁷; Elizabeth Chapman⁵; Jed Gonzalo²; Ethan Kuperman³; Max Lopez⁸; Christopher J. Smith⁴; Joseph R. Sweigart⁹; Cecilia Theobald¹⁰; Robert E. Burke^{1, 6}. ¹Denver VA Medical Center, Denver, CO; ²Penn State College of Medicine, Hershey, PA; ³University of Iowa Carver College of Medicine, Iowa City, IA; ⁴University of Nebraska Medical Center, Omaha, NE; ⁵University of Wisconsin School of Medicine and Public Health, Madison, WI; ⁶University of Colorado School of Medicine, Aurora, CO; ⁷St Joseph Medical Center, Denver, CO; ⁸University of Vermont, Burlington, VT; ⁹University of Kentucky, Lexington, KY; ¹⁰Vanderbilt University School of Medicine, Nashville, TN. (Tracking ID #2196402)

BACKGROUND: Adverse events after discharge from the hospital are common and costly. Preventing these requires that inpatient providers adopt safe discharge practices. Willingness to adopt these practices is dependent upon providers' perceived responsibility for patients in the transition period, yet these attitudes have not yet been studied in depth. Prior work suggests that one in four hospitalists feels that responsibility for patients ends at the time of discharge. Little is known about the degree to which Internal Medicine residents feel responsible for ensuring safe transitions of care for their patients.

METHODS: We performed a cross-sectional survey of 408 Internal Medicine residents at four academic institutions throughout the country. The 24-question survey was developed through iterative revision from faculty with extensive experience in the field of transitions of care. The survey was further refined through cognitive interviewing. Residents were invited to complete the survey electronically or through hard copy via local site-coordinators between September and November 2014. Data was analyzed using descriptive statistics for frequencies and Chi-square and Fisher's exact tests for comparisons between post-graduate year (PGY) groups.

RESULTS: Two-hundred fifty of 408 residents responded (61 %). Of respondents, 40 % were PGY-1, 30 % PGY-2, and 30 % PGY-3. In response to the question, "How many days are inpatient providers responsible for their patients after they are discharged?" 26 % of residents reported that responsibility ends at the time of discharge while 23 % reported responsibility extends to 15–30 days beyond discharge. The perceived duration of responsibility did not differ between PGY groups ($p=0.36$). One-hundred percent of respondents believed it was their responsibility to complete an accurate discharge summary within 48 h of discharge. Fifty-five percent of respondents believed they were responsible for contacting patients' primary care providers by email or phone at the time of discharge. Eighty-nine percent of residents believed they were responsible for ensuring their patients had a follow-up appointment scheduled prior to discharge. In contrast, only 22 % believed they were responsible for ensuring that patients actually attended their follow-up appointments. Ninety-nine percent of residents agreed that it was their responsibility to ensure that patients left the hospital with an accurate medication list; 86 % felt it was their responsibility to ensure that patients received in-person medication counselling prior to discharge.

CONCLUSIONS: Internal Medicine residents have variable perceptions of their responsibility for patients being discharged from the hospital. Further work is needed to determine what clinical and educational exposures modulate residents' sense of responsibility for ensuring safe transitions of care.

INTERPROFESSIONAL COLLABORATIVE CARE CHARACTERISTICS AND THE OCCURRENCE OF BEDSIDE INTERPROFESSIONAL ROUNDS: A CROSS-SECTIONAL ANALYSIS OF 18 HOSPITAL-BASED UNITS Jed Gonzalo¹; Brian McGillen¹; Judy N. Himes³; Vicki Shifflet³; Erik B. Lehman². ¹Penn State College of Medicine, Hershey, PA; ²Pennsylvania State University, Hershey, PA; ³Penn State Hershey Medical Center, Hershey, PA. (Tracking ID #2194897)

BACKGROUND: Interprofessional collaborative care (IPCC), or the process through which different professional groups work together to deliver care, is a national health policy focus specifically in the proposed changes to repayment models in the Affordable Care Act. Given hospitalized patients' care involves mutual relationships, collaboration, and decision-making between all healthcare providers, namely physicians, nurses, and patients, the need for IPCC delivery methods to improve quality in hospital settings is significant. Bedside interprofessional rounds (BIR) is a primary method of promoting collaboration in hospital-based settings, but the occurrence of BIR in medicine, pediatrics, and intensive care units demonstrate a wide variation in frequency from 1 to 80 %. No studies have investigated the frequency of BIR across different hospital-based units, or identified unit-based characteristics that may be associated with increased BIR. Following our institution's implementation of a quality metric related to BIR, we sought to: (1) examine the frequency of BIR in 18 different clinical units, and, (2) determine whether the frequency of BIR is attributable to spatial, staffing, patient, or nursing perception characteristics.

METHODS: In 2012, our 501-bed, university-based acute care hospital began an initiative to increase BIR, defined as "encounters that include at least one attending-level physician and nurse discussing the case at the patient's bedside." All front-line teams were expected to perform BIR on ≥ 80 % of patients per day in each clinical unit. Following this new initiative, we performed a prospective cross-sectional assessment (Nov. 2012-Oct. 2013) regarding BIR in 18 units providing care for both pediatric and adult patients within our hospital. The primary outcome was the frequency of BIR occurring in each unit, which was obtained from each unit's nurse manager performing "audits" on ≥ 5 randomly selected days each month during the study period. We developed 4 categories of variables hypothesized to affect BIR: (1) spatial factors, including unit type, number of beds/unit, square feet in unit/bed, (2) staffing factors including nurse-to-patient ratios, (3) patient factors, including hospital length of stay and severity of illness, and, (4) nursing perceptions of unit collegiality, staffing adequacy, support, and use of a BIR script. Data were obtained from floor plans, our hospital's clinical data warehouse, the Nursing Quality Indicators Practice Environment of the Nursing Work Index survey, and paper-based surveys administered to nurse managers. Based upon variation in BIR frequency between units, we stratified the variable into two groups: high (≥ 80 %) and low (< 80 %). Logistic regression techniques were used to identify unadjusted predictors of the main outcome.

RESULTS: Of the 18 units, six were classified as intensive care units (ICUs), four were classified as intermediate care (IMC), and eight were classified as acute care units. The average number of beds in each unit was 27 (range 14–44), with a mean 549 square feet per bed (range 203–987), with a mean nurse-to-patient ratio of 1–3.2 (range 1.5–4.5). During the study period, 29,173 patients (mean 23.5 patients per unit/day) were assessed during 1241 audited unit-days, with 21,493 patients receiving BIR (74 %). The range in the frequency of BIR was 35–97 %. Factors associated with a high occurrence of BIR were ICU (OR 13.65, [CI 4.30–43.34]), ICU vs. acute care), IMC (OR 2.83, [CI 1.19–6.73], IMC vs. acute care), nurse-to-patient ratio $\leq 1:3$ (OR 4.71, [CI 1.73–12.85]), use of rounding script (OR 3.18, CI [1.11–9.13], score of ≥ 4 vs. < 4), and provider and leadership support (OR 3.24, [CI 1.17–8.97], score of ≥ 17 vs. < 17). Number of beds, square feet in unit and per bed, patient length of stay, and severity of illness were not significantly associated with increased occurrence of BIR.

CONCLUSIONS: In our hospital-based units, the frequency of BIR exceeded 70 %, with higher frequencies occurring in ICUs than IMC or acute care units. Additional factors associated with increased occurrence of BIR were lower nurse-to-patient ratios, and nursing leadership's perceived support by providers and use of a BIR script; spatial- and patient-level factors were not associated with increase BIR. These results advance our understanding about factors impacting the occurrence of BIR in hospital units and highlight potential barriers hindering ideal patient-centered care for all admitted patients. The awareness of benefits for IPCC is increasing, and potentially will become more integrated into quality performance measures. As a result, IPCC may become more widely used in models of reimbursement for hospitals. Therefore, formal investigations into the processes of IPCC in hospitals are required to inform improvement and offer a theoretical model for informing the redesign of clinical units to be more integrated practice units that achieve higher value.

INTERPROFESSIONAL COMMUNICATION PATTERNS DURING PATIENT DISCHARGES: A SOCIAL NETWORK ANALYSIS Vincent A. Pinelli¹; Klara K. Papp²; Jed Gonzalo¹. ¹Penn State College of Medicine, Hershey, PA; ²Penn State University College of Medicine, Hershey, PA. (Tracking ID #2195653)

BACKGROUND: Optimal care delivery requires timely, efficient, and accurate communication among numerous providers and their patients, especially during the hospital discharge process. Although the ideal discharge process involves collaboration amongst care providers, existing research provides a relatively poor understanding of how professionals communicate in medicine units during patient discharges. To our knowledge, no studies have examined the discharge process using social network analysis. We sought to assess: (1) the frequency and type of communication patterns, and, (2) the network of communication patterns between providers and patients during the discharge process in a hospital-based medicine unit.

METHODS: To investigate the research objectives, we applied methods of social network analysis. Network analysis is presented as a useful way of extending understanding of conventional forms of analysis pertaining to hospital discharges. Any one individual has a limited view of the complex network in which they are involved, and by illustrating the interactions in the network that conversations might occur allows for the identification of potential improvement areas and ways to advance discharge planning research and theory. During seven days in March 2014, following a screening process of patients who had an anticipated discharge on that day and were fully oriented, starting with the soon-to-be discharged patient, one investigator performed 1:1 semi-structured interviews with the patients and all providers involved with the discharge process. To identify all potential providers in the network, a chain-sampling technique was used whereby participants known to be involved in the discharge process were interviewed first and asked to identify other providers with whom they communicated. The survey was developed for the purposes of this study, and asked respondents to report all synchronous and asynchronous communication channels within 24-h of discharge, with the following questions: (1) how often they communicated about the discharge with individuals in the network (e.g. face-to-face), (2) how often they relied on asynchronous communication (e.g. EMR) from other providers to be informed about discharge plans, and, (3) importance of that role in enabling the patient's discharge (Likert-scale 1–7, 1=not at all important, 7=extremely important). Frequencies and comparison of communication and perceived importance of each role in the discharge process were analyzed using descriptive statistics and the chi-square test. NodeXL Graphics software was used to construct sociograms of the communication channels related to patients' discharges.

RESULTS: Of the 42 patients screened, seven patients who were fully oriented and able to complete an interview and all providers who participated in their care during the discharge were selected for inclusion in the analysis. In all, 72 healthcare professionals contributing to the discharge process were interviewed (100 % response), including physicians, nurses, therapists, pharmacists, care coordinators, social workers, and

nutritionists. Patients' mean age was 63, length-of-stay was 7.8 days, and most (86 %) were discharged to home. On average, 11 roles were involved with each discharge. The majority of communication was synchronous (562 events vs. 469 asynchronous events, $p=0.004$). Most communication events occurred between the primary nurse and patient, and the care coordinator and primary nurse (mean 3.9 and 2.3 events/discharge, respectively). Intern physicians were identified as most important in the discharge process (mean 6.0, potential maximum=7), with the primary nurse (5.3) and care coordinator (5.3) rated next in importance. The intern physician was the most likely role to contribute to both the discharge instructions and discharge summary (3.0 and 2.0 contributions/discharge, respectively). The primary network diagram has a density of 0.625 (suggesting a dense network), with the intern physician and primary nurse being central to the network, with close ties to the patient. Attending physicians, charge nurses, and social workers had fewer interactions, on average, with patients around the time of discharge.

CONCLUSIONS: The process of discharging patients from the medicine service is a complex, multi-faceted process involving numerous care providers and the patient. Numerous synchronous and asynchronous methods are used amongst all providers to coordinate the patient's discharge. Intern physicians, in particular, have a pivotal role and are centrally-positioned in the network of communication during a patient's discharge, raising important questions regarding the implications of such a design, specifically related to house staff education and the ideal model for patients' discharges. Potential improvements in coordinating patients' discharges are possible by reorganizing systems to optimize efficient communication.

INTIMATE PARTNER VIOLENCE DISCUSSIONS IN THE HEALTHCARE SETTING: CONTEXT, CONTENT, AND PATIENT PERCEPTIONS Jennifer McCall-Hosenfeld; Alexa Swales; Erik Lehman. Pennsylvania State University College of Medicine, Hershey, PA. (Tracking ID #2182685)

BACKGROUND: Intimate partner violence (IPV)—psychological, physical, or sexual abuse occurring in an intimate relationship—affects almost half of US women and results in myriad physical and mental health sequelae. Given this, healthcare providers are uniquely positioned to identify and address IPV exposure. In 2013, the United States Preventive Services Task Force (USPSTF) recommended screening all women of reproductive age for IPV in the healthcare setting. This followed similar recommendations from the Institute of Medicine, the Affordable Care Act, and numerous professional organizations, which have long provided guidance governing IPV screening and response in healthcare settings. However, since the 2013 USPSTF recommendation, research has not examined the frequency of IPV screening and guideline adherent responses. We developed a survey to examine the context and content of IPV screening in the clinical setting, as well as patient perceptions of screening discussions, subsequent to the USPSTF recommendation. In addition to a descriptive analysis of the context and content of IPV screening, we hypothesize that reproductive age (18–46) (in concordance with USPSTF guidelines) and past-year history of IPV will be associated with increased frequency of screening.

METHODS: We developed and pre-tested a survey examining IPV screening in the healthcare setting in the past year. Survey content incorporated evidence-based guidelines from the USPSTF, AMA, Futures Without Violence, and the American College of Obstetricians and Gynecologists. This survey examined: 1) IPV screening context (provider specialty, gender, and the presence of others during screening), 2) content (topics discussed, educational outcomes, and actions taken by the provider), and 3) women's perceptions of screening (satisfaction, comfort, and privacy) in addition to demographics, IPV exposure, and healthcare use. Participants were women recruited from ambulatory clinics and domestic violence shelters in Pennsylvania. Inclusion criteria included female gender, age 18–65, and lifetime history of IPV measured by the Humiliation-Afraid-Rape-Kick (HARK) screening tool. All analyses used SAS version 9.3.

RESULTS: Of 213 women attending a healthcare appointment in the past year, 39 % discussed IPV with their healthcare provider, and 8 % reported initiating the discussion without being asked. Fifty-five percent were of reproductive age (18–46), and 23 % of women had experienced IPV in the past year. Forty-nine percent of all women who experienced IPV in the past year received screening. In bivariate analyses, 40 % of reproductive-aged women (18–46) compared to 42 % of older women (47–65) had screening or counseling discussions with their providers ($p=0.7$). Women with past-year IPV history received screening more frequently (49 %) than women with lifetime IPV (40 %); however, this finding was not significant ($p=0.3$). **Screening Context:** Screening providers were 58 % female, 40 % Primary Care, 16 % OB/GYN, 11 % Physician Extender, 3 % Emergency, and 2 % Mental Health. During IPV-related discussions, 10 % of women reported someone else was in the room. **Discussion Content:** Guideline-concordant topics discussed included: patient's concern about IPV (34 %), emotional (21 %) or physical (12 %) health, safety assessment (19 %), nature of IPV

(17 %), partner's substance abuse (10 %), effects on friends/family (9 %) and children (5 %). Guideline-concordant outcomes of these discussions included learning about available resources (14 %), validation of patient's experience (18 %), and development of a safety plan (13 %). Actions taken by providers included providing prescription medication (15 %), scheduling a follow-up (14 %) or mental health appointment (5 %), providing information regarding IPV (3 %) or social services (2 %), and contacting law enforcement (1 %). **Patient Perceptions:** Of 88 women who discussed IPV with their providers in the past year, none reported having confidentiality concerns. Fifty-eight percent of women reported being "extremely/very satisfied", and 53 % reported being "extremely/very comfortable" discussing IPV with their healthcare providers. Two percent had concerns that they felt were not addressed. Notably, of 139 women who attended a healthcare appointment in the past year and did *not* have a discussion about IPV, 7 % indicated that they would have liked to have this discussion.

CONCLUSIONS: Despite current recommendations, only 39 % of this high-risk population received IPV screening. Contrary to our hypothesis, women of childbearing age were no more likely to receive screening than older women. While many screening conversations regarding IPV resulted in guideline-concordant discussion and response, relatively few action-based outcomes, such as providing information regarding resources or scheduling a follow-up appointment occurred. Dedicated focus should remain on educating providers on the importance of IPV screening and guideline-concordant, action-based responses to IPV disclosure.

INVASIVE PROCEDURE TRENDS AMONG INTERNAL MEDICINE RESIDENTS AT A UNIVERSITY PROGRAM Teresa Brown¹; Ryan Wilson¹; Ramy Sedhom²; Amay Parikh¹; Ranita Sharma^{3, 1}. ¹Rutgers Robert Wood Johnson Medical School, Westfield, NJ; ²Rutgers- Robert Wood Johnson, Staten Island, NY; ³Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ. (Tracking ID #2194709)

BACKGROUND: The American Board of Internal Medicine (ABIM) expects trainees to develop competency related to the knowledge and understanding of a limited set of procedures but does not specify a minimum number of procedures needed to demonstrate competency or to satisfy training completion requirements. Graduating residents pursuing procedural based specialties (PBS) rank procedural access and skills as an important aspect of their career decision. There is little information in the current literature related to subspecialty interest among internal medicine residents and its influence on the number of procedures performed by residents.

METHODS: We conducted a retrospective analysis to determine the number of procedures performed by internal medicine residents who began training between 2006 and 2011. Preliminary year interns and residents who transferred into or out of the program during the study period were excluded. The primary end point was the difference in the total number of procedures performed over 3 years by residents pursuing PBS versus those pursuing NPBS. Invasive procedures were defined as arterial lines, femoral, jugular, and subclavian central line insertions, lumbar punctures, paracentesis, and thoracentesis.

RESULTS: One hundred nineteen residents who began training between 2006 and 2011 performed an average of 25.4 procedures (SD 20.2) during their 3 year training. Residents entering PBS ($n=29$) performed more procedures than residents entering NPBS ($n=90$) (30.7 vs 23.7, $p<0.05$). Residents entering Pulmonary/Critical Care Medicine performed the highest number of procedures amongst all residents with an average of 55.7 (statistically significant). Residents entering Cardiology and Gastroenterology performed an average of 23.1 and 23.3 procedures respectively. Residents entering Nephrology, a NPBS, performed an average of 31.9 procedures and those pursuing general medicine (hospital medicine versus outpatient medicine not specified) performed an average of 24.7 procedures. The number of procedures per resident declined by 3.0 procedures per year over the study period with no statistical difference between the PBS and NPBS groups. Procedures performed by men entering PBS declined less than women (0.7 vs 4.7 procedures/year, $p<0.01$).

CONCLUSIONS: Procedural skills are recognized as an essential part of internal medicine training. Our findings suggest that residents entering PBS performed more procedures than residents pursuing NPBS. Residents entering Pulmonary/Critical Care Medicine perform the most procedures compared to residents entering other fields. This data correlates with information obtained in post graduation surveys in which residents entering PBS viewed access and ability to perform procedures as an important part of their fellowship decision. We report an overall decline in the total number of procedures performed by residents throughout their 3 years of training from 2006 to 2011. Further research is needed to determine whether the ACGME duty hour restrictions, the increasing use of Interventional Radiology for procedures, access to simulation training and/or changes to the ABIM training requirements related to procedural competencies are responsible for these trends.

INVITING PATIENTS AND CAREGIVERS TO IMPROVE PRIMARY CARE: DEVELOPMENT OF PATIENT AND FAMILY ADVISORY COUNCILS IN THE COMPREHENSIVE PRIMARY CARE INITIATIVE Ashok Reddy^{1, 2}; Laura L. Sessums²; Edith Stowe²; Tim Day²; Janel Jin²; Bruce Finke²; Asaf Bitton². ¹University of Pennsylvania, Philadelphia, PA; ²Center for Medicare & Medicaid Innovation, Baltimore, MD. (Tracking ID #2197529)

BACKGROUND: Growing evidence suggests that engaging patients, families, and caregivers in an active partnership with the healthcare system can lead to better quality care. Despite delivery system reforms to create patient-centered primary care, evidence is limited on the structures and processes primary care practices use to engage patients in improving care delivery. The Comprehensive Primary Care initiative (CPC) is a large-scale, multi-payer test of a new primary care payment and practice transformation model developed by the Center for Medicare and Medicaid Innovation. One of the major pillars of this work is supporting patient and caregiver engagement. To our knowledge, this is the first federal primary care initiative with an explicit focus on patient engagement within the quality improvement work of primary care practices. The primary goal of our study is to describe the development of patient and family advisory councils (PFACs), one of the main structures used by primary care practices to engage patients in quality improvement. Our study describes the regional variation, membership size, composition, areas of focus, and dissemination efforts of the councils being used by CPC practices to improve patient engagement.

METHODS: CPC Practices are given three options to support patient and caregiver engagement: a) utilize quarterly in-office surveys, b) establish a PFAC, or c) to do a combination of both. Practices that choose to develop PFACs are asked to report on the following areas: content focus, composition, meeting frequency, and methods of communication about the PFAC to other patients in the practice. In our descriptive analysis, we linked practice-level characteristics gathered at the start of CPC initiative to these areas of focus.

RESULTS: In 2014, 205 of 483 CPC practices decided to develop PFACs: 35 % (22 practices) in Arkansas, 86 % (63) in Colorado, 31 % (21) in New Jersey, 50 % (36) in New York, 11 % (8) in Ohio/Kentucky, 35 % (23) in Oklahoma, and 48 % (32) in Oregon. Baseline characteristics of these practices include a median of 4 providers (IQR 2–6) and 477 (IQR 271–769) Medicare beneficiaries. Beyond regional location, there were no other statistically significant practice characteristic differences between the practices that established PFACs and those that conducted surveys. Major areas of PFAC focus include: Access (73 %), communication (62 %), care coordination (46 %), shared-decision making (42 %), care management for high-risk patients (26 %), and self-management support (25 %). The composition of PFACs included: a median of 2 (IQR 1–3) clinical staff, 7 (IQR 4–9) patients, 0 (IQR 0–1) family or caregivers, and 2 (1–3) administrative staff. Practices communicated information about the PFACs to their patients via posting material in the office (47 %), brochure in the office (35 %), website (18 %), brochure in the mail (15 %), or other (53 %) strategies (e.g., Facebook).

CONCLUSIONS: Engaging patients in primary care practice health care quality improvement efforts is a critical element of patient-centered care. Over forty percent of practices in a large-scale, multi-payer primary care transformation are actively engaged in implementing PFACs, and most are developing ways to improve patient access and communication with their patients. The CPC initiative offers an unprecedented opportunity to learn about the feasibility and scalability of PFACs, a powerful way to engage patients in primary care transformation.

IS AUTOMATED IDENTIFICATION OF HIGH-RISK PATIENTS FOR TARGETED INTERVENTIONS AS HELPFUL AS HOPED?—A PILOT STUDY

Brook Watts^{1, 2}; Renee H. Lawrence¹; Erin Lea¹; Mary M. Hasenstaub¹; Kimberley Schaub¹. ¹Cleveland VAMC, Cleveland, OH; ²Case Western Reserve University, Cleveland, OH. (Tracking ID #2199066)

BACKGROUND: There is substantial interest in proactive methods to identify patients at high risk for adverse outcomes (hospitalization, death), who may have modifiable factors that, if addressed, may improve outcomes or decrease costs. Application of existing risk models which incorporate a variety of clinical and socio-demographic parameters may be a useful tool for interdisciplinary teams who seek to target care for high risk populations in an efficient manner. However, little is known about the effectiveness of this type of automated approach in identifying patients for whom targeted intervention can make a positive difference. In an effort to address this knowledge gap, we sought to explore in depth the clinical characteristics of patients identified by one validated automated risk assessment model, the Care Assessment Needs (CAN) model.

METHODS: The CAN model, which has been shown to be an accurate predictor of morbidity and mortality in veteran populations, is being used as part of a Veterans Health

Administration (VHA) quality improvement pilot program, the Patient Intensive Management (PIM) program. As part of the PIM program, a population of 50 patients at our busy urban VHA teaching hospital whose CAN scores placed them in the top 10 % of overall 3-month risk for morbidity or mortality and who had had at least one acute care visit in the last 6 months was identified. In order to assess appropriateness for our team-based intervention to target modifiable factors, each of the 50 patients' charts was reviewed in a group setting by an interdisciplinary team, including at least one primary care physician, a nurse practitioner, a health psychologist, and two former military medics who function as health coaches. After initial reviews of patient charts, team members expressed concerns about the identified cohort having few factors that were potentially modifiable (e.g. patient with severe heart failure who had already received a ventricular assist device and was being followed by an advanced cardiac team), therefore we elected to apply a screening methodology that included components from other well-established high risk patient management programs (such as the Camden Coalition hot-spotting program). The relevant medical documentation for each patient in the cohort was then assessed for potential modifiable risk factors, including two or more chronic conditions, in addition to at least two of the following characteristics: five or more medications, difficulty accessing health care services, lack of social support, mental health disorder, or active drug use. In cases where there was felt to be unanswered questions after the chart review, primary care physicians were contacted for additional input. Based on this assessment, eligibility and appropriateness for the PIM intervention was determined by team discussion.

RESULTS: Fifty patients with CAN scores in the top 10 % for risk were reviewed for modifiable factors. At the time of the clinical review, two patients were determined to be long term nursing home residents, one patient was enrolled in hospice, and one patient had already died, leaving 46 patients who were potentially eligible for the PIM intervention. Using the screening protocol, 14 patients (30.4 %) of the 46 patients were classified by the interdisciplinary team as appropriate for the PIM intervention. Prior to contacting the patients for interest in enrollment, we discussed each of the 14 patients with his/her primary care provider. The providers of three patients declined to have the PIM program intervene because of extensive existing services already being provided. Each of the remaining 11 patients was contacted by phone or in person at other routine clinic visits and offered enrollment in the PIM program. Of the 11 patients, 4 patients (36.4 %) declined the intervention citing co-pay costs or lack of interest in the program. Thus, of the 50 patients originally identified by the risk assessment methodology, 7 patients with potentially modifiable factors were successfully enrolled in the PIM program.

CONCLUSIONS: Using an established risk-based model to identify a primary care population that might benefit from an intensive management program generated fewer patients than expected who were appropriate and able to be enrolled. Application of risk models to identify high-risk patients may be limited by their ability to successfully incorporate potentially modifiable factors, such as psycho-social issues, which currently require clinical chart review.

IS EXCESS MEDICATION ASSOCIATED WITH MORTALITY AMONG HIV+ AND UNINFECTED PATIENTS?

E. J. Edelman¹; Kirsha S. Gordon¹; Kathleen M. Akgün²; Cynthia Gibert³; Vincent Lo Re⁴; David Rimland⁵; Julie Womack²; Christina Wyatt⁶; Melissa Skanderson⁷; Janet P. Tate¹; Amy C. Justice². ¹Yale University School of Medicine, New Haven, CT; ²Yale University, VACT West Haven, New Haven, CT; ³DC VAMC and George Washington University, Washington, DC; ⁴University of Pennsylvania, Philadelphia, PA; ⁵VA Medical Center, Decatur, GA; ⁶Mount Sinai School of Medicine, New York, NY; ⁷VA Pittsburgh and University of Pittsburgh, Pittsburgh, PA. (Tracking ID #2199417)

BACKGROUND: Polypharmacy, typically defined as ≥ 5 medications, is common especially among HIV-infected (HIV+) patients. Polypharmacy has been associated with mortality, yet there is concern that these results are biased due to confounding by indication. Accounting for expected number of long-term non-antiretroviral (ART) medications, we sought to determine whether medication in excess of expectation is associated with mortality among a sample of HIV+ and uninfected patients.

METHODS: Using data from VACS, we conducted a retrospective study of ART treated HIV+ and age/race/ethnicity-matched uninfected participants engaged in care within the Veterans Affairs Healthcare System. Participants had no cancer diagnosis and received at least one long-term medication (≥ 90 day supply) in fiscal year 2009. We created a propensity model to predict expected long-term non-ART medication count (referred to as "expected medication count"). Our primary independent variable was receipt of two or more long-term non-ART medications in excess of the expected medication count. Adjusting for expected medication count and for overall disease severity using the VACS Index, we used Cox proportional hazards models to determine all-cause mortality risk over a one year follow-up.

RESULTS: Our final analytic sample included 14,592 HIV+ and 46,950 uninfected participants; of whom 3 and 2 % died, respectively. The propensity model predicting expected medication count demonstrated good fit. Disease severity, specific comorbid medical conditions, gender, age, and race/ethnicity were all significant predictors of expected medication count. Adjusting for expected medication count and the VACS Index, excess medication receipt was associated with an increased risk of mortality in both HIV-infected and uninfected participants. This did not significantly differ by HIV status.

CONCLUSIONS: Both HIV+ individuals on ART and uninfected individuals experience higher mortality when exposed to excess medication. Interventions focused on limiting medications to those most essential to quality of life and survival are needed among those aging with and without HIV.

Table. Excess Medications and All-Cause Mortality, Cox Proportional Hazards Model

Characteristic	Overall HR (95 % CI) N=61542	HIV-Infected HR (95 % CI) n=14592	Uninfected HR (95 % CI) n=46950
Expected Non-ART Medication Count	1.17 (1.15, 1.19)	1.18 (1.14, 1.22)	1.15 (1.13, 1.17)
≥2 Excess Medications	1.26 (1.09, 1.46)	1.48 (1.20, 1.83)	1.26 (1.08, 1.46)
VACS Index (5 point increments)	1.12 (1.11, 1.13)	1.07 (1.05, 1.09)	1.20 (1.17, 1.22)
HIV status	1.03 (0.89, 1.20)		
HIV*≥2 Excess Medications†	1.16 (0.90, 1.51)		

IS OVERWEIGHT OR OBESITY ASSOCIATED WITH ADVANCED LIVER DISEASE AMONG HISPANICS WITH CHRONIC HCV? Barbara J. Turner^{1, 2}; Barbara S. Taylor^{1, 2}; Joshua T. Hanson^{1, 2}; Yuanyuan Liang^{3, 2}; Jasdeep Sandhu¹. ¹University of Texas Health Science Center at San Antonio, San Antonio, TX; ²University of Texas at San Antonio, San Antonio, TX; ³UT Health Science Center at San Antonio, San Antonio, TX. (Tracking ID #2198346)

BACKGROUND: Hispanics are disproportionately affected by obesity and obesity-related diseases including nonalcoholic steatohepatitis (NASH). Among patients with chronic hepatitis C infection, it is unclear whether obesity contributes to accelerated liver

disease, possibly related to associated NASH. Among baby boomers diagnosed with chronic HCV infection in an inpatient screening program, Hispanics were over three times more likely to have advanced liver disease on ultrasound or CT imaging than non-Hispanic whites (NHW). We hypothesized that obesity may contribute to this disparity.

METHODS: Never screened baby boomers admitted to a safety net hospital in San Antonio from 12/1/2012 to 9/30/2014 were screened with anti-HCV antibody (anti-HCV) and reflex HCV RNA. Patients with newly diagnosed chronic HCV infection (HCV RNA positive) were followed through 12/10/2014 for evaluation of liver disease including results of liver ultrasounds and CT scans from system-based electronic medical records and outside imaging services. Reports were independently reviewed by 2 clinicians for evidence of likely cirrhosis or hepatocellular carcinoma (HCC). Because NASH risk is greater for overweight and obesity (heavy), BMI was categorized as lean (<25) and heavy (25+) and race-ethnicity was categorized as Hispanic and non-Hispanic (NHW/black/other). Unadjusted and adjusted odds of cirrhosis/HCC on imaging were examined for Hispanics (Y/N) and BMI (<25, 25+) using a 4-level variable for the interaction of these two factors. Other covariates included: age, gender, alcohol use (none, current non-problem drinker, past drinker, current problem drinker), and insurance status (yes/no).

RESULTS: Of 175 patients with chronic HCV infection, 125 (71 %) had subsequent liver imaging. Among imaged patients, mean BMI was similar for Hispanics and non-Hispanics who were categorized as lean or heavy (Table). Overall, 60 (48 %) patients had evidence of cirrhosis or HCC (C/HCC) on imaging but proportions with C/HCC varied widely by weight-ethnicity category. Before adjustment, the odds of C/HCC for heavy Hispanics were nearly five-fold greater than for lean non-Hispanics while the odds ratio (OR) of 2.6 for lean Hispanics versus lean non-Hispanics was not statistically significant. After adjustment, the OR of C/HCC increased to over six for heavy Hispanics versus lean non-Hispanics. In regard to other predictors, only age was associated with the odds of C/HCC increasing by 12 % per 1-year increase in age ($p=0.022$).

CONCLUSIONS: In this baby boomer cohort, we found concerning evidence that overweight and obesity in Hispanics was strongly associated with C/HCC but not in non-Hispanics. Because this effect does not appear to be explained by a difference in BMI between heavy HCV-infected Hispanics and non-Hispanics, it requires further investigation into mechanisms by which obesity and other comorbidities such as NASH, diabetes, or insulin resistance may predispose Hispanics to more rapid progression of liver disease. It also suggests that clinicians may need to address the detrimental effects of overweight/obesity in chronically HCV-infected Hispanics who have not yet developed advanced disease.

Table 1. Association of Weight and Hispanic Ethnicity with Cirrhosis or HCC on Imaging of Baby Boomers with Chronic HCV Infection

Group	N (%) N=125	BMI Mean (SD)	Cirrhosis or HCC, n (%)	Unadjusted OR (95 % CI)	Adjusted OR* (95 % CI)
Lean non-Hispanics	29 (23.2)	21.74 (2.31)	8 (27.6)	1	1
Heavy non-Hispanics	25 (20.0)	31.84 (6.39)	9 (36.0)	1.48 (0.47, 4.68)	1.66 (0.46, 6.02)
Lean Hispanics	22 (17.6)	21.76 (2.74)	11 (50.0)	2.62 (0.82, 8.43)	2.91 (0.76, 11.15)
Heavy Hispanics	49 (39.2)	30.72 (5.76)	32 (65.3)	4.94 (1.81, 13.49)	6.61 (2.01, 21.70)

* Adjusted for age, gender, alcohol use and insurance status

IS TAILORING TO HEALTH LITERACY OR NUMERACY EFFECTIVE? RESULTS OF A SYSTEMATIC REVIEW Marilyn M. Schapira⁴; Sheila Swartz¹; Pamela S. Ganschow²; Joan Neuner¹; Kathryn Fletcher^{2, 1}. ¹Medical College of Wisconsin, Milwaukee, WI; ²Milwaukee VAMC/Medical College of Wisconsin, Milwaukee, WI; ³Stroger Hospital/Rush University Medical Center, Chicago, IL; ⁴University of Pennsylvania, Philadelphia, PA. (Tracking ID #2192080)

BACKGROUND: The availability of scales to measure health literacy and numeracy present the option to tailor decision support interventions to the level of health print or numeric literacy in an individual. However, the use of a contingent versus universal approach to communication in populations that have low literate persons is debated. The objective of this study is to conduct a systematic review of the literature to address this question.

METHODS: A search strategy was developed requiring terms pertaining to 1) communication, patient education, decision making, or tailoring and 2) numeracy, mathematics, health literacy, statistics, graphical literacy, 3) screening or measurement or testing, and 4) randomized controlled trials, observational study, or experimental clinical trials. Articles were restricted to Human and English. Pub Med was searched up to July, 2014. All abstracts underwent review to ensure that they met the following initial criteria: primary research conducted, baseline assessment of education level or health literacy included, and

methods incorporated an intervention. Abstracts that met the initial criteria then underwent a full review using PICOS criteria (Population, Intervention, Comparator, Outcome, Study). PICOS criteria required a design including an intervention tailored to the individual patients' level of health literacy and a comparator group.

RESULTS: The search strategy yielded 1907 abstracts. Initial review of abstracts identified 387 that went on to full article review using the PICOS criteria. Of these 5 were identified that met the full criteria (Table). The five studies measured health literacy at baseline using the Test of Functional Health Literacy in Adults (TOFHLA), (1 study); the S-TOFHLA (3 studies); and the Rapid Evaluation of Adult Literacy in Medicine (REALM), (1 study). The 5 studies each used a randomized design. The clinical context of the interventions used included diabetes ($n=2$), hypertension ($n=1$), heart disease ($n=1$), and glaucoma ($n=1$). The methods used to tailor the intervention included the following: notification of patient health literacy level to the pharmacist or health educator delivering an intervention ($n=2$); notification of patient health literacy level to the treating physician ($n=1$); adjusting reading level of print materials ($n=1$); and adjusting level of language used to communicate information (1). Outcomes evaluated included A1C level, hypertension knowledge, communication strategies, medication adherence, satisfaction with provider, blood pressure control, satisfaction with visit, and self-efficacy of patients. Among the 5 studies, 3 reported improved outcomes in the intervention vs. control group and 2 reported no significant differences between groups. The studies reporting significant

improvements were in the clinical context of diabetes and hypertension and used tailoring approaches of 1) notifying the pharmacist, diabetic care coordinator, or physician of the patients health literacy level, and 2) adjusting the reading level of educational materials to literacy level. Studies finding no significant difference were in the clinical domains of glaucoma and heart disease and used tailoring approaches of 1) adjusting language in an educational video to literacy level, and 2) using a pharmacist based intervention that was “sensitive to patients literacy”.

CONCLUSIONS: Interventions designed for low literacy patients can be resource intensive. These findings suggest that a strategy of screening for health literacy and tailoring interventions to the patients individual literacy level may be an effective way to improve outcomes among general populations. Additional studies are needed to determine the clinical context and type of tailoring interventions that are best suited to this approach.

ISN'T THE E-CIG SAFE, BECAUSE MY DOCTOR RECOMMENDED IT?: TOBACCO QUITLINE EXPERIENCES WITH ELECTRONIC CIGARETTES

Sara Kalkhoran¹; Linda A. Bailey²; Nicolas Sheon¹; Pamela M. Ling¹. ¹University of California, San Francisco, San Francisco, CA; ²North American Quitline Consortium, Phoenix, AZ. (Tracking ID #2198488)

BACKGROUND: Electronic cigarette (e-cigarette) use is increasing in the United States. Common reasons for use are as a substitute where smoking is prohibited, to cut down or quit cigarettes, and health-related reasons. Long-term health effects of e-cigarettes are unknown, and studies on efficacy for smoking cessation have had mixed results. Given the paucity of data on clinical practice related to e-cigarettes, we aimed to identify what quitlines hear from callers about e-cigarettes and their practices regarding counseling, advising, and tracking use among callers.

METHODS: In August-September 2014, key informant phone interviews were conducted with the 13 quitline call centers that provided services to all 50 US states, District of Columbia, Puerto Rico, and Guam. These state quitlines receive about 1.3 million calls and 175,000 referrals for help in quitting tobacco use each year. The key informants were individuals responsible for supervising quitline counselors. They were asked to reflect on experiences with calls to the quitline about e-cigarettes and about practices related to e-cigarettes in the last two years. All questions were sent to the informants a week before the interview to allow them time to discuss with the quitline counselors. The transcripts from these interviews were analyzed to identify common themes.

RESULTS: Quitline supervisors reported that the issues that callers brought up most frequently to counselors included e-cigarette safety, efficacy for cessation, callers wondering if they would be considered as having quit smoking or as tobacco-free if they were still using e-cigarettes, and soliciting counselors' opinion on e-cigarettes. Most respondents reported that callers primarily asked about e-cigarette safety (e.g., one quitline counselor recalled being asked this kind of question from a caller: “E-cigs only have water, which is not harmful, right?”) and efficacy for quitting or reducing cigarette consumption; many counselors were asked whether they would recommend e-cigarettes. Other frequently asked questions included whether it was safe or recommended to use nicotine replacement therapy (NRT) with e-cigarettes, and whether the quitline provided e-cigarettes. The quitline supervisors reported that the reasons callers most frequently gave for using e-cigarettes were for use in places where

smoking is prohibited, for cutting down or quitting cigarettes, or for safety/risk reduction. Many quitline supervisors expressed concern about the amount of nicotine exposure that might result from use of e-cigarettes with NRT, and asked for guidance on how to advise e-cigarette users about NRT use or dosing. Most quitlines reported having either official or unofficial policies or protocols regarding e-cigarettes. Most quitlines asked about e-cigarette use at intake and told callers about the unknown health risks of e-cigarettes or lack of product regulation; all offered only FDA-approved cessation aids to callers. When asked what approaches quitlines would use with callers who ask for help quitting e-cigarettes, most quitlines offered counseling and/or NRT. Quitlines differed in whether they classified e-cigarette users who no longer smoked cigarettes as having quit or not quit, which has implications for re-engagement with quitline services and measuring overall quit rates among quitline callers. Quitline policies also varied with respect to use of NRT and e-cigarettes: some either did not provide NRT to those using e-cigarettes or referred the caller to a physician or pharmacist for assistance with dosing.

CONCLUSIONS: Tobacco quitline callers are increasingly asking about e-cigarettes, and quitlines are viewed as a reliable source of information about these products. Quitlines currently recommend only FDA-approved therapies for smoking cessation and generally caution callers about use of an unregulated product with unknown long-term health risks. Practices vary in screening for e-cigarette use, classification of users, and information provided to callers. Research, shared informational resources, and standardized practices are needed to help providers address e-cigarette use among patients, to encourage smoking cessation rather than dual product use, and to document and track evolving patterns of e-cigarette use.

IT TAKES TWO TO TANGO: A DYADIC APPROACH TO UNDERSTANDING THE INFLUENCE OF THE MEDICATION DIALOGUE IN PATIENT-PHYSICIAN RELATIONSHIPS ON MEDICATION ADHERENCE

Antoinette Schoenthaler¹; Tessa West²; Meher Singh¹; Gbenga Ogedegbe¹. ¹NYU School of Medicine, New York, NY; ²NYU Psychology, New York, NY. (Tracking ID #2197929)

BACKGROUND: Analyses of audiotaped clinical encounters have systematically documented deficits in physicians' and patients' information exchange and question-asking behaviors related to the medication dialogue. However, most studies used one-dimensional coding schemes that tally utterances spoken by either the patient or physician, not how one influences the other thereby producing a one-sided view of the conversation. The objective of this study was to describe typologies of dyadic communication exchanges between primary care physicians and their hypertensive patients about medication-taking, and how these exchanges relate to patient medication adherence.

METHODS: Qualitative analysis of 95 audiotaped patient-physician encounters, using grounded theory methodology. Transcripts were coded using open coding (examining, categorizing data); axial coding (reorganizing data in categories based on relationships among these categories); and selective coding (identifying and describing central themes) according to patient-physician communication behaviors (e.g., question-asking type) and issues related to medication-taking (e.g., side effects). Patient medication adherence was assessed with the 4-item Morisky Medication Adherence Scale. Patients were considered non-adherent if they responded ‘yes’ to any of the 4 questions. Frequency distributions and chi-square were used to compare the association between the typologies and adherence.

RESULTS: Majority of patients were black/African American (74 %), female (58 %), unemployed (70 %), and had Medicaid (30 %) with an average age of 59 years. Physicians (n=41) were predominately female (63 %) and white (82 %), with an average age of 37 years. Physicians practiced at the clinic for an average of 5 years. Four types of dyadic exchanges emerged: **Harmonious** exchanges (45 % of interactions) are characterized by a shared power dynamic. Patients are well-informed about their condition, frequently ask questions, offer their opinion on treatments, and suggest alternatives. In response, physicians use autonomy supportive statements to affirm patients' knowledge and ask questions to elicit patients' unique knowledge about their condition. **Divergent** exchanges (29 % of interactions) are also characterized by high patient question-asking and information-seeking behaviors however; the primary purpose is to clarify physician medical language. Physicians' responses are in

the form of monologues with high frequency of directives and little assessment of patient comprehension, accentuating power imbalances. In *traditional* exchanges (19 % of interactions), patients give physicians permission to take charge of their health, agreeing with recommended treatments without question. Physician's attempts to actively engage patients in decision-making by asking probing questions and eliciting information are often unsuccessful. In *detached* exchanges (7 % of interactions), patients challenge physicians' advice and divert the conversation away from medical topics to social problems. Physicians demonstrate low engagement and use closed questions to redirect the conversation. Overall, 43 % of patients reported perfect adherence to their antihypertensive medications. Adherence rates varied by the dyadic exchange type. On average, 46.2 % of patients in harmonious exchanges reported perfect adherence compared to 30.8 % in divergent exchanges. Alternatively, only 23 % of patients in traditional exchanges reported being adherent to their medications. Finally, no patients in detached exchanges reported being adherent. The differences in adherence across typologies were non-significant.

CONCLUSIONS: Examining the mutual influence of patient-physician communication behaviors provides greater insight into the communication processes that may affect patient adherence behaviors. Preliminary findings from this research suggest that relationships characterized by a shared power dynamic between the patient and physician is associated with better patient adherence. More research is needed to identify the patient and physician predictors of the typologies of communication exchanges in order to develop targeted interventions to improve the patient-physician relationship and patient health behaviors.

JOURNAL CLUB MOBILE APP USAGE IN DEVELOPING AND DEVELOPED COUNTRIES Timothy Plante¹; Nisa Maruthur². ¹Johns Hopkins University, Baltimore, MD; ²Johns Hopkins University School of Medicine, Baltimore, MD. (Tracking ID #2200319)

BACKGROUND: Use of mobile applications ("apps") has grown in parallel with mobile technology over the past decade. Even developing countries have shown rapid uptake of mobile technology, often leapfrogging conventional communication technologies such as landline telephone networks. The Journal Club app is consistently among the most downloaded for-sale medical education apps. To understand the potential of medical education apps in developing countries, we evaluated global usage of the Journal Club app. Whether there are differences in trends for visitation between developed and developing countries is unknown.

METHODS: Journal Club is an independent medical education mobile app that provides concise summaries of medical trials with content developed and maintained by physician editors in the US; Journal Club has never been advertised formally. The novel distribution platform Journal Club is available for a fee in the international Google Play and Apple App stores. Using the Google Analytics web analytics platform, which was fully integrated into the Apple iOS v1.3.2 and Google Android v1.3.2 platforms as of 11/10/14, we downloaded anonymized Journal Club app visitation data for a 5-week period (11/16/2014–12/20/2014). We identified developing countries based on the International Statistical Institute (ISI) list (2014). Using session (defined as a unique user interaction with the app at which time tracking data is collected) as the unit of usage, we compared session characteristics between developing and developed countries. We used screen display resolution in pixels (px) as a surrogate for degree of technology advancement with increased screen resolution indicating greater advancement.

RESULTS: Any use (>1 session) of the Journal Club app occurred in 77 countries. Of 139 ISI-defined developing countries, 36 had any usage of the app. Of 16,904 total sessions, 5.4 % were from developing countries (Malaysia, 19.3 %; Brazil, 15.0 %; Thailand, 8.8 %). Mean session duration (min:s) was 4:44 in developing countries vs. 4:16 in developed countries ($P=0.709$). The Android platform was more popular in developing countries (57.7 % of sessions) while the iOS platform was more popular in developed countries (70.9 % of all sessions; $P<0.001$). In developing countries, the most common screen resolutions used during sessions were 320×568 px (19.0 %), 720×1280 px (14.2 %), and 1080×1920 px (11.8 %). In developed countries, the most common screen resolutions were 320×568 px (37.4 %), 1080×1920 px (13.6 %), and 375×667 px (12.8 %). Summaries of trials in sepsis (ARISE),

coronary heart disease (DAPT), and heart failure (SOLVD) were most commonly accessed in developing countries with similar content accessed in developed countries [sepsis (ARISE and ProCESS) and coronary heart disease (DAPT)].

CONCLUSIONS: Despite a fee and the absence of a formal advertising program, more than 5 % of the use of the widely-used, independent Journal Club medical education app occurred in developing countries. Duration and content of sessions were similar in developing and developed countries. Users in developing countries appeared to use more advanced technology vs. those in developed countries and may not be representative of their countries' populations. While our results imply potential for medical education apps in developing countries, models to improve global reach to underserved areas, such as an advertising-supported model, should be evaluated. Also, future research to evaluate the effectiveness of apps in medical education is needed.

KIDNEY FUNCTION OUTCOMES IN OVERWEIGHT AND OBESE LIVING KIDNEY DONORS: A SYSTEMATIC REVIEW AND META-ANALYSIS Kalyani Murthy¹; Marwa El-Sabbahy¹; Ethan Balk². ¹Lahey Hospital and Medical Center, Burlington, MA; ²Brown Evidence-based Practice Center, Providence, RI. (Tracking ID #2198205)

BACKGROUND: Chronic kidney disease (CKD) and progression to end stage renal disease is on the rise, with more patients requiring kidney transplantation and a parallel increase in need for living kidney donors (LKD). Therefore, overweight (body mass index [BMI] 25–30 kg/m²) and obese (BMI ≥30 kg/m²) donors are increasingly being considered. Hypertension, metabolic syndrome, and CKD risk are significantly higher among overweight and obese patients and lead to higher morbidity and mortality. A recent meta-analysis showed that overweight individuals have a 40 % higher risk and obese individuals have 83 % higher risk of CKD. A recent post-transplant outcomes study (Ibrahim et al., Study 7, Table 1) showed that donors with a higher BMI had a 12-fold higher risk of having a glomerular filtration rate (GFR) <60 ml/min. However, there are limited data on short and long term kidney outcomes among overweight and obese LKDs. We aim to evaluate kidney function outcomes before and after donation among overweight and obese LKD in comparison to donors with normal BMI.

METHODS: We performed a systematic review of longitudinal studies comparing kidney outcomes in overweight/obese versus normal BMI LKDs. We conducted random-effects model meta-analyses of changes in kidney function (GFR and serum creatinine [S_{cr}])

RESULTS: Nine studies (6 retrospective and 3 prospective) provided data on obese and/or overweight donors (Table 1). Studies 1–6 included in meta-analyses provided information on GFR and S_{cr} among normal BMI and obese donors. Among them, Studies 1–3 provided complete data on kidney function outcomes for overweight, obese, and normal donors at baseline and follow-up (f/up). Study 4 excluded overweight donors. Studies 5 and 6 compared obese to normal and overweight donors. Meta-analysis of Studies 1–3 showed no statistically significant differences at f/up for both GFR (net difference=−0.7 ml/min; 95 % CI −2.4, 1.3) and S_{cr} (net difference=0.03 mg/dl; 95 % CI −0.001, 0.053) for overweight and obese donors versus normal donors. Studies 1–3 had f/up ≤1 y. Meta-analysis of Studies 1–4 (normal vs. obese donors) did not show any statistically significant differences in GFR (net difference=−0.9 mL/min; 95 % CI −3.1, 1.6) and S_{cr} (net difference=0.06 mg/dL; 95 % CI −0.02, 0.16) between the two groups. However, f/up of >1 y was limited to study 4.

CONCLUSIONS: Of 9 studies reporting kidney function outcomes among obese and/or overweight donors, we noted significant heterogeneity in data reporting including use of BMI cut-offs, f/up duration, GFR estimation methods, and reporting of S_{cr} . The heterogeneity resulted in our being able to meta-analyze only 4 of the 9 studies. In addition, reporting of important kidney function related outcomes such as proteinuria and hypertension was not uniform in most studies. Our study did not show conclusive evidence for changes in kidney function among overweight and obese donors. Given the heightened risk of CKD in patients with obesity and cardiovascular consequences of the metabolic syndrome it is essential to institute appropriate long-term f/up and documentation of kidney function outcomes among overweight and obese donors with expansion of the living donor pool.

KNOWLEDGE, ATTITUDES AND PRACTICES OF INTERNAL MEDICINE RESIDENTS REGARDING MANAGEMENT OF OBESITY Muhammad Umair Mushtaq; Lakshmi Mohan Viji Das; Malini Ganesh; Hussein Hamad; Ankit Mangla; Krzysztof Pierko. John H Stroger Jr. Hospital of Cook County, Chicago, IL. (Tracking ID #2199271)

BACKGROUND: Nearly 78 million adults in United States deal with the health and emotional effects of obesity every day. Obesity-related medical treatment costs nearly \$147 billion per year. Considering the huge burden of obesity-related medical issues which plague our health system, it would seem imperative that the training to deal with this epidemic should start at least at the residency level. This study was conducted amongst the internal medicine residents at two inner city teaching hospitals of Chicago to determine their knowledge, attitudes and practices (KAP) regarding the management of obesity.

METHODS: A cross-sectional study was conducted involving 110 internal medicine residents at John H. Stroger, Jr. Hospital of Cook County and MacNeal Hospital in Chicago. A standardized questionnaire was used to ascertain KAP regarding management of obesity. Respondents were asked to rate a total of 49 questions on a scale of one (strongly disagree) to five (strongly agree). A KAP score was formulated based on responses to 49 questions. Bivariate analysis, using t-test as the test of trend, was conducted to explore correlates of knowledge, attitude and practices. Linear regression was used to quantify the independent predictors of KAP score.

RESULTS: Fifty six percent of respondents were male, and 63 % were international medical graduates (IMGs). Overall, respondents' demonstrated lack of knowledge, attitude and practices (mean score, SD 144.9, 11.3; scale 49–245). A significantly higher KAP score was observed in IMGs as compared to US medical graduates ($P<0.001$), and in those who had practiced medicine for upto 5 years after graduation compared to those who started residency after completing medical school ($P=0.026$). Being an IMG was a significant independent predictor of higher KAP score (regression coefficient 7.1, 95 % CI 2.2–12.0, $P=0.005$). Respondents scored significantly low in all sections, including: knowledge regarding obesity management (mean score, SD 18.4, 1.9; scale 6–30), attitude regarding management of obese patients (mean score, SD 30.7, 3.5; scale 10–50), perceived treatment options available at their institution (mean score, SD 21.8, 4.6; scale 9–45), perceptions regarding etiology of obesity (mean score, SD 35.4, 3.6; scale 10–50), perceived personal characteristics of obese patients (mean score, SD 18.5, 3.9; scale 8–40), and interventions for effective weight management (mean score, SD 20.1, 3.3; scale 6–30). Gender of the respondents was not associated with knowledge, attitude and practices. Being an IMG predicted a higher mean score in attitude regarding management of obese patients ($P=0.005$), perceived treatment options available at their institution ($P=0.005$) and interventions for effective weight management ($P=0.007$). Those who had practiced medicine prior to joining residency (up to 5 years) had a higher mean score in

interventions for effective weight management when compared with residents who started residency soon after completion of medical school ($P=0.049$). Most of the respondents agreed that residents should be trained in nutrition counseling (80 %), exercise counseling (78 %), motivational interviewing (73 %) and weight loss medications (75.5 %). Primary care physician (23 %), nutritional dietitian (25 %), behavioral psychologist (3 %), nurse (3 %), endocrinologist (1 %) and any of these (45 %) were responded as the best health care providers to address the issue of weight management and obesity.

CONCLUSIONS: Our results show a significant lack of knowledge, attitude and practice amongst internal medicine residents in managing obesity. Our results also show that, IMGs and those, who have practiced medicine prior to joining residency, showed a better KAP than American medical graduates and those, who joined residency soon after completion of medical school. Our results indicate a perceived need for improved medical education of residents related to management of obesity and its complications.

LEARNING DURING TRANSFORMATION: A QUALITATIVE STUDY OF RESIDENTS AT PRIMARY CARE CLINICS TRANSITIONING TO TEAM-BASED CARE Joanna V. Brooks³; Antoinette S. Peters⁴; Meredith Rosenthal²; Alyna T. Chien¹; Sara Singer². ¹Harvard Medical School, Boston, MA; ²Harvard School of Public Health, Boston, MA; ³Harvard University, Cambridge, MA; ⁴Harvard Medical School, Brookline, MA. (Tracking ID #2194896)

BACKGROUND: With a decreasing number of medical graduates interested in primary care careers, the experience and perception of primary care that residents develop through their participation in primary continuity clinics is critical. However, the persistent problems of fragmented clinic sessions and disorganized clinic operation can undermine positive aspects of this experience. In 2012, the Academic Innovations Collaborative (AIC), a primary care learning collaborative for academically affiliated practices, introduced an initiative to transform concurrently educational experience and patient care at primary care clinics. At 19 sites, clinics have been working to improve primary care delivery through team-based care, patient empanelment, population management, and patient engagement. However, the impact of these changes on residents' experiences and perceptions of learning is unknown. The objective of this study is to understand residents' views on how primary care transformation to team-based care has (1) impacted their learning environment at the clinic and (2) affected their perspective on primary care careers.

METHODS: Qualitative in-depth interviews were conducted with residents who were interested in primary care careers and had spent at least one full year at one of 16 AIC clinic sites. Interviews took place between August 2014 and December 2014; 37 residents were interviewed before theoretical saturation was reached. Interviews ranged from 3/4 to

1.5 h (averaging 1 h), and followed a semi-structured interview guide. All interviews were audio-recorded and transcribed. Transcripts were uploaded to NVivo 10 qualitative data analysis software and analyzed using open coding and the constant comparative method, with intermittent discussions among investigators to reflect on findings in light of relevant literature.

RESULTS: Residents report that limited time at clinic often hinders their ability to integrate fully into a team, the key practice change objective of the AIC. Although pockets of authentic teaming are occurring for some residents, it remains an exception to more common superficial teaming, in which residents' knowledge of their "team" has few practical implications for their patient care or clinic duties. Hectic half-day clinic sessions remain a notable obstacle to residents' enjoyment of primary care, in part because scheduling often prevents trainees from being fully mentally and emotionally present during clinics. Despite these challenges, however, residents generally like learning at a clinic that is undergoing transformation. According to one resident: "getting us excited about primary care and primary care transformation is the best thing that you can do during residency." Residents believe in the value of exposure to a continually improving environment. They cite the importance of learning about both the obstacles and facilitators of real change at their clinics. Finally, interviews indicate that brief exposure during elective rotations to additional transformed primary care practices can have a positive impact on residents' perceptions about the attractiveness of primary care.

CONCLUSIONS: Although formidable obstacles remain to integrating residents into primary care change initiatives, resident trainees positively view exposure to transformation and teaming efforts. Despite the difficult work required to include "transient" residents during transformation, residents indicate that these efforts can improve their weekly experience at clinic. Exposing residents to primary care transformation also creates excitement about their future careers. Findings imply that primary care transformation leaders should (1) increase efforts to expose residents to the change process; (2) provide opportunities for resident involvement that are feasible within trainee-specific time constraints; and (3) focus on efforts to resolve the ability of residents to participate in teaming at their clinics.

LIFETIME AND RECENT INCARCERATION AND RISK OF UNCONTROLLED BLOOD PRESSURE CONTROL IN A MULTI-SITE COHORT Benjamin A. Howell¹; Jessica Long³; E. J. Edelman^{3, 4}; Kathleen A. McGinnis²; David Rimland¹; David A. Fiellin^{3, 4}; Amy C. Justice^{3, 4}; Emily A. Wang³. ¹VA Medical Center, Decatur, GA; ²VA Pittsburgh Healthcare System, Pittsburgh, PA; ³Yale School of Medicine, New Haven, CT; ⁴Center for Interdisciplinary Research on AIDS, New Haven, CT. (Tracking ID #2182563)

BACKGROUND: The United States has the highest rate of incarceration worldwide, such that more than 13 million individuals have been incarcerated in jail or prison at some point in their lives. Incarceration is associated with increased risk of hypertension and cardiovascular disease mortality. Our objective is to measure the independent impact of a history of incarceration on control of hypertension and receipt of antihypertensive medications.

METHODS: The Veterans Aging Cohort Study (VACS) is a longitudinal, prospective, multi-site observational study of HIV-infected and matched uninfected patients seen in the Veterans Health Administration (VHA). VACS contains survey data linked to the electronic medical record. Among participants who completed study follow-up between October 1, 2009 and September 30, 2010, we examined the role of self-reported incarceration history on control of blood pressure in the subsequent 12 months. We restricted our sample to those participants who responded to questions on incarceration history, had at least one blood pressure measurement in the 12–24 months before and in the 12 months after the survey, and who met criteria for having hypertension prior to the survey. Participant's self-reported incarceration history was defined as a recent history of incarceration (within the last 12 months), a past history of incarceration (during lifetime but not during the prior 12 months), or no history of incarceration. We considered participants to meet criteria for hypertension if at any point during the 12–24 month period prior to the survey they had a systolic blood pressure ≥ 140 , a diastolic blood pressure ≥ 90 , or were treated with an antihypertensive drug. Hypertension treatment was measured using the VHA pharmacy records and individuals were categorized as having received treatment if they had filled at least one antihypertensive medication in that time frame. We measured the effect of both recent incarceration and past history of incarceration on hypertension control in the subsequent 12 months following the survey. Uncontrolled hypertension was defined as having a systolic blood pressure ≥ 140 or a diastolic blood pressure ≥ 90 in the 12 months following the study survey. To analyze the independent effect of incarceration on hypertension control and receipt of antihypertensive medications, we used logistic

regression to control for age, race/ethnicity, gender, educational attainment, income, illicit drug use, unhealthy alcohol use, HIV status, and history of smoking.

RESULTS: Among the 3515 VACS participants who completed study follow-up between October 1, 2009 and September 30, 2010, 2580 participants met our inclusion criteria. Of this group, 180 (7 %) reported recent incarceration, and 1031 (40 %) reported a past history of incarceration. Participants with recent incarceration were significantly more likely to be younger and male, to have low income, to not have completed high school, and to report illicit drug and unhealthy alcohol use compared with those never incarcerated. In our sample, 1391 (54 %) were HIV-infected and there was no difference in percent of subjects HIV-infected according to incarceration history ($p=0.52$). In an unadjusted model, recent incarceration (OR=2.06 95 % CI: 1.37–3.11) and past history of incarceration (OR=1.32 95 % CI: 1.10–1.59) were associated with uncontrolled hypertension in the year after the survey when compared with those who were never incarcerated. The association between recent incarceration and uncontrolled hypertension persisted after controlling for age, educational attainment, race/ethnicity, low income, illicit drug use, unhealthy alcohol use, HIV status, and history of smoking (AOR=1.69 95 % CI: 1.11–2.58) when compared with those who were never incarcerated. However, the association between past history of incarceration and uncontrolled hypertension did not persist in the adjusted model (AOR=1.17 95 % CI: 0.96–1.42). Recent history of incarceration was not associated with decreased receipt of antihypertensive medications while past history of incarceration was, though this result similarly did not persist after adjustment.

CONCLUSIONS: Among patients with a history of hypertension, recent incarceration is independently associated with having uncontrolled hypertension in spite of receiving treatment for hypertension.

LIKE HAVING A FAVORITE CHILD? PRIMARY CARE PHYSICIAN EXPERIENCES WITH FAVORITE PATIENTS Joy L. Lee¹; Albert W. Wu²; Mary Catherine Beach². ¹Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; ²Johns Hopkins University, Baltimore, MD. (Tracking ID #2192216)

BACKGROUND: It is human nature to like some people more than others. As with the 'difficult patient,' many physicians have favorite patients, yet little is known about the attributes of these patients. This analysis describes physician experiences with favorite patients and how such patients may influence how they provide care.

METHODS: Semi-structured key informant interviews were conducted with 25 primary care physicians at a large academic medical center, practicing at several clinic settings. We recruited faculty participants from the Division of General Internal Medicine via email, and conducted thematic analysis on the transcribed interview data.

RESULTS: About 75 % of participants admitted to having favorite patients. Participants generally defined favorite patients as one they looked forward to seeing. One respondent, for example, characterized a favorite patient as "someone who when I do see on my schedule, I have a little extra smile for the day." For many, favorite patients were not necessarily the most compliant patients, or those most similar to the physicians in personality or demographic characteristics. Instead, many were defined by experiences that strengthened the patient-physician bond or long term relationships during which mutual fondness and trust were developed. As one respondent explained, "They're favorites for [different reasons]. Just like you have different children and you like your children all equally, but they're different." Comparisons to challenging or 'difficult' patients often arose in the interviews. However, many respondents also recounted experiences in which once-challenging patients became favorites over time. Respondents felt sustained by bonds with favorite patients but did not think the care favorites received differed from those of other patients. "If I get a call from my difficult patient, versus my average difficult patient, versus my favorite patient, I still return that call within the same amount of time. It's not like I wait to call back. Everything is based on the triaging of, can this wait until tomorrow? Is this urgent need?"

CONCLUSIONS: Primary care physicians value patient relationships and benefit from deep bonds. A better understanding of how favorite patients benefit primary care physicians could help inform efforts to reduce professional burn-out.

LONGITUDINAL EVALUATION OF ERRORS IN DIAGNOSES: DIAGNOSIS ERRORS AND DELAYS OVER AN INTERNSHIP YEAR Joshua M. Liao; Mayya Volodarskaya; Gordon D. Schiff. Brigham and Women's Hospital, Boston, MA. (Tracking ID #2194882)

BACKGROUND: Diagnostic errors (DEs)—missed, delayed, and wrong diagnosis—are common sources of patient harm, with reported incidence of 5–15 %. DEs can include failure to make correct diagnoses at certain points in time as well as failure to follow-up

abnormal lab results. Utilizing a panel of consecutive patients cared for by a single resident over an entire internship year, this study aims to describe the epidemiology of DE by evaluating the rates of diagnosis change and abnormal lab result follow-up.

METHODS: Of 272 total patients admitted during the study period, those who were personally admitted by the intern, plus those “inherited” and cared for >2 days, were included. The primary diagnosis for each patient was tracked using written documentation from the following “time nodes”: 1. Encounters during 3 months preceding index admission (upstream records) 2. Emergency Department (ED) note associated with index admission 3. Admission note from index admission 4. Discharge summary from index hospitalization 5. Encounters during 3 months following index hospitalization (downstream records) Changes in the principle diagnosis were recorded. The Diagnostic Error Evaluation and Research (DEER) taxonomy was used to identify “where” in the diagnostic process (e.g., history, physical, lab testing, assessment) DEs occurred. Patients’ EMRs were reviewed to evaluate follow-up of abnormal results for 4 common lab types—hemoglobin/hematocrit (H/H), sodium (Na), creatinine (Cr), and thyroid stimulating hormone (TSH). For patients admitted with abnormal values, upstream records were reviewed for other abnormal values; similarly, downstream records were reviewed for patients discharged with abnormal lab values. A maximum of two abnormal values (one upstream, one downstream) were recorded per lab type per patient. For patients with multiple abnormalities per lab type, priority was given to values closest to index hospitalization and those associated with clinical encounters. Each abnormal was reviewed to see if it was noted (explicit mention of result) or assessed (documentation of diagnostic/therapeutic plan in response to result) by a clinician.

RESULTS: Of 272 patients, 197 met the study inclusion criteria. Within this cohort, 33 had their primary diagnosis changed during the study period, yielding a diagnosis change rate of 17 %. Of these, 48 % (16/33) had evidence of DEER DEs. A total of 144 DEER DEs were identified among 55 patients (28 %). Sixty-seven percent (37/55) of these patients had > 1 DEER DEs, and 37 % of total DEs occurred in the assessment step. Of 197 patients, 176 (89 %) had an abnormal result for at least 1 included lab type at admission and/or discharge. Review of upstream and/or downstream records for these patients with abnormal inpatient labs revealed 392 lab values in the 6 months surrounding the index admission. Of these selected labs, 45 (12 %) were normal (patient had no abnormal values 3 months pre/post admission) and 347 (88 %) were abnormal. These abnormal values were noted and assessed in 46 % of cases, noted but not assessed in 7 % of cases, and neither noted nor assessed in 35 % of cases. Among abnormal values that were neither noted nor assessed, 77 % (106/138) were associated with an encounter with a healthcare provider. Our analysis included documentation during two care transitions—from ED to inpatient care and from inpatient to outpatient care. For the four included lab tests, 66 % (91/139) of abnormal values obtained in the ED were neither noted nor assessed in ED notes. Forty-three percent (82/190) of results that were abnormal at discharge were neither noted nor assessed in discharge summaries.

CONCLUSIONS: Significant numbers of patients had diagnosis changes, errors in the diagnostic process, and abnormal test results that were overlooked. Multiple DEs were seen in many of the cases and occurred most frequently in the “assessment” step of the diagnostic process. Longitudinal lab follow-up tracking suggest that abnormal labs often fail to be noted or assessed by providers (35–66 % of cases across multiple care settings), even when abnormal tests were associated with health care encounters.

LORCASERIN IMPROVES THE NASH CLINICAL SCORE IN THE MAJORITY OF HIGH-RISK PATIENTS: A RETROSPECTIVE ANALYSIS OF THREE PHASE 3 STUDIES Wajahat Z. Mehal¹; Randi Fain²; Alan Glicklich³; Yuhon Li²; William Shanahan²; William Soliman². ¹Yale University, New Haven, CT; ²Eisai Inc, Woodcliff Lake, NJ; ³Arena Pharmaceuticals, San Diego, CA. (Tracking ID #2198502)

BACKGROUND: Moderate weight loss has been shown to result in histologic improvement in non-alcoholic steatohepatitis (NASH). Lorcaserin (LOR) is a selective 5-HT_{2C} agonist approved for chronic weight management. Three large, double-blind, randomized studies (BLOOM: *N Engl J Med*. 2010;363:245–56; BLOSSOM: *J Clin Endocrinol Metab*. 2011;96:3067–77; BLOOM-DM: *Obesity*. 2012;20:1426–36) have demonstrated the effectiveness of LOR in inducing weight loss in patients with a body mass index of 27 to 45 kg/m². We conducted a retrospective analysis to determine the ability of 52 weeks of LOR 10 mg twice daily (BID) to improve NASH. The NASH clinical score predicts the presence of histologic NASH and was used as an indicator of NASH activity.

METHODS: Data were pooled from 3 clinical trials of similar design comparing LOR and placebo (PBO) in overweight or obese patients with or without type 2 diabetes mellitus (NCT00603902, NCT00395135, NCT00603291). All patients received diet and exercise counseling. The modified intent-to-treat (MITT)/last observation carried forward (LOCF) population was analyzed for patients with both baseline and end of treatment NASH clinical score data. Liver parameters (alanine aminotransferase [ALT],

aspartate aminotransferase [AST]) and weight loss in the MITT/LOCF population were assessed as % change from baseline. The NASH clinical score was analyzed by comparing proportions of patients shifting from high or very high scores at baseline to low or intermediate scores at week 52.

RESULTS: Approximately 7 % of control (182/2519) and LOR-treated (190/2702) patients had a high- or very high-risk NASH clinical score at baseline. LOR-treated patients showed significant improvements vs PBO in ALT (% change from baseline to week 52, –2.4 vs 3.0), AST (0.1 vs 2.6) as well as significant weight loss (–5.8 vs –2.4), all $p < 0.001$. In an analysis of the time course of treatment effect, significant weight loss with LOR vs PBO was seen as early as week 2, with peak effect at week 36; peak effect of LOR on liver enzyme levels was at between weeks 24 and 36. Significantly more patients treated with LOR (120/190, 63.2 %) vs PBO (89/182, 48.9 %) switched from NASH high- or very high-risk at baseline to NASH low- or intermediate-risk at week 52 ($p = 0.006$).

CONCLUSIONS: LOR treatment for 52 weeks was associated with greater improvement in serum liver function test parameters than PBO, and improvement in NASH clinical score in the majority of high-risk patients. LOR may be a treatment option for overweight/obese patients with non-alcoholic fatty liver disease/NASH.

LOW BONE MINERAL DENSITY IN ADULTS WITH DEVELOPMENTAL DISABILITIES Mailee Hess¹; Elizabeth Campagna, MS²; Kristin M. Jensen². ¹University of Colorado, Denver, CO; ²University of Colorado School of Medicine, Aurora, CO. (Tracking ID #2194237)

BACKGROUND: Adults with developmental disabilities (DD) have increased risk for low bone mineral density (BMD) due to high-risk medication use, poor mobility, and endocrine abnormalities. However, no formal guidelines exist to adapt screening recommendations for this population. We sought to identify the prevalence rates, risk factors and screening patterns for low bone mineral density among a cohort of adults with DD.

METHODS: In this retrospective observational cohort study, we evaluated screening patterns and risk factors for low BMD among patients ages ≥18 years, who received ≥2 months of care during 2013 at a regional state-run facility for adults with DD. Our outcome of low BMD was defined as a Z-score or a T-score ≤ -1. We assessed for known risk factors for low BMD, including severity of cognitive delay, medication use including anticonvulsants and antiepileptics, endocrine diseases, presence of CKD and vitamin D deficiency. Subgroup comparisons were then made among persons with low BMD. T-tests and Pearson’s chi-squared tests were used when appropriate.

RESULTS: We identified 140 persons with DD meeting our study criteria of whom, 69 % were male with a median age of 43.5 yo. Out of our cohort, 46 % were screened for low BMD; of those screened, 89 % were diagnosed with low BMD (median age at diagnosis = 42yo). Those with low BMD were more likely to be older (median age: low BMD 52yo, normal BMD 46yo, $p = 0.031$), non-weight bearing (low BMD 60 %, normal BMD 14 %, $p = 0.039$), Caucasian (low BMD 82 %, normal BMD 43 %, $p = 0.025$) and have more severe cognitive delay (severely delayed: low BMD 82 %, normal BMD 43 %, $p = 0.033$). Neither anti-epileptic nor anti-psychotic drug use for >12 mo was significantly associated with increased rates of low BMD in our cohort.

CONCLUSIONS: This cohort of 140 adults with developmental disabilities had significant risk factors for decreased BMD, yet less than half were screened. We observed extremely high prevalence of low bone mineral density among those screened. Age at diagnosis in this cohort was approximately 20 years younger than USPSTF’s recommended age at which to start screening. While anti-epileptic and anti-psychotic use were not significant risk factors with respect to low BMD, we suspect this is likely due to the low number of patients with normal BMD within our cohort. Prospective studies are needed to validate these findings and inform treatment algorithms accordingly.

LOW-VALUE SERVICES IN YEAR 1 OF THE PIONEER ACO PROGRAM Aaron L. Schwartz; Bruce E. Landon; Michael E. Chernew; J. Michael McWilliams. Harvard Medical School, Boston, MA. (Tracking ID #2196053)

BACKGROUND: Reducing wasteful health care utilization is a central goal of many government and private initiatives. However, because measuring overuse is challenging, evaluations of these initiatives tend to track outcomes like overall spending or specific quality measures. This approach may fail to characterize effects on overuse accurately. For example, although recent global payment initiatives have been associated with reduced spending and improved or stable performance on certain quality measures, such findings could have resulted from reductions in high-value services affecting unmeasured quality rather than from reductions in overuse. Using claims-based measures of low-value care, we examined whether the 2012 Medicare Pioneer Accountable Care Organization (ACO) initiative was associated with reductions in the use of low-value services.

METHODS: Using 2009–2012 Medicare fee-for-service claims data, we conducted a difference-in-differences analysis comparing low-value service utilization between beneficiaries served by Pioneer ACOs and local control beneficiaries before vs. after the start of Pioneer contracts. Medicare Beneficiaries were attributed to one of 32 Pioneer ACOs (ACO group, $n=301,663$) or to a non-ACO taxpayer identification number (control group, $n=5,955,736$) according to annual allowed charges for primary care services. We constructed 32 measures of low-value care based on evidence-based lists of services that provide minimal clinical benefit. Using regression analysis, we estimated differential changes in per-beneficiary annual counts of low-value services for the ACO group vs control group, adjusted for beneficiaries' sociodemographic and clinical characteristics, as well as hospital referral region (HRR) and HRR-level changes in service use (HRR-by-year fixed effects). We decomposed overall effects according to characteristics of the low-value services (clinical category, price, and sensitivity to patient preference) and characteristics of the ACOs (financial integration between physicians and hospitals, baseline 2008 use of low-value services in the ACO service area, baseline 2008 use of low-value services in the ACO relative to the local average, and whether the ACO dropped out of the program).

RESULTS: Beneficiaries received an average of 0.45 low-value services per year, with 29.4 % of beneficiaries receiving at least one per year. Prior to 2012, annual trends in use of low-value services were similar for the ACO and control groups ($p=0.521$). In 2012, Pioneer contracts were associated with a 1.6 % overall reduction in use of these services ($p=0.001$) compared with the control group. The greatest differential reductions occurred for low-value cancer screening (-2.1 %, $p=0.006$), imaging (-1.8 %, $p=0.04$), and cardiovascular testing and procedures (-6.3 %, $p=0.05$). Differential reductions were similar for higher-priced (-1.4 %, $p=0.145$) and lower-priced services (-1.7 %, $p=0.011$), and for services sensitive (-1.4 %, $p=0.057$) and insensitive (-2.0 %, $p=0.004$) to patient preferences. Effects were greatest for ACOs with baseline use of low-value services that was higher than the local average (-3.1 %, $p<0.001$). Service reductions were unrelated to physician-hospital integration, baseline use in the ACO service area, and Pioneer program drop out.

CONCLUSIONS: The Pioneer ACO program, which introduced incentives for reducing overall spending, was associated with modest reductions in the use of low-value services during its first year. Reductions were concentrated among ACOs with high baseline use of these services relative to the local average. Financial integration between physicians and hospitals does not appear to be a prerequisite for reducing overuse under global payment reforms. Overuse measures may be a valuable addition to outcomes like spending and traditional quality measures in future evaluations of health policy interventions.

LOWER RATES OF PROMOTION OF GENERALISTS IN ACADEMIC MEDICINE Deborah Blazey-Martin¹; Phyllis Carr²; Norma Terrin¹; Janis Breeze¹; Carolyn Luk¹; Anita Raj³; Samantha E. Kaplan⁴; Karen Freund¹. ¹Tufts Medical Center, Boston, MA; ²Massachusetts General Hospital, Boston, MA; ³University of California San Diego, San Diego, CA; ⁴Boston University School of Medicine, Boston, MA. (Tracking ID #2181792)

BACKGROUND: Prior cross-sectional research has found that generalists, and especially women generalists, have lower rates of academic advancement than their counterparts in medical and surgical specialties and basic sciences. We conducted a longitudinal follow-up to assess whether these patterns persist or change over the course of an academic career, and to understand the factors including grant and publication activities that predict academic promotion.

METHODS: We conducted a follow-up survey of the 1995 National Faculty Survey cohort, which was drawn from a random sample of 24 US medical schools, and oversampled generalists, underrepresented minority faculty, and women in senior leadership positions. We supplemented online survey responses with publicly available data on academic rank, publications and grant funding. We looked at two outcomes: 1) proportion of faculty promoted to full professor, and 2) mean number of peer reviewed publications, comparing generalists with medical specialists, surgical specialists and basic scientists. We adjusted analyses by gender, race/ethnicity, and years in academics, and controlled for publications in the model for academic advancement. To determine if there were gender-specific effects, we included interaction terms for gender and specialty in the models.

RESULTS: We report on 1275 physicians who participated in the 1995 survey; half were women and 25 % were generalists. Generalists were the least likely to attain the rank of full professor by 2012 (53 %) compared with medical specialists (67 %), surgeons (66 %), and basic scientists (78 %, $p<.0001$). In unadjusted models, generalists had a lower mean publication rate (mean=44) than their three counterparts (mean=56, 57, and 83 respectively, $p<.0001$). Generalists were as likely to have federal grant funding (26 %) compared to medical (21 %) and surgical specialists (21 %), but less likely compared to basic scientists (51 %, $p<.0001$). In an adjusted analysis, all other specialty groups had more

publications than generalists. In an adjusted model, there were no differences in academic promotion between generalists and the other groups after controlling for publications. Women achieved the rank of professor at a similar rate to their male colleagues when controlling for publications, with no significant interaction between gender and specialty in the model.

CONCLUSIONS: While men and women in general medicine were less likely to be promoted than other groups of academic faculty, there were no longer significant differences in academic advancement after adjusting for number of peer reviewed publications. Further investigation into the reasons that both women and generalists have fewer publications may shed light on the barriers they face in achieving the rank of full professor, and guide interventions needed to advance their academic promotion.

Adjusted Models Predicting Number of Publications and Academic Rank

	Total Peer Reviewed Publications		Achieving Rank of Professor	
	Relative Means	95 % Confidence Interval	Odds Ratio	95 % Confidence Interval
Surgeons vs. generalists	1.3	.99–1.7	.89	.51–1.6
Medical specialists vs. generalists	1.3	.98–1.6	.78	.49–1.3
Basic scientists vs. generalists	1.5	1.2–2.0	.82	.47–1.4
Women	.73	.58–.94	.83	.58–1.2
Minority	.76	.64–.91	.67	.42–1.1

MASSACHUSETTS HEALTH CARE REFORM REDUCED EMERGENCY DEPARTMENT VISITS Amresh D. Hanchate^{1, 2}; James Feldman³; Kalpana N. Shankar³; Danny McCormick⁴; Karen E. Lasser²; Chen Feng²; Nancy R. Kressin^{1, 2}. ¹VA Boston Healthcare System, Boston, MA; ²Boston Medical Center/Boston University School of Medicine, Boston, MA; ³Boston University School of Medicine, Boston, MA; ⁴Harvard Medical School / Cambridge Health Alliance, Cambridge, MA. (Tracking ID #2197977)

BACKGROUND: Large-scale insurance expansions, such as the Affordable Care Act (ACA), increase use of health care; whether use of the emergency department (ED) increases or decreases remains unclear, although this weighs heavily on the likely impact on health care costs. Using the quasi-experimental setting of the Massachusetts (MA) insurance expansion (2006–07), upon which the ACA was modeled, we examined the change in ED use associated with the reform.

METHODS: Applying a difference-in-differences design we compared post-reform changes in MA with corresponding changes in New Jersey (NJ), a state without health reform, to isolate the change in ED visits associated with reform. Using comprehensive administrative data, we identified all ED visits, including visits that resulted in inpatient admission, during 2004–2010 in MA and NJ among state residents aged 18 to 64. Population counts were obtained from the census data files. We estimated population rates of ED use (# ED visits per 100 census population) during 21 months prior to the start of reform (7/1/2006) and 21 months following coverage expansion (1/1/2008). Aggregating ED visits in each state by age and sex, we used difference-in-differences Poisson regression models with fixed effects for time to estimate change in ED use associated with reform. We performed similar analysis for the state population stratified by race/ethnicity (Hispanics, non-Hispanic blacks and non-Hispanic whites) and socioeconomic status (SES) based on median zip code income obtained from national census data. We performed sensitivity of estimates by varying model specifications, including aggregated counts at county and zip code levels.

RESULTS: We identified a total of 8,425,539 and 9,694,312 ED visits in MA and NJ, respectively. Pre-reform, there were 39.8 ED visits per 100 population aged 18–64 in MA; this rate increased to 41.9 ED visits in the post-reform period, indicating a 5.3 % overall increase. Adjusting for secular trends, health reform was associated with a decrease of 3.4 % (95 % confidence interval (CI) [–4.4 %, –2.3 %]) in ED use in MA. This estimate was robust to alternative aggregation of counts at county (–3.5 %) and zip code (–3.4 %) levels. Stratified analysis for minorities indicated that health reform was associated with a larger decrease in ED use among blacks (–12.4 %, 95 % CI [–14.8 %, –9.9 %]), but an increase among Hispanics (10.3 %, 95 % CI [6.1 %, 14.5 %]).

95 % CI [7.6 %, 13.0 %]). Similar analysis by SES groups indicated no significant change in ED use, associated with health reform, among the population in the poorest quartile of zip codes in MA.

CONCLUSIONS: MA health reform was associated with a decrease in overall ED use. Our finding, based on the use of an out-of-state comparison population (NJ), was robust to alternate methods, especially the choice of the geographical unit of area (state, county or zip code). In contrast, findings from previous studies, which used within-state (MA) comparison population, differed with the choice of unit of area. Further research adding data from other comparison states is needed to evaluate the robustness of the findings, particularly for racial/ethnic minorities. Additional research needs to explore the factors underlying this finding, separating change in ED use relating to health reform (e.g., improved outpatient care access) and that relating to other secular changes (e.g., growth of urgent care clinics and change in co-payments). While our finding suggests similar potential for ACA nationwide, the role of other facilitating factors, such as adequate provider availability, also need to be taken into account.

MATERNAL HEALTH SERVICES USE: COMPARING REFUGEE, IMMIGRANT AND NATIVE POPULATIONS Katherine Kentoffio³; Seth A. Berkowitz²; Steven J. Atlas²; Sarah Oo¹; Sanja Percac-Lima². ¹Massachusetts General Hospital, Chelsea, MA; ²Massachusetts General Hospital, Boston, MA; ³Harvard Medical School, Boston, MA. (*Tracking ID #2198223*)

BACKGROUND: Recent policy efforts have focused on expanding access to maternal healthcare for refugee and immigrant women. However, little is known about utilization of these services by refugee and immigrant women in a setting of near-universal health insurance coverage. We hypothesized that use of recommended maternal healthcare would be lower among refugee and immigrant women despite similar access to care.

METHODS: We created a longitudinal cohort of refugee women, age ≥ 18 years, who arrived to the US between January 1, 2001 and December 31, 2013. These women were then matched by age, gender, and date of care initiation in a 1:3 ratio, to a) Spanish-speaking non-refugee immigrants, and b) English-speaking controls. All patients received care at a single community health center in Eastern Massachusetts that serves a diverse, low-income community and is a state-designated refugee center. Our outcomes were: initiation of obstetrical care prior to the guideline recommended 10 weeks of gestational age, number of obstetrical visits during the pregnancy, and whether patients received a postpartum visit within 8 weeks after delivery. We also collected information on patient age, educational attainment (< vs. \geq high school diploma), insurance type, and baseline body mass index (BMI). To account for neighborhood differences, patient addresses were geocoded and we abstract median household income at the census tract level. For unadjusted analyses, we used chi-squared tests for dichotomous outcomes and ANOVA for continuous outcomes. For adjusted analyses, we used logistic (for dichotomous outcomes) and Poisson (for count outcomes) regression, with random effects to account for clustering introduced by repeated pregnancies among patients.

RESULTS: Of 1642 refugee and matched control women, 375 had at least one pregnancy during the study period, including 17 % (53/309) of refugee women, 27 % (186/688) immigrant women, and 21 % (136/645) control women. Only 5.9 % of women did not have health insurance, and this did not differ between groups ($p=0.20$). There were 763 total pregnancies (116 refugee, 368 immigrant, and 279 control) over a median follow up of 5.7 years (interquartile range 2.6–8.4 years). Among refugee patients, the most common countries of origin were Somalia (25.9 %), Bhutan (13.0 %), Iraq (7.4 %), and Haiti (7.4 %). Both refugee and immigrant statuses were associated with delayed initiation of prenatal care: 33.6 % of refugee women and 27.6 % of immigrant women had their first obstetric visit after 10 weeks gestational age, compared with 16.2 % of control women ($P<.001$). Refugee status was also associated with fewer prenatal care visits compared with controls (median: 12 vs. 14 visits, $p<.001$). However, once in care, refugee (73.3 %) and immigrant women (78.3 %) were more likely to have had a postpartum visit than controls (54.8 %), $p<.001$. After adjustment for the above covariates and accounting for clustering, both refugee (OR 2.76 95%CI 1.33–5.73) and immigrant (OR 1.93 95%CI 1.09–3.43) statuses remained associated with delay in initiating prenatal care, and refugee status remained associated with fewer prenatal visits (Incident Rate Ratio 0.84 95%CI 0.71–0.99). In adjusted models, refugee

(OR 2.00 95%CI 1.04–3.85) and immigrant (OR 2.83 95%CI 1.72–4.66) women remained more likely to have a postpartum visit.

CONCLUSIONS: Both refugee and immigrant women had significantly increased risk for delay in initiating maternal healthcare compared with age matched controls from the same community, despite similar access to healthcare. However, once in care, refugee and immigrant were more likely to follow-up for postpartum care. In addition to ensuring insurance coverage for maternal healthcare, targeted outreach to bring vulnerable women into care earlier may be needed to improve women and infant health for refugees and immigrants.

MEDIATORS OF DISPARITIES IN SURVIVAL AMONG PATIENTS WITH NON-SMALL CELL LUNG CANCER Anish Mehta^{1, 4}; Shannon Stock⁵; Stacy Gray⁶; David Nerenz⁷; John Z. Ayanian³; Nancy L. Keating². ¹Case Western Reserve University, Cleveland, OH; ²Harvard Medical School, Boston, MA; ³University of Michigan, Ann Arbor, MI; ⁴Harvard University, Cambridge, MA; ⁵College of the Holy Cross, Worcester, MA; ⁶Dana Farber Cancer Institute, Boston, MA; ⁷Henry Ford Health System, Detroit, MI. (*Tracking ID #2190348*)

BACKGROUND: Non-small-cell lung cancer (NSCLC) patients who are non-white, have low incomes, Medicaid or no insurance have worse survival than other patients. However, it is unclear how clinical and treatment differences contribute to the survival differences. We assessed whether racial/ethnic or socioeconomic disparities in survival for patients with NSCLC were attributable to sociodemographic factors, clinical characteristics at diagnosis, or treatments received.

METHODS: Data were collected as a part of the Cancer Care Outcomes Research and Surveillance (CanCORS) Consortium, a multi-regional observational study of newly-diagnosed lung and colorectal cancer patients. Among 4071 patients diagnosed with incident NSCLC in 2003–2005, we excluded 984 patients from one study site with <5 % non-white patients and 32 without vital status data for a final cohort of 3250 patients. Vital status was followed through 2012. We used unadjusted Cox proportional hazard analyses to estimate risk of death associated with race/ethnicity, annual income, education attainment, and insurance status. We used multivariable proportional hazard models adjusting sequentially for sociodemographic characteristics (age, race/ethnicity, sex, marital status, income, education, insurance, smoking status, integrated health system); clinical characteristics at diagnosis (stage, number of comorbid conditions); and treatments received (radiation, surgery, chemotherapy). All models adjusted standard errors for clustering by study site.

RESULTS: Overall, 65 % of patients were white, 16 % black, 7 % Hispanic, 7 % Asian, and 5 % other race/ethnicity; 36 % of patients had incomes <\$20,000/year; 23 % of patients had not completed high school; 2 % were uninsured and 4 % had Medicaid insurance. The median survival time was 494 days after diagnosis. In unadjusted analyses, mortality was higher for patients with lower income, less education, and no insurance, Medicaid, or Medicare versus private insurance (Table, all $P<.05$). After adjustment for sociodemographic factors, Hispanic patients had worse survival than white patients, as did patients with incomes <\$60,000/year vs. >\$60,000/year, non-high school graduates vs. some college or more, and Medicaid or Medicare only vs. private insurance (Table). After adjustment for clinical characteristics (stage and comorbidity), the survival disadvantage for Hispanic ethnicity and education were no longer evident, although income <\$40,000/year, uninsurance, and Medicaid insurance remained associated with worse survival. Additional adjustment for treatment explained much of the uninsurance difference, but a survival disadvantage among patients with incomes <\$20,000/year and those with Medicaid insurance persisted. After adjustment for treatment, black and Asian patients had better survival than whites (Table).

CONCLUSIONS: Survival disparities in NSCLC exist for patients with low income and Medicaid insurance, even after adjustment for sociodemographic, clinical, and treatment factors. Clinical characteristics at diagnosis account for most of the survival disparity by education, but not income. Differences in treatments received explained much of the survival disparity between uninsured and insured patients. Additional efforts are needed to assure timely diagnosis and use of effective treatment as well as improved post-treatment care to lessen these disparities.

Hazard Ratios for Mortality by Patient Characteristics, Unadjusted and with Sequential Adjustment for Sociodemographic Factors, Clinical Factors, and Treatments

Patient Characteristics	Unadjusted HR (95 % CI)	Sociodemographic HR (95 % CI)	Sociodemographic+Clinical HR (95 % CI)	Sociodemographic+Clinical+Treatment HR (95 % CI)

MEDICAID IN YOUR NEIGHBORHOOD: ASSESSING THE PRIMARY CARE INFRASTRUCTURE FOR NEW YORK CITY'S MEDICAID EXPANSION Bryant C. Webb. NewYork-Presbyterian Hospital, New York, NY. (*Tracking ID #2200181*)

BACKGROUND: Since its passage, the Patient Protection and Affordable Care Act's expansion of eligibility for the state-administered Medicaid programs has been a contentious issue for both political and practical reasons. Despite moral and system-based imperatives to expand insurance coverage, as well as long-term projected health system savings, significant concerns persist about the unintended consequences of so greatly expanding American health care's least generous payor. In New York, nearly one million previously uninsured adults across the state were expected gain health insurance through the Medicaid program—a statistic that is the source of both celebration and concern. With the second year of open enrollment underway, the impact of the expansion on New York's Medicaid roll has become a bit clearer. New York City (NYC), alone, saw the enrollment of nearly 660,000 new Medicaid beneficiaries in the first 12 months of the expansion. We set out in this analysis to further analyze the potential impact of this Medicaid expansion on NYC's primary care infrastructure.

METHODS: We used zip code level data to assess the impact of the Medicaid expansion on primary care in NYC. We selected zip codes as our geographic unit, as they were both large enough to offer adequate data points, but small enough to capture a community's primary care environment. First, we compiled the 2012 totals for Medicaid beneficiaries in each of NYC's 176 zip codes. Next, we collected Medicaid enrollment numbers from October 1, 2013—September 19, 2014. Finally, we obtained the Primary Care Health Professions Shortage Area score (HPSA score) for each NYC zip code. Of note, five zip codes were omitted from the final analysis due to an absence of Medicaid enrollment during the defined period, leaving a total of 171 zip codes included in the analysis. After splitting the zip codes into those that are and those that are not HPSAs, we compiled descriptive statistics for both groups. We calculated Pearson correlation coefficients to describe the relationship between HPSA scores and four variables describing the expansion in Medicaid: the total number of new enrollees, the percent increase in Medicaid enrollment, the percentage of the population in each zip code enrolled in Medicaid after the open enrollment period (described as "Medicaid Saturation"), and the change in Medicaid Saturation from pre- and post-Medicaid expansion.

RESULTS: The 85 zip codes that were in HPSAs accounted for two-thirds of the new Medicaid beneficiaries in the City. While there was a larger average increase in Medicaid enrollment in non-HPSA zip codes (23.0 % compared to 17.8 %), the Medicaid Saturation for HPSA zip codes increased more (8.9 % compared to 5.7 %), with nearly 60 % of the individuals in HPSA zip codes now enrolled in Medicaid. The Pearson's correlations were significant for a moderate positive correlation between HPSA scores and Medicaid Saturation in each zip code after the Medicaid expansion ($r=0.6134$, $p<0.00001$), as well as a moderate positive correlation between HPSA scores and the percent change in Medicaid Saturation in each zip code ($r=0.5123$, $p<0.00001$).

CONCLUSIONS: These findings illustrate the reality of the strain to the existing New York City primary care infrastructure. They suggest that many of the City's neighborhoods under the greatest stress for primary care services saw the greatest increase in the population percentage now newly insured by Medicaid. This realization bears important implications for clinical practice and public policy. Based on these findings, providers can anticipate increases in new Medicaid patients establishing care at their practices. The

implications of the influx of new Medicaid patients is particularly important given that the ACA's enhanced Medicaid reimbursement rates for primary care services ended with 2014. Given the New York Medicaid-to-Medicare Fee Index of only 0.42, providers and practices must extrapolate these data to better prepare for the financial implications of the Medicaid expansion. Using zip code-level Medicaid enrollment numbers also highlights the importance of implementing strategies to address the exacerbation of the primary care physician shortage. By identifying zip codes and HPSAs with the greatest enhanced need in primary care providers, existing programs can further designate priority areas in the wake of the Medicaid expansion. Finally, the concept of Medicaid Saturation at a zip code level is an important concept to guide for future conversations of optimizing physician participation and reimbursement in the Medicaid program.

Comparison of NYC Medicaid Enrollment in HPSA Zip Codes and Non-HPSA Zip Codes

	n	New Medicaid Enrollees	Average Increase in Medicaid Enrollment	Medicaid Saturation: Average Population % Enrolled in Medicaid	Average Increase in Medicaid Saturation
Non-HPSA Zip Codes	86	218,316	22.97 %	33.1 %	5.72 %
HPSA Zip Codes	85	441,274	17.83 %	60.1 %	8.94 %

Statistical Correlations Between HPSA Scores and Selected Variables

	# of New Medicaid Enrollees	% Increase in Medicaid Enrollment	Medicaid Saturation	% Increase in Medicaid Saturation
HPSA Score	$r=0.4133$ $p<0.00001$	$r=-0.3834$ $p<0.00001$	$r=0.6134$ $p<0.00001$	$r=0.5123$ $p<0.00001$

MEDICAL INTERPRETERS' HIDDEN ROLES—FINDINGS FROM A QUALITATIVE STUDY IN A SAFETY NET SETTING

Irene Yen^{1, 2}; Nancy J. Burke¹; Davida Flattery²; Julie A. Sladek²; Sambo Ly²; Linda Engelstad². ¹University of California, San Francisco, San Francisco, CA; ²Alameda Health System, Oakland, CA. (*Tracking ID #2194163*)

BACKGROUND: In 2013, nearly 62 million Americans (approximately 20 % of the US population) spoke a language other than English at home. In California the proportion was 45 %. Limited English Proficient (LEP) patients, defined as those unable to communicate effectively in English, need interpreters to help them with their medical appointments. Lack of professional interpretation is associated with medical errors and decreased quality of and satisfaction with care. Published professional standards for medical interpreters indicate that they should convey only what was said (without adding, omitting, or

substituting content) and should use an equivalent level of sophistication of language (referred to as “register”) as the speaker. We sought to understand how closely interpreters adhere to these standards, what they perceive as the scope of their professional role, and the challenges they face in their work.

METHODS: We conducted in-person, qualitative interviews with 17 members of the interpreting team (10 women, 13 languages). We created an interview guide which contained questions about typical patient interactions, problems interpreters regularly encounter, how they cope with these problems and how clinicians help or hinder effective communication. Interviews were digitally recorded and transcribed. Investigators developed a codebook following an open coding methodology informed by Grounded Theory. Two team members coded each transcript independently, met regularly to discuss emerging codes and discrepancies in coding until consensus was reached.

RESULTS: Key themes are summarized in Table 1. We provide representative quotes from interpreters and compare them to the 2005 published national standards for interpreter conduct. Interpreters reported informal expansion of duties beyond those outlined in the professional standards to improve and support clinical communication and institutional navigation. Strategies employed include modifying interpretations in order to simplify meaning to facilitate patient understanding, developing personal relationships with patients, and assisting with navigating the health care system (e.g. insurance, scheduling). Several identified themselves as community leaders both within and outside of the clinical setting.

CONCLUSIONS: Gaining insight into the valuable roles medical interpreters play can help clinicians and other members of the healthcare team optimize their interactions with interpreters in order to better serve LEP patients.

Table 1. Key Themes

Theme	Participant Quote	2005 Professional Standards
Interpreters make adaptations to technique, “lower the register,” to be effective in their roles	“The way that he asked the question, ... it was vague. He wanted to know specifically. He wanted me to emphasize. But when I ask the questions the patient was not ... right to the point. The patient would say, ‘Well, you know what, I...’ I said, ‘Sorry, but the doctor is asking this question.’ And then, ‘[says own name], could you help him with that?’ ... You have to understand that. When we interpret... The doctor asks a question and we have to go by a register and ask... And if we see that there’s some problems ... we have to come down on register.”	“The interpreter renders all messages accurately and completely, without adding, omitting, or substituting. For example, the interpreter repeats all that is said, even if it seems redundant, irrelevant, or rude.”
Interpreters are active advocates supporting patients to navigate a complex health care system	“But I explain to them this is not too much blood in your body, because they turn around and they say, ‘Why don’t you take out more blood from my body and then I don’t have high blood pressure?’ So, what I did, I told them it’s like a pipe; the water flow very fast, like a garden hose, and then if it’s flowing fast, pretty soon it’s gonna burst and you have a stroke.”	“The interpreter replicates the register, style, and tone of the speaker. For example, unless there is no equivalent in the patient’s language, the interpreter does not substitute simpler explanations for medical terms the provider uses...”
Interpreters play a range of social roles in their communities	“I explain to them the system that we are using here.... And after that, if they wish to come into our clinic in the future, ... I do make the appointment, follow up appointment for them, whatever they need. In some cases sometimes they need to use medication right away. Sometimes I directly help them with own pocket money ... to get their medicine right away because they need to use it right away.”	[see above and below]
	... my job you think it’s not only interpret. Outside that, many, many, many... the people have... needs help, outside. They call at night during Sunday and Saturday, ... because they need so many things, these welfare things. And they need so many things;	“Interpreter limits personal involvement with all parties during interpretation assignment.”

MEDICAL STUDENTS’ PERCEPTION OF THE PATIENT-CENTERED LEARNING ENVIRONMENT Mark V. Wilcox²; Megan S. Orlando²; Cynthia S. Rand²; Janet Record¹; Colleen Christmas¹; Roy C. Ziegelstein²; Laura Hanyok¹. ¹Johns Hopkins Bayview Medical Center, Baltimore, MD; ²Johns Hopkins University School of Medicine, Baltimore, MD. (Tracking ID #2196272)

BACKGROUND: Patient centered (PC) care has been identified as a core aspect of quality health care by multiple organizations, including the Institute of Medicine. PC care is now regularly taught in formal undergraduate medical education; however other aspects of the learning environment may impact students’ adoption of PC beliefs and behaviors. Some research suggests that students’ PC attitudes decrease as they progress through medical school. It is unclear how PC attitudes differ by gender.

METHODS: We sent an online anonymous survey to all 498 medical students (years 1–4) in one medical school using a modified version of the Communication, Curriculum, and Culture (C3) instrument, a validated questionnaire that quantitatively measures 3 PC domains: role modeling, students’ experience, and support for students’ own PC behaviors. We also included two qualitative survey items to characterize students’ personal PC experiences and analyzed these responses for common themes. Quantitative data were compared by gender and class year.

RESULTS: One hundred fifty-six of 498 students responded, for a response rate of 31.3. Forty-nine percent of respondents were female and 51 % were male. The response rate for preclinical and clinical students was similar, with 77 year 1/2 (preclinical) and 79 year 3/4 (clinical) student responses. Preclinical students reported greater patient centeredness than clinical students in all three domains: role modeling (mean 5.27 vs. 4.96 on 7-point Likert scale, $P=0.03$), students’ experience (mean 3.84 vs. 3.22 on 5 point Likert scale, $p<0.0001$), and support for students’ own patient-centered behaviors (mean 4.24 vs. 3.76 on

5-point Likert scale, $P=0.0009$). Aggregated across all four years, female students reported decreased support for their own PC behaviors compared to male students (mean 4.15 vs. 3.83, $P=0.03$). Qualitative analysis of students’ responses to survey items asking about their most positive PC experiences revealed the following themes as important to students: (1) explicit PC teaching in the curriculum, (2) positive role modeling, (3) independent time to interact with patients, and (4) students’ views of themselves as patient advocates. Themes that were identified from descriptions of students’ most negative PC experiences are the following: (1) negative role modeling (with subthemes of ignoring patient concerns, poor communication, and lapses in professionalism), (2) students discouraged from performing PC behaviors, and (3) objectification/lack of humanism.

CONCLUSIONS: In this single-institution study, students’ reports of patient-centeredness decreased as students progressed from preclinical to clinical years. Female students reported less support for their own PC behaviors. Themes from the qualitative analysis indicated that formal learning methods in courses and on clinical teams contributed to PC learning experiences. Positive and negative role modeling were also important. This study could serve as a needs assessment for improving the PC education that medical students receive and for examination of potential changes in learning environments in the preclinical and clinical years in other schools.

MEDICARE FEE CUTS AND PHYSICIAN-HOSPITAL INTEGRATION Zirui Song^{2, 1}; Jacob Wallace³; Hannah Neprash³; Michael McKellar¹; Michael E. Chermew¹; J. Michael McWilliams¹. ¹Harvard Medical School, Boston, MA; ²Massachusetts General Hospital, Boston, MA; ³Harvard University, Boston, MA. (Tracking ID #2193920)

BACKGROUND: Physician practices are increasingly integrating with hospitals. For physicians, the expansion of risk contracts (e.g. accountable care organizations) makes independent practice more challenging. For hospitals or health systems, acquiring practices helps them control referral patterns, coordinate care, and improve their bargaining power with payers. Physician fee cuts might also accelerate integration by reducing payments in the office relative to the hospital setting. In cardiology, for example, Medicare cut office-based fees by 10–40 % in 2010. Office payment for a myocardial perfusion image was cut 26 % and for an echocardiogram 16 %, while hospital outpatient department (HOPD) fees for these services remained relatively unchanged. This widened the already existing payment gap favoring HOPDs—by 2013, an echocardiogram cost Medicare 141 % more in HOPDs than in the office. The American College of Cardiology (ACC) projected a surge of integration, with physicians giving up ownership for more predictable salaries. Understanding to what extent this happened is important given current fee cut debates.

METHODS: We analyzed 2007–2012 claims in a continuously-enrolled national sample of traditional Medicare beneficiaries and commercially-insured adults. We studied prices and volume in the office versus HOPD setting before and after the fee cut. We measured physician-hospital integration by calculating the share of volume billed in HOPDs. This captures both shifts in care to HOPDs and changes in practice patterns induced by integration. We focused on 3 categories of services—myocardial perfusion imaging (MPI), echocardiograms, and electrocardiograms—as well as cardiovascular imaging in aggregate and cardiovascular medicine services in aggregate. We expected estimates to trend in the same direction. As falsification tests, we examined endoscopies, which can be provided in the office or HOPD but did not undergo a fee cut, and office visits, which are billed by physicians across specialties. We used segmented regression to assess changes in integration growth after the fee cut. Independent variables included age, sex, trend, post-intervention indicator, and the interaction between post-intervention and trend. We also included quarter and metropolitan statistical area (MSA) fixed effects, and risk scores where possible. In sensitivity analyses, we tested alterations in the variables and model. Standard errors were clustered by MSA.

RESULTS: Our sample included 806,266 Medicare beneficiaries averaging 75.7 years old, 53.3 % female, representing all states, and 12,567,069 commercially-insured individuals between 55 and 64 years of age, 52.8 % female, with a similar geographic distribution. Across all services, prices favored the HOPD setting after 2010. In Medicare, 21.1 % of MPI took place in HOPDs before the fee cut; this increased to 32.4 % after the fee cut. Growth in the HOPD share was 5.9 percentage points per year ($p < 0.001$) faster after 2010. Similarly, 22.1 % of echocardiograms and 29.9 % of electrocardiograms were done in HOPDs before 2010. After 2010, these increased to 31.7 and 35.2 %, respectively. HOPD shares grew faster by 3.9 and 2.7 percentage points per year ($p < 0.001$), respectively, after 2010. Aggregate analyses of all cardiovascular imaging and cardiovascular medicine services produced qualitatively similar results. Similar results were also found in commercial populations, suggesting that integration was associated with comparable effects across payers. Sensitivity analyses supported the main estimates. In falsification tests, the share of endoscopies in HOPD did not change after 2010. Moreover, the HOPD share growth of office visits before 2010 was lower than that of cardiovascular services, suggesting that cardiologists were not integrating faster before the fee cut.

CONCLUSIONS: Integration accelerated after the fee cuts. This is consistent with the 2010 ACC Practice Consensus, which found that 40 % of cardiologists planned to integrate with hospitals due to the fee cuts and 13 % were considering it. The Medicare Payment Advisory Commission estimated that if cardiac imaging alone continued to migrate to HOPDs, nearly all would be provided there by 2021 costing an additional \$1.1 billion per year to Medicare and \$290 million per year in beneficiary cost-sharing. Our results may not be causal or generalizable. The effect of any given fee cut depends on its magnitude and substitution opportunities from higher-margin services or payers. Ultimately, integration may offset fee cuts, both because facility fees are higher and because of higher prices via market power. HOPDs can be appropriately more expensive due to costs of maintaining standby capacity, licensing requirements, ancillary services, and more complex patients. But it may be inappropriately expensive if equivalent quality care can be delivered in the office. Policies to narrow payment differences across settings may be increasingly discussed given potential fee cuts across payers.

MEETING THE PRIMARY CARE NEEDS OF TRANSGENDER PATIENTS: USING AN OBJECTIVE STRUCTURED CLINICAL EXAM CASE TO ASSESS RESIDENT PHYSICIANS' ABILITY TO PROVIDE PRIMARY CARE TO TRANSGENDER PATIENTS Richard E. Greene; Colleen Gillespie; Kathleen Hanley; Jennifer Adams; Sondra Zabar. NYU School of Medicine, New York, NY. (*Tracking ID #2198889*)

BACKGROUND: Transgender patients often report limited access to comprehensive, affirming primary care and many providers report inadequate knowledge and training in transgender health issues. We developed a transgender health OSCE case in order to assess resident physicians' comfort with and skills in addressing routine health concerns of a transgender patient.

METHODS: The transgender health case involved a 45-year old transgender woman is returning a month after a brief initial visit for a routine check-up to monitor her blood pressure and follow-up on blood tests. The clinical challenge for residents is to address the patient's high potassium levels which are associated with the androgen suppressant she is taking (spironolactone). This case was completed by 24 primary care internal medicine residents as part of a 10-station annual OSCE. A highly trained standardized patient (SP) rated the core communication and patient activating skills of the residents as well as specific items tailored to each clinical case which for this case included: asking about gender identity, eliciting medically relevant information regarding transition (use of hormones, surgery history), and recognizing link between androgen suppressant and high potassium levels and importance of this medication to the patient. Assessment items used a behaviorally anchored scale with not done, partly done and well done as response options. Frequencies are reported for specific items assessing transgender health competencies and mean communication s and patient activating scores were compared between this case and other OSCE cases using repeated measures ANOVA. SP's comments about the performance of residents are reported as were residents comments about the case, collected through a survey administered after the OSCE.

RESULTS: While overall communication and patient activating scores for this case did not differ significantly from other cases in the same OSCE, results suggest both strengths and weaknesses in residents' comfort with and skills in addressing transgender health issues. Eighty-five percent of residents fully and sensitively elicited relevant medical information regarding transition, 71 % recognized the link to high potassium levels, and 88 % recognized the importance of the androgen suppressant medications to the patient. However, only 38 % directly asked about the patient's gender identity and 58 % made the patient feel comfortable, normalizing her gender identity and not making her feel different than other patients. The SP reported that most residents treated her with sensitivity although one resident suggested a referral to a psychiatrist and another said that she "was not my typical patient". Residents reported not being as familiar with transgender health issues as they would have liked as well as wanting to become more comfortable addressing transgender health, "being honest about" what the resident didn't know, and generally knowing more about transition and how to ask questions about gender identity and transition in a sensitive manner.

CONCLUSIONS: Performance in this case and residents' self-reports suggest the need for greater education and training in both core transgender health issues and in how to provide affirming and supportive healthcare. While most residents addressed the core health issues faced by this transgender patient, fewer residents appeared fully comfortable exploring her gender identity and experiences.

MENTAL HEALTH TRAINING NEEDS ASSESSMENT IN INTERNAL MEDICINE RESIDENCY PROGRAM Lucille M. Torres-Deas²; Angela Jeffers²; Kristin A. Swedish²; Viraj V. Patel¹; Deborah Swiderski². ¹Albert Einstein College of Medicine, Bronx, NY; ²Montefiore Medical Center, Bronx, NY. (*Tracking ID #2198906*)

BACKGROUND: Mental health disorders are prevalent in primary care; however, it is unknown if internal medicine residents feel prepared to address mental health in the primary care setting and what gaps may exist in their training. We conducted a needs assessment to evaluate internal medicine residents' training needs on depression, anxiety, and psychological distress to inform curricular development and improvements.

METHODS: We conducted a cross-sectional survey assessing the attitudes towards training needs on diagnosis, counseling, and pharmacological management of depression and anxiety, and diagnosis and counseling of psychological distress to internal medicine housestaff in the categorical and primary care tracks at a large urban academic medical center between November 2013–April 2014. Measures were adapted from a survey that was administered to residency training directors published by Leigh, et al. in 2005. We also collected information on year of training, residency track category (primary care vs. categorical), future career plans, gender, and attitudes regarding the role of primary care providers providing mental health care. We conducted descriptive analysis calculating means and frequencies using SPSS 18.

RESULTS: Seventy-six of 159 (48 %) residents completed the survey between November 2013–April 2014, of which 65 % were from the categorical track and 35 % from the primary care track. The majority of residents indicated receiving some education in diagnosis and pharmacological management of depression, anxiety, and psychological distress. Less than half had received training in counseling, regardless of program (categorical vs. primary care). Most residents felt that their training in the diagnosis of depression, anxiety, and psychological distress was adequate, but fewer felt that their training in counseling of patients with depression (50 %), anxiety (43 %) and psychological distress (58 %) was adequate. Regarding pharmacological management of depression and anxiety, 53 and 33 % (respectively) felt that their training was adequate. The majority of responders desire more education in counseling patients with depression (68 %), anxiety (64 %), and psychological distress (71 %) and in the pharmacological management of depression (68 %) and anxiety (76 %). Eighty percent believe that primary care providers should treat uncomplicated psychiatric conditions. Fewer than half of responders did not think that any patient with a psychiatric condition needed to be referred to a psychiatrist.

CONCLUSIONS: While most residents had received training in diagnosis and pharmacological management in common mental health problems seen in primary care, the majority felt that they would like more training to develop their skills to address mental health issues in counseling and pharmacological management. Curricula addressing these skills may help fill important gaps in resident education.

MOBILE TECHNOLOGY ACCESS, USAGE, AND ATTITUDES AMONG LOW-INCOME, MINORITY INDIVIDUALS IN EAST HARLEM, NY Victoria L. Mayer^{1, 1}; Kezhen Fei¹; Brigitte Buquez¹; Rennie Negron¹; Ellen P. Simon²; Carol R. Horowitz^{1, 1}. ¹Icahn School of Medicine at Mount Sinai, New York, NY; ²Union Settlement Association, New York, NY. (Tracking ID #2199397)

BACKGROUND: Chronic diseases and their complications disproportionately affect low-income and racial/ethnic minority populations in the United States. Mobile technology, accessible on hand-held cellular phones and smartphones, has been championed as a method of improving population health and reducing health disparities. The Pew Research Center estimates that nationally over 90 % of African-American, Hispanic/Latino and White adults own cell phones, as do 84 % of those with a household income under \$30,000; 14 % of adults use technology to track health. Few studies have examined mobile technology use related to health in specific vulnerable populations. As part of a community-driven process of developing a technology platform to disseminate diabetes-prevention strategies, we characterized access to, usage of, and attitudes towards mobile technology, particularly for health promotion purposes, in East Harlem, NY.

METHODS: Members of the Community Action Board (CAB) of the East Harlem Partnership for Diabetes Prevention, a 10-year old community-academic collaboration, were involved in all stages of survey design, data collection, and analysis. Survey items included questions from the Pew Research Center surveys on technology use, supplemented by items developed by CAB members related to preferences for a diabetes prevention app and use of social media for community change. After survey piloting and revision, we invited English- and Spanish-speaking adults to complete the five minute written or verbally administered survey. We utilized a convenience sample of adults attending Community Based Organizations, including a food pantry, a school, a church, several social service delivery sites and health clinics. We examined the demographics of our sample, frequency data for each item, and relationships between demographics and electronic health tracking, using chi-square tests and multivariable logistic regression models.

RESULTS: We surveyed 104 individuals (67 % response rate); 73 % were female, 65 % Hispanic and 26 % African-American. The mean age was 37 years old (SD 13). Many were low-income (48 % with <\$30,000 in income/year), 40 % had less than a high school education and 36 % were uninsured. Most (82 %) owned a cell phone, 87 % of whom had smartphones. Of smartphone owners, 39 % reported having an app to help track or manage their health (30 % for exercise, 13 % diet, 4 % diabetes). Respondents were interested in using their phones to share information to change their community (62 %), recognize symptoms of health problems (87 %), prevent diabetes (77 %), find out about local health events (70 %), and track exercise and diet (69 %). Many (69 %) were concerned about maintaining privacy while online. African-Americans were more likely to track their health electronically (through website,

online tool or smartphone) (41 % vs. 12 % of Hispanic/Latinos vs. 10 % of those of other race/ethnicity, $p=0.004$). Respondents who had graduated from high school were more likely to track their health information electronically (27 % vs. 5 % of those with less than a high school education, $p=0.006$). There were no significant differences in health tracking by income or gender. Multivariable logistic regression indicated that while African-Americans were more likely to track health electronically (OR 4.22; 95 % CI: 1.28–13.88), this effect was no longer significant after adjusting for education (OR=2.46; 95%CI: 0.66–9.23).

CONCLUSIONS: This population of low-income minority adults has high cellular and smartphone ownership, and many use apps to manage their health. Despite privacy concerns, many more would like to use health promoting apps that not only provide interactive individualized health tools, but also offer information about health and local resources and allow users to participate in promoting social and community change. In order to reach vulnerable populations, mobile tools for health promotion will need to be tailored, especially for those with less than a high school education.

MOBILIZATION OF VULNERABLE ELDERLY IN ONTARIO (MOVE ON): A MULTISITE INTERRUPTED TIME SERIES EVALUATION OF AN IMPLEMENTATION INTERVENTION TO INCREASE PATIENT MOBILIZATION Barbara A. Liu^{1, 2}; Julia E. Moore³; Ummukulthum Almaawiy¹; Wai-Hin Chan³; Sobia Khan³; Jemila Hamid³; Jocelyne Ewusie⁴; Sharon Straus³. ¹Regional Geriatric Program of Toronto, Toronto, ON, Canada; ²Sunnybrook Health Sciences Centre, University of Toronto, Toronto, ON, Canada; ³Li Ka Shing Knowledge Institute of St Michael's, University of Toronto, Toronto, ON, Canada; ⁴McMaster University, Hamilton, ON, Canada. (Tracking ID #2194865)

BACKGROUND: Older patients admitted to hospital are at risk for hospital-acquired morbidity related to immobility. During hospitalization, older patients spend a median of 4 % of the day out of bed. Bed rest is associated with multiple complications including delirium, decubitus ulcers, venous thrombosis, pneumonia, and muscle atrophy. One of the most profound and immediate effects of bed rest is the loss of muscle strength. Each day spent immobile is associated with 1 to 5 % loss of muscle strength. In a vulnerable senior, this can quickly result in the loss of ability to transfer and ambulate independently, key functional abilities required for return to living in the community. The objective of this project was to implement and evaluate the impact of an evidence-informed strategy to promote early mobilization and prevent functional decline in older patients admitted to hospitals in Ontario.

METHODS: We used an interrupted time series design to evaluate the impact of the intervention over the course of 3 time periods—pre-intervention (10 weeks), during intervention (8 weeks) and post-intervention (20 weeks). The study took place in 14 hospitals in Ontario, Canada and included patients aged 65 years and older who were admitted to inpatient medicine units between January 2012 and December 2013. The early mobilization implementation strategy was multi-component and tailored to the local context, but all hospitals implemented three core messages: 1) patients should be assessed for mobilization status within 24 h of admission; 2) mobilization should occur at least three times a day; 3) mobilization should be progressive and scaled. The primary outcome was patient mobility assessed by visual audits of “out of bed” status. Secondary outcomes included length of stay, discharge destination, falls and functional status.

RESULTS: Thirteen thousand five hundred eighty-three patients (mean age 79.9 years (SD=8.32) participated. Compared to pre-intervention, during the intervention 3.12 % more patients were out of bed per day (slope change=0.40 % (95 % CI: [-0.32, 1.11]) compared to pre-intervention). After the intervention, mobilization continued to increase (slope change=0.31 %, 95 % CI: [-0.13, 0.75], compared to pre-intervention) with 10.56 % (95 % CI: [4.94, 16.18]; $p=0.0002$) more patients out of bed per day at the end of the study period compared to pre-intervention. Median length of stay post-intervention was 6.1 (95%CI: [-11, -1.2]; p -value=0.0147) days shorter than pre-intervention.

CONCLUSIONS: This is the first large scale study to evaluate an early mobilization knowledge translation strategy in older, general medical patients. The positive outcome of this educational intervention on an important functional goal of getting more patients out of bed is a striking success for improving care for hospitalized older patients. Several factors likely contributed to the success of this intervention, including: tailoring the intervention to local context; using implementation coaches; and planning for sustainability.

Weekly visual audit results for out of bed status

MODELING INDIVIDUAL (RATHER THAN SOCIETAL) PREFERENCES FOR COLORECTAL CANCER SCREENING Glen B. Taksler, Cleveland Clinic, Cleveland, OH. (Tracking ID #2197834)

BACKGROUND: Colorectal cancer screening is generally recommended for individuals aged 50–75 years. From a societal perspective, there are large benefits, about 200–270 life-years gained per 1000 persons screened. On average, each person gains 2–3 months of life expectancy. However, gains are not evenly distributed, as most individuals experience negligible harm (due to discomfort of test preparation), a few individuals gain many years and the rare individual experiences serious harm. The optimal screening strategy for an individual depends on how s/he values these different outcomes based on attitudes toward risk. We devised a model to recommend personalized colorectal cancer screening strategies based on individual preferences.

METHODS: We modeled a hypothetical individual's decision to screen for colorectal cancer, based on his/her individual preferences, rather than societal goals. Every year, the individual could choose between screening and not screening for disease using 3 methods: colonoscopy, flexible sigmoidoscopy, or fecal occult blood testing (FOBT). An individual who screened realized a large probability of no change in life-years (associated with a negative screening test, or positive screening test with late diagnosis), a small probability of additional life-years (associated with early diagnosis), and a small probability of screening test complications. An individual who did not screen realized no change in survival probabilities. Risk preferences were assessed by simulating the increase in life expectancy that an individual would require to accept the potential for serious harm from screening (defined as perforation, hemorrhage, other events requiring hospital admission, or death from colonoscopy or flexible sigmoidoscopy; minimal risk from FOBT). Each pattern was informed by baseline life expectancy, obtained from national life expectancy tables. We then estimated expected lifetime utility by summing the probability distributions for life-years survived in each scenario, each multiplied by individual utility as a function of remaining life expectancy. Using data from the Surveillance, Epidemiology, and End Results (SEER) survey between 2000–2011, we estimated expected utility for combinations of screening method, frequency, start and stop ages (colonoscopy, every 1–20 years; flexible sigmoidoscopy, every 1–10 years; FOBT, every 1–3 years; start age, 20–75 years, stop age, 20–75 years) as compared with no screening, and rank-ordered results, to help understand how individual preferences impact screening decisions. Sensitivity analyses extended the maximum allowable age of screening cessation to 85 years.

RESULTS: For an average-risk individual whose preferences mirrored those of guideline-recommended care (requiring only actuarial gains in life expectancy to be willing to undergo screening—about 2 months for colonoscopy), the model predicted that s/he would choose to undergo colonoscopy every 11 years, from age 53–75 years, nearly identical to national guidelines. However, for a similar individual who was moderately

risk-averse (requiring a 4-month increase in life expectancy to be willing to accept the potential risks of colonoscopy), the model predicted that s/he would prefer to undergo colonoscopy every 14 years, still obtaining 3 lifetime colonoscopies, but over a longer time period than currently recommended. For an individual with higher risk aversion (7-month required increase in life expectancy), the model predicted that s/he would prefer to undergo just 2 lifetime colonoscopies, at ages 52 and 72 years. Biannual FOBT was predicted in individuals at high-risk of screening-related complications, such as bleeding from polypectomy for patients with severe systemic disease. Therefore, although informed individuals may screen less-often than guideline-recommended, they still should choose to obtain voluntary, regular screening. By contrast, for an individual who poorly understood the benefits of early detection (such as incorrectly assuming that a 2–3 month increase in life expectancy would occur with certainty, rather than a larger benefit with cancer diagnosis and minimal-to-no benefit without cancer diagnosis), the model predicted that s/he would prefer triennial FOBT or no screening, depending on risk aversion.

CONCLUSIONS: Quantitative models might help individualize colorectal cancer screening based on patient preference. Future research should consider the potential of such recommendations to improve patient adherence, and how to reduce the gap between individual-preferred vs. guideline-recommended frequency.

MOTIVATIONAL INTERVIEWING IMPROVES MEDICATION ADHERENCE

Ana M. Palacio²; Benjamin Langer²; Desiree Garay²; Janielle Taylor²; Barbara A. Wood¹; Leonardo Tamariz². ¹University of Miami, Miami, FL, ²University of Miami, Miami, FL. (Tracking ID #2198249)

BACKGROUND: Motivational Interviewing (MI) is among the few interventions reported to improve adherence that can be easily disseminated. To determine the effect of MI on adherence to medications and the impact that delivery format, length, and intensity of the intervention have on objective and subjective measures of adherence.

METHODS: We searched the MEDLINE database for studies published from 1966 until September 2014. We conducted manual searches of bibliographies of key relevant articles. We included randomized trials that compared MI to one or more control groups and reported a numerical measure of medication adherence. Two pairs of reviewers abstracted data on previously developed tables and used the CONSORT form to evaluate quality. The main outcome was medication adherence defined as any subjective or objective measure reported as the percentage of subjects adherent at 80 % or higher.

RESULTS: We included 16 studies that randomized 1123 subjects into the MI arm and 900 subjects to the control group. The RR of being adherent for MI was 1.13; (95 % CI 1.05–1.22) when compared to a control. Comparing MI delivered in different formats (figure) against the control group, the RR of being adherent was 1.17; (95 % CI 1.04–1.33)

for in person individual MI, 1.14; (95 % CI 1.08–1.21) for telephonic MI and 1.26; (95 % CI 0.90–1.78) for group MI. The impact on adherence was more consistent for interventions with 6–12 months of follow up and those with 4–6 MI encounters ($p < 0.01$).

CONCLUSIONS: MI delivered in person or by phone successfully improves medication adherence. Studies that compare different targeting and delivery approaches in real world settings are needed.

MULTIMORBIDITY AND MORTALITY IN COMMUNITY-DWELLING WOMEN: SIMPLE DISEASE COUNTS, THE CHARLSON INDEX, AND A NOVEL MULTIMORBIDITY WEIGHTED INDEX Melissa Y. Wei^{1,2}; Kenneth Mukamal^{1,2}.
¹Beth Israel Deaconess Medical Center/Harvard Medical School, Boston, MA; ²Harvard T.H. Chan School of Public Health, Boston, MA. (Tracking ID #2199692)

BACKGROUND: The Charlson comorbidity index was developed and validated to predict inpatient mortality and is one of the most cited methods for comorbidity adjustment in hospital, clinic, and population-based research studies. We developed and internally validated a Multimorbidity Weighted Index (MWI) that weights 81 chronic diseases and conditions by their impact on physical health-related quality of life (HRQOL) in three large cohorts of community-dwelling adults, the Nurses' Health Study (NHS), NHS II, and Health Professionals Follow-up Study (HPFS). Diseases varied several-fold in their impact on physical HRQOL. We assessed the criterion validity of the Multimorbidity Weighted Index and compared it with other metrics for mortality prediction in the NHS and HPFS cohorts of middle-aged and older adults. Our index provided the best fitting model and had excellent discrimination for 10-year mortality prediction compared with the Charlson index and simple disease count. Our current study extends prior work by examining the MWI and mortality prediction in young and middle-aged women.

METHODS: NHS II is a prospective cohort of 116,686 female nurses aged 25–42 years when participants enrolled in 1989. We included NHS II participants who completed a questionnaire in 2001 on physician-diagnosed diseases and conditions and had complete follow-up through December 31, 2010. The Multimorbidity Weighted Index, disease count, and Charlson index were examined as continuous and categorical variables. Incident rate ratios for models with the best performance (minimum Akaike Information Criterion, AIC) were estimated using Cox proportional hazards modeling. To quantify how accurately the model discriminates between survival outcomes, we computed the concordance (C) statistic for survival analysis, where 0.5 indicates discrimination due to chance, and 1 indicates perfect discrimination. The Cox proportional hazards assumption was not violated based on Schoenfeld residuals.

RESULTS: In 2001, 95,122 participants had a mean age of 46 (SD 5) years, multimorbidity index of 2.9 (median 1.8, range 0–35), disease count of 2.2 (median 2.0,

range 0–18), and Charlson index of 0.20 (median 0, range 0–7). After follow-up, 1260 (1.3 %) deaths occurred. The Multimorbidity Weighted Index spanned the widest distribution of multimorbidity. Eighty-seven percent of adults had a Charlson index of 0 compared with 20 % of adults with a multimorbidity index and disease count of 0. Participants with the highest quartile multimorbidity index had nearly quadruple the hazard rate of mortality than those in lower quartile (Hazard Ratio, HR 3.95, 95 % CI: 3.23–4.41, p-trend <0.0001). The HR was 3.33 (95 % CI: 2.74–4.04, p-trend <0.0001) for the highest vs. lowest quartile of disease count. For the Charlson index, the hazard ratio could only be computed for the highest decile versus all other deciles: HR 4.48 (95 % CI: 4.00–5.01, p<0.0001). The multimorbidity index yielded the minimum AIC (AIC 28403 quartiles, 28313 linear) compared with disease count (AIC 28489 quartiles, 28363 linear). The C-statistics for quartiles of mortality were marginally higher for the multimorbidity index (0.69, 95 % CI: 0.67–0.71) compared with disease count (0.67, 95 % CI: 0.65–0.70). The multimorbidity index was only moderately correlated with Charlson (Pearson $r=0.44$) and strongly but not perfectly correlated with disease count ($r=0.87$).

CONCLUSIONS: In this cohort of over 95,000 young and middle-aged women, the Multimorbidity Weighted Index and disease count were applicable across a wide distribution of multimorbidity. The multimorbidity index was significantly associated with 9-year mortality and provided the best-fitting model and discrimination compared with disease count. In contrast, 87 % of participants did not have a Charlson index. While the Charlson index accurately predicted mortality, its use was limited to the few participants with a calculable Charlson index. Thus, the Multimorbidity Weighted Index may be a more appropriate method for mortality prediction and risk-adjustment in this sample of women with increased mortality risk from diseases and conditions captured in the multimorbidity but not Charlson index. Our easily computed and implemented Multimorbidity Weighted Index was sensitive to the accumulation and severity of diseases with increased mortality, which may enable earlier opportunities to intervene in multimorbidity progression in young and middle-aged community-dwelling adults.

MUSLIM PATIENTS AND HEALTH CARE UTILIZATION DURING RAMADAN Nadaa Ali¹; Harry Reyes Nieva²; Sanja Percac-Lima³; Helen M. Shields¹; Jeffrey A. Linder¹; Nora Osman². ¹Brigham and Women's Hospital, Boston, MA; ²Brigham and

Women's Hospital/Harvard Medical School, Boston, MA; ³Massachusetts General Hospital, Chelsea, MA. (Tracking ID #2191681)

BACKGROUND: During the month-long fast of Ramadan, Muslims abstain from food and water from sunrise to sunset. Whether clinicians counsel Muslim patients about fasting during Ramadan, and whether fasting during this month, increases healthcare utilization has not been previously examined. To describe demographic differences between Muslim and non-Muslim primary care patients; to measure rates of counseling and health care utilization for Muslim patients during Ramadan compared to non-Muslim patients.

METHODS: We conducted a retrospective review of Partners HealthCare billing and electronic medical records of Muslims and non-Muslims who made at least one primary care visit during Ramadan or the month prior from 2008 through 2013. We measured the rates of primary care visits, emergency department (ED) visits, and hospitalizations during Ramadan. To assess rates of counseling about fasting during Ramadan, we conducted text analysis of physician notes to detect mention of Ramadan or Muslim faith during and within 30 days of the start of Ramadan. To evaluate the independent association of Muslim faith with health care utilization during Ramadan, we used multivariate negative binomial regression models adjusted for patient factors and baseline visit rates.

RESULTS: There were 2069 Muslim and 128,916 non-Muslim patients during the study period. Muslim patients were younger (mean age 44 versus 51 years); less educated (10 % had an 8th grade education or less versus 4 %); less often commercially insured (81 versus 91 %); and more likely to have Medicaid (17 % versus 4 %; $p < 0.0001$ for all comparisons). The prevalence of diabetes was significantly higher in Muslims (14 % versus 12 %; $p = 0.003$). The primary care visit rate for Muslim patients was 1394 per 1000 patients the month before Ramadan and 1361 per 1000 during Ramadan ($p = 0.39$). Hospitalization rates for Muslim patients were 77 per 1000 patients the month before Ramadan and 84 per 1000 patients during Ramadan, respectively ($p = 0.43$). For Muslim patients, the ED visit rate was 49 per 1000 patients the month before Ramadan and 46 per 1000 patients during Ramadan ($p = 0.70$). In multivariate models, during Ramadan, Muslims had a higher rate of primary care visits (odds ratio [OR], 1.05; 95 % confidence interval [CI], 1.03–1.08), ED visits (OR, 1.68; 95 % CI, 1.44–1.95), and hospitalizations (OR, 1.23; 95 % CI, 1.07–1.41) compared to non-Muslims during Ramadan. For Muslim patients, mention of Ramadan or Muslim faith in primary care visit notes was low (2 %) the month prior to Ramadan and increased to 5 % during Ramadan ($p < 0.0001$).

CONCLUSIONS: Muslims were more likely to visit primary care physicians, the ED, or hospital during Ramadan. Clinicians mentioning Ramadan or Muslim faith increased during Ramadan, but it remained very low. Efforts to decrease healthcare utilization during Ramadan and improve care for Muslims require further analysis, physician and patient education, and potentially health system and public health interventions.

NATIONAL ESTIMATES OF DISPARITIES IN AMBULATORY CARE SENSITIVE CONDITION HOSPITALIZATIONS AMONG HISPANICS Chen Feng²; Nancy R. Kressin^{2, 3}; Michael Paasche-Orlow⁴; Lenny Lopez¹; Jennifer E. Rosen⁵; Amresh D. Hanchate^{2, 3}. ¹Harvard University, Boston, MA; ²Boston Medical Center/ Boston University School of Medicine, Boston, MA; ³Dept of Veterans Affairs and Boston University, West Roxbury, MA; ⁴Boston University, Boston, MA; ⁵MedStar Washington Hospital Center, Washington, DC. (Tracking ID #2197901)

BACKGROUND: Hispanics, the largest minority nationally, are at higher risk of inadequate access to healthcare, due to relatively higher rates of uninsurance compared to (non-Hispanic) whites and blacks. However, limits in national data, including misreporting Hispanic ethnicity, have restricted research on access barriers based on actual health care utilization. With a view to develop a national estimate of disparities in access barriers among Hispanics, relative to whites and blacks, we pooled comprehensive inpatient administrative data from 15 states containing over 85 % of the national Hispanic population. Following the Agency for Healthcare Research & Quality (AHRQ), we estimated the prevalence of admissions for ambulatory care sensitive conditions (ACSCs), including heart failure, pneumonia, and diabetes, as an indirect measure of access barriers to timely and good quality outpatient care.

METHODS: We identified the 15 states—Arizona, California, Colorado, Florida, Massachusetts, Maryland, Nevada, New Jersey, New Mexico, New York, Oregon, Pennsylvania, Texas, Virginia and Washington—based on the size of Hispanic population and completeness of patient race/ethnicity data, and obtained comprehensive inpatient administrative data for 2010–2011. We pooled these data and identified admissions with the principal diagnosis of one of the 12 ACSCs relating to adults aged 18 and older in accordance with the AHRQ Prevention Quality Indicators (PQI) protocol. Data on counts of ACSC admissions and census population, stratified by state, race/ethnicity, age, and sex were used to estimate ACSC admission rates per 100,000 population by direct standardization. We further adjusted for socioeconomic status (SES)—using zip code median income—and county-level indicators of provider availability using Poisson regression models, and obtained relative rates of ACSC admissions among Hispanics and blacks relative to whites, expressed in terms of the incidence rate ratio [IRR]. In addition, to examine heterogeneity among Hispanics, we compared prevalence rates by national origin grouped into four categories: Mexican, Puerto Rican, Cuban and Others.

RESULTS: We identified 3,631,028 ACSC admissions by patient race/ethnicity: Hispanics (13 %), blacks (16 %), whites (64 %), others (5 %) and missing (2 %). The most common ACSCs were heart failure (22 %), chronic obstructive pulmonary disorder (20 %) and pneumonia (18 %); this pattern was similar across race/ethnicity. Crude ACSC admission rates for Hispanics were higher than among whites, but lower than among blacks, in all 15 states. Adjusting for age, sex and state, the overall ACSC admission rate among Hispanics (1427 per 100,000 population; IRR 1.11, 95 % CI [1.07, 1.14]) was higher than among whites (1269). However, after additional adjustment for indicators of SES and provider availability, this disparity was reversed, with lower relative rates among Hispanics (IRR 0.96, 95 % CI [0.93, 0.98]). In contrast to Hispanics, ACSC rates were consistently higher among blacks, relative to whites, across both models. Among Hispanics, Cuban Hispanics had the highest ACSC rate, and the other nationality groups had similar rates.

CONCLUSIONS: Based on near-national data for Hispanics, we found that crude rate of ACSC admissions among Hispanics was 11 % higher compared to whites, and this difference was largely mediated by differences in socioeconomic status and provider

availability. In contrast, both crude and adjusted ACSC rates for blacks were higher compared to whites. **Keywords:** Hispanics, disparity, race, ethnicity, ambulatory care sensitive conditions

NATIONAL TRENDS IN PRIMARY CARE VISITS BY OLDER ADULTS AT SAFETY NET SITES, 2006–2010 Anna H. Chodos^{1, 3}, Kanan Patel¹, W. John Boscardin¹, Christine Ritchie², ¹UCSF, San Francisco, CA; ²University of California San Francisco, San Francisco, CA; ³UCSF, SFGH, San Francisco, CA. (Tracking ID #2198726)

BACKGROUND: Socioeconomically disadvantaged adults aged 65 and older (“older adults”) are a growing demographic. Safety net settings are an important source of care for this population, and may experience increasing demand for care from this demographic. We describe recent trends and characteristics of older adults’ visits in safety net primary care to understand the potential impact of growing health care demand from this demographic in this sector.

METHODS: Using nationally-representative annual survey data, the National Ambulatory Medical Care Survey and National Hospital Ambulatory Medical Care Survey, we examined the number of primary care visits among adults seen at safety net sites, which includes community health centers and safety net hospital outpatient departments. We defined primary care as ambulatory care visits to any physician or mid-level provider in general medicine, general practice, internal medicine, or family medicine. We compared utilization in older adult age groups (≥65) to those of middle-age (45–64) and younger adults (18–44) using a linear trend test. We also describe characteristics of visits, including among older adult subgroups by age (65–74, 75–84, 85+). Survey data were analyzed with established survey weights.

RESULTS: From 2006 to 2010, older adults’ visits accounted for 17.9 % of all visits among adults ≥18. Adults 85 and older accounted for 1.7 % of all visits. For trends among adult age groups, see Table 1 showing visits by year. There were no significant trends in patient characteristics associated with visits in the 5-year period. However, we present selected characteristics by age group in a representative year, 2010. Table 2 shows that older adults in all age subgroups have a higher prevalence, compared to adults 18–44 and 45–64, of living in a rural area; having Medicare or Medicare and Medicaid; not being a current smoker; having more chronic conditions; having 6 or more visits in the last year (i.e. frequent visits); and being seen for a chronic condition.

CONCLUSIONS: Primary care visits among older adults at safety net sites, including those 65 and older, was stable from 2006 to 2010, and there were no clear trends in demographic or visits characteristics among older age subgroups. However, they represent a distinct group compared to younger adults (<65 years) in that they are sicker, use visits more frequently and for chronic care. As numbers of older adults with socioeconomic disadvantage increase, particularly after 2011 due to the aging of the baby boomer cohort, more may seek care at safety net sites and this trend should be monitored to inform resource allocation.

NEED TO REBOOT? RETENTION OF PATIENT-CENTERED EMR USE SKILL Wei Wei Lee; Lolita Alkureishi; Jeanne M. Farnan; Vineet M. Arora. University of Chicago, Chicago, IL. (Tracking ID #2196169)

BACKGROUND: Studies demonstrate that Electronic Medical Record (EMR) use in exam rooms can be detrimental to patient-doctor communication. Despite rapid EMR adoption, few providers receive formal EMR-based communication skills training. Our aims are to 1) Evaluate retention of patient-centered EMR use skills one year after curricular intervention 2) Compare Observed Structured Clinical Exam (OSCE) performance of second-year medical students (2013-MS2s) who received training in 2013 to their subsequent performance as third-year students (2014-MS3s) and 3) Compare OSCE performance of 2014-MS3s, who received training, to 2013 MS3 students (2013-MS3s), who received no formal training.

METHODS: In 2013, MS2s received a 1-hour patient-centered EMR use lecture and participated in a group OSCE (1 student interacted with Standardized Patient (SP), 3 observed). The OSCE was repeated in 2014 for all MS3s who received training as MS2s. A historical control group of 2013 MS3 who did not receive training also completed the OSCE. We compared OSCE performance of 17 students with paired 2013-MS2 and 2014-MS3 data. OSCE performance of 2014-MS3s ($n=83$), who received training as MS2s, was compared to 2013-MS3s ($n=88$) who received no training.

RESULTS: Using a 16 item checklist (range: 15–80), standardized patient (SP) ratings of students ($n=17$) showed significantly lower performance 1 year after MS2 training [73.4 (SD=4.7) v. 60.8 (SD=14.8), $p=0.001$; average change score from 2013 to 2014= -12.6 (SD 13.3)]. SP ratings of 2014-MS3s ($n=83$) who received training 1 year ago, were not statistically different from the historical control group of 2013- MS3s ($n=88$) who received no training [60.8 (SD=13.4) vs 58.1 (SD=13.1)].

CONCLUSIONS: One year after receiving patient-centered EMR use training, students’ performance deteriorated to a level that was indistinguishable from a historical control group that received no training. These findings may reflect negative role-modeling from residents and faculty and support the need for continued training during third year for sustained change in practice.

NET HARMS OF AGGRESSIVE BLOOD PRESSURE CONTROL ON CARDIOVASCULAR EVENTS AND FALL INJURY IN OLDER AMERICAN ADULTS Lillian Min^{1, 4}, Eve A. Kerr³, Deborah A. Levine¹, Kenneth M. Langa^{1, 5}, Caroline Blaum², Timothy Hofer³, ¹University of Michigan, Ann Arbor, MI; ²New York University, New York, NY; ³University of Michigan and VA Center for Clinical Management Research, Ann Arbor, MI; ⁴Ann Arbor VA Medical Center, Ann Arbor, MI; ⁵Ann Arbor VA Medical Center, Ann Arbor, MI. (Tracking ID #2199448)

BACKGROUND: Treating systolic blood pressure (BP) of 150 mmHg with multiple medications prevents cardiovascular events and death. However, modest antihypertensive medication use is associated with an increase in fall injury risk. It is unclear whether the harms outweigh the benefits, and whether the net effects vary by degree of BP control. We aimed to quantify the net effect of increasingly aggressive hypertension control (AHC) on cardiovascular benefit versus fall-related harm in a nationally-representative sample.

METHODS: Longitudinal study of 5518 participants of the Health and Retirement Study (HRS) aged 65 or older with self-reported hypertension and taking BP medications, and who had BP measured at baseline by an enhanced HRS exam in 2008 or 2010 (two randomly-assigned, mutually exclusive cohorts). The sample was categorized by increasing AHC: (1) **untreated** SBP ≥160 mmHg, (2) **poorly controlled** and treated SBP ≥160 mmHg, (3) **adequate control**, defined as treated SBP 121–159 mmHg or untreated SBP 140–159 mmHg, and (4) **overly aggressive** SBP treated to <120 mmHg. The 120 and 160 mmHg cutoffs ensured that the over-and under-control groups were truly different from 140 mmHg. We determined the effect of AHC over a 2-year follow-up (2008–10 or 2010–12) on incidence of self-reported fall injury requiring medical care, acute stroke, myocardial infarction, and acute heart failure. We used multinomial logistic regression to consider fall injury only, any cardiovascular (CV) outcome, and both fall and CV outcome (compared to neither outcome), controlling for age at baseline and sex, to calculate net absolute changes in risk across increasing levels of AHC. We considered AHC classes first as a numeric predictor (where greater=more aggressive) and second as a categorical predictor. We calculated net effect of increasing AHC from one category to the next higher category, in units of absolute percentage points, with bootstrapped confidence intervals (95 %) around the net effect to determine statistical difference from zero.

RESULTS: Two-year incidence of fall injury (11 % overall) increased with age and was more prevalent than any CV event (5 % overall). Most of the sample ($n=3676$, 66 %) was classified in group 3 (BP 120–160 mmHg). Group 4, the over controlled group with BP < 120 mmHg, included $n=1037$ (19 %). The poorly controlled groups 1 and 2 were small ($n=223$ [4 %] and $n=582$ [11 %], respectively). When we considered AHC as a continuous predictor (greater=more aggressive), **per level of AHC increased risk of fall**

injury (RR 1.15 [95 % CI 1.0-1.3]), but not cardiovascular events (RR=1.08 [.81–1.44]) or both (RR=1.33 [.94–1.9]). When net harm was considered across advancing age, net harm was associated with group 4 (<120 mmHg) compared to group 3 (BP 120–160 mmHg). The net harm associated with overly-treated BP ranged from 2 absolute %-points at age 65, increasing to 10 absolute %-points at age 85, with net harm statistically different from zero above the age of 73 (Figure), mostly due to fall injury.

There were no differences in net benefit or harm between group 3 (120–160 mmHg) compared to the poorly-controlled groups (1 and 2).

CONCLUSIONS: Aggressiveness of BP control should be individualized by patient to steer clear of net harm, especially for older adults at advanced ages. Those with overly-controlled BP and at risk of net harm should be considered for de-escalation.

Figure 1: Patients who know their A1C goal

NON-MEDICAL USE OF PRESCRIPTION OPIOIDS AND EMERGENCY DEPARTMENT UTILIZATION: RESULTS OF A NATIONAL SURVEY Joseph W. Frank^{1, 2}; Ingrid A. Binswanger^{1, 3}; Susan L. Calcaterra¹; Cari Levy². ¹University of Colorado Denver, Denver, CO; ²VA Eastern Colorado Health Care System, Denver, CO; ³Kaiser Permanente Colorado, Denver, CO. (Tracking ID #2197865)

BACKGROUND: Drug overdose is the leading cause of accidental death among adults in the United States, and a majority of all prescription drug overdose deaths involve non-medical use (NMU) of prescription opioids. From 2004 to 2008, Emergency Department (ED) visits related to NMU of opioids increased by 111 %. ED-based interventions have shown promise in the treatment of alcohol use disorders, but little is known about the potential role of ED-based interventions to screen for and treat NMU of opioids. We sought to examine trends and correlates of ED utilization among a nationally representative sample of adults who report NMU of prescription opioids.

METHODS: We conducted a serial cross-sectional analysis of the 2008–2013 National Survey on Drug Use and Health (NSDUH), a nationally representative survey of the non-institutionalized U.S. civilian population (N=228,556). We identified adult respondents (age ≥18) with self-reported past year NMU of prescription opioids, defined as use of a prescription pain medication “that was not prescribed for you or that you took only for the experience or feeling it caused”. We examined the association between past year NMU of prescription opioids and self-reported past year ED utilization. Among adults reporting past year NMU of opioids, we examined sociodemographic and clinical correlates of past year ED utilization. Specifically, we assessed the following attributes of NMU of opioids: frequency of past year NMU (1–29 days, 30–99 days, 100–199 days, 200–365 days), source of prescription opioids (1 or more physicians, all other sources) and past year opioid withdrawal symptoms (Yes, No). We used the chi-square test to examine bivariate associations and multivariable logistic regression to adjust for sociodemographic characteristics, self-reported health status and other co-occurring substance use disorders. All analyses were conducted using SAS version 9.3.

RESULTS: In the United States, an estimated 10.5 million adults reported past year NMU of opioids, representing 4.6 % of U.S. adults. Past year ED utilization was more common among adults with past year NMU of opioid compared to the general population (39 % vs. 27 %, $P < .001$). Adults reporting past year NMU of opioids accounted for an estimated 9.4 million annual ED visits, representing 7.3 % of all annual ED visits. In a multivariable logistic regression model, past year NMU of opioids was significantly associated with past year ED utilization (odds ratio [OR] 1.37, 95 % confidence interval [CI] 1.30–1.44). By comparison, past year alcohol use disorder (OR 1.07, 95 % CI 0.95–1.21) and marijuana use disorder (OR 1.07, 95 % CI 0.90–1.26) were not associated with past year ED utilization. Among individuals with past year NMU of opioids, 8 % reported NMU of

opioids on ≥200 days in the past year, 20 % reported one or more physicians as the primary source of opioids, and 14 % reported experiencing opioid withdrawal symptoms in the past year. In a multivariable logistic regression model, independent predictors of past year ED utilization included NMU of opioids on ≥200 days in the past year (OR 1.43, 95 % CI 1.17–1.76) vs. 1–29 days, physician source of opioids (OR 1.87, 95 % CI 1.60–2.19) vs. all other sources, and past year opioid withdrawal (OR 1.67, 95 % CI 1.44–1.95).

CONCLUSIONS: In this nationally representative sample, an estimated 10.5 million adults reported past year non-medical use of prescription opioids, and these individuals accounted for 1 in 13 adult ED visits nationally. ED utilization was more common among individuals reporting more severe NMU of opioids and by those reporting a physician source of opioids. Increased ED utilization may represent patients’ efforts to obtain opioid medications or may result from complications of NMU such as opioid overdose. As pain is not assessed by the NSDUH, the role of acute and chronic pain in both ED utilization and NMU of opioids could not be examined and warrants further study. Interventions to screen for non-medical use of prescription opioids, to facilitate substance use treatment and to prevent opioid overdose death (i.e. naloxone distribution) should consider ED settings given the prevalence and severity of NMU of opioids among ED patients nationally.

OOPS, I DIDN’T NOTICE THAT! PATIENT, PROVIDER, AND SYSTEM FACTORS ASSOCIATED WITH FAILURE TO RECOGNIZE AND FOLLOW-UP ELEVATED RANDOM GLUCOSE VALUES IN AMBULATORY PRACTICE Kazeen Abdullah²; Zahra Merchant²; Riya Joshi¹; Deepa Bhat¹; Jason Fish¹; Ethan Halm¹; Michael E. Bowen¹. ¹UT Southwestern Medical Center, Dallas, TX; ²University of Texas Southwestern Medical Center, Dallas, TX. (Tracking ID #2197803)

BACKGROUND: Random blood glucose (RBG) can identify patients at increased risk for diabetes (DM) and is commonly used as a de facto screen for DM in clinical practice. However, up to 60 % of elevated RBG values in real-world practice go unrecognized, and the reasons for this are poorly understood. This study seeks to characterize patient, provider, and system factors associated with failures to recognize and follow-up elevated RBG values.

METHODS: We conducted a retrospective chart review of non-pregnant adults age ≥18 without diagnosed DM who had ≥1 ambulatory visit at an academic medical center between 1/1/2011 and 12/31/2013. Eligible patients had at least one ambulatory RBG ≥125 mg/dL and no resulted A1C in the 2 years before the RBG value. The RBG threshold was selected based on evidence that RBG values ≥125 mg/dL can identify DM. Of 20411 patients seen during this period, 367 patients met study criteria and 150 were randomly selected. A comprehensive electronic medical record has been used across all care settings

since 2005 and provided all data. We created a data abstraction tool based on a conceptual model of ambulatory clinical errors, and two trained chart abstractors entered data into an electronic database. A 10 % random sample ($n=15$) was reviewed by both abstractors and Kappa calculated. We collected data on patient, provider, and system factors and examined associations with failure to follow-up elevated RBG values using Wilcoxon, chi2, and Fisher's Exact tests as appropriate. Successful follow-up was defined as 1) A1C ordered (30 days); 2) A1C resulted (12 months); 3) comment on the RBG value (30 days); or, 4) result communication to the patient (30 days).

RESULTS: Of 150 charts reviewed, 53 failed to meet study criteria and were excluded for: active cancer in the past 3 years ($n=32$), diagnosed DM ($n=6$), inpatient or ED RBG value ($n=18$). The interrater reliability was Kappa=0.73 ($p<0.002$). The median age was 68 years, 56 % were female, 26 % were non-white, and 59 % had Medicare. Half of elevated RBGs were ordered by medical specialists, 40 % by primary care providers, and 9 % by surgical specialists. Ordering indications included: chronic medical diagnoses (35 %), oncology diagnoses (28 %), gastrointestinal diagnoses (15 %), renal diagnoses (8 %), and health maintenance (7 %). The median (IQR) RBG value was 133 mg/dL (128–148 mg/dL), and 20 % of patients had >1 elevated RBG. Only 36 % of elevated RBG values were followed-up. No differences in follow-up by patient characteristics or ordering provider type were observed (Table 1). Patients on oral steroids were more likely to have their elevated RBG ignored ($p=0.02$). Although 100 % of RBG values were viewed by ordering providers according to electronic time stamps, a trend towards successful follow-up was seen in values viewed sooner (3 vs. 5 days; $p=0.09$). All patients had at least one outpatient visit in the 12 months after the elevated RBG. Those seen sooner by the ordering provider ($p<0.001$) and more frequently ($p=0.07$) were more likely to have the elevated RBG missed. Of follow-up successes, ($n=35$), 71 % of results were communicated to the patient, 57 % of results were commented on, 54 % had DM testing ordered, and 17 % were “caught” by the primary care provider even when they did not order the test. Of results commented on by the ordering provider ($n=20$), 90 % were communicated to the patient; however, 44 % of providers commented that the elevated RBG value was normal. Of resulted A1C values ($n=11$), 55 % were abnormal.

CONCLUSIONS: Failure to recognize elevated RBG values in outpatient practice is common and represents a missed opportunity to identify patients at risk for DM. The lack of patient, provider, and process of care predictors of follow-up suggests that providers largely ignore elevated RBGs regardless of the situation. Systems-based approaches to recognize and communicate elevated RBG results to patients are needed.

Table 1. Patient, Provider, and System Characteristics Associated with Elevated RBG Follow-up.

	Follow-up Success (N=35)	Follow-up Failure (N=62)	p-value
Patient Factors			
Median Age, y, (IQR)	68.8 (55.2–73.4)	67.7 (49.8–76.8)	0.99

OPIOID PRESCRIBING AFTER NONFATAL OVERDOSE AND ASSOCIATION WITH REPEAT OVERDOSE Marc Laroche^{1,2}, Jane M. Liebschutz¹, Fang Zhang², Dennis Ross-Degnan², James F. Wharam². ¹Boston University School of Medicine and Boston Medical Center, Boston, MA; ²Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, MA. (Tracking ID #2194707)

BACKGROUND: Opioid overdose and overdose death are increasing in the United States. Presentation to an emergency department or hospital with a nonfatal opioid overdose represents an opportunity for identification of opioid misuse and referral for treatment. Opioid prescribing guidelines specify that misuse of opioids and opioid-related adverse events are indications to discontinue long-term opioid therapy. However, patterns of treatment, including rates of continued opioid prescribing, following nonfatal opioid overdose are unknown.

METHODS: We conducted a retrospective cohort study of commercially insured members aged 18–64 years between May 2000 and December 2012 from a large national United States health insurer. We identified 2365 members experiencing an index nonfatal opioid overdose during chronic opioid therapy for non-cancer pain. We identified nonfatal opioid overdose using ICD-9 codes from emergency department or inpatient claims. The primary outcome was reduction in morphine-equivalent dosage of opioids dispensed from the 90 days before to 90 days after the index overdose. We categorized dosage reduction as minimal or none (<25 %), moderate (<25 to 75 %), or large (>75 %). We used standardized provider identifiers to examine the primary prescriber of opioids in the 90 days before and after the index overdose. The secondary outcome was time to repeat opioid overdose with the follow-up period beginning 90 days after the index overdose and censoring for health plan disenrollment, reaching age 65, or end of the study period. We used a propensity score adjusted survival model to determine if dosage reduction was associated with time to repeat overdose.

RESULTS: Ninety percent (2121) of members taking chronic opioids continued to receive opioid prescriptions after a nonfatal opioid overdose. One thousand two hundred sixty-six members (54 %) received no or minimal reduction in opioid dosage following the index opioid overdose, 581 members (25 %) received a moderate dosage reduction, and 518 members (22 %) received a large dosage reduction. We identified a primary prescriber in the pre-and post-overdose periods for 73 % (1541) of members continuing to receive opioids after the index overdose. For 1395 (91 %) of these members, the primary prescriber for the post-overdose period was either the primary (1083; 70 %) or a secondary (312; 20 %) prescriber from the pre-overdose period. Median follow-up time was 1.3 years. A total of 168 members (7 %) experienced a repeat opioid overdose. Compared to members receiving a large dosage reduction (referent), moderate dosage reduction and no or minimal dosage reduction were associated with increased hazard of repeat opioid overdose (adjusted HRs 2.05 [95 % CI 1.18–3.54] and 2.41 [95 % CI 1.46–3.98], respectively).

CONCLUSIONS: Almost all patients taking chronic opioids continued to receive opioid prescriptions after a nonfatal opioid overdose, with more than half receiving the same or higher dosage. Opioid discontinuation or receipt of a large dosage reduction was associated with a significantly lower risk of repeat overdose. Opioid prescribing practices following nonfatal opioid overdose are alarming and might represent health system fragmentation, but provide a major opportunity to improve patient safety.

OPIOID USE WITH MENTAL HEALTH DISORDERS: ARE WE OVER-PRESCRIBING? Brian Halbert, Sarah N. Chiodi, Roger B. Davis, Christina C. Wee. Beth Israel Deaconess Medical Center, Boston, MA. (Tracking ID #2198236)

BACKGROUND: The recent rise in opioid use has led to an increase in overdose deaths, opioid abuse, and medication diversion. Individuals with mental health disorders (MHD) are at higher risk for opioid-related adverse events, but are often over-represented in populations using opioids. Whether this disproportionate use is attributable to a higher prevalence of pain conditions, higher prevalence of opioid use for pain, or a higher transition to long-term opioid use is unclear.

METHODS: We used the nationally-representative Medical Expenditure Panel Surveys (MEPS) to characterize the relationship between MHD, pain conditions, and opioid use from 2006–2011. Individuals with MHD were identified using clinical classification software (CSS) diagnosis codes during the individuals' first year in MEPS. Pain conditions were identified using CCS codes and categorized as acute or chronic. The acute pain category included fractures, tooth and jaw pain, sprains, traumatic joint disorders, and injuries due to external causes. The chronic pain category included osteoarthritis, rheumatoid arthritis, non-traumatic joint pain, back pain, headache, connective tissue disorders, neurologic pain, and generalized pain. We identified individuals who received opioid treatment for these pain conditions using therapeutic class codes, and defined long term opioid therapy as having ≥ 3 opioid prescriptions. We excluded methadone use because of its use in substance abuse disorders. Individuals <18 years old, with cancer, receiving hospice care, or without full follow-up were also excluded. We measured the prevalence of acute pain conditions, chronic pain conditions, and opioid use in year one of MEPS. Among individuals who did not report any opioid use in the first year of MEPS, we estimated the prevalence of new opioid use and chronic opioid use in year two of MEPS. We used logistic regression to compare the prevalence of pain conditions, opioid use, new opioid use, and long-term opioid use between individuals with and without MHD after

considering demographic and socio-economic factors. The final model adjusted for the confounding variables age, race, SF-12 PCS score, SF-12 MCS score, access to usual care provider, and number of additional pain conditions. All analyses were run using SAS 9.3 (Cary, NC) and accounted for the complex survey design of MEPS.

RESULTS: Our sample included 59,865 unique individuals representing an annualized weighted sample of 200,734,038 persons. Of these, 17.5 % had MHD ($n=9611$, weighed sample 35,028,649). Compared to those without MHD, individuals with MHD were older (mean age 46.9 vs 44.3, $p<0.001$) and more likely to be female (63.6 % vs 49.1 %, $p<0.001$). Mean PCS scores (46.7 vs 50.9 $p<0.001$) and MCS scores (43.4 vs 52.5, $p<0.001$) were also significantly lower in the MHD group. The MHD group also had a higher prevalence of white individuals, higher Charlson comorbidity scores, more pain conditions, higher levels of poverty, and higher rates of insurance and access to usual care providers. Education beyond high school was not different between the groups. Individuals with MHD had a significantly higher prevalence of acute pain conditions (20.5 % vs 13.9 %, aOR 1.15 [1.06, 1.24]) and chronic pain conditions (57.0 % vs 31.3 %, aOR 1.87 [1.75, 2.01]). After adjustment, those with MHD were not more likely to use opioids for acute pain conditions (23.3 % vs 20.1 %, aOR 1.02 [0.85, 1.22]). However, individuals with MHD were more likely to use opioids for chronic pain conditions (20.0 % vs 12.2 %, aOR 1.16 [1.03, 1.32]). Among individuals with pain and no prior opioid use, those with MHD were not more likely to initiate opioids for acute pain conditions (15.7 % vs 15.0 %, aOR 1.00 [0.82, 1.22]) or chronic pain conditions (8.7 % vs 7.8 %, aOR 0.96 [0.81, 1.14]). The transition to long-term opioid use after initiating opioids for an acute pain condition was not statistically different in MHD and non-MHD individuals (13.2 % vs 8.1 %, aOR 1.25 [0.65, 2.38]). However, individuals with MHD were more likely to transition to long-term opioid use after initiating opioids for a chronic pain condition (30.3 % vs 17.9 %, aOR 1.53 [1.02, 2.31]).

CONCLUSIONS: Our study suggests that there is a higher prevalence of pain conditions in individuals with MHD compared to those without MHD. After adjusting for demographic, socio-economic, and functional status, individuals with MHD were more likely to use opioids for chronic pain conditions, but they were not more likely to initiate opioids for acute or chronic pain conditions. Once opioids were initiated for chronic pain conditions, patients with MHD were more likely to transition to long-term opioid therapy. These findings suggest that the high prevalence of opioid use in MHD patients may reflect a higher rate of transition from short-term to long-term opioid use, rather than a higher likelihood of opioid initiation.

ORAL VERSUS INTRAVENOUS FLUOROQUINOLONES FOR THE INITIAL TREATMENT OF COMMUNITY ACQUIRED PNEUMONIA IN HOSPITALIZED PATIENTS Michael B. Rothberg³; Raquel K. Belfort¹; Tara Lagu²; Sarah Haessler⁴; Penelope S. Pekow¹; Aruna Priya²; Daniel Skies⁴; Thomas Higgins¹; Mihaela S. Stefan¹; Peter K. Lindenauer¹. ¹Baystate Medical Center, Springfield, MA; ²Baystate Medical Center, Florence, MA; ³Cleveland Clinic, Cleveland, OH; ⁴Baystate Medical Center, Springfield, MA. (Tracking ID #2198009)

BACKGROUND: Fluoroquinolones are widely used in the treatment of community-acquired pneumonia (CAP) and they have equivalent oral (PO) and intravenous (IV) bioavailability, but patients hospitalized with CAP are generally treated intravenously. We compared the outcomes of hospitalized patients with CAP initially receiving intravenous vs. oral respiratory fluoroquinolones.

METHODS: We conducted a retrospective cohort study of adult patients hospitalized for CAP at 340 hospitals between 2007 and 2010. We included patients who could tolerate PO medication, who were not in a critical care setting, and who received IV or PO levofloxacin or moxifloxacin during the hospitalization. The primary outcome was in-hospital mortality; secondary outcomes included treatment failure (defined as adding other broad spectrum antibiotics on hospital day 2 or later), admission to intensive care (ICU), invasive mechanical ventilation (IMV), and use of vasopressors initiated on or after the second hospital day (defined as “late ICU” or “late IMV”), hospital length of stay (LOS), and hospitalization cost. Including only hospitals where at least one person was treated with a PO quinolone ($n=178$), we developed a propensity model for PO treatment that included patient demographics, co-morbidities and other initial treatments (c-statistic=0.82). We then applied the propensity model to the entire cohort and created Stabilized Inverse Probability of Treatment Weighting (SIPTW) models for each of the outcomes. Multivariable hierarchical generalized linear models were developed to assess the independent association between initial treatment with a PO quinolone and each outcome adjusted for patient characteristics, other early treatments, propensity for PO treatment, predicted mortality, and hospital characteristics. SAS software procedure GLIMMIX was used to account for the hierarchical nature of the data (patients clustered within hospital and with hospital as a random effect).

RESULTS: Of the 36,405 patients who met inclusion criteria, 34,200 (94 %) were initially treated with an IV respiratory quinolone and 2205 (6 %) received PO treatment. Rates of initial PO use across hospitals varied from 0 to 90 % (median 4.4 %, interquartile

range 1.7 to 7.9 %). Patients who received initial oral quinolones were younger (67 vs. 71 years), more likely to be black (13.5 vs. 11.0 %) or obese (11.3 vs. 9.9 %), and to have a diagnosis of chronic obstructive lung disease (46.7 vs. 44.1 %); they were less likely to have a principle diagnosis of sepsis (6.5 vs. 9.4 %) and to have sputum cultures (8.6 vs. 13.9 %), blood cultures (74.2 vs. 88.3 %), or blood lactate levels (4.2 vs. 7.6 %) drawn ($p<0.001$ for all comparisons). Of patients initially receiving PO treatment, 54 % completed treatment PO and 34 % were switched to an IV quinolone. Of those beginning with IV quinolones, 55 % completed their course IV and 31 % were switched to a PO quinolone prior to discharge. Compared with those who received IV quinolone, those who received PO quinolones had lower unadjusted mortality (2.5 vs. 1.4 %, $p=0.001$), less treatment failure (16.9 vs. 19.3 %, $p=0.007$), shorter mean hospital length of stay (5.3 ± 4.8 vs. 5.0 ± 4.1 , $p<0.001$) and lower median hospital cost (\$5585 vs. \$5456, $p=0.07$). There were no significant differences in late ICU (4.2 vs. 3.9 %, $p=0.53$), late IMV (3.0 vs. 3.1 %, $p=0.76$), or late vasopressors use (2.7 vs. 2.6 %, $p=0.78$). In multivariable models, PO treated patients had lower rates of treatment failure (OR 0.84; 95 % CI 0.74–0.96), but no statistically significant differences in hospital mortality (OR 0.82; 95 % CI 0.58–1.15), hospital length of stay (RR 1.01; 95 % CI 0.98–1.03), hospital costs (RR 1.00; 95 % CI 0.98–1.02), late ICU admission (OR 1.04; 95 % CI 0.80–1.36), late use of IMV (OR 1.17; 95 % CI 0.87–1.56), or late use of vasopressors (OR 0.94; 95 % CI 0.68–1.30) between the 2 groups.

CONCLUSIONS: Among patients hospitalized for CAP who tolerate oral medications, respiratory quinolones administered orally on admission are associated with similar outcomes when compared to intravenous administration.

ORGANIZATIONAL APPROACHES EFFECT SAFETY-NET HOSPITALS' CANCER CARE QUALITY Nina A. Bickell²; Allie Moss³; Maria Castaldi⁴; Ajay Shah⁵; Alan Sickles⁶; Peter Pappas⁷; Theophilus Lewis⁸; Margaret Kemeny⁹; Shalini Arora¹⁰; Lori Schleicher¹¹; Anitha Srinivasan¹²; Leslie L. Montgomery¹³; Kezhen Fei¹; Bonnie Bellacera²; Rebeca Franco²; Ann S. (Tracking ID #2195955)

BACKGROUND: Safety-net hospitals, historically at higher risk for delivering poor-quality care, provide a disproportionate amount of care to vulnerable populations. Some safety-net institutions deliver excellent quality cancer care. We undertook this study to determine the impact of organizational factors on breast cancer care quality.

METHODS: We abstracted charts of 389 breast cancer patients treated in 2009–12 at 9 inner-city safety-net hospitals with high proportions of minority breast cancer patients to measure underuse of needed adjuvant treatment. We interviewed 90 key informants ($n=59$ clinical; $n=16$ administrative; $n=12$ clerical; $n=3$ other) about how care is coordinated and delivered. Using Qualitative Comparative Analysis, we defined “conditions” —handoffs, no-shows, organizational culture—that particularly impact care coordination, categorized hospitals into low (<10 %), intermediate (10–20 %) and high (>20 %) underuse of needed adjuvant therapies, and calibrated each of the “conditions.” Hierarchical models assess impact of organizational and patient factors on underuse.

RESULTS: Underuse ranged from 8 to 29 %. Higher quality sites designated individuals to track & follow-up no-shows; shared clinical information during handoffs; had fully integrated EHRs enabling providers and clerks to transfer responsibility across specialties; had strong system support; paid close organizational attention to clinic patients; and allocated adequate resources for the cancer clinics. Organizations with a patient-centered culture focused on making processes easier for patients. Poor quality sites lacked these organizational characteristics. Multivariate modeling found that beyond patient older age (RR=1.89; 1.14–3.15), hospitals with strong approaches to follow-up affect underuse rates (RR=0.24; 0.08–0.738).

CONCLUSIONS: At safety-net hospitals, underuse of needed cancer therapies is affected by patient older age and organizational approaches to track and follow-up treatment. These findings offer strategies to safety-net hospitals to improve cancer care quality.

OUTPATIENT PROGRESS NOTE QUALITY USING MEDICAL SCRIBES VS. USUAL CARE Anita D. Misra-Hebert¹; Linda Amah¹; Bo Hu¹; Andrew J. Rabovsky²; Michael B. Rothberg¹. ¹Cleveland Clinic, Cleveland, OH; ²Cleveland Clinic and Case Western Reserve University School of Medicine, Beachwood, OH. (Tracking ID #2198563)

BACKGROUND: As primary care delivery is redesigned to meet the complex needs of our patient populations, many team-based models of care are using medical scribes to

improve the efficiency of the patient encounter, often to counter the time intensity required for electronic documentation. It is unknown how the use of scribes in the outpatient setting may impact the quality of the visit progress notes. A new team-based model of care delivery being implemented in our health system's primary care clinics involves medical assistants scribing notes during the outpatient primary care encounter. We hypothesized that the quality of the outpatient physician notes written by medical assistant scribes would be similar to the quality of notes written by the same physicians without a scribe.

METHODS: The Physician Documentation Quality Instrument 9 (PDQI-9) is a validated instrument designed to assess physician note quality. The PDQI-9 consists of 9 individual items rated subjectively on a 5-point Likert scale, including assessment of whether notes are Up to Date, Accurate, Thorough, Useful, Organized, Comprehensible, Succinct, Synthesized, and Internally Consistent, as well as a total score. The PDQI-9 has been previously used in the inpatient and outpatient settings to assess note quality. At the time of this study, nineteen primary physicians had transitioned to the new team-based model with medical assistants acting as scribes. We conducted a retrospective chart review of ambulatory progress notes from all of these physicians. All physician notes either with a visit diagnosis of diabetes or a visit slot designated as "same day" for all providers practicing in our new team-based model using scribes were requested for the following time frames: 3 months preceding the use of scribes (Time Period 1), and 3 to 6 months after starting the new model (Time Period 2). The principal investigator and one medicine resident independently coded 10 randomly selected progress notes using the PDQI-9 tool, as well as a 5-point redundancy scale, and discussed the results. The process was repeated for a total of 20 notes, after which consensus was reached with >70 % agreement on each attribute of the PDQI-9. The resident then evaluated a random sample of notes written by each physician including notes from same-day appointments and notes from a diabetes encounter in Time Periods 1 and 2. The paired t-test was used to compare the non-scribed and scribed note quality scores.

RESULTS: We reviewed 89 notes from Time Period 1 and 63 notes from Time Period 2, which were written by 19 physicians and 33 scribes. Compared to notes written by the physician alone, scribed notes did not differ in overall quality (mean total PDQI-9 score 29 for non-scribed notes vs. 30 for scribed notes, $p=0.28$). Scribed notes were rated as more Up to Date (mean item score 3.6 vs. 3.3, $p=0.03$), Thorough (mean 3.8 vs. 3.4, $p=0.03$), and Useful (mean 3.8 vs. 3.4, $p=0.008$), but also more redundant (Table). For diabetes encounters, scribed notes did not differ in overall PDQI-9 score, but were rated as more Useful (mean 3.8 vs. 3.4, $p=0.02$) and Comprehensible (mean 3.4 vs. 3.0, $p=0.02$) but also more redundant (mean item score 3.6 vs. 3.2, $p=0.04$) while for same day appointments notes did not differ for scribed and non-scribed notes. Scribed progress notes were longer (mean word count (SD) 608(267) for scribed notes vs. 516(267) for non-scribed notes, $p=0.04$).

CONCLUSIONS: The overall quality of ambulatory notes scribed by medical assistants is similar to that of physicians writing alone. Scribed notes may be more thorough, up to date, comprehensible, and useful, but also more redundant. The quality of notes written by professional scribes or in other settings remains unknown.

The relationship between Scribed and Non-Scribed notes and PDQI-9 scores

	Time Period 1 (Non- scribed Notes)	Time Period 2 (Scribed Notes)					
	N	Mean	SD	N	Mean	SD	p value

OUTPATIENT VISIT FREQUENCY AND CHRONIC DISEASE CONTROL AMONG MEDICAID-INSURED VERSUS UNINSURED INDIVIDUALS: A NATIONAL PERSPECTIVE. Andrea S. Christopher¹, ¹Danny McCormick²; Steffie Woolhandler³; David Himmelstein³; David Bor⁴; Andrew P. Wilpers. ¹Cambridge Health Alliance, Boston, MA; ²Harvard Medical School / Cambridge Health Alliance, Cambridge, MA; ³City University of New York School of Public Health, New York, NY; ⁴Cambridge Health Alliance, Cambridge, MA; ⁵University of Washington School of Medicine, Boise, ID; ⁶Harvard Medical School, Boston, MA. (Tracking ID #2198585)

BACKGROUND: Medicaid's ability to improve health outcomes remains controversial. The Oregon Health Insurance Experiment found modest increases in outpatient visits, but did not find significant changes in selected measures of physical health for those newly covered by Medicaid. However, that study was conducted in a single metropolitan area with a strong medical safety-net, and may not be nationally representative. We sought to determine the impact of Medicaid coverage on the frequency of outpatient visits and on awareness and control of chronic medical conditions among low-income adults nationally.

METHODS: We analyzed data from the 1999–2012 National Health and Nutritional Examination Surveys, which annually collected interview, laboratory and physical examination data on a nationally representative sample of the United States population. We identified adults aged 18 to 64 with incomes below the federal poverty level who were either uninsured ($n=2975$) or had Medicaid ($n=1485$). We used logistic regression to estimate the association between having Medicaid (versus being uninsured) and the frequency of outpatient visits, controlling for demographic and clinical characteristics. We also estimated the effect of having Medicaid on the likelihood that persons with chronic diseases (diabetes, hypertension, hyperlipidemia and overweight/obesity) knew of their condition, and whether their condition was controlled. Diagnosis and control for each condition was based on patient report, prescription drug usage, laboratory and physical exam findings, and established clinical guidelines (diabetes: HgA1C>6.5 % or fasting glucose>125 mg/dL, hypertension: SBP>140 mmHg or DBP>90 mmHg, hyperlipidemia: total cholesterol>240 mg/dL, overweight/obesity: body mass index>25).

RESULTS: Individuals with Medicaid coverage were more likely than the uninsured to have at least two outpatient physician visits annually (versus zero or one visit), even after controlling for patient characteristics (OR 3.54, 95 % CI, 2.91 to 4.32). Results were unchanged in sensitivity analyses using alternative cut-points of visit frequency. Among persons with objective evidence of hypertension, those with Medicaid were more likely to be aware of their condition (OR 1.83; 95 % CI, 1.26, 2.66) and to have their blood pressure controlled (OR 1.69; 95 % CI, 1.32, 2.27). Medicaid enrollees were also more likely to be aware of being overweight/obese (OR 1.30; 95 % CI, 1.02, 1.67). Medicaid coverage was not associated with awareness or control of diabetes or hyperlipidemia.

CONCLUSIONS: Among poor adults nationally, Medicaid coverage is associated with a substantial increase in outpatient visit frequency, awareness of hypertension and overweight/obesity, and hypertension control. Our study suggests that among low-income adults in the United States, Medicaid offers protection against some common chronic conditions.

OVERDOSE EDUCATION AND NALOXONE PRESCRIBING FOR PATIENTS ON CHRONIC OPIOIDS: A QUALITATIVE STUDY OF PATIENTS PRESCRIBED OPIOID MEDICATIONS Ingrid A. Binswanger^{1, 2}; Steve Koester^{2, 2}; Shane Mueller^{1, 2}; Edward M. Gardner³; Kristin Goddard¹; Jason M. Glanz^{1, 4}. ¹Kaiser Permanente Colorado, Denver, CO; ²University of Colorado Denver, Denver, CO; ³Denver Health and Hospital Authority, Denver, CO; ⁴Colorado School of Public Health, Aurora, CO. (Tracking ID #2198188)

BACKGROUND: Substantial increases in fatalities from opioid overdose have been observed across the United States in the last decade. Naloxone is an effective opioid antidote which may be prescribed to individuals at risk for overdose for administration by a bystander in the event of respiratory depression. While patients on chronic pharmaceutical opioids for pain could benefit from naloxone prescription, our prior interviews with primary care providers suggest that providers are worried about how patients would respond to education about overdose and naloxone. Thus, this study was designed to elucidate the knowledge, attitudes and beliefs about overdose prevention and naloxone among patients prescribed chronic opioid medications.

METHODS: We conducted semi-structured qualitative interviews with patients in two large health systems in Colorado—a system of federally qualified health centers (Denver Health) and a large integrated managed care organization (Kaiser Permanente Colorado). An interview guide was developed using domains from the Theory of Planned Behavior and the Health Belief Model. Interviews were audio recorded, transcribed, then and coded using ATLAS.ti® qualitative software. Our overall qualitative analysis approach included both inductive and deductive coding and theme development.

RESULTS: We enrolled 13 English speaking patients ages 21–65 who received three or more high dose (≥ 100 MME daily dose) DEA Schedule II controlled opioid prescriptions, such as oxycodone, hydromorphone, or fentanyl, in the last 6 months. We excluded patients who had a Do Not Resuscitate status or with a cancer diagnosis in the last 12 months. Nine (82 %) patients were enrolled from Denver Health and 4 (18 %) were enrolled from Kaiser. Seven (54 %) patients were female, mean age was 52 years (range 33–63 years), 10 were white, 2 were Hispanic or Latino, and 1 was African American. Participants had been prescribed opioid medications for a median of 5 years (range 2–40 years). The following themes emerged (see table for illustrative quotes): Patients identified several behaviors that they believed decrease the risk of pharmaceutical opioid overdose, including taking the medications at consistent times, not doubling up on medications, having been prescribed the medications for a long time, and only taking medications prescribed to them. They also revealed histories and risk behaviors, such as alcohol use, that they were reluctant to share with their provider for fear of having their opioid medications discontinued. While prior experience and knowledge of overdose and naloxone was limited, being prescribed naloxone was highly acceptable. Patients with long term trusting relationships with primary care providers expressed openness to discussions about overdose and naloxone. Patients in our study easily identified existing family and caregiver supports who could administer naloxone, if trained. Some patients feared that their provider would wean them from opioids if they identified them at risk for overdose.

CONCLUSIONS: Our qualitative interviews with patients on high-dose chronic opioids for pain suggest that naloxone prescription is acceptable to patients, particularly when they have established long-term relationships with their providers. However, patients lacked some knowledge about overdose and had not discussed key risk behaviors with their providers. Based on our findings, providers may wish to avoid coupling discussions about overdose and naloxone with discussions about weaning opioids. Further research is needed to see if our qualitative findings represent the broader population of patients on chronic opioids.

Table: Emerging Themes and Illustrative Quotations

Emerging Theme	Illustrative Quotation
Patients identified behaviors which they believed decrease the risk of pharmaceutical opioid overdose, including taking the medications at consistent times, not doubling up on medications, having been prescribed the medications for a long period of time, and only taking medications prescribed to them.	Quote 1: "They're severely at risk because if the...like the two they just prescribe for me, I take two, whereas they may take two and not feel nothing so they take two more or two more. Before you know it, they take six or eight and then there's a lot bigger chance for them to overdose." Quote 2: "Somebody who is just now starting out on them because like I say, they'll take two that's supposed to help them but the pain is so great that it doesn't help so then they'll take two more but me I know...I know what the...how the pain is going to affect me and how the medicine affects me so I know basically the do's and don'ts to keep my pain at a tolerable level." "You know, it's like I don't drink. And I know you're not supposed to drink on them, but every now and then I figure why not (laughing). I don't know if that's wrong or that's right..."
Patients also revealed histories and risk behaviors that they were reluctant to share with their provider for fear of having their opioid medications discontinued. While prior experience and knowledge of overdose and naloxone was limited, being prescribed naloxone was highly acceptable.	Quote 1: "I don't know much about overdose. I don't have any personal experience with it. I don't know anybody who has overdosed except what I've read in the newspapers." Quote 2: "Well, I believe that every person that is prescribed an opiate should be let known about this new drug [naloxone] and in case the overdose does happen, there's something available to counter act that and I don't know if it would be in the insurance policy or every person that gets the prescription will be able to get that. What I believe it'll be important, it'll probably save a lot of lives."

(continued)

Long term trusting relationships with primary care providers enhanced openness to discussions about overdose and naloxone.

Quote 1:

"Oh, Dr. Lxxx is like I say she's great... she communicates well. We just click together. I mean, you know? She...you know, and at first, I mean it took a couple years to build that trust up, you know, that I'm not a drug seeker and, you know, and once we've gotten that trust not only her with me, but me with her, it makes things a lot easier, you know? And, I can talk, you know, and I'm not scared to ask questions."

Quote 2:

"Well, I've known my doctor for a while now so me and her are best buds (laughing) so it took a while to get to that point though, but she knows me. She knows like if my attitude has changed, she'll go I want a UA (laughing)."

Quote 1:

"Yeah. And I know she [my wife] can do the shots cause I am hypoglycemic and stuff and they give me a shot...a thing to carry, you know, some powdered stuff and you've got to put the medicine...the liquid inside the powder, shake it up and then redraw it and then..."

Quote 2:

I: "So has she had to give you a shot before then?"

R: "Yeah, so I know she can."

Patients had existing family and caregiver supports who could be trusted to administer naloxone, if trained

PALLIATIVE CARE QUALITY INDICATORS FOR PATIENTS WITH END STAGE LIVER DISEASE Anne Walling⁴; Sangeeta Ahluwalia²; Neil Wenger³; Patty Smith²; Marika Booth²; Carol Roth²; Karl Lorenz⁶; Fasiha Kanwal⁷; Sydney M. Dy¹; Steven Asch⁵. ¹Johns Hopkins, Baltimore, MD; ²RAND Corporation, Encino, CA; ³UCLA, Los Angeles, CA; ⁴UCLA, Studio City, CA; ⁵VA, Menlo Park, CA; ⁶VA Greater Los Angeles Healthcare System, Los Angeles, CA; ⁷Houston VA, Houston, TX. (*Tracking ID #2196734*)

BACKGROUND: End stage liver disease is a common condition and cause of death. While there are guidelines and quality indicators for the medical management of cirrhosis, quality indicators focusing on standards for palliative aspects of end stage liver disease care are needed because measurement can lead to improvement in care.

METHODS: We convened a 9-member, multidisciplinary expert panel and used RAND/UCLA modified Delphi methods to develop palliative care quality indicators for patients with cirrhosis. Experts were provided with a report based on a systematic review of the literature that contained the evidence supporting the proposed candidate quality indicators. Panelists rated each quality indicator prior to a planned meeting using a standard 9-point RAND appropriateness scale. These ratings guided discussion during a day-long telephone conference meeting, and final ratings were then provided by panel members. Final indicator scores were computed and quality indicators with a final median score of greater than or equal to 7 and no disagreement were included in the final set.

RESULTS: Among 28 candidate quality indicators, the panel rated 19 as valid measures of quality care. These 19 quality indicators cover care related to information and care planning (13) and supportive care (6). An example of a quality indicator in the information and care-planning domain is: IF a patient with advanced end stage liver disease is newly diagnosed with hepatic encephalopathy and does not have advance care planning previously documented, THEN the medical record should document advance care planning or lack of ability to do so within one month, BECAUSE patients with a history of hepatic encephalopathy are at a higher risk of lacking capacity to make decisions for themselves and care should be guided by their goals and preferences. An example of a quality indicator in the supportive care domain is: IF a patient has advanced end stage liver disease, THEN the patient should not be prescribed NSAIDs, BECAUSE of the increased risk of renal toxicity and bleeding.

CONCLUSIONS: These quality indicators are evidence-based process measures of care that can be used to ensure that patients with cirrhosis receive high quality palliative care. Research is needed to better understand the quality of palliative care provided to patients with cirrhosis.

PARTNERING WITH PATIENTS FOR SAFETY: THE OPENNOTES PATIENT REPORTING TOOL Sigall K. Bell¹; Roanne Mejilla¹; Mary Barry³; Tom Delbanco³; Beth French³; Macda Gerard³; Amy B. Goldman³; Heidi S. Jay³; Susan E. Johnson³; Gila Kriegel³; Julia Lindenberg³; Lawrence J. Markson³; Elana Premack-Sandler⁵; Kenneth Sands²; Jan Walker¹; Gail Wood³; Patricia H. Folcarelli³. ¹BIDMC, Brookline, MA; ²Beth Israel Deaconess, Boston, MA; ³Beth Israel Deaconess Medical Center, Boston, MA; ⁴Beth Israel Deaconess Medical Center, Brookline, MA; ⁵Jewish Social Service Agency, Washington, DC. (Tracking ID #2201030)

BACKGROUND: Safety experts struggle to improve patient engagement and reduce error in ambulatory care. OpenNotes, a national movement to invite patients to review their clinicians' visit notes online, can offer opportunities for patients to report possible errors in their notes, yielding potential safety benefits.

METHODS: In collaboration with Health Care Quality, Information Systems, Patient Relations, Health Information Management, Social Work, the Patient and Family Advisory Council, and clinicians in our hospital-based primary care practice which offers patients access to signed notes, we developed and implemented an online patient reporting tool linked to OpenNotes. Through email notification on the patient portal, we invited patients in 2 of 10 practice teams to participate. A link at the end of the open note led to a 10-question survey with quantitative and qualitative questions. "Potential safety concerns" were defined as not understanding the plan of care or reporting a possible inaccuracy in a note, and patient relations personnel shared safety concerns with providers and documented whether changes were made to the record or practice.

RESULTS: We analyzed the first 105 reports submitted between Aug-Dec 2014. Patients comprised 95 % of respondents; informal caregivers with proxy access to the patient portal also used the tool (5 %). Nearly all participants reported understanding the note (98 %); of those, 90 % thought it accurately described the visit. The vast majority (95 %) of respondents reported understanding the plan of care. Patients and caregivers documented "potential safety concerns" in 22 % of reports. Concerns included possible inaccuracies in medications (30 %); something important missing from the note (22 %); inaccurate report of symptoms (17 %), past medical history (13 %), family history (10 %); or "other" (35 %) (for example, documenting that a patient declined a PSA exam, when he was interested in having one). Nine percent of patients reported physical exam inaccuracies, including parts of the physical exam documented but not done. The majority of safety concerns resulted in a change to the record or care. In response to an optional open-ended query, 71 % of respondents provided positive feedback about providers and/or open notes. Asked what they liked about or learned from their notes, patients and caregivers commented on the ability to catch mistakes. They reported that reading notes helps "double check I didn't miss anything if I was not feeling well or was too overwhelmed," and "Reading the note takes the burden off of me to remember the details of what we discussed." Others reported that open notes helped clear up misunderstandings from the visit, remember next steps, access test results faster, and contextualize results: "I like knowing what the results of my tests mean. The records shows the numbers, but the notes provides the interpretation in regards to my personal health status." Some found it "helpful for my style of learning to see it in writing, in addition to hearing the information." A caregiver noted, "We are grateful to receive notes to be able to review the visit and procedures (if any) performed. [Open notes are] especially helpful for older patients who may have hearing and/or some cognitive/memory loss." Some patients used notes to check how well they were communicating, and whether they were heard and understood by their providers. Finally, patients noted that the reporting tool "gives me an opportunity to play an active role in my health care," and that it "supports my strong belief that this is a partnership between me and my medical providers." Another added, "Health care should be a two-way conversation; this forum provides another opportunity for that." The majority of reporting tool users found it "very valuable" and would use it again (87 %); an additional 13 % found it "somewhat valuable." Assuming similar activity and extrapolating to the 10 teams in our ambulatory practice, these data predict over 1200 reports and almost 300 otherwise unidentified risks annually, reflecting a nearly 50 % increase in ambulatory reporting through our hospital's online event report system.

CONCLUSIONS: Although skeptics wonder whether patients can really understand notes, the overwhelming majority of participants reported they did. Patients and informal caregivers can find inaccuracies and reported them in about one-quarter of reports, resulting in a change in the record or care in the majority of cases. An online patient reporting tool linked to open notes can help engage patients as safety partners, support providers with positive feedback, and inform organizations of opportunities to improve care.

PATIENT AND CARE TEAM FACTORS ASSOCIATED WITH OPTIMIZING CARE IN DIABETIC PATIENTS WITH POOR GLYCEMIC CONTROL You Wu¹; Hong Xiao²; Richard W. Grant². ¹Kaiser Permanente, Oakland, CA; ²Kaiser Permanente Northern California, Oakland, CA. (Tracking ID #2199766)

BACKGROUND: Prolonged hyperglycemia can lead to diabetic complications and increased health care costs. In the optimal case, prompt management changes would be

made to regain glycemic control when a previously well-controlled patient has an elevated hemoglobin A1c (HbA1c). As health care shifts towards accountable care organizations and integrated delivery systems, many health care institutions have adopted team-based strategies to optimize diabetes care, including population management by nurses, proactive outreach, and pre-approved treatment algorithms implemented by pharmacists. While studies have validated the use of nursing case management and pharmacist-based protocols, few studies have examined the contribution of patient factors, different components of the care team, and types of care team interventions in returning poorly controlled patients to more effective glycemic control.

METHODS: We conducted a case control study to examine patient- and team-level factors associated with persistence vs. resolution of elevated HbA1c levels within a 3-month period. Among patients with type 2 diabetes receiving care in Kaiser Permanente Northern California from 2011 to 2014, we identified a cohort with newly elevated HbA1c (i.e. 2 A1c levels of $\leq 8\%$ followed by an "index" elevated HbA1c $\geq 10\%$). From this cohort, we selected cases with persistent HbA1c elevation (subsequent two HbA1c values after the index HbA1c remained $\geq 10\%$, $n=100$) and controls who regained glycemic control (subsequent two HbA1c's after index HbA1c both $\leq 8\%$, $n=100$).

RESULTS: We found several significant differences between cases and controls in patient-level factors. Cases (persistent poor control) were more likely to be female (OR=2.03, 95 % CI [1.15, 3.60], $p=0.01$), to be on insulin prior to index HbA1c (4.5, [2.0, 10.2], $p<0.001$), and to have longer DM duration (OR >10 years duration=2.71, [1.38, 5.33], $p=0.004$), but had similar prevalence of any psychiatric diagnosis (33 % vs 33 %, $p=0.52$) compared to controls who regained glycemic control. Initial team response to the index elevated HbA1c was similar between cases and controls. Both groups were contacted within 3–5 days ($p=0.125$), initial encounter types (e.g. by phone, mail, secure message or in-person) were similar ($p=0.41$), and success rates in reaching patients were similar (52–59 %, $p=0.10$). However, cases required more outreach attempts (1.35 attempts vs 0.65 attempts, $p=0.005$) and more phone calls (1.34 calls vs 0.61 calls, $p=0.01$). Cases took longer to establish contact with their PCP (61 days vs 22 days, $p<0.001$), had fewer visits with their PCP (2.6 vs 4.2, $p=0.004$), were less likely to have their regimen intensified (0.26 [0.11, 0.64], $p=0.004$), and had a lower proportion of follow-up visits within 3 months that were DM-specific (58 % vs 68 %, $p=0.02$). They also took longer to obtain their follow up HbA1c serum blood test (146 days vs 103 days; $p<0.001$). Both groups had similar no show rates ($p=0.7$). Cases also had greater odds of self-monitoring blood glucose (7.05, [3.39, 14.67] $p<0.001$) and having noted stressors (e.g. family death, caregiving, financial issues) compared to the control group (2.5, [1.3, 4.7], $p<0.01$).

CONCLUSIONS: We sought to understand how healthcare delivery is different between patients who rapidly regained diabetic control and patients who remained out of control. We found that patients who took longer to regain control had both disease-related factors (longer diabetes duration, more insulin use) and patient-related barriers (more life stressors, less self-monitoring). Earlier PCP involvement in patient's diabetes care and more visits with PCP were both associated with earlier return to diabetic control. Both case and controls received similar initial team responses to the index elevated HbA1c, but cases required more frequent subsequent outreach, were less likely to have regimen intensification, and had fewer diabetes-specific in-person PCP visits. Our findings suggest that within a team-based care model, earlier PCP involvement with visits focused specifically on diabetes management may enable more rapid return to glycemic control. As diabetes care increasingly shifts to multidisciplinary care teams, the PCP retains a pivotal role for more challenging patients with poor glycemic control.

PATIENT BELIEFS ABOUT THE BENEFITS OF HYPERTENSION AND DIABETES MEDICATIONS: THE ON-TIME STUDY Demetra Gibson¹; Paige Fairchild²; Neda Laiteerapong². ¹University of Chicago Medical Center, Chicago, IL; ²University of Chicago, Chicago, IL. (Tracking ID #2193456)

BACKGROUND: Treatment for hypertension (HTN) and type 2 diabetes (DM2) is focused on controlling blood pressure (BP) and sugar levels in order to prevent future complications; however, adherence to chronic disease medications is as low as 40 %. Because hypertension and diabetes are largely asymptomatic diseases, patients may feel few benefits from taking medications, and so, patient beliefs about their medications' long-term benefits may greatly influence their adherence. We sought to understand what benefits patients ascribe to their hypertension and diabetes medications, and to determine if associations existed between their beliefs and their characteristics, adherence and disease control.

METHODS: In this mixed methods study, we included 60 patients with both HTN and DM2 treated with oral medications, randomly selected from an academic primary care clinic. Semi-structured interviews were conducted, audiotaped and transcribed. All patients were asked open-ended questions about the benefits they expected from their HTN and DM2 medications and their medication adherence. Data analysis used a modified template approach to text analysis. Five trained reviewers independently analyzed

transcripts. Each transcript was reviewed by at least two reviewers and coded by consensus. Baseline demographic and clinical data were collected from the medical record. Chi-square tests were performed to look for associations between beliefs and patient characteristics, medication adherence and disease control. Benefits were categorized as short-term benefits (BP/sugar or symptom control) or long-term benefits (e.g., decreased risk of complications).

RESULTS: All 60 participants identified at least one benefit they expected from HTN medicine, and 59/60 identified at least one benefit from DM2 medicine. For both HTN and DM2, more participants named short-term than long-term benefits (HTN: 78 % vs. 53 %, $p=0.004$; DM2: 77 % vs. 37 %, $p<.001$). The most frequent short-term benefit identified was to control BP (68 %) and sugars (70 %). Other short-term benefits included decreased headache, dizziness and swelling for HTN medicines, and avoiding insulin and decreased thirst and blurry vision for DM2 medicines. More participants identified long-term benefits from HTN than DM2 medications, although the difference was not significant (53 % vs. 37 %, $p=0.07$). The most prevalent long-term benefits were decreased stroke (28 %) and heart disease (23 %) for HTN and decreasing complications in general (15 %) for DM2. Other less frequently mentioned long-term benefits of DM2 medications included decreasing amputation, eye disease and kidney disease. In bivariate analysis, younger age (<60 vs. ≥ 60 years) was associated with identifying a short-term benefit of HTN medications (92 % vs. 67 %, $p=0.03$). Females named long-term benefits of HTN medications and identified both short and long term benefits more frequently than males (67 % vs. 29 %, $p<0.01$; 41 % vs. 14 %, $p=0.04$, respectively). Participants who reported never missing any HTN medications in the last 7 days were able to name a short-term benefit of HTN medications more often than those who missed at least 1 day (100 % vs. 71 %, $p=0.03$). There were no significant associations between identifying short- or long-term benefits and race, marital status, education, income, HTN duration, or BP control. For DM2, education level and income were associated with identifying both short- and long-term benefits of medications. Among individuals with annual income $\geq \$35,000$, 37 % named both a short- and long-term benefit, compared to only 10 % of participants with income $< \$35,000$ ($p=0.047$). Among those individuals with HS education or less, no one (0 %) named both a short and long-term benefit, compared to 34 % of those with at least some college education ($p=0.049$). There were no significant associations between identifying short- or long-term benefits and age, gender, race, marital status, DM duration, A1c control, or adherence.

CONCLUSIONS: Our findings indicate that patients attribute multiple benefits to their chronic disease medications. In general, they identify more short-term than long-term benefits, and those patients who identified short-term benefits were more adherent with their HTN medications. A minority of patients were able to identify long-term benefits for their diabetes medications. Increased education on the long-term benefits of HTN and DM2 medications is necessary and may improve medication adherence.

PATIENT CHARACTERISTICS AND OUTCOMES OF OUTPATIENT PARENTERAL ANTIMICROBIAL THERAPY (OPAT): A RETROSPECTIVE STUDY.

Marie Yan¹; Marion Elligsen²; Nick Daneman². ¹University of Toronto, Toronto, ON, Canada; ²Sunnybrook Health Sciences Centre, Toronto, ON, Canada. (Tracking ID #2198985)

BACKGROUND: Outpatient parenteral antimicrobial therapy (OPAT) is a safe and effective alternative to hospitalization for many patients with infectious diseases. Although some institutions have established specialized clinics to provide OPAT services, this practice is not yet widespread. The objective of this study was to describe the OPAT experience at a Canadian tertiary academic centre in the absence of a formal OPAT program.

METHODS: A retrospective chart review was conducted for patients who were discharged home with parenteral antimicrobials from Sunnybrook Health Sciences Centre (SHSC) within a 1-year period. Descriptive statistics were performed.

RESULTS: Between June 1, 2012 and May 31, 2013, 104 patients were discharged home with parenteral antimicrobials. The median age was 63 years (interquartile range: 43–74) and the median length of stay was 7 days (interquartile range: 6–10). The most commonly treated syndromes include surgical site infections (33 %), osteomyelitis (25 %), and bacteremia (17 %). The most frequently prescribed antimicrobials were ceftriaxone (21 %) followed by cefazolin (20 %) and cloxacillin (14 %). Only 58 % of the patients received follow-up care from an infectious diseases specialist. In terms of outcomes, 43 % of the patients returned to the emergency room and 26 % required readmission within 60 days of discharge. The most common reasons for return visits were infection relapse/treatment failure (48 %) and OPAT-related complications (24 %).

CONCLUSIONS: A significant number of patients receive OPAT each year at SHSC and many have unplanned health care encounters because of issues related to their infection or

treatment. The creation of a formal OPAT clinic may streamline the care of these patients and reduce readmission and/or emergency room use. The results of this study have contributed to the funding and development of a 1-year pilot OPAT program at SHSC.

PATIENT NAVIGATION FOR COMPREHENSIVE CANCER SCREENING IN VULNERABLE PATIENTS USING A POPULATION-BASED HEALTH IT SYSTEM: RESULTS OF A RANDOMIZED CONTROL TRIAL

Sanja Percac-Lima²; Jeffrey M. Ashburner²; Adrian Zai²; Yuchiao Chang²; Sarah Oo¹; Erica Guimaraes¹; Steven J. Atlas². ¹Massachusetts General Hospital, Chelsea, MA; ²Massachusetts General Hospital, Boston, MA. (Tracking ID #2198588)

BACKGROUND: Patient navigation (PN) can improve rates of cancer screening in vulnerable populations. Most cancer PN programs are located in community health centers and focus on a single cancer. However, many patients who could benefit from PN may receive care in settings where on-site PN is not practical or may be overdue for more than one cancer screening test. The objective of this study was to evaluate a PN program to help vulnerable patients obtain breast, cervical, and/or colorectal cancer screening within a large, diverse academic primary care network using a population-based information technology (IT) system.

METHODS: We implemented a visit-independent, population health management system to identify adult patients overdue for preventive cancer screening in an 18 practice primary care network with an integrated IT infrastructure. To identify overdue patients at increased risk for non-adherence with testing, we used an algorithm that included primary language spoken, number of overdue screening tests, and no-show visit history. We identified and randomized 1612 patients to intervention ($n=792$) or control ($n=820$) groups over an 8-month study period (April–December 2014). In the intervention arm, patient navigators used the IT system to track and navigate patients to obtain breast, cervical, and/or colorectal cancer screening. Control patients received usual care including automated mailed reminder letters in English or Spanish. The primary outcome was the average cancer screening test completion rate over 8-months of follow-up for each eligible patient, with all overdue cancers combined using unadjusted linear regression models. Additionally we also examined the percentage of time screening was up to date among each individual cancer overdue at baseline.

RESULTS: Among 1612 overdue patients, 46 % were overdue for 1 screening, 18 % were overdue for 2 screenings, and 36 % were overdue for 3 screenings at baseline with a similar distribution among intervention and control groups. There were no differences in age, gender, primary language, or insurance among intervention and control groups, while intervention group patients were slightly less likely to be white (62 % vs. 66 %, $p=0.02$). Among 792 intervention patients, 181 (23 %) could never be reached by telephone. Among the remaining 611 patients, 155 (25 %) were deferred for all overdue cancers (e.g. patient declined, competing comorbidity) and 202 (33 %) successfully completed an overdue cancer screening. The average proportion of time patients were up to date with screening over 8-months of follow-up among all eligible and overdue screening exams was higher in intervention patients for all cancers combined (10.2 vs. 6.8 %, $p<0.001$), and for breast (14.7 vs. 11.0 %, $p=0.05$), cervical (11.1 vs. 5.7 %, $p=0.002$), and colon (7.6 vs. 4.6 %, $p=0.005$) cancer screening compared to control patients.

CONCLUSIONS: Patient navigation using a visit-independent population management system significantly improved preventive cancer screening for breast, cervical and colorectal cancer for vulnerable patients at increased risk for non-adherence with testing in a large primary care practice network. Additional work is needed to increase the efficiency of patient navigators by designing a population management referral system and/or improving the algorithm to better identify high risk patients who could benefit from PN. Using patient navigators who are integrated into population health management activities for vulnerable patients within a practice network may help improve equity of care.

PATIENT OUT OF POCKET COSTS FOR HOSPITAL OBSERVATION SERVICES

Brian Doyle¹; Teryl K. Nuckols². ¹UCLA, Los Angeles, CA; ²Cedars Sinai Medical Center, Los Angeles, CA. (Tracking ID #2196720)

BACKGROUND: The use of hospital observation services has expanded dramatically in the last decade and should continue to increase with the Center for Medicare and Medicaid Services' implementation of the upcoming "two midnight rule." Because Medicare reimburses observation services through Medicare Part B rather than Part A, many authors have speculated that Part B's 20 % coinsurance rate may increase patient out of pocket costs. We sought to better characterize this phenomenon using both primary and secondary insurance payment information since 87 % of Medicare patients have a secondary insurer.

METHODS: We analyzed billing data from one year of observation encounters at UCLA Ronald Reagan and Santa Monica Medical Centers, categorizing each encounter's charges into clinical categories. We then calculated out of pocket costs (total charges minus all payments and adjustments) using data from both primary and secondary insurers.

RESULTS: Overall, median out of pocket costs were \$5.63 for all insured patients. By primary payer, median out-of-pocket costs were \$1.99 for Medicare, \$0.00 for private insurance, and \$100.98 for Medicaid. For encounters with Medicare as the primary insurer, 10.9 % had unpaid costs that exceeded the Part A inpatient deductible after all Medicare payments and adjustments. An average of 41 % of unpaid costs were covered by secondary insurers for patients with a secondary insurer. This phenomenon resulted in 4.9 % of Medicare patients with out of pocket costs greater than the Part A inpatient deductible after accounting for secondary insurer payments, and increasing overall secondary insurer payment by 3.4 %. Medicare observation encounters with hospital procedures or surgeries, administration of blood products, pharmacy costs over \$1000, or encounters lasting more than 48 h were significantly associated with potential unpaid costs greater than the Part A inpatient deductible.

CONCLUSIONS: While out of pocket costs for observation encounters are modest for most patients, a minority of Medicare encounters shift costs to the secondary insurer or patient, leaving patients without secondary insurance particularly vulnerable to increased costs and increasing overall secondary payer payment.

PATIENT PERCEPTION OF INTERPRETER QUALITY: A QUALITATIVE ANALYSIS OF PATIENT EXPERIENCES Alissa Detz¹; Gery Ryan³; Ron Hays^{1, 3}; Xavier Bermudez²; Leo Morales⁴; Gerardo Moreno². ¹University of California, Los Angeles, Los Angeles, CA; ²UCLA, Los Angeles, CA; ³RAND Corporation, Santa Monica, CA; ⁴University of Washington, Seattle, WA. (Tracking ID #2195965)

BACKGROUND: Approximately 9 % of individuals in the U.S. have limited English proficiency (LEP), defined as speaking English less than “very well.” Providing professional interpreters for LEP patients improves the patient experience and outcomes of care. Despite such benefits, access to interpreters is low across healthcare settings, and the quality of medical interpreters is not well studied. This study explores patient perceptions of a high quality medical interpreter.

METHODS: Spanish-speaking LEP adults 18 and older who used a medical interpreter for ambulatory care in the past year were recruited from 4 community sites in Los Angeles. We defined an interpreter as someone who helped communicate with an English-speaking doctor including in-person professional interpreters, telephone interpreters, video interpreters, bilingual medical staff, family, and friends. We conducted semi-structured interviews to explore patient experiences with language barriers and medical interpreters. Each participant described 3 encounters with a medical interpreter in the past 12 months: the most recent, the best and the worst experience. Participants were asked to reflect on the positive and negative aspects of the interpreter and interaction between the interpreter and physician. They were also asked about experiences with language barriers in the healthcare setting. Interviews were audio recorded and transcribed. All transcripts were reviewed, and themes were generated using a grounded approach. Qualitative analysis was conducted with Atlas.ti.

RESULTS: We interviewed 22 individuals (9 males and 13 females) with a mean age of 65. Individuals had lived in the U.S. for an average of 34 years, and most ($n=18$) had come to the U.S. from Mexico. Most individuals ($n=15$) had less than a high school education and all had annual incomes of $\leq \$30,000$. Respondents primarily discussed experiences with bilingual staff, family, or phone interpreters. Participants discussed challenges in seeking medical care including feeling ignored, uncertainty about interpreter access, and poor care when no interpreter was present. Three main factors valued in interpreters were 1) personal attributes, 2) communication and 3) extra-linguistic roles. Participants valued “displays of kindness” such as an interpreter smiling or greeting them. They described feeling uncomfortable when interpreters were antagonistic or frustrated. Participants placed importance on attentiveness, describing the benefits of an interpreter who was not rushed and who focused on interpreting for the duration of the encounter. Trust was also important in creating a positive experience, and interpreters were trusted if they treated people well, were helpful during a medical encounter and were easily understood. Participants recognized the role of the interpreter as facilitating communication with the physician. Although participants recognized their limited ability to judge interpreter linguistic proficiency, many emphasized the importance of an interpreter being fluent in English and Spanish and having knowledge of medical terminology. Individuals described selective communication, where interpreters filtered information between the patient and physician, or excluded the patient from the conversation. Participants also highlighted explanatory power, noting the advantage of an interpreter adequately communicating their concerns and ensuring they understood the physician’s assessment and instructions. In addition to assisting with communication, interpreters played several other vital roles, including providing health information beyond what was given by the physician, helping to navigate the healthcare system, offering psychological support during medical encounters, and serving as patient advocates.

CONCLUSIONS: Our respondents described multiple factors they valued in their medical interpreter beyond direct interpretation. Interpreter training programs should

consider teaching interpersonal skills and strategies to ensure communication with individuals of diverse socioeconomic and educational backgrounds in addition to focusing on linguistic ability. Improving care delivery for LEP patients requires adequate communication and support for patients as they navigate a complex healthcare system. Quality measures that incorporate the patient perception of interpreters may be important to evaluate medical interpreters and guide improvement efforts.

PATIENT RISK-STRATIFICATION AS A TOOL FOR ALLOCATING ADULT CARE COORDINATION SERVICES Tracy L. Johnson²; Michael J. Duffee²; Rachel Everhart²; Carlos Oronce²; Daniel Brewer²; Mary vander Heijde²; Deborah Rinehart²; Kathy Thompson³; Diana Botton¹; Jeremy Long²; Vishnu Kulasekaran²; Holly A. Batal². ¹DHMC, Denver, CO; ²Denver Health, Denver, CO; ³Denver Health and Hospital Authority, Denver, CO. (Tracking ID #2198696)

BACKGROUND: Multiple studies affirm that medical home-based transitions of care/care coordination services are associated with improved quality and patient satisfaction. However, evidence for net cost avoidance has been more mixed. We sought to implement a patient risk stratification methodology to identify patients in need of complex care coordination services and to evaluate the impact of this population health approach on overall health care costs as well as population-specific costs. Denver Health (DH) is an integrated safety net delivery system serving predominantly uninsured and publicly-insured patients. DH has explicitly defined an accountable population of 60,000 adult patients for which DH is—or should be—providing comprehensive, patient-centered, primary care-based services. Using a combination of clinical information, utilization history, and a predictive modeling tool, DH dynamically stratified this population and identified four broad categories (tiers) of care needs. A graduated set of enhanced clinical and HIT services are matched to each risk tier and allocated according to individual needs within tiers, with more and higher intensity services reserved for higher tier patients. The highest risk tier (Tier 4) patients were eligible for a variety of primary care-based interventions depending on additional individual-level factors. A transition of care (TOC) intervention was implemented for recently discharged patients to ensure prompt primary care follow-up and identification of any additional follow-up needs. TOC patients were referred, as needed, to on-going complex care coordination services as were other Tier 4 patients identified as high-risk by clinical teams. Individuals with repeat readmissions (“super-utilizers”) were screened for eligibility for separate primary care clinic for exclusively high-risk patients, organized according to ambulatory-ICU model.

METHODS: We analyzed Medicaid managed care data to validate the financial stratification. We quantified overall health care costs via an independent actuarial analysis of the entire patient population inclusive of high- and low-risk adults. Hypothesizing that Tier 4 would contribute disproportionately to any cost avoidance achieved, we also assessed overall Tier 4 program reach, overall Tier 4 costs, and utilization trends for Tier 4 super-utilizers.

RESULTS: The actuarial analysis confirmed that baseline Medicaid per member per month (PMPM) costs increase by risk strata: Tier 1 (\$343.71 PMPM); Tier 2 (\$814.05 PMPM); Tier 3 (\$2887.07 PMPM); Tier 4 (\$7741.93 PMPM). Preliminary actuarial findings based on the first 11 months of program data estimated a 2.7 % overall reduction in Medicaid spending—driven primarily by a 6.1 % reduction in Tier 4 spending—relative to the prior (baseline) year’s spending, adjusted for inflation.

CONCLUSIONS: Improved precision in targeting of intensive care coordination services to adult patients most likely to benefit may enable self-sustaining care models that result in reduced hospitalization and lower overall health care costs.

PATIENT TEACHER IN PATIENT SAFETY: LEARNING ALONGSIDE PATIENTS AND FAMILIES William Martinez²; David Browning³; Pamela Varrin³; Barbara Sarnoff¹; Sigall K. Bell¹. ¹BIDMC, Boston, MA; ²Vanderbilt University Medical Center, Nashville, TN; ³Boston Childrens, Boston, MA. (Tracking ID #2201064)

BACKGROUND: Experts recommend engaging patients in safety efforts, but robust partnering experiences are limited. We developed a workshop on medical error disclosure and prevention bringing interprofessional clinicians together with patients/family members.

METHODS: A prepost survey design was used to evaluate the impact of workshops on concordance of clinician and patient/family views regarding error disclosure. Survey items utilized a 5-point Likert-scale from strongly disagree=1 to strongly agree=5.

RESULTS: Baseline surveys were completed by 96 % (53/55) of interprofessional clinicians who registered for workshops and 81 % (71/88) of patients/family members from two hospital advisory councils. Patient expectations regarding error disclosure were significantly different from clinician expectations across 72 % (8/11) of survey items. Regarding error disclosure, patients were more likely than clinicians to believe “patients want to know all the details of what happened” (mean, 4.72 v. 4.20, $p<0.001$), and less

likely than clinicians to believe “patients find explanation(s) more confusing than helpful” (mean, 1.64 v. 2.64, $p < 0.001$), and “patients no longer trust their doctor” (mean, 2.35 v. 3.10, $p < 0.001$). Presented an error vignette (antibiotic administered despite allergy with no immediate adverse effect), patients were more likely than clinicians to agree that the error should be disclosed (mean, 4.77 v. 4.30, $p = 0.005$), that the patient/family would want to know (mean, 4.63 v. 4.30, $p = 0.02$), and less likely to agree that the disclosure would do more harm than good (mean, 1.67 v. 2.14, $p = 0.02$). Following the workshop, patient and clinician expectations showed greater concordance, with differences between patient and clinician views across $< 50\%$ of expectation items, and no significant differences in the vignette responses. All patients (9/9) and 84 % (46/55) of clinicians completing the program felt comfortable discussing errors together and nearly all (96 %) clinicians reported patient/family participation was valuable to their learning. At 3-month follow-up, 79 % (30/38) of clinicians stated workshop participation helped to make their patient interactions more collaborative.

CONCLUSIONS: A workshop including patients/family members in error disclosure and prevention training is feasible and effective. Even with motivated, self-selecting clinicians, collaborative learning with patients/families highlights important differences in patient/clinician perspectives at baseline, and brings patient and clinicians views about disclosure closer together.

PATIENT-CENTERED MEDICAL HOME IMPLEMENTATION AND BURNOUT AMONG VA PRIMARY CARE EMPLOYEES. Joseph A. Simonetti³; Philip W. Sylling⁷; Karin M. Nelson²; Sandra Joos¹; David Mohr⁴; Idamay Curtis⁷; Leslie Taylor³; Chip B. Harvey⁷; Gordon Schechtman⁶; Stephan D. Fihn⁷; Christian D. Helfrich⁵. ¹Portland VA Medical Center, Portland, OR; ²University of Washington, VA Puget Sound, Seattle, WA; ³VA, Seattle, WA; ⁴VA Boston Healthcare System, Boston, MA; ⁵VA Puget Sound Healthcare System, Seattle, WA; ⁶Veterans Affairs Central Office, Milwaukee, WI; ⁷Veterans Health Administration, Seattle, WA. (Tracking ID #2198324)

BACKGROUND: Burnout is common among primary care staff and is associated not only with expressed intent to leave clinical practice but also less desirable patient and provider outcomes (e.g., depression). Patient-centered medical home (PCMH) models entail changes in primary care delivery, such as improvements in team functioning, that have been shown to be associated with lower burnout. In 2010, the VA began implementing a PCMH model, called the Patient-Aligned Care Team (PACT), at more than 900 primary care clinics. Previous studies of the PCMH's effect on burnout have produced mixed results, though a recent VA study reported lower staff burnout at sites with more effective PACT implementation. The aims of this study were to estimate the change in burnout prevalence among the VA primary care staff from 2012 to 2013, determine whether extent of clinic-level PACT implementation was associated with clinic burnout prevalence, and determine whether clinic-level progress in PACT implementation from 2012 to 2013 was associated with change in clinic-level burnout.

METHODS: We performed a retrospective analysis using data from the 2012 and 2013 VA All Employee Survey (AES), a human resources survey fielded annually to all VA employees (response rates 62.3 and 56.3 %, respectively). We included respondents who identified “primary care” as their main job role, responded to a question about burnout, worked in a clinic that had at least 1 respondent from each study year, and worked in one of four occupational categories that comprise the core PACT team: 1) primary care provider; 2) nurse care manager or registered nurse; 3) clinical associate (e.g., licensed practical nurse); or 4) administrative clerk. Primary outcomes were the change in overall VA primary care staff burnout prevalence from 2012 to 2013, clinic-level burnout prevalence, and change in clinic-level burnout prevalence from 2012 to 2013, which we assessed using a validated, single-item measure from the Physician Worklife Study that asked respondents to rate their level of burnout using a 5-level ordinal scale. Consistent with previous studies, we dichotomized burnout as absent (1–2) or present (3–5). To assess change in VA primary care burnout from 2012 to 2013, we aggregated respondent burnout to the clinic level and used linear regression with change in overall clinic-level burnout prevalence from 2012 to 2013 as the outcome. To assess the association between clinic-level PACT implementation and burnout, we used the PACT Implementation Progress Index (PI²), a validated metric measuring implementation among VA clinics. Clinic PI² scores range from –8 to 8; higher scores indicating more extensive PACT implementation, which we categorized by tertile. We used linear regression to model clinic-level burnout prevalence in 2013 as a function of 2012 clinic PI² scores and to model change in clinic-level burnout prevalence from 2012 to 2013 as a function of change in clinic-level PACT implementation between years. Each model adjusted for differences in respondent and clinic characteristics.

RESULTS: Among 8135 and 7510 primary care respondents working in 421 VA clinics included in the sample from the 2012 and 2013 AES surveys, 33.0 and 36.5 % screened positive for burnout, respectively. After aggregating to the clinic-level and adjusting for differences in clinic and respondent characteristics between years, we estimated that the change in burnout among VA primary care staff from 2012 to 2013 was +5.0 % ($p < 0.01$).

In unadjusted and adjusted models, there was no association between extent of PACT implementation as measured by PI² and clinic-level burnout prevalence, or between change in clinic-level PACT implementation and change in clinic-level burnout between years.

CONCLUSIONS: Burnout among VA primary care employees is high, and increased from 2012 to 2013. The extent to which clinics had implemented the PACT model in 2012 and their implementation progress from 2012 to 2013 were not associated with clinic-level burnout. While medical home models, including PACT, may prove to lower burnout among the primary care workforce, their effectiveness in doing so in the short-term remains unclear.

PATIENT-REPORTED BARRIERS TO SHARED DECISION-MAKING (SDM): TARGETS FOR BEHAVIORAL INTERVENTION Joseph Plaksin²; Sarita Kundrod²; Helen Hu³; Andrew B. Wallach¹; Sondra Zabar²; Adina Kalet²; Lisa Altschuler². ¹Bellevue Hospital, New York, NY; ²NYU School of Medicine, New York, NY; ³New York University, New York, NY. (Tracking ID #2184550)

BACKGROUND: Type 2 diabetes mellitus (DM) affects an estimated 12.5 % of adults in New York City (NYC), and diabetes-related complications account for 50 % of all hospital beds in the city. Patients with DM who take an active role in their healthcare and participate in shared decision-making (SDM) with their healthcare providers (HCPs) are better able to accomplish their management goals and maintain their health. However, due to patients' perceptions of their role, desires to be a “good patient,” and the difference in knowledge and power between patients and HCPs, many patients do not feel empowered to take an active role in their medical care. We aim to develop a Patient Empowerment Program (PEP) that will reframe the roles of the patient and HCP and democratize the patient-HCP relationship so patients can fully participate in SDM. To inform intervention development, we conducted a qualitative study to explore patient 1) experiences in HCP offices that facilitate or impede participation in SDM, 2) difficulties with diabetes care, and 3) willingness to participate in PEP.

METHODS: Patients with DM were recruited from Primary Care clinics at three public hospitals in NYC that primarily serve a low-income, low health literacy population. Eligibility criteria included English-speaking adults who have had DM for at least 1 year with a current hemoglobin A1c between 6.5 and 9 %. The initial interview questions were revised after the first 2 focus groups in order to better address all relevant topics of discussion. After completing 6 focus groups, no new significant themes emerged. All sessions were audio-recorded and transcribed by a professional company. Two independent coders reviewed one segmented transcript to develop a coding schema, then met to negotiate a finalized set of codes that were applied to the remaining transcripts. Dedoose software was used to assist with coding and thematic analysis.

RESULTS: We recruited 46 patients to participate in the focus groups, 30 were scheduled to attend, and 26 attended one of 6 focus groups. Participants were predominately female (62 %), and all were ethnic minorities, most commonly African-American or Hispanic. Other demographic and clinical information was not collected. Participants varied widely in terms of empowerment. Some felt comfortable taking charge of their healthcare and believed it was in their best interest to do so. One participant said, “if you help the doctor you help yourself. Go for your appointments, go for your blood work, and get involved. I noticed my blood sugar is better when I work with myself.” Others relied on their doctors to make decisions for them and believed the patient's role was to “go along because we're the patient” or “conform day-to-day by taking medication.” Thematic analyses focused on the communication and teamwork aspects of SDM and what helps or hinders participation in SDM. Participants initially reported overall positive experiences with doctors, stating they “felt at ease” with them or they know “if I need her, I can call her.” But, after further questioning, they were able to discuss negative experiences with doctors who did not communicate well, stating “it was like she didn't hear me” or “they will give you drugs without telling you the side effect[s].” Some were sympathetic to doctors, realizing that “they never say they're rushing but you can sense it.” But for others these difficulties led them to feel disengaged and frustrated to the point where they would refuse medication. One participant said “when the doctor says you need this or that, and gives me a lot of pills—I am not taking all [of] that.” Despite these concerns, very few participants reported changing doctors in order to find one they could have a better relationship with. Participants were also able to recognize communication issues from their own perspective, particularly when it came to diabetes. Multiple participants reported that they “didn't think [they were] sick” or that it took “a long run for them to start understanding how serious their condition [was],” usually after they began experiencing symptoms or, in one case, had a stroke. Thematic analyses also showed common difficulties with the daily aspects of diabetes care, but many participants did not tell their doctors for varying reasons, such as not knowing that financial difficulties were something they could discuss with their doctor, believing their doctor was too busy, or not believing the doctor would be receptive to their concerns.

CONCLUSIONS: Patients from a low-income and low health literacy population are able to recognize differences in HCP communication skills and discuss how behaviors of patients and HCPs are barriers to SDM. These results suggest that PEP can give patients concrete skills to communicate better with their HCPs, which can increase participation in SDM and empower patients to become active participants in their healthcare.

PATIENT-REPORTED DISCHARGE READINESS IS NOT ASSOCIATED WITH POST-DISCHARGE ADVERSE EVENTS: A PROSPECTIVE COHORT STUDY Darren Lau; Raj S. Padwal; Sumit R. Majumdar; Jenelle Pederson; Sara Belga; Sharry Kahlon; Miriam Fradette; Debbie Boyko; Finlay A. McAlister. University of Alberta, Edmonton, AB, Canada. (Tracking ID #2196826)

BACKGROUND: Readmissions to hospital after discharge are frequent, but clinicians are inaccurate at predicting in whom they will occur. We examined whether patients may be able to judge their own readiness for discharge using a gold standard of readmission or death at 30 days.

METHODS: We performed a prospective cohort study of adult patients discharged home from general internal medicine wards in Edmonton, Alberta, from 2013 to 2014. Patient-reported discharge readiness was measured using an 11-point Likert scale, with "readiness" defined by a score ≥ 7 . Discharge readiness and other covariates (including the LACE index for readmission risk, PHQ-9, GAD-2, and EQ-5D scores) were assessed at the time of discharge by structured personal interview.

RESULTS: Of 495 patients (mean age 62 years, 51 % female), 383 (77 %) reported being ready for discharge. Patients reporting being ready for discharge were less depressed and less anxious, and had fewer previous hospitalizations and greater perceived health status despite being older and having more comorbidities. At 30 day follow-up, 96 patients (19 %) had been readmitted or died, with no significant difference between those who reported they were ready for discharge (20 %) and those who reported they were not (19 %, $p=0.84$), even after multivariate adjustment (aOR 1.19, 95 % CI 0.66–2.15). Variables associated with a higher risk of readmission or death included the LACE index and depressive symptoms.

CONCLUSIONS: Patient reported discharge readiness was not associated with risk of readmission or death in the first 30 days after discharge. Future efforts should focus on improving interdisciplinary team assessments of discharge readiness using objective measures.

PATIENT-REPORTED MEDICATION ADHERENCE BARRIERS AMONG VETERANS AFFAIRS PATIENTS WITH CARDIOVASCULAR RISK FACTORS Leah L. Zullig^{3, 5}; Karen Stechuchak⁴; Karen M. Goldstein¹; Maren Olsen⁴; Felicia A. McCant⁴; Susanne M. Danus⁴; Matthew Crowley²; Eugene Oddone⁴; Hayden BOSWORTH⁴. ¹Durham VA; Duke University, Durham, NC; ²Durham VAMC, Durham, NC; ³Durham Veterans Affairs Medical Center, Durham, NC; ⁴Durham VA Medical Center, Durham, NC; ⁵Duke University, Duke, NC. (Tracking ID #2197594)

BACKGROUND: Cardiovascular disease (CVD) is a leading cause of morbidity and mortality in the United States. In addition to lifestyle changes, medication management is often required to control CVD risk factors. Many patients experience barriers making it difficult to take CVD risk factor-related medications as prescribed. The Cardiovascular Intervention Improvement Telemedicine Study (CITIES) was a tailored behavioral pharmacist-administered, telephone-based intervention for reducing CVD risk (ClinicalTrials.gov Identifier: NCT01142908). Our objectives were to: 1) describe patient-reported barriers to taking their medication as prescribed; and 2) evaluate patient-level characteristics associated with reporting medication barriers.

METHODS: We recruited patients receiving care at Durham Veterans Affairs Medical Center-affiliated primary care clinics. Eligible patients had poorly controlled hypertension and/or hypercholesterolemia as defined as blood pressure of $>150/100$ mmHg and/or low-density lipoprotein value >130 mg/dL. At the time of enrollment, patients completed an interview asking 7 questions derived from a validated measure of medication barriers. We describe patient characteristics and individual medication adherence barriers. We then use multivariable linear regression to examine the association between a medication barrier score and patient characteristics, including health literacy, financial status, and social support, among others.

RESULTS: Most patients ($n=428$) were married or living with a partner (57 %), were male (85 %), and had a diagnosis of both hypertension and hyperlipidemia (64 %). Nearly 57 % of the sample endorsed at least one barrier. The most commonly reported barriers were having too much medication to take (31 %) and forgetting whether medication was taken at a particular time (24 %). In adjusted analysis, those who were not employed (1.32; 95 % CI 0.50–2.14) or did not have someone to help with household tasks if needed (1.66; 95 % CI 0.42–2.89) reported higher medication barrier scores. Compared to those diagnosed with hypertension and hyperlipidemia, those with only hypertension (0.91; 95 % CI 0.04–1.79) reported higher medication barrier scores.

CONCLUSIONS: Despite access to low-cost or free medications in the VA healthcare system, barriers to medication adherence were common in this sample of veterans at high-risk for cardiovascular disease. Screening for medication barriers, including an evaluation of sociodemographic characteristics such as employment status and lack of adequate social support, may help identify patients at risk for potential adherence problems. Tailored scalable interventions that address medication barriers will be essential to continue decrease the impact of cardiovascular disease in this population.

PATIENTS' PERSPECTIVES ON TAPERING OF CHRONIC OPIOID THERAPY: A QUALITATIVE STUDY Joseph W. Frank^{1, 2}; Karen Mellis¹; Susan L. Calcaterra^{1, 3}; Steve Koester⁴; Daniel Matlock¹; Cari Levy^{2, 1}; Ingrid A. Binswanger^{1, 5}. ¹University of Colorado School of Medicine, Aurora, CO; ²VA Eastern Colorado Health Care System, Denver, CO; ³Denver Health Medical Center, Denver, CO; ⁴University of Colorado Denver, Denver, CO; ⁵Kaiser Permanente Colorado, Denver, CO. (Tracking ID #2198192)

BACKGROUND: There is inadequate evidence of long-term benefit and growing evidence of harms of chronic opioid therapy (COT) in the management of chronic pain. As many of these risks increase in a dose-dependent manner, opioid dose reduction, or opioid tapering, may reduce the risks of COT. However, little is known about patients' experiences during and after opioid tapering. We sought to explore patients' perceptions of barriers to and facilitators of opioid tapering.

METHODS: We conducted a qualitative study of patients with current or recent experience with chronic opioid therapy for chronic pain ($N=12$). We recruited patients from primary care settings in two medical centers: an urban, safety-net medical center in Denver, CO and an academic medical center in Aurora, CO. Inclusion criteria included self-reported musculoskeletal pain ≥ 6 months duration, age ≥ 18 years old and fluency in English. We used a purposive sampling strategy to recruit patients both with and without experience with opioid tapering (i.e. ongoing COT, current opioid taper or opioid discontinued within prior 3 years). We conducted semi-structured, audio-recorded interviews. We analyzed transcribed interviews using a team-based, mixed inductive and deductive approach, guided by Social Cognitive Theory and the Transtheoretical Model. We iteratively refined emerging themes in consultation with an advisory group consisting of experts in opioid medications, palliative care and medical decision-making.

RESULTS: Participants had a mean age of 57 years old, were 33 % male and 75 % White. Two participants (16 %) were on COT and not tapering, 7 patients (59 %) were currently tapering COT, and 3 (25 %) had discontinued COT. Seven participants (58 %) were recruited from the academic medical center, and 5 from the urban, safety-net hospital. We identified 3 main domains related to the experience of opioid tapering: Opioid withdrawal, patient-provider interactions, and outcomes after tapering. First, participants emphasized the central role of opioid withdrawal symptoms in both COT and opioid tapering. Experiences with opioid withdrawal coalesced around 3 subdomains: Intensity of withdrawal symptoms, fear of future withdrawal, and withdrawal as a barrier to dose reduction. Second, participants described both the importance of a relationship with a trusted physician as well as the potential for patient-provider conflict when discussing opioid tapering. Finally, participants with experience with opioid tapering recounted largely positive outcomes following opioid tapering.

CONCLUSIONS: Patients' experiences identified both barriers to and facilitators of opioid tapering in the context of COT for chronic pain. Patients' expectations prior to opioid tapering focused on withdrawal symptoms and increased pain while experiences after tapering were largely positive. Future efforts to support opioid tapering should elicit perceived barriers to tapering and should be prepared to manage opioid withdrawal symptoms during tapering. Further trials

are needed to elucidate the impact of opioid tapering on patient-reported outcomes such as pain and function.

Representative Quotes of Main Domains

Domain	Representative quote
Opioid withdrawal	
Intensity of withdrawal	"I don't think they're aware of how bad withdrawals are. I mean there's vomiting bile. There's stomach cramps, there's the cold shakes and fever...I mean it's pretty bad even from somebody that's just on them for a few months and then stops."
Fear of future withdrawal	"I also had lots of fears about, let's say, there was an apocalypse in our society. What would happen to me? Where would I get my medication from? I would get so sick not having those drugs 'cause I was physically dependent on these drugs'
Barrier during tapering	"I go through the withdrawal from these drugs every time I taper a little. I just can't believe the power, and the drugs actually talk to me in my mind... The drugs are actually saying, don't do it, don't do it."
Patient and provider interactions	
Importance of trust in prescriber	"I think I would have trusted her and I think I would have started tapering if she would have said, I really want you to try tapering."
Potential for conflict	"I would be offended, you know, because to say I should just decrease my dose means that my pain is not real."
Outcomes after tapering	
Pain	"It's not much worse without the medication as it is with it. After you've taken it for a while, it doesn't do any good. That's what I've found. But that's hard to convince people of it. They look at me like I'm nuts. But it's true. I mean my pain is not any more severe than it was when I was taking all that stuff."
Function	"I am more alert since I stopped taking [OxyContin] and I need less sleep, which is a blessing. So I'm able to do more things with my life."

PATIENTS' EXPERIENCES MANAGING CARDIOVASCULAR DISEASE RISK FACTORS IN PRISON Emily H. Thomas¹; Emily A. Wang¹; Leslie Curry²; Peggy G. Chen³. ¹Yale School of Medicine, New Haven, CT; ²Yale School of Public Health, New Haven, CT; ³RAND Corporation, Santa Monica, CA. (Tracking ID #2197876)

BACKGROUND: More than two million individuals are incarcerated in U.S. correctional facilities. Prisoners disproportionately suffer from many chronic conditions, including hypertension, diabetes, and cardiovascular disease (CVD). The most common cause of death amongst prisoners is CVD, and prisoners, in the 2 years post release, are twice as likely to die from CVD as matched peers in the community. Despite the greater risk of CVD mortality in patients with a history of incarceration, little is known about how correctional settings confer this risk and how risk factors for CVD are managed in prison. We elicited patients' perspectives about how correctional systems support CVD management and self-care practices to inform future interventions that may realign constraints of the correctional system with best practices for chronic care.

METHODS: To assess patient experiences with chronic disease management, we conducted 26 semi-structured, in-depth interviews with a purposeful sample of men and women who had been released from prison within the prior 6 months. All participants had CVD or a CVD risk factor (diabetes, hypertension, hyperlipidemia, or obesity). In accordance with grounded theory, we inductively generated themes about chronic disease care, access, and supports in the correctional setting. Our interdisciplinary team coded the transcripts independently, and in weekly group meetings, we negotiated consensus in coding interpretations. Data collection and analysis occurred iteratively using the constant comparative method to refine themes and to allow for unifying themes to emerge from interview transcripts.

RESULTS: Four themes emerged about CVD management and self-care practices: (1) Access to care for chronic conditions is present, yet complicated in the correctional setting. An acute care paradigm and barriers to care, including non-medical gatekeepers, application-based triage, and copays, detract from continuity in prisoners' care for chronic conditions. (2) Patient-provider partnerships can be undermined by providers' competing correctional and medical roles. For example, participants report that providers may issue punitive tickets or send patients to solitary confinement for medication non-adherence. A

mutual distrust between patients and providers may follow and impair collaboration to individually tailor care. (3) Informal support systems through peers in prison and family members in the community can fill gaps in the system and facilitate self-management education and skills development. (4) The trade-off between prisoner security and patient autonomy influences opportunities for self-management. As a result, prisoners may not acquire skills for medication self-administration, self-injecting insulin, self-monitoring, and complication management that are crucial to self-care upon re-entry to the community.

CONCLUSIONS: CVD management may be improved by shifting the medical care paradigm in prison from acute "sick visits" to routine chronic disease monitoring; clarifying and separating the correctional and medical roles of health care providers; strengthening informal partnerships for peer-led education; and creating more opportunities for practice of self-management skills. Future interventions should explore ways that prisoners can practice chronic disease management and receive provider feedback on medication adherence, self-monitoring, and complication management while minimizing punitive correctional oversight. These interventions should be targeted to improve not only clinical outcomes in the correctional setting, but also transitions of care from the correctional setting to the community.

PATIENTS' FEELINGS OF BEING UNDERSTOOD BY THEIR PHYSICIAN MEDIATES THE ASSOCIATION BETWEEN HEALTH BELIEFS AND MEDICATION ADHERENCE Pablo Buitron de la Vega; Chieh Chu; Nancy R. Kressin. Boston Medical Center / Boston University, Dorchester, MA. (Tracking ID #2198855)

BACKGROUND: Poor adherence to antihypertensive medications continues to be a major challenge for chronic disease management. Patients' beliefs and health literacy can interfere with adherence; studies show that greater concerns about medications, less belief in their necessity and lower health literacy are associated with poor adherence, and better doctor-patient relationships are generally associated with better adherence, though less is known about how feelings of being understood by one's physician may influence adherence. Rarely have the effects of this array of factors, together with other known socio-demographic influences (age, sex, race) on adherence, been examined simultaneously. The aim of our study is to understand the association between health beliefs and medication adherence in adult patients with hypertension, controlling for the known effects of sociodemographics (age, sex, race and health literacy), and to understand whether the patient's perception of being understood by the physician mediates that association.

METHODS: This study is a secondary analysis of a cross-sectional study done in 2004 that included adult hypertensive white and black patients from the primary care clinics of an urban safety-net hospital. Patients' characteristics were obtained from a questionnaire administered after the clinic encounter and from the patient's electronic medical record. The "Beliefs about medicines questionnaire" was used to assess concerns about medications and beliefs in the necessity of medications. To assess medication adherence, we used the "Hill-Bone compliance to high blood pressure therapy scale". The REALM- short form was used to assess patient's health literacy. An additional item assessed patients' perceptions of the degree to which they felt understood by their physician. A bivariate analysis was used to determine which of the independent variables: concerns about medications, beliefs in the necessity of medications, patient's perceptions of being understood by their physician and socio-demographics (health literacy, race, gender and age), were associated with medication adherence. We used the independent variables that were significantly associated on the bivariate level (excluding patient's perceptions of being understood by their physician), to conduct a multiple linear regression analysis and examine their simultaneous association with medication adherence. Then, we added patients' perceptions of being understood by their physician into the multiple linear regression analysis to examine its mediating effect on the association between health beliefs (concerns about medications and beliefs in the necessity of medications) and medication adherence.

RESULTS: Eight hundred six hypertensive patients were included in the analysis. Sixty-five percent were females, 57 % black and the overall mean age was 59 years. In the bivariate analyses, we found that greater concerns about medications, less beliefs in the necessity of medications, more negative patient's perceptions of being understood by their physician, poor health literacy, black race, female gender, and younger age were associated with poor medication adherence (all p's <0.05). The multiple linear regression analysis showed that less belief in the necessity of medications and greater concerns about medications were significantly associated with poor medication adherence after adjusting for socio-demographics (age, gender, race, health literacy). Finally, the inclusion of patients' perceptions of being understood by their physician into the multiple linear regression, eliminated the significant effect of concerns about medication on adherence.

CONCLUSIONS: Patients' positive perceptions of being understood by their physician can ameliorate the negative impact of concerns about medications on adherence. This

finding underscores the importance of physician empathy and patient-centered care, oriented towards understanding each individual patient and their needs and goals for care.

PERCEPTION AND UNDERSTANDING OF OVERUSE OF MEDICAL RESOURCES BY HOUSESTAFF AND FACULTY AT AN ACADEMIC MEDICAL CENTER Erik Bartholomew; Brandon Combs. University of Colorado, Denver, CO. (Tracking ID #2200584)

BACKGROUND: Growing concern about the unsustainable growth in health care spending and the potential harms from unnecessary medical care has spurred interest in educational initiatives focused on teaching value to medical trainees. To our knowledge, no data exist regarding resident perceptions on the scale of low value care and ability to recognize medical overuse in the inpatient setting. Using the Right Care survey, we aimed to better understand these issues among residents at a large academic medical center to guide further development of high value care curricula aimed at reducing medical overuse.

METHODS: Resident physicians in internal medicine and family medicine at the University of Colorado were recruited by email to respond to a 10 item survey via Survey Monkey. The Right Care survey comprised questions meant to assess perceptions of the scale of overuse in the inpatient setting, its drivers, and how it manifests. Data were compiled anonymously.

RESULTS: Sixty-five of 204 residents completed the right care survey (response rate 32 %). Participants were evenly split between PGY1-3 levels of training. Fifty-nine percent of participants appropriately recognized medical overuse in a given scenario. Among a list of frequently ordered tests and imaging studies, "sometimes" was most commonly selected when asked how often each intervention was likely to influence management. Sixty-four percent of participants felt that tests and procedures unlikely to influence management were ordered daily. The most important perceived drivers of such interventions were supervisor expectation and diagnostic uncertainty. Sixty-five percent felt that up to 10% of tests and procedures were performed on patients, who if fully informed, would have declined them. Only 34 % of respondents "agreed or strongly agreed" that they fully consider patient preferences when ordering a test or study. Seventy percent of respondents indicated desire for their training program to devote more time to teaching about medical overuse.

CONCLUSIONS: Our study suggests that residents in internal medicine and family medicine believe that medical overuse and the provision of low value care in the hospital are common though recognition may be difficult. Encouraging clinicians to point out low value care when it occurs may help with trainee recognition. Since important drivers of overuse appear to be attending expectations and diagnostic uncertainty, educational efforts may need to target senior clinicians and promote a culture that embraces uncertainty. Limitations include single center study so results may not be applicable to other institutions.

PERCEPTIONS OF AFFORDABILITY OF CARE AND ACCESS TO INFORMATION ABOUT HEALTH INSURANCE AMONG IMMIGRANTS AFTER MASSACHUSETTS HEALTH REFORM Ye Jin Kang²; Danny McCormick³; David Bor¹; Leah Zallman¹. ¹Cambridge Health Alliance, Cambridge, MA; ²Harvard Medical School, Houston, TX; ³Harvard Medical School / Cambridge Health Alliance, Cambridge, MA. (Tracking ID #2198825)

BACKGROUND: Under the Affordable Care Act (ACA), immigrants are eligible to gain insurance through Medicaid expansion and subsidized private insurance, although undocumented and legally present immigrants in the US for <5 years will continue to be barred from federally sponsored coverage, including Medicaid. Because immigrants often have limited financial resources, concern about the affordability of care under the ACA remains a concern. In addition, because of limited English language proficiency and limited experience with the US health care system, accessing information about newly available health plans could be a particular challenge for some immigrants. The ACA was modeled on Massachusetts' (MA) 2006 health reform law. Thus, although the MA law covered some low-income legally residing immigrants who are not eligible under that ACA, the MA reform may serve as a bellweather for immigrants' experiences with national health reform, begun only 1 year ago. Despite MA's efforts to provide insurance to immigrants, no studies have investigated immigrants' experience with perceptions of affordability of care or knowledge of insurance under MA health reform.

METHODS: Between August 2013 and January 2014, we conducted face-to-face surveys in four languages of a convenience sample of 1306 (response rate of 81 %) patients in three Emergency Departments at the 2nd largest safety net institution in MA. We interviewed 647 immigrants and 664 US-born patients with private (commercial) insurance, no insurance, Medicaid and Commonwealth Care, subsidized insurance made available under the MA reform to low income individuals (including legally residing immigrants). We assessed knowledge about insurance and views on affordability of care

and insurance. We determined the percentage of immigrants and non-immigrants experiencing each outcome and then performed comparisons using chi square analyses. We also conducted multivariable logistic regression analyses to adjust for age and gender.

RESULTS: Immigrants reported higher levels of financial burden than did non-immigrants; they were more likely to report that they could not afford basic needs due to medical bills (17 % vs 12 %, $p=0.0163$) and more likely to be worried about the cost of their current hospital visit (36 % vs 22 %; $p<0.0001$). Immigrants reported more difficulty affording their insurance (14 % vs 9 %, $p=0.0141$) and were more concerned about paying their premiums (28 % vs 11 %, $p=0.0003$). Immigrants were also less likely to know their copayment for regular doctor visits and medications (44 % vs 58 %, $p=0.0002$), less likely to have received insurance information in their primary language (29 % vs 1 %, $p<0.0001$), and more likely to report that signing up for insurance would be easier with fewer plans (50 % vs 33 %, $p=0.0187$). Among those with any chronic disease, immigrants reported no more cost-related barriers to seeking medical care (28 % vs 30 %, $p=0.6294$). Overall, adjustment for age and gender did not alter the findings.

CONCLUSIONS: Despite efforts to provide affordable insurance and information for all residents under MA health reform, immigrants continued to report more difficulty affording and understanding their insurance, though no higher cost-related barriers to care, as compared to non-immigrants. Our findings suggest that disparities in affordability and knowledge about insurance may persist for immigrants insured under the ACA. While some ACA measures—such as increased funding for insurance navigators—could help alleviate the disparities identified here, our study highlights the need for careful monitoring of and likely additional provisions to reduce disparities and improve immigrants' experiences affording care.

PERCEPTIONS OF AUTONOMY IN INTERNAL MEDICINE, PEDIATRICS, AND COMBINED INTERNAL MEDICINE-PEDIATRICS Alexandra E. Mieczkowski³; Allen Friedland¹; Robert J. Habicht⁴; Reed Van Deusen²; Alda Maria Gonzaga². ¹Christiana Care Health System, Newark, DE; ²University of Pittsburgh, Pittsburgh, PA; ³University of Pittsburgh Medical Center, Pittsburgh, PA; ⁴University of Maryland School of Medicine, Baltimore, MD. (Tracking ID #2195687)

BACKGROUND: Many Internal Medicine (IM) programs assist in training combined Internal Medicine-Pediatrics (MP) residents. MP residents must negotiate the domains of two separate specialties including differing expectations of supervision and autonomy, both essential aspects of training. It has been shown that MP residents perceive significant differences in the autonomy they experience in the two specialties, with MP residents more likely to agree that they receive appropriate autonomy while on IM rotations. Previous research has also shown that MP residents are more likely to agree that they receive too little oversight on IM compared to pediatrics. It is not known whether categorical peers share MP residents' perceptions, or how resident perceptions compare to those of faculty.

METHODS: Three institutions with IM, Pediatrics, and MP training programs agreed to participate: (University of Pittsburgh Medical Center (UPMC) and Children's Hospital of Pittsburgh, University of Maryland Medical Center, and Christiana Care Health System and Nemours/DuPont Children's Hospital). An online survey previously developed for use with MP residents was modified and pilot-tested on faculty and chief resident volunteers. Categorical IM and pediatrics residents received a survey with specialty-specific questions. MP residents received a survey containing identical question blocks for both specialties. The block with which a combined respondent began the survey was randomized in an attempt to avoid bias within the MP respondents. A similar procedure was taken for faculty, with the exception of dual-trained faculty who were only provided questions for both specialties if they consistently attended on both specialties. The study was approved as IRB Exempt by UPMC. Data was analyzed descriptively and where appropriate with t tests using Stata 13.1.

RESULTS: MP residents perceived significant differences in the autonomy they received between the two specialties. MP residents were more likely to agree that they received an appropriate level of autonomy while on IM rotations, with a mean score of 4.3 on 5 point Likert scale (1=strongly disagree, 5=strongly agree), relative to pediatric rotations (mean of 2.7, $p<0.001$). There was no difference in the general perception of MP residents compared to their IM peers (means 4.3 and 4.4, $p=0.47$), which is in contrast to a significant difference between the perceptions of MP residents to their pediatric resident peers (means 2.7 and 4.0, $p<0.001$). IM and MP residents (means 2.1, 2.5) in turn had similar perceptions of their autonomy compared to their categorical IM and MP faculty (means 2.4, 2.6) who attend on the generalist wards (p values >0.05). However, MP residents were significantly more likely to agree that they received too little oversight on IM relative to their categorical peers (means 2.5 and 2.1, $p=0.008$).

CONCLUSIONS: MP residents generally had similar perceptions of the level of autonomy they receive to their categorical IM peers and agreed they received an appropriate amount of autonomy, but were more likely to perceive too little oversight on the specialty than their categorical IM peers. These results may be related to the ability of MP residents

to directly compare between the two specialties, but further study is required to determine whether, how, and for whom the expectations of or practice of oversight should be modified.

PERCEPTIONS OF OPIOID-ASSOCIATED OVERDOSE RISK: A QUALITATIVE STUDY OF PRIMARY CARE PROVIDERS AND THEIR PATIENTS IN THE SAFETY NET. Emily E. Hurstak; Margot Kushel; Christine Miaskowski; Jamie Chang; Rachel Ceasar; Kara Zamora; Kelly Knight. University of California San Francisco, San Francisco, CA. (Tracking ID #2196915)

BACKGROUND: Chronic Non Cancer Pain (CNC) is pain that persists longer than 3 months that is not caused by a malignancy nor related to pain at the end of life. CNC is prevalent and is more common in individuals with a history of a substance use disorder (SUD). Individuals with a SUD are known to be at higher risk for opioid analgesic misuse, but they are also more likely to receive opioids for the management of CNC. The risk of opioid-related overdose in this population is a particular concern to clinicians and regulatory agencies. Risk for overdose is higher in those with a history of a SUD due to opioid misuse and the synergistic effects of alcohol, illicit substances, and opioid analgesics.

METHODS: Pain Management in the Clinic and the Community (PMCC) is a multi-modal qualitative study examining primary care providers' (PCPs) and patients' pain management practices in diverse safety net healthcare settings. Study staff conducted in-depth qualitative interviews with 23 PCPs (MD, nurse practitioner or physician assistant) recruited from six safety-net clinics across four counties in the San Francisco Bay Area. The study enrolled 1-5 patients of each PCP to create patient-PCP dyads. Patient enrollment criteria included: having CNC managed by the PCP and having a documented past or current history of a SUD. Interviews were digitally recorded, transcribed, and coded and entered into ATLAS-ti qualitative data management software. Major themes were identified using grounded theory methodology. We qualitatively describe PCP and patient perspectives on opioid-associated overdose risk and clinic safety strategies to reduce risk.

RESULTS: Sixty-five percent of safety net PCPs were male. All clinical settings had implemented at least one of the following strategies to reduce risk of opioid misuse and overdose: pain agreements, dose limitations on prescribed opioids, urine toxicology screening, and the prescription of intranasal naloxone. PCPs repeatedly identified the risk of opioid analgesic-associated overdose as a key concern associated with the prescription of opioid analgesics to patients with substance use. Patients reported fewer concerns that opioid analgesics alone could lead to unintentional overdose. Instead, patients were concerned about the risk of physical dependence due to opioid analgesics and overdose due to illicit drugs. Both patients and PCPs described changes in clinic opioid policies as abrupt and, at times, punitive. Most PCPs described new clinic policies as supportive of their clinical pain management strategies, while they also expressed concern that patients may leave primary care or return to illicit drug use as result of limited access to opioid analgesics. Patient experiences with clinic policy changes ranged from perceptions of intense policing and racial discrimination to slight inconvenience and indifference. Both patients and PCPs expressed concerns about fairness while also the desire for care to be individualized.

CONCLUSIONS: Primary care providers in safety net clinics in the San Francisco Bay Area were more concerned about the risk of opioid overdose in patients with a history of substance use than were patients with SUD and CNC. While PCPs viewed clinic safety innovations and government policy changes as positive innovations for patient safety, both patients and clinicians had concerns about the unintended consequences of these policies. We found a disconnect between PCP and patient perspectives on overdose risk. If patients who are at high risk for opioid related overdose do not identify this hazard, clinic safety strategies around opioid overdose may be less effective. Future research is needed on improving patient education on the risks of opioid analgesic treatment for chronic non-cancer pain.

PERCEPTIONS OF SAFETY, EFFICIENCY, AND EDUCATION IN HOLD-OVER SIGNOUT: A QUALITATIVE STUDY Trevor Jensen; Jonathan Duong; Sasha Morduchowicz; Lekshmi Santhosh; Sarah Schaeffer; James D. Harrison; Bradley A. Sharpe; Sumant Ranji. University of California San Francisco, San Francisco, CA. (Tracking ID #2196899)

BACKGROUND: Signout of newly admitted patients from a night admitting physician to a primary team is common, making up roughly 40 % of admissions to the inpatient medical service at our hospital. Nevertheless, little is known about these "holdover" signouts, and there is no standardized format for ensuring they contain appropriate information transfer and maximize patient safety.

METHODS: We designed a qualitative study using focus groups and interviews of internal medicine (IM) residency leadership, hospitalists, and IM residents at our academic

tertiary care hospital. We used a standardized set of nine questions developed by the study investigators after review of signout literature. The questions explored participants' perceptions of the safety, efficiency and education of current holdover signout and elicited ideas about how to improve these domains. All sessions were audio recorded, transcribed, and analyzed by two investigators using content analysis.

RESULTS: We conducted three focus groups and eight structured interviews comprising 12 hospitalists and 15 residents. No significant differences were noted between resident and hospitalist opinions. Participants thought the purpose of holdover signout was safe and efficient transfer of patient care to a primary team. They noted that no formal framework exists for this signout at our institution and that presentation style varies. Participants thought that holdover signout was often inefficient due to repetition of information and poor logistics. Safety concerns were common, and involved unclear code status and severity of illness, delays in seeing patients, and poor medication reconciliation [Figure 1]. Formal education was rarely present. Participants agreed that holdover signout should use several best practices previously identified in the signout literature, including quiet location, minimal interruption, and verification of understanding and to-dos. Most thought that holdover presentations should be shorter than the traditional new patient history and physical, and should take fewer than 15 min. Most favored creating a standardized format that minimizes presentation of objective data that is available in the chart. Participants identified feedback on presentation skills and clinical reasoning as the most important educational opportunity.

CONCLUSIONS: Holdover signout is common, but minimal literature exists for this process. Our study found that holdover signout faces both common and unique challenges compared to other signouts and may benefit from some but not all established signout best practices. While our study was limited to a single academic center and residency program, our findings suggest that holdover signout may benefit from a unique standardized format.

Safety, Efficiency, and Educational Concerns with Holdover Admissions

FIGURE 1		
Categories	Subcategories	Subcategory Quotes
Based on literature Safety	Identified by content analysis	
	Delay in Seeing Patients	"Often times there is a big lag between when they get signed out and when they put in orders or call consults. That's what I worry about, particularly if there are more urgent concerns"
	Medication Reconciliation	"We assume that people have done an accurate med rec... but that is hard overnight... and then when things don't line up that's really confusing"
	Unclear severity of illness	"When you're the night team, it's just a really transient process... you don't really know them... things evolve... they were very stable and then they totally unraveled"
	Code Status	"We always mention code status... but I think there are instances where it isn't actually discussed much, and then was just assumed full code... and someone was really DNR/DNI... and that's a safety issue"
Efficiency	Repetitive information Logistics	"[The presentation] includes a lot of the data that is readily available on the computer and it can be looked up." "There are many teams who are receiving holdovers and different people handing off different things to different teams that I think the movement and coordination takes time."
Education	Process education Feedback Medical Teaching	"I think the education should really derive from teaching people how to make a presentation more succinct, more efficient while conveying the most important information." "As an attending, I am in a great position to give feedback on how the presentation was in terms of whether it meets my need as a person that's taking care of the patient now and whether any important information was missed from the presentation." "Sometimes we'll bring interesting articles to the table about how and why we approached specific care. And I think that's important for the resident and me or whoever is admitting the patient to share that information."

PHYSICIAN AWARENESS AND USE OF OVERTREATMENT GUIDELINES IN PRACTICE: A NATIONAL SURVEY OF US INTERNISTS

Kira L. Ryskina⁵; Eric Holmboe¹; Elizabeth C. Bernabeo²; Esther J. Kim⁵; Judy A. Shea⁴; Judith Long³. ¹ACGME, Philadelphia, PA; ²American Board of Internal Medicine, Philadelphia, PA; ³Philadelphia VA Center for Health Equity Research and Promotion, Philadelphia, PA; ⁴University of Pennsylvania, Philadelphia, PA; ⁵University of Pennsylvania, Philadelphia, PA. (Tracking ID #2199369)

BACKGROUND: Overtreatment guidelines that recommend against the use of tests and procedures have received increasing attention as a tool to reduce healthcare waste. Physicians' awareness and use of overtreatment guidelines and factors that influence those views are not well understood. We surveyed a national sample of internists on their views and practice of overtreatment guidelines, including factors that may influence their adoption, such as current practice and training characteristics.

METHODS: In July through September of 2014, we mailed a survey to a random sample of 1005 internal medicine physicians selected from the AMA Masterfile who completed residency within the last 10 years. The survey included questions about practice characteristics, training environment, overtreatment guidelines, and reported practice in hypothetical patient scenarios. Using factor analysis we developed a 9-item scale of residency cost-consciousness from physicians' perceptions of their residency training based on a number of characteristics. We then employed descriptive statistics to report physicians' views on overtreatment guidelines and multivariable logistic regression to test the associations between residency cost-consciousness, reported awareness and use of overtreatment guidelines, and hypothetical practice according to case scenarios.

RESULTS: Of the 441 (44 %) internal medicine physicians who returned the survey at the time of this submission, 41 % were in private practice and 65 % were salaried. Mean time from completing residency training was 6.7 years (SD 3.0). Most physicians discuss costs of care with patients: 42 % reported discussing costs "occasionally", 37 % "frequently", and 4 % "always". 88 % of physicians reported being familiar with overtreatment guidelines in their specialty and 80 % reported that the guidelines were useful in their practice. Compared to their current practice, 52 % of physicians reported that their practice style in residency was somewhat or a lot less cost-conscious while 19 % reported that their practice style in residency was somewhat or a lot more cost-conscious. There was considerable variation in physician training experiences related to costs of care: the mean residency cost-consciousness score was 27.1 (SD 5.3, range 10–41 out of 45). In residency, 37 % of physicians reported being exposed to teaching about cost-conscious care rarely or never, while 24 % reported frequent exposure. Compared to the bottom quintile, physicians who scored in the top quintile of residency cost-consciousness were more likely to bring up overtreatment guidelines in discussions with patients (OR=2.9, 95 % CI 1.2–7.2, $p=0.02$). Physician practice patterns measured using hypothetical scenarios based on current overtreatment guidelines varied (for example, 16 % of physicians reported never ordering antibiotics for acute mild-to-moderate sinusitis while 17 % reported ordering antibiotics for over half of their patients with the same presentation). Also, self-reported practice did not correlate with self-perceived use of overtreatment guidelines in practice or residency cost-consciousness.

CONCLUSIONS: The majority of US internists discuss costs of care with patients, but many report receiving scant training in this area during residency. Overtreatment guidelines are reported to be a useful tool in patient discussions. However, physician practice measured using hypothetical patient scenarios based on the guidelines does not appear to correlate with training factors or self-perceived use of guidelines.

PHYSICIAN-NURSE COLLABORATION IN A TERTIARY CARE ACADEMIC MEDICAL CENTER: DIFFERENCES BY PROFESSION

Georgia N. McIntosh; Darci Bowles; Reena H. Hemrajani; Nathan Schwartz; Miao-Shan Yen; Allison E. Phillips; Alan Dow. Virginia Commonwealth University, Richmond, VA. (Tracking ID #2196124)

BACKGROUND: A lack of effective physician-nurse collaboration has long been recognized to adversely impact patient and organizational outcomes. Despite substantial efforts towards developing strategies to improve interprofessional collaboration (IPC) in the acute care setting, consistent realization of this ideal remains elusive. Some studies have suggested that nurses and physicians have different perceptions of interprofessional collaboration and this lack of a shared mental model for interprofessional collaboration hinders improvement in this arena. We sought to evaluate for a difference in the perception of interprofessional collaboration between nurses and physicians and identify any potential contributing factors and barriers.

METHODS: Data were collected from 47 nurses, 29 housestaff physicians and 17 hospitalists providing care for medicine service patients in a large tertiary care academic medical center between June and November, 2014. Via an electronic survey, we gathered responses for the 14-item IPC scale, a reliable and valid measure of individual perceptions

of the level of collaboration in a healthcare environment. Each IPC item is scaled from 1–5 (strongly disagree—strongly agree). The IPC sum scores were calculated as the outcome variable (range: 14–70). Generalized linear models were used to correlate the IPC scores with the other variables. Pairwise comparisons were examined using Tukey's Honestly Significant Difference test (HSD).

RESULTS: Data analysis revealed an overall average IPC sum score of 47.87±9.60 (nurse: 42.8±8.68; housestaff: 53.81±7.08; hospitalist: 51.7±8.23). The result of the generalized linear regression indicated that the average IPC sum scores were significantly different by group ($F_{(2,90)}=18.9$, $p<.0001$). Pairwise comparisons revealed that the average sum score of nurses was significantly lower than either the housestaff physicians ($p<0.0001$) or hospitalist physicians ($p=0.0006$). Analysis also revealed that the average number of patients per day between the two physician groups (housestaff and hospitalist) and nurses were significantly different ($F_{(2,89)}=34.7$, $p<.0001$). A generalized linear regression was used for examination of the effect of number of patients per day on the IPC average sum scores. As the number of patients per day increased, IPC scores increased ($F_{(1,90)}=14.5$, $p=0.0003$).

CONCLUSIONS: While we observed that nurses had lower IPC scores than did the physicians, other results in the literature have found the opposite result. This variation suggests there may be unique environmental elements or influences impacting physician-nurse collaboration ratings in different settings. In addition, IPC scores increased with patient census, perhaps suggesting that busier practitioners rely more on collaboration. Given the known relationships between effective physician-nurse collaboration and superior patient and organizational outcomes, further examination of possible predictors of IPC scores is warranted, such as job satisfaction, characteristics of nurse and physician leadership, and geographic co-location of physicians with nursing units.

PHYSICIAN-PATIENT COMMUNICATION AND OUTCOMES: A MIXED METHODS STUDY

Surekha Bhamidipati¹; Seema Sonnad²; Daniel J. Elliott³; LeRoi S. Hicks³; Dr. Janine Jordan²; Patty McGraw²; Bailey Ingraham-Lopresto³; Elizabeth Ivey²; Edmondo Robinson². ¹CCHS, Newark, DE; ²Christiana Care Health Services, Newark, DE; ³Christiana Care Health System, Newark, DE. (Tracking ID #2198018)

BACKGROUND: Communication between physicians and patients around diagnoses and plan of care often is ineffective, leaving patients with incomplete knowledge about their care¹. This knowledge gap has appeared in studies of acute general medicine units². The impact of this gap on quality and efficiency outcomes has not been studied. Our goal was to assess hospitalized patients' knowledge of their care plan and examine the relationship between knowledge and outcomes.

METHODS: We prospectively enrolled a cohort of hospitalist's patients admitted to general medicine units. Patients and their hospitalists were separately interviewed on the second hospital day to assess patient knowledge of diagnosis scheduled tests and procedures and their planned discharge day compared to the same information from their physicians. Two reviewers graded physician and patient responses as none, partial or complete agreement for each plan of care, scheduled tests/procedures, and discharge date.

RESULTS: There were 84, 54 and 87 patients in the no, partial and complete concordance groups respectively, indicating that over one third of patients did not understand information received from their physician about diagnosis, plan of care and discharge date. The median LOS in the no concordance group was 3.9 days while in the combined partial or complete concordance group it was 2.2 days ($p=0.0001$). To account for the potential differences in the groups, we adjusted the LOS by case mix index when the index was available. This analysis included 73, 37 and 62 patients in the no, partial and complete concordance groups respectively. The median adjusted LOS for the no concordance group was 4.1 days and the partial and complete concordance group was 2.9 days ($p=0.03$).

CONCLUSIONS: Patient LOS is lower in patients who have greater knowledge of their plan of care. This difference remains after adjustment for illness severity. The causal pathway between patient knowledge and decrease in LOS is not clear. It is possible that patients who understand their plan of care are better prepared for discharge leading to a more efficient discharge. References: 1. Coran JJ, Koropecy-Cox T, Arnold CL. PLEASE, DOC I NEED MEDICINE!: CAN RESIDENTS DIAGNOSE AND MAN-

AGE OPIATE USE DISORDER? Kathleen Hanley; Colleen Gillespie; Mrudula Naidu; Irina Nudelmann; Jennifer Adams; Mack Lipkin; Sondra Zabar. NYU School of Medicine, New York, NY. (Tracking ID #2198784)

BACKGROUND: Drug overdose was the leading cause of accidental death in 2012. Over 70 % of these deaths involved prescription opioids. In 2008, there were 14,800

deaths connected with prescription painkillers. In response to this epidemic, many states have implemented prescription-monitoring programs and guidelines for responsible prescribing are being promoted. We implemented a standardized patient case to assess our residents' approach to a patient seeking help for addiction to prescription opioids as a needs assessment for our addiction medicine curriculum.

METHODS: We incorporated into our annual 10 station performance based assessment (OSCE) a case involving a young woman with shoulder pain who exhibits many signs of opioid use disorder and whose hidden agenda is to get help for her addiction. Standardized patients evaluated residents using a behaviorally anchored checklist (response options: not done, partly done, well done) that included items assessing general communication and patient activation skills as well as items specific to this case including assessment of substance use, recognition of opioid use disorder, and treatment plan/next steps. Analyses include frequencies for specific items focused on opioid use and treatment as well as a post-OSCE survey administered to all the residents that assessed what they found challenging about this case. T tests were used to compare communication and patient activation performance (percent items rated as well done) on these cases with residents' overall performance on all cases.

RESULTS: Of the 24 residents who saw the case, 54 % asked what type and amount of pain medication the patient was taking but only 38 % discovered that the patient had also used heroin. Only 17 % assessed her use of alcohol, tobacco and other illicit drugs. In terms diagnosing an opioid use disorder, 42 % assessed for tolerance, 50 % for cravings and 71 % for withdrawal. However, only 17 % inquired about effects of opioid use on her social functioning and only 38 % determined that the patient had unsuccessfully attempted to cut back. Few (29 %) residents did a good job of explaining the diagnosis of opioid use disorder and guided her to an agreeable treatment plan. Only 4 % of SPs felt that the visit would help them to change their drug uses although 54 % felt it helped them recognize they had a problem and 67 % were motivated to change. Patient activation measures were uniformly poor with none of the SPs feeling that the doctor helped them feel confident that they could stop using opiates and only 13 % understanding the available treatment options. Patient activation scores were lower in the opiate case than for the rest of the cases (mean 8 % vs 38 % well done, $p < .001$) but overall communication scores were not significantly different ($p < .76$). SPs reported that more than half of the residents ran out of time and many of the residents reported that they found it challenging to directly explore opioid abuse.

CONCLUSIONS: Residents recognized the problem of opioid use disorder but did not perform a comprehensive assessment of the patient's substance use and lacked information and/or skills to counsel the patient on treatment options. Curricula need to be enhanced for residents to have the skills and confidence to treat and manage patients with this increasingly common and devastating substance use disorder.

POOLED ANALYSES OF RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED STUDIES OF A BREATH POWERED NASAL DELIVERY SYSTEM CONTAINING 22 MG SUMATRIPTAN POWDER (AVP-825) IN THE TREATMENT OF EPISODIC MIGRAINE Roger K. Cady²; Per G. Djupesland³; Ramy A. Mahmoud⁴; John Messina⁴; Laszlo L. Mechtler⁵; Scott Siegert¹; Joao Siffert¹; Ken Shulman¹. ¹Avanir Pharmaceuticals, Inc., Aliso Viejo, CA; ²Headache Care Center, Springfield, MO; ³OptiNose AS, Oslo, Norway; ⁴OptiNose US Inc., Yardley, PA; ⁵Dent Neurologic Institute, Buffalo, NY. (Tracking ID #2188713)

BACKGROUND: AVP-825 is an investigational Breath Powered™ Bi-directional™ product containing low-dose sumatriptan powder (22 mg) that delivers drug to the mucosa beyond the nasal valve where it can be rapidly and efficiently absorbed. The purpose of these analyses was to evaluate the efficacy and safety of AVP-825 using pooled data from Phase 2 and 3 (TARGET, NCT01462812) placebo-controlled trials in adults with episodic migraines.

METHODS: Multicenter, randomized, double-blind, parallel-group, placebo-controlled studies in which a single migraine of moderate or severe intensity was treated with AVP-825 or an identical placebo delivery system. Headache severity scores were recorded pre-dose and at multiple timepoints through 48 h post-dose. Efficacy assessments included percentage of patients with pain relief, defined as reduction in headache severity score from severe (3) or moderate (2) to mild (1) or no pain (0), and rescue medication use through 48 h. Safety evaluation included adverse events (AEs).

RESULTS: The pooled population for efficacy analyses was AVP-825 ($n=143$) and placebo ($n=136$), and for safety was AVP-825 ($n=151$) and placebo ($n=150$). A significantly greater percentage of patients achieved pain relief with AVP-825 vs placebo at all timepoints from 30 to 120 min post-dose: 30 min (44.8 vs. 27.9 %, $P=.0052$), 60 min (60.1 vs. 36.8 %, $P=.0001$), 90 min (69.2 vs. 41.2 %, $P<.0001$), 120 min (70.6 vs. 44.9 %, $P<.0001$). Headache improvement was sustained through 48 h with AVP-825, including a lower rate of rescue medication use vs. placebo (35.7 vs. 54.4 %). The most common AEs (≥ 2 % of patients), generally transient and mild, were more frequent with AVP-825 and included abnormal taste (20 vs. 3 %), nasal discomfort (11 vs. 1 %),

rhinorrhea (5 vs. 2 %), and rhinitis (2 % vs. 0 %). Chest pain or pressure was not reported for any patient. One patient taking AVP-825 reported mild paresthesia, but there were no other triptan sensations reported. There were no deaths or serious AEs.

CONCLUSIONS: AVP-825 delivers low-dose sumatriptan and provides rapid headache relief that was sustained through 48 h, as demonstrated in placebo-controlled clinical trials. Treatment was well tolerated with predominantly mild and transient administration-site AEs. If approved, AVP-825 will constitute an important treatment option for patients with migraine.

POPULATION WELL-BEING AND GEOGRAPHIC DISPARITIES IN LIFE EXPECTANCY Anita S. Arora¹; Erica S. Spatz²; Jeph Herrin²; Carley Riley^{1,3}; Brita Roy³; Brian Wayda⁵; Elizabeth Rula⁶; Carter Coberley⁶; Harlan M. Krumholz⁴. ¹Yale-New Haven Hospital, New Haven, CT; ²Yale University, Charlottesville, VA; ³Yale University, New Haven, CT; ⁴Yale University School of Medicine, New Haven, CT; ⁵New York Presbyterian, New York City, NY; ⁶Healthways, Franklin, TN. (Tracking ID #2195159)

BACKGROUND: Geographic disparities in life expectancy across the United States are substantial, and not fully explained by race, socioeconomic status and physical health. Emotional well-being, a construct capturing emotional health and life evaluation, has previously been associated with mortality at the individual level, but a community-level association with life expectancy in a national population has not yet been studied. Understanding whether a population's emotional well-being is associated with life expectancy at the community level may help inform efforts to reduce geographic disparities in longevity.

METHODS: We assessed the association of emotional well-being with life expectancy at the county level ($N=3132$). We used the 2010 Gallup-Healthways Well-Being Index, a national survey of community-residing individuals ≥ 18 years. The construct of emotional well-being is captured by emotional health (index of 9 daily experiences and emotions plus diagnosed depression) and life evaluation (ranking of life situation now and 5 years from now), each measured on a scale of 0 to 100. Life expectancy estimates for men and women for 2009 were based on mortality data within each county. At the time of this analysis, well-being data was available at the congressional district (C.D.) level and was mapped to counties to match life expectancy estimates; 11 counties without life expectancy estimates were excluded. We assessed the distribution of life expectancy for men and women separately and stratified counties into quartiles based on life expectancy. We examined emotional health and life expectancy index scores across quartiles, along with county-level estimates of race (Census data), income (SAIPE) and education (American Community Survey) and three additional well-being domains included in the survey: basic access, physical health and healthy behaviors. We performed unadjusted and adjusted linear regressions of emotional health and life evaluation with life expectancy, adjusting for characteristics previously described.

RESULTS: County life expectancies ranged from 73 to 83 years for women and 63 to 82 years for men. County emotional health index scores ranged from 70 to 85 while life evaluation index scores ranged from 35 to 64. The mean emotional health score among counties in the lowest quartile of life expectancy was 77.2 compared to 80 in the highest quartile, for both women and men. The mean life evaluation score in all four quartiles only ranged between 47.5 and 48.5 for both females and males. Counties in the lowest quartile of female and male life expectancy were located in the South, had a high percentage of Blacks, and lower education and income compared with counties in the highest quartile of life expectancy, the majority of which were located in the Midwest. Emotional health and life evaluation were both significantly associated with female and male life expectancy at the county level. For every 1 point higher emotional health index at the county level, female life expectancy was 0.40 years higher and male life expectancy was 0.56 years higher ($p < .001$ for both). Similarly, a 1 point higher life evaluation index was associated with a 0.04 year higher female life expectancy and a 0.05 year higher male life expectancy ($p < .001$). When socio-demographic covariates (race, income, education and basic access) were introduced, the associations of emotional health and life evaluation with life expectancy reversed for females and became insignificant for males. Similarly, when adjusted for physical health and healthy behaviors, the associations of emotional health and life evaluation with life expectancy reversed for both males and females.

CONCLUSIONS: In this national study, emotional health and life evaluation were positively associated with life expectancy at the county level, but more research is needed to explore this complex relationship. Associations became insignificant or negative when socio-demographic and physical health covariates were introduced, perhaps because emotional well-being interacts with or mediates the effects of other covariates known to influence life expectancy. In addition, since congressional district level well-being data was mapped to counties, variation in well-being and the strength of associations were likely minimized. We intend to update these analyses with county-level well-being data, which will be made available within the next month; these analyses may more accurately describe the relationship between community emotional well-being and life expectancy. In

conclusion, emotional well-being may serve as a marker of life expectancy at the county level. Additional studies are needed to explore the relationship between emotional well-being and life expectancy within geographic and socially coherent communities.

POTENTIAL BENEFITS TO PATIENTS OF SHOPPING FOR PRESCRIPTION DRUGS FOR CHRONIC CONDITIONS Jeff Kullgren^{1, 2}; Joel E. Segel²; Chris Cheung²; Michael Slowik²; Simone Singh². ¹VA Ann Arbor Healthcare System, Ann Arbor, MI; ²University of Michigan, Ann Arbor, MI. (Tracking ID #2199247)

BACKGROUND: State governments, health insurance plans, and consumer groups are increasingly reporting health care price information to patients in the hopes of reducing cost-related access barriers for the growing number of Americans who face high out-of-pocket health care expenditures (e.g., through enrollment in high deductible health plans). However, little is known about how much money patients who face high out-of-pocket expenditures could anticipate saving by using price information to shop for routine services such as prescription drugs for chronic conditions, or about which patients could benefit most from using price comparison tools in their decision making.

METHODS: We conducted systematic searches of 4 state government operated websites (Michigan, Missouri, New York, and Pennsylvania) that publicly report retail prices for 6 drugs commonly prescribed to treat chronic conditions: Advair, atorvastatin, Lyrica, metoprolol, Nasonex, and Spiriva. For each state-drug combination we collected from a 25 % stratified random sample of ZIP Codes ($n=1330$) the number of pharmacies reporting prices within 5 miles of each ZIP Code centroid. When pharmacies reported retail prices, we collected data on the highest and lowest prices for a monthly supply of a commonly prescribed dose of the drug. In our analysis we used chi-square tests to compare how often pharmacies reported any price information across drugs within each state and across states for each drug. We then used Kruskal-Wallis tests to compare the median potential monthly out-of-pocket savings (defined as the difference between the highest reported retail price and the lowest reported retail price) across drugs within each state and across states for each drug.

RESULTS: Across the 24 state-drug combinations, retail price information was available for only 59 % of ZIP Codes with at least 1 pharmacy within 5 miles of the ZIP Code centroid. There was significant variation in the availability of prices ($P<0.001$ across drugs within each state as well as across states for each drug), ranging from 1 % for atorvastatin in Michigan to 77 % for Advair in Pennsylvania. When pharmacies reported retail price information for prescription drugs there was significant variation in median potential monthly out-of-pocket savings ($P<0.001$ across drugs within each state as well as across states for each drug), ranging from a minimum of \$24 [interquartile range (IQR) \$15–\$54] for Nasonex in Missouri to a maximum of \$159 (IQR \$113–186) for atorvastatin in Pennsylvania.

CONCLUSIONS: Across 4 state government operated websites which publicly report retail prices for 6 commonly prescribed medications for chronic conditions, price information is often deficient. Yet, when retail prices are actually reported, the monthly savings for patients could be substantial, particularly for certain medications. Given these potential savings and the growing number of Americans who are facing high out-of-pocket expenditures for health care, policymakers and clinicians should work to ensure that retail prices for commonly used prescription drugs are more consistently available as well as develop new strategies to optimize patients' use of this information.

POTENTIAL HEALTH-CARE SERVICE UTILIZATION SUBSTITUTION EFFECTS INDUCED BY CASE MANAGEMENT FOR EMERGENCY DEPARTMENT FREQUENT USERS Karine Moschetti^{2, 8}; Katia Iglesias⁶; Stéphanie Baggio³; Venetia - Sofia Velonaki¹⁰; Omella Ruggeri⁵; Olivier Hugli⁴; Bernard Burnand⁸; Jean-Bernard Daepfen⁹; Jean-Blaise Wasserfallen¹; Patrick Bodenmann⁷. ¹CHUV, Lausanne, Switzerland; ²Health Assessment Unit, Lausanne, Switzerland; ³Lausanne University, Lausanne, Switzerland; ⁴Lausanne university hospital, Lausanne, Switzerland; ⁵University Hospital of Lausanne (CHUV), Lausanne, Switzerland; ⁶University of Neuchâtel, Neuchâtel, Switzerland; ⁷Vulnerable Population Center, Lausanne, Switzerland; ⁸Institute of Social and Preventive Medicine, Lausanne, Switzerland; ⁹Alcohol Treatment Centre, Lausanne, Switzerland; ¹⁰PhD, Department of Community Medicine and Public Health, Lausanne, Switzerland. (Tracking ID #2199681)

BACKGROUND: In most of the emergency departments (ED) in developed countries, a subset of patients visits the ED frequently. Despite their small numbers, these patients are the source of a disproportionally high number of all ED visits, and use a significant proportion of healthcare resources. They place a heavy economic burden on hospital and healthcare systems budgets overall. Several interventions have been carried out to improve the management of these ED frequent users. Case management has been shown in some North American studies to reduce ED utilization and costs. In these studies, cost analyses have been carried out from the hospital perspective without examining the costs induced by healthcare consumed in the community. However, case management might reduce ED

visits and costs from the hospital's perspective, but induce substitution effects, and increase health service utilization outside the hospital. This study examined if an interdisciplinary case-management intervention—compared to standard ED care—reduced costs generated by frequent ED users not only from the hospital perspective, but also from the healthcare system perspective—that is, from a broader perspective taking into account the costs of healthcare services used outside the hospital.

METHODS: In this randomized controlled trial, 250 adult frequent emergency department users (5 or more visits during the previous 12 months) who visited the ED of the University Hospital of Lausanne, Switzerland, between May 2012 and July 2013 were allocated to one of two groups: case management intervention (CM) or standard ED care (SC), and followed up for 12 months. Depending on the perspective of the analysis, costs were evaluated differently. For the analysis from the hospital's perspective, the true value of resources used to provide services was used as a cost estimate. These data were obtained from the hospital's analytical accounting system. For the analysis from the health-care system perspective, all health-care services consumed by users and charged were used as an estimate of costs. These data were obtained from health insurance providers for a subsample of participants. To allow comparisons in a same time period, individual monthly average costs were calculated. Multivariate linear models including a fixed effect "group" were run using socio-demographic characteristics and health-related variables as controlling variables (age, gender, educational level, citizenship, marital status, somatic and mental health problems, and risk behaviors).

RESULTS: At the end of the 12-month follow-up, 115 patients were in CM and 115 in SC (20 had died). The mean age of patients was 44.4 (± 17.9); 46 % were Swiss; 57 % were male, and 80 % were French-speaking; 25 % had a low educational level (compulsory education); 69 and 51 % suffered from somatic or mental health problems, respectively; and 33 % presented risk behaviors. Multivariate models showed that a higher age, Swiss citizenship, and having somatic health problems increased costs significantly. In the multivariate models of the cost analysis, the regression coefficient associated with the CM group compared to SC group was negative (meaning lower costs) from the hospital system perspective, but positive in the analysis from the healthcare system perspective (meaning higher costs). However, these two coefficients were not statistically significant.

CONCLUSIONS: The role of the CM team is to guide patients through the care process and provide social support. Patient-centered care is part of a continuous integration of medical and social dimensions and, as such, the place of intervention is not limited to the hospital but often extends into the community. The results of the CM intervention implemented at the University Hospital of Lausanne, Switzerland, had previously showed a significant reduction in the number of emergency department visits. The reduced costs from the hospital perspective of the CM group were likely a result of the success of CM in reducing the number of ED visits. On the other hand, the evaluation of costs from the health-care system perspective suggests that the CM intervention has also impacted the utilization of healthcare services by reorienting patients to medical and social services provided in the community. Further investigations into a larger sample, to increase the power of the analysis, and over a longer study period are required to validate to what extent the decrease in the number of emergency visits induced by case-management interventions translates into a reduction of the economic burden that ED frequent users place on hospital budgets, but also on health-care systems overall.

PRACTICAL LESSONS FROM A LONGITUDINAL PRAGMATIC TRIAL OF PERSONALIZED DECISION SUPPORT FOR OLDER ADULTS Jennifer Cooper¹; Elbert S. Huang³; Aviva G. Nathan². ¹The University of Chicago, Chicago, IL; ²University of Chicago, Chicago, IL; ³University of Chicago, Chicago, IL. (Tracking ID #2198727)

BACKGROUND: Geriatric care guidelines for type 2 diabetes encourage individualization of glycemic targets (A1C goals) based on life expectancy (LE) and patient preferences. It is unclear how to operationalize these guidelines over time in clinical practice. We longitudinally pilot-tested a web-based decision support tool that provides individualized prognostic information to patients and physicians and elicits patient preferences.

METHODS: Physicians and their patients were randomized to the decision support tool, with 3:1 recruitment starting in the summer of 2012. Patients were ≥ 65 years, had A1C ≥ 6.5 %, and no dementia. Prior to a physician encounter, intervention patients interacted with the tool and generated a printout for their physician that included individual patient's LE estimates, geriatric screening results and treatment preferences. Control patients received an A1C pamphlet. Physicians and patients were surveyed before and after the encounter. Both patient arms were asked to return for longitudinal follow-up. The main outcomes of interest were 1.) feasibility surrounding patient retention and interaction with the decision support tool in a real-world clinical setting and 2.) patient knowledge of A1C goals over time.

RESULTS: Sixty-seven (53 intervention, 14 control) of the original 100 patients enrolled returned for a second encounter with the research staff. Patients did not return due to disinterest in longitudinal participation ($N=10$), death ($N=7$), their primary care physician

leaving the hospital network ($N=7$), loss to follow-up ($N=4$), serious health reasons ($N=3$), increased cognitive impairment ($N=1$) and financial reasons ($N=1$). The average time between patient visits was 546 days (322–896 days). Sixty-two percent of intervention patients reported that they went over the printout with their physician during their clinic visit and approximately half of these patients stated their physician went over the entire printout. Almost half of the intervention patients said they would like to interact with the decision support tool at every doctor's appointment and 61 % said that they would like to be able to access the decision support tool at home via the web. In both patient arms, A1C knowledge fluctuated over the study time period (Figure 1), with the highest percentage of patients stating they knew their A1C goal after a clinical encounter (71 % intervention and control post visit 1, 69 % intervention and 71 % control post visit 2). The percentage of patients who knew their A1C decreased (16 % in intervention patients, 29 % in control patients) from the time between the end of visit 1 and start of visit 2.

CONCLUSIONS: A personalized decision support tool continues to be a promising option for increasing individualization of glycemic goals among older adults with diabetes. A more prescriptive approach to future randomized controlled trials surrounding decision support in older adults may improve patient follow-up and patient knowledge of individual A1C goals.

PREDICTING ALL-CAUSE 30-DAY HOSPITAL READMISSIONS USING ELECTRONIC HEALTH RECORD DATA OVER THE COURSE OF HOSPITALIZATION: MODEL DERIVATION, VALIDATION AND COMPARISON Oanh K. Nguyen^{1, 1}; Anil N. Makam^{1, 1}; Christopher Clark²; Song Zhang¹; Bin Xie²; Ruben Amarasingham^{2, 1}; Ethan Halm^{1, 1}. ¹UT Southwestern Medical Center, Dallas, TX; ²Parkland Center for Clinical Innovation, Dallas, TX. (Tracking ID #2195966)

BACKGROUND: Predicting those at highest risk readmission can help target resource-intensive interventions to those most likely to benefit. However, current models have only modest discriminatory power. This study sought to: 1) derive and validate a risk prediction model incorporating EHR data from the 'full' hospital stay, including data on hospital complications and clinical trajectory, and 2) compare 'full-stay' model performance to other risk prediction models.

METHODS: This was an observational study using EHR data from 6 hospitals in the Dallas-Fort Worth metroplex, including safety net, community, teaching, and non-teaching sites. We included hospital discharges from all internal medicine inpatient services among adults (≥ 18 years) between Nov. 1, 2009 and Oct. 30, 2010. We excluded inpatient deaths, transfers to an acute care facility, or those who left against medical advice. For patients with multiple hospitalizations, we included only the first one. Patients were randomly split into derivation and validation cohorts. The primary outcome was a non-elective readmission within 30 days to any of 75 acute care hospitals in north Texas ascertained using an all-payer regional hospitalization database. For comparison, we used

our group's separately derived and validated readmission model using EHR data from the first hospital day and two previously validated full-stay models based on claims data: the LACE and HOSPITAL models.

RESULTS: Among 32,922 admissions (derivation=16,492; validation=16,430), 12.7 % had a 30-day readmission. In addition to predictors from the first day of hospitalization, we identified hospital complications such as C. difficile infection (AOR 2.01, 95 % CI 1.17–3.45); clinical instability on discharge (AOR 1.25 per instability, 95 % CI 1.15–1.36); lab abnormalities on discharge, such as hyponatremia ($\text{Na} < 135 \text{ mEq/L}$; AOR 1.35, 95 % CI 1.20–1.53); and length of stay (AOR 1.06 per hospital day, 95 % CI 1.04–1.07) as significant additional predictors. The full-stay model had statistically better discrimination than other models though the improvement was modest (Table). Though the full-stay model was also able to predict a broader range of probabilities for readmission risk (Table), it was only slightly better in identifying the highest risk quintile compared to other models (LR+ 2.38 vs 1.84–2.18 for other models).

CONCLUSIONS: Incorporating clinically granular EHR data from the full hospital stay modestly improves prediction of 30-day readmissions. Despite drawing on data from diverse settings and being able to adjust for sociodemographic factors and many in-hospital clinical severity, comorbidity, and trajectory factors, our findings suggest that many factors driving hospital readmission remain unmeasured and unaccounted for.

Model Discrimination and Comparison to Existing Models for 30-Day Hospital Readmission

Model Name	C-statistic (95 % CI)	IDI (95 % CI)	NRI (95 % CI)	Predicted Risk, %	Lowest Decile	Highest Decile
Full-stay model						
Derivation cohort	0.72 (0.70–0.73)	–	–	4.1	36.5	
Validation cohort	0.69 (0.68–0.70)	[Reference]	[Reference]	4.1	36.5	
First-day model	0.67 (0.66–0.68)	–0.012 (–0.014 to –0.010)	–0.054 (–0.085 to –0.024)	5.8	31.9

PREDICTING LENGTH OF STAY (LOS) AMONG HEART FAILURE (HF) ADMISSIONS: CAN SIMPLE SEVERITY OF ILLNESS (SOI) SCORES BE USED TO PREDICT LOS IN COMPLEX PATIENT POPULATIONS? Madeline R. Sterling; Ashley Beecy; Parag Goyal; Caroline Andrew; Andrew Warner; Carla Boutin-Foster; Erica Jones. New York Presbyterian—Weill Cornell, New York, NY. (Tracking ID #2194947)

BACKGROUND: Heart Failure (HF) accounts for 1 million hospitalizations each year in the United States. Factors associated with hospitalization Length of Stay (LOS) among heart failure patients remain variable by institution. Many algorithms to predict LOS require numerous clinical variables and physiologic data. Less is known about the ability of a severity of illness (SOI) score, which is 4 part score applied to patient charts on admission by hospital administrators, to predict LOS in complex patient populations. Here we sought to first identify demographic and clinical characteristics of heart failure patients associated with LOS. Using these factors, our objective was to determine if SOI had the ability to predict LOS at our institution.

METHODS: This is a retrospective cohort study of adult patients with CHF admitted to the cardiology step-down-unit (SDU) of a large, urban, academic medical center for a six month period for HF related diagnoses. Data was collected using an electronic database. Length of Stay (LOS) (days) in the hospital during admission was the primary outcome. LOS was categorized as 0–10, 11–20, 21–30 and 31–40 days. Descriptive statistics of the study population's demographic (4) clinical (11) and hospital-based characteristics (2) were performed. These covariates were identified using a priori knowledge and validated criteria. Chi squared and Fisher exact tests were used for bivariate analysis of each variable with LOS. A series of multivariable linear regression models were built to estimate

associations between clinical characteristics and LOS. Transformations of the dependent variable were performed such that the assumptions of MLR were met in the final model.

RESULTS: During a period of 6 months, 346 patients were admitted for HF. Of them, 61 % were men, 35 % white, 10 % black, 22 % non-white Hispanic and 32 % Asian, Indian or other. The majority of the population were older than 65 years (70 %) and 44 % of the population lived alone. Most patients had two or more comorbid conditions, most commonly coronary artery disease, atrial fibrillation and left ventricular dysfunction. Severity of Illness (SOI) scores ranged from 1 to 4, with 4 being most severe. The majority of the population had scores of 2 (30.6 %) and 3 (44.5 %). Of the 346 admissions, 297 admissions (85.8 %) had LOS of 0–11 days; 11 % had LOS of 11–20 days, 2–3 % had LOS greater than 21 days. The mean LOS was 5.88 days (SD). Independent predictors of increased LOS were SOI ($p<.001$), Aortic Stenosis ($p=0.05$) and CVA ($p=0.04$). In adjusted models, patients with Atrial fibrillation, Diabetes, COPD and CVA were associated with higher LOS (7 days) compared to patients who didn't have any of the aforementioned diseases. Also, those with Prior Stents and Dementia had a higher mean LOS (6 days) compared with those who had neither of these diseases. Co-morbidity scores and LOS had a positive linear relationship until a point; we found that having 5 or more co-morbidities was associated with decreased LOS. The final log transformed model met all OLS assumptions and found SOI to have significant predictive bearing on LOS such that a 1 point increase in SOI would yield a 0.72 % change in LOS ($b=0.7187$ $P<0.0001$).

CONCLUSIONS: The severity of illness score (SOI), which is based on 4 variables and assigned to patients by hospital administrators upon admission, has significant predictive ability at our institution. To date, it has been underutilized and represents a cost-effective, simple and time-sensitive way for health care providers and administrators to predict LOS in complex patient populations admitted with heart failure.

PREDICTING READMISSION RISK FOLLOWING CORONARY REVASCULARIZATION AT THE TIME OF ADMISSION Daniel J. Elliott; Paul Kolm; Zaher Fanari; carla russo; William S. Weintraub. Christiana Care Health System, Newark, DE. (Tracking ID #2198936)

BACKGROUND: Reducing readmissions following hospitalization for coronary revascularization is a national priority. Identifying patients at high risk for readmission early in a hospitalization would enable hospitals to target these individuals for enhanced discharge planning. Traditional risk models identify patients based on characteristics that may not be available until after discharge. We sought to compare the model performance for models based on data that is available at the time of hospitalization.

METHODS: We developed models to predict 30-day inpatient readmission to our institution for a cohort of patients who were received Percutaneous Coronary Revascularization (PCI) at our institution between January 2010 and November 2014. We developed three models using data available at three different time points in the hospitalization: 1) at admission, 2) at discharge and 3) discharge plus registry data from the American College of Cardiology CathPCI registry. Candidate variables for the admission model included demographics, comorbidities, and previous utilization within our system. The discharge model added new comorbidities, length of stay, and discharge disposition. The third model included clinical data such as angina classification, TIMI flow, number of revascularized vessels, and discharge medications. We assessed each model using the c-index.

RESULTS: Our cohort included 5949 PCI patients. The overall readmission rate was 7.2 % in the PCI group. The admission model had a c-statistic of 0.734. The addition of discharge variables did not statistically improve the model (c-statistic=0.734). The addition of registry variables slightly improved the model (c-statistic=0.745). The improvement was statistically significant ($p=0.011$). The factors most strongly associated with readmission in the admission model were age (OR 1.23 per decade, $p<0.001$), previous hospitalization within 6 months (OR 1.27, $p<0.001$), a previous diagnosis of CHF (OR 1.97, $p<0.001$), and elective status (OR=0.36, $p<0.001$). The associations persisted through all the models except for the association of CHF, which was attenuated by the addition of LOS and registry variables.

CONCLUSIONS: Risk prediction models using data available from clinical registries and discharge data minimally improved the performance of models based solely on demographic and utilization data available at the time of admission. These simplified models may be sufficient to identify patients at highest risk of readmission following coronary revascularization early in the hospitalization. This would allow providers and health systems to target high-risk patients with enhanced discharge planning during the course of the hospitalization, and this may improve the ability to avoid readmissions.

PREDICTING RECURRENCE IN ELDERLY PATIENTS WITH UNPROVOKED VENOUS THROMBOEMBOLISM: PROSPECTIVE VALIDATION OF THE UPDATED VIENNA PREDICTION MODEL Tobias Tritschler¹; Marie Méan^{1, 2}; Andreas Limacher³; Nicolas Rodondi¹; Drahomir Aujesky¹. ¹Bern University Hospital, Bern, Switzerland; ²University Hospital of Lausanne, Lausanne, Switzerland; ³University of Bern, Bern, Switzerland. (Tracking ID #2193984)

BACKGROUND: The updated Vienna Prediction Model has been developed to risk-stratify patients with unprovoked venous thromboembolism (VTE) according to their recurrence risk based on their sex, VTE location and D-dimer. We prospectively evaluated the accuracy of the updated Vienna Prediction Model in identifying elderly patients with unprovoked VTE who are at low risk of VTE recurrence.

METHODS: We followed-up 156 in- and outpatients aged ≥ 65 years with symptomatic, unprovoked VTE from 9 Swiss university and non-university hospitals (09/09-12/13), starting 12 months after the index VTE. All patients had previously completed a 3 to 12-month course of anticoagulation. Unprovoked VTE was defined as the occurrence of deep vein thrombosis or pulmonary embolism in the absence of risk factors, such as active cancer, immobilization, major surgery, or estrogen therapy. All patients underwent quantitative D-dimer testing (ELISA, VIDAS®, bioMérieux, France). The outcome was the recurrence of symptomatic, objectively confirmed VTE within 12 and 24 months, adjudicated by a committee of three blinded clinical experts. We determined the proportion of patients classified as low risk (lowest quartile of predicted 12-month risk of VTE recurrence) according to the updated Vienna Prediction Model and compared the proportion of VTE recurrence at 12 and 24 months between low- and higher-risk patients. We also assessed the discriminative power of the predicted 12-month risk of VTE recurrence by calculating the area under the receiver operating characteristic (ROC) curve for VTE recurrence at 12 and 24 months.

RESULTS: The median age was 74 years and 41 % of patients were women. The proportion of VTE recurrence was 11 % after 12 months and 17 % after 24 months. Patients with a predicted 12-month risk below 6.2 % were classified as low-risk based on the updated Vienna Prediction Model. The proportion of recurrent VTE at 12 months (13 vs. 10%; $P=0.767$) and 24 months (15 % vs. 17%; $P=1.0$) did not differ between low vs. higher-risk patients. The area under the ROC curve for predicting VTE recurrence at 12 and 24 months was 0.39 (95 % CI 0.25 to 0.52) and 0.43 (95 % CI 0.31 to 0.54), respectively.

CONCLUSIONS: In our prospective multicenter study of elderly patients with unprovoked VTE, the updated Vienna Prediction Model did not discriminate between patients who developed recurrent VTE from those who did not. The updated Vienna Prediction Model may not be suitable for identifying elderly low-risk patients with unprovoked VTE who do not benefit from extended anticoagulation.

PREDICTORS OF ADHERENCE TO TELEPHONE COUNSELING FOR SMOKING CESSATION AMONGST VETERANS PRESENTING TO VA MENTAL HEALTH CLINICS Matthew R. Augustine²; Helene Strauss²; David M. Levine²; Priyanka Chugh²; Binhuan Wang²; Ellie Grossman^{2, 1}; Erin Rogers^{3, 1}; Scott Sherman^{3, 2}. ¹New York University, New York, NY; ²New York University Medical Center, New York, NY; ³VA NY Harbor Healthcare System, New York, NY. (Tracking ID #2199147)

BACKGROUND: Smoking is a leading cause of preventable morbidity and mortality and disproportionately affects Veterans and those with mental health conditions. Proactive telephone quitline counseling is effective compared to no counseling, self-help, and pharmacotherapy. Despite its wide use, little is known about optimal implementation. Few studies have analyzed the baseline factors predictive of adherence to the quitline treatment process. This secondary analysis of a regional telephone smoking cessation program evaluates factors that predict adherence to telephone counseling and the relationship between adherence and smoking cessation.

METHODS: TeleQuitMH was a 6 month multi-centered, randomized trial of a proactive telephone counseling program among veterans with mental health conditions. From a baseline patient questionnaire, we selected nineteen potential predictors to explore, including demographics, motivation, stage of change, and environment/support. Bivariate analysis was used to build a multivariate model to determine factors associated with adherence to counseling sessions. A bivariate analysis then explored the association between adherence to counseling sessions and smoking cessation at 6 months.

RESULTS: One thousand two hundred six patients were referred to TeleQuitMH for telephone counseling, of which 577 were enrolled and 270 were randomized to receive VA-based telephone counseling. In bivariate and multivariable models, increased age ($p<0.05$) and motivation to quit ($p<0.05$) were associated with adherence to more counseling sessions. Participants who reported 30-day abstinence at 6 months completed more counseling sessions (6.88, SD 3.36 vs. 2.97, SD 2.90; OR 1.43, CI 1.29–1.60).

CONCLUSIONS: In a proactive quitline counseling program for Veterans in care of mental health providers, increased age and motivation are associated with increased adherence to telephone counseling. As adherence to the treatment regimen was strongly associated with smoking cessation, research targeted at enhancing adherence offers a potential way to increase rates of cessation.

PREDICTORS OF QUALITY OF LIFE AMONG AFRICAN AMERICANS WITH PERIPHERAL ARTERY DISEASE Tracie C. Collins¹; Jasjit Ahluwalia⁴; Nikki Nollen⁵; Nicole Rogers³; Rosalee Zackula². ¹KU School of Medicine—Wichita, Wichita, MN; ²University of Kansas School of Medicine-Wichita, Wichita, KS; ³Wichita State University, Wichita, KS; ⁴University of Minnesota, Minneapolis, MN; ⁵Kansas University Medical Center, Kansas City, KS. (Tracking ID #2199233)

Research reported in this publication was supported by the National Heart, Lung, and Blood Institute of the National Institutes of Health under Award Number R01HL098909. The content is solely the responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health.

BACKGROUND: African Americans are at increased risk for peripheral artery disease (PAD)—atherosclerosis of the abdominal aorta and arteries of the lower extremities. PAD is a major risk factor for poor quality of life but the risk factors associated with this outcome are not well known. We sought to determine the risk factors associated with quality of life among a cohort of African Americans with PAD.

METHODS: We analyzed baseline data from an ongoing NIH funded clinical trial in which we seek to determine the efficacy of a behavioral intervention to improve walking distance among African Americans with PAD. To be eligible for the trial, participants self-identify as African American and screen positive for PAD [ankle-brachial index (ABI) \leq 0.99]. Participants are excluded if they have undergone leg revascularization within the preceding 3 months, contraindications to exercise, or a treadmill test positive for coronary ischemia. Participants complete three visits which include baseline, 6-, and 12 months. We collect laboratory data (lipid profile and glycosylated hemoglobin) and vital signs. We also administer validated surveys to ascertain medical history (Lifestyle and Clinical Survey), quality of life (Medical Outcomes Study Standard Form-12), leg symptom subtypes (San Diego Claudication Questionnaire), exercise self-efficacy (Exercise Self-Efficacy Scale), walking impairment (Walking Impairment Questionnaire), perceptions of unfair treatment because of race, and race centrality (i.e., determining whether race is a core component of how one defines him/herself). For this analysis, we used generalized linear regression modeling with the dependent variables of the MOS SF-12 Physical Summary Scale (PSS) and MOS SF-12 Mental Summary Scale (MSS) scores. Independent variables considered for each model included ABI (<0.9 versus 0.9 or higher), leg symptom subtypes of intermittent claudication or atypical leg symptoms versus asymptomatic disease, exercise self-efficacy, walking impairment (distance, speed, stair climbing scores of 0 to 100 %), medical history, race centrality (scale of 1 to 10) and unfair treatment (scale of 1 to 10).

RESULTS: Among 107 African Americans enrolled, 75 % women, the mean age of the cohort is 64 years (SD 12). Within the cohort, 92 (86 %) have hypertension, 38 (36 %) have diabetes mellitus, 26 (24 %) are current smokers, 59 (55 %) have hyperlipidemia, 58 (54 %) are past smokers, and 41 (38 %) have osteoarthritis. Risk factors positively associated with the PSS score included the ABI [β coefficient 5.004 ($P=.005$)], and distance subscale score [β coefficient .111 ($P<.001$)]. Factors negatively associated with PSS scores included exercise self-efficacy [β coefficient -3.765 ($P=.045$)] and race centrality [β coefficient $-.588$ ($P=.050$)]. The risk factor positively associated with the MSS score was osteoarthritis [β coefficient 4.729 ($P=.014$)] and the risk factor negatively associated with the MSS score was the perception of unfair treatment because of race [β coefficient -1.293 ($P=.021$)].

CONCLUSIONS: Predictors of quality of life among African Americans with PAD included disease severity, walking ability, exercise self-efficacy, osteoarthritis, importance of race for self-identity, unfair treatment because of race. Early diagnosis of PAD, walking ability, self-efficacy for exercise, osteoarthritis, and unfair treatment because of race may be targets to improve quality of life among African Americans with PAD.

PRELIMINARY FINDINGS FOR A MULTIFACETED INTERVENTION DESIGNED TO REDUCE TREATMENT DISPARITIES IN EARLY STAGE, NON-SMALL CELL LUNG CANCER Samuel Cykert¹; Paul Walker²; Peggie Dilworth-Anderson³; Maria Cirino-Marciano⁴; Lloyd Edwards³. ¹University of North Carolina, Chapel Hill, NC; ²Brody School of Medicine, Greenville, NC; ³University of North Carolina-Chapel Hill, Chapel Hill, NC; ⁴University of South Carolina School of Medicine, Columbia, SC. (Tracking ID #2199260)

BACKGROUND: African-Americans (AA) with lung cancer experience a higher annual death rate compared to Whites (W) with AA men particularly affected (78.5 vs 65.7 deaths per 100,000 population). Despite this risk, Bach and others have shown that over the last 3

decades surgical rates for AA patients with potentially curable stage 1 and 2, non-small cell cancer lag behind surgical rates for W patients. The treatment difference is more remarkable given that Gray et al. demonstrated that areas of the U.S. with high surgical rates (>79 %) have less lung cancer mortality than areas with lower surgical rates even considering high risk patients. In this report, we describe early results from a multifaceted intervention trial designed to optimize lung surgery rates for all patients and reduce disparities associated with AA race.

METHODS: We first performed a 3-year retrospective chart review for all patients with biopsy proven lung cancer at 3 academic institutions to establish baseline surgical rates according to demographic features, including race, and severity of illness. We then applied an intervention that applied electronic systems, quality improvement techniques and an enhanced care team at each study site. The specific intervention components are: (1) a real time electronic registry that provides a warning if either a patient misses an appointment or doesn't reach a designated milestone in care, (2) quarterly feedback of surgical rates by race and co-morbid illness to providers and other cancer care personnel, and (3) a specially trained navigator to enhance communication with affected patients and between those patients and the care team. Given that electronic health records are now ubiquitous, (1) and (2) were used for all patients and compared to retrospective controls. Consented patients were randomly assigned (3). Patients were identified at initial visit either through biopsy proven disease or a Bayesian probability algorithm. Those who were later shown to have benign or advanced disease were withdrawn.

RESULTS: Baseline surgical rates from the retrospective analysis of 714 early stage, non-small cell patients were 69 % for W and 66 % for AA patients. When controlling comorbidities, COPD, age, and other demographic data, the Odds Ratio for surgery for AA compared to W lung cancer patients was 0.64 (95 % CI 0.43, 0.96). To date 157 patients have been recruited prospectively including 54 AA (34 %). The mean age to date for the study group is 65 years; 53 % are female. Forty-nine percent were assigned to special navigation. Preliminary findings show an overall surgical rate of 81 % (82 % W, 78%AA, $p=0.5$). In multivariate analysis, using demographic variables, comorbid illness, pulmonary function, and patient perceptions of communication as independent variables, age >70 (OR 0.18, 95 % CI 0.38, 0.83) and a forced expiratory volume <40 % of predicted (OR 0.04, 95 % CI .001, 0.19) were associated with lower surgical rates. Notably, AA race and medical comorbidity scores did not affect rates.

CONCLUSIONS: Early results from a multifaceted intervention designed to optimize lung cancer surgery and narrow the surgical gap between AA and W patients appear promising.

PREPARING GENERAL INTERNAL MEDICINE (GIM) RESIDENTS FOR THE REAL WORLD—CAN WE PREDICT GIM HUMAN RESOURCE NEEDS IN A CHANGING HEALTH LANDSCAPE? Sharon E. Card; Heather A. Ward; Lindsey Anderson. University of Saskatchewan, Saskatoon, SK, Canada. (Tracking ID #2194161)

BACKGROUND: A key feature of the discipline of GIM worldwide is the ability of General Internists to adapt their practice to context. This adaptability to context strengthens GIM's value to the health care workforce. We hypothesize it also constrains GIM health care workforce planning due to variation in physician practice patterns both within and between health regions. Residency programs are charged with the task of "career planning" for graduates but this is difficult when human resource needs are rapidly changing and differ geographically. This study aimed to identify the range of scope of practice of GIM both current and anticipated throughout the province of Saskatchewan, Canada. The objective was to determine if it was possible to identify specific future GIM employment opportunities and to link these needs to educational programming within the GIM Residency program.

METHODS: Saskatchewan is a province of approximately 1.1 million in the center of Canada. There are 12 distinct health regions. A practicing General Internist, recruitment personnel and administrative personnel were contacted in each health region for an interview. Quantitative and qualitative data were gathered either in person or via telephone using a standardized template. The interview identified both current and anticipated GIM human resource needs as well as the scope of practice or skills needed within each region. The goal was to obtain three interviews per health region with a minimum of one. Quantitative data is presented as ranges and medians. Qualitative data was analyzed for themes.

RESULTS: Although regions anticipated need for an incremental number of General Internists over the next 10 years, there was a consistent difficulty in establishing an exact number needed in any time frame due to uncertainties in physician recruitment and retention as well as changing health region needs. There was a consistent reactive versus proactive approach to recruitment. For example, regions would be unable to anticipate if current MDs would stay in a community, resulting in attempts to fill vacancies after a physician left. Interviews confirmed that the current scope of practice of GIM is widely variable across the province and at different practice location types. It also changes over

the course of a physician's career. Competency in cardiac, gastrointestinal, respiratory and cerebrovascular diseases were felt to be consistently important due to the prevalence of these disorders in the province. Particularly outside the large urban cities critical care skills were identified as being vital. Each region had particular and differing future skill needs (example Echocardiography or Colonoscopy skills, generally only needed in one graduate over several years). Respondents emphasized that General Internists must possess the full generalist scope of practice instead of subspecializing, with the ability to adjust scope to meet the health needs of their patients. All regions identified a need for expansion of the role of GIM in the ambulatory care setting. Expanded training in procedural skills; electro diagnostics; Point of Care ultrasound; healthcare administration and leadership; practice management were perceived as needs for all graduates to allow them to practice to the full scope of their potential. Respondents had difficulty establishing suggestions for improving the links between the educational system and eventual practice needs. Suggestions included enhancing distributed learning; expanding the skill set of GIM graduates to facilitate practice in rural locations; as well as enhancing tele health between distributed sites and the urban areas to allow more frequent communication—for example at journal clubs.

CONCLUSIONS: Linking GIM training to human resource planning is critical to ensure a stable workforce. Understanding the scope of practice of General Internists in Saskatchewan's changing health care system will allow the GIM residency program to adapt and train physicians for future needs. A recurrent theme of the skills and attitudes that GIM brings to the health care environment worldwide is that of a combination of a broad scope of practice but at the same time an adaptable set of skills that is unique for each practitioner for their own community. To fully understand health human resource planning for GIM an understanding of the range of scope of practice in each community that a residency program "serves" is needed. With the rapidly changing human resource needs we suggest that each residency program needs to link with the community for whom it is creating practitioners to understand needs and plan for them with individual graduates. As the Competence by Design project commences at the Royal College of Physicians and Surgeons of Canada this will be an ideal time to truly link education to future practice.

PREVALENCE AND CORRELATES OF ACTIONS TAKEN BY WOMEN IN RESPONSE TO RECENT INTIMATE PARTNER VIOLENCE (IPV) Jennifer McCall-Hosenfeld; Carol S. Weisman; Erik B. Lehman. Penn State College of Medicine, Hershey, PA. (Tracking ID #2169911)

BACKGROUND: Intimate Partner Violence (IPV)—physical violence, sexual violence, stalking, and psychological aggression perpetrated by a current or former partner—is a prevalent public health threat for women. Nearly half of all U.S. women have experienced psychological aggression and almost a quarter of all women have experienced severe physical violence perpetrated by a partner in their lifetimes. Recent scholarship regarding IPV has focused on specific actions taken by women in response to IPV, but little is known about the correlates of these actions. We investigate specific actions taken in response to IPV by exposed women, and examine the psychosocial and health-related correlates of these actions.

METHODS: A sample of women ages 18–64 was selected from primary care practices and domestic violence agencies serving Central Pennsylvania. Women who reported recent (past-year) IPV exposure using the HARK (humiliation-afraid-rape-kick) screener were asked about specific actions taken in response to this exposure to IPV, using the Intimate Partner Violence Strategies Index (Goodman, 2003) supplemented with open-ended questions based on our prior work. Multi-item scales were created for each action type. We developed a conceptual model identifying psychosocial and health-related factors as determinants of action taking. Possible determinants included type of violence exposure (physical vs. nonphysical IPV), adverse childhood experiences with violence or household dysfunction (ACEs), social support, any mental health disorder (depression, anxiety, bipolar or post-traumatic stress disorder), and sociodemographics (having children at home, marital/partner status, poverty, education, rurality.) Multiple logistic regression identified factors associated with each action type.

RESULTS: Among 109 women reporting recent IPV, 23 % reported physical IPV (rape/kick), 58 % reported high exposure to ACEs, and 49 % reported any adverse mental health condition. We identified four multi-item scales reflecting women's prevalent actions in response to IPV, all with good to excellent internal consistency. Scales were categorized as: *placating* (scale $\alpha=0.78$, examples: "tried to avoid an argument with my partner," 64 %; "tried not to cry," 48 %), *help-seeking* (scale $\alpha=0.68$, examples: "reached out to my friends or family," 62 %; "talked to a doctor or nurse," 24 %), *resistance* (scale $\alpha=0.80$, example: "fought back verbally," 61 %; "refused to do what my partner wanted" 47 %), *safety planning* (scale $\alpha=0.90$, examples: "kept money/[valuables hidden]," 31 %; "worked out an escape plan," 16 %), and past-year *alcohol/drug use*, (single item, 33 %). In multivariable analyses, physical IPV (versus nonphysical) was independently associated with alcohol/drugs, (aOR=3.07, (1.02, 9.22)), resistance (aOR=5.73 (1.59, 20.72)), and placating (aOR=4.00, (1.20, 13.37)) strategies. Having a mental health

diagnosis was associated with both safety planning (aOR=3.54, (1.28, 9.79)), and help-seeking (aOR=2.99 (1.09, 8.21)) strategies. At or near poverty (versus not poverty) was significantly associated with help-seeking (aOR=3.32, (1.06, 10.38)). We found no independent effects of rural residence, having children at home, or social support on types of actions taken.

CONCLUSIONS: This study identified key types of actions in response to past-year IPV exposure; these actions included both potentially helpful and harmful behaviors. Physical IPV exposure discriminated between women who did and did not use specific actions in response to IPV (alcohol/drugs, resistance and placating strategies). Because much physical violence arises from nonphysical abuse, identification of non-physical violence before it escalates may help healthcare providers to support women in pursuing helpful actions, and reducing harmful actions. Moreover, the associations we found between both safety planning and help-seeking behaviors and having a mental health diagnosis may reflect reverse causality in these cross-sectional data, i.e., women who have a mental health diagnosis may be engaged in care (thus seeking help) and within those care systems may learn about safety-planning. These findings reinforce the importance of primary healthcare systems (where half of all mental health is treated) in assisting IPV-exposed women with safety planning.

PREVALENCE AND EFFECTS OF LAPSES IN PUBLIC INSURANCE COVERAGE AMONG SAFETY NET PATIENTS FOLLOWING MASSACHUSETTS HEALTH CARE REFORM Carolyn Koulouris; Rebecca Rogers; Dylan Bothamley; Jennifer Huang; Neil N. Shah; Paula Lueras; Amy Pastemack; Christina Phillips; Judy Y. Kwok; Gaurab Basu; Danny McCormick. Cambridge Health Alliance, Cambridge, MA. (Tracking ID #2198194)

BACKGROUND: Lapses in public health insurance programs such as Medicaid are common. They are often caused by involuntary disenrollment when required paperwork such as re-applications or income verification data is not periodically received by the program (due to enrollee's failure to submit this information or to receive notification that it is due, e.g.). Furthermore, such lapses are associated with substantial barriers to accessing affordable care. The Massachusetts health care reform of 2006, the template for national reform, sought to increase access through a major expansion of Medicaid (and redesign of its eligibility determination process), creation of subsidized insurance plans available through a health insurance exchange and a tax penalty enforced mandate to maintain coverage. No prior studies, however, have examined the frequency or potential consequences of lapses experienced by those in public insurance programs created by the Massachusetts reform.

METHODS: We conducted face-to-face structured interviews with 644 publicly insured (Medicaid and Commonwealth Care plans) and 310 privately insured patients presenting to three emergency departments at a large integrated safety net health care system in the greater Boston area. We confirmed insurance type using a statewide database that is updated daily. We included patients aged 18–64, who spoke English, Portuguese, Spanish, or Haitian Creole. We excluded severely ill patients. The survey collected data on patients' demographic characteristics, experiences with current insurance plan, including lapses, and potential economic and medical consequences of lapses in coverage. We calculated the frequency of lapses in coverage for those with public and private insurance plans. Among the publicly insured, we then examined the association between demographic characteristics and plan experiences and having had a lapse using odds ratios and 95 % confidence intervals [CI]. We also examined the association of experiencing a lapse and potential economic and medical harms in the same manner.

RESULTS: Of publicly insured patients, 25.9 % experienced a lapse in their current insurance plan, compared with 3.8 % of privately insured patients. Among publicly insured patients who experienced a lapse, 44.9 % reported having to delay or forego medical care due to this lapse. The frequency of lapses did not differ between Medicaid and Commonwealth Care insured patients. We found no association between age, gender, English as the primary spoken language or race; US-born patients were more likely to experience a lapse than foreign-born patients (30 % vs 22 %, OR=1.4, 95 % CI=1.1–1.8), however. Having to fill out additional paperwork to maintain enrollment and having difficulty with completing paperwork were both associated with greater likelihood of experiencing a lapse (34 % vs 19 %, OR=1.8, 95%CI=1.3–2.4 and 42 % vs 29 %, OR=1.4, 95 % CI=1.0–1.9, respectively). We found, in turn, that experiencing a lapse was associated with a greater likelihood of being contacted by bill collectors for medical costs (30 % vs 14 %, OR=2.0, 95%CI=1.5–2.6) and with delaying or foregoing primary care or medication purchases due to cost (11.2 % vs 5.0 %, OR=2.2 95%CI=1.3–4.0 and 19.4 % vs 11.3 %, OR 1.7, 95 % CI=1.2–2.6, respectively).

CONCLUSIONS: High rates of lapses seen in prior studies of public insurance programs persist in public insurance programs that were expanded (Medicaid) or created (Commonwealth care) under the Massachusetts health care reform. These lapses limited access

to care and were associated with economic harms for patients. In Massachusetts public insurance programs should seek to minimize lapses, perhaps in part through better enrollee education and minimizing the burden of paperwork.

PREVALENCE OF CARDIOVASCULAR EVENTS IN PATIENTS WITH CANCER: ANALYSIS OF 12-YEAR DATA FROM NATIONAL HEALTH AND NUTRITION EXAMINATION SURVEY 1999–2010 Saurabh Aggarwal^{1,2}; Rohit S. Loomba⁵; Navdeep Gupta⁵; Anushree Agarwal⁶; Gaurav Aggarwal⁸; Venkata M. Alla³; Manu Kaushik²; Claire Hunter³; Syed Mohiuddin³; Dennis Esterbrooks¹; Rohit Arora⁷; Aryan Mooss⁴. ¹Creighton University, Omaha, NE; ²Creighton University Medical Center, Omaha, NE; ³Creighton University School of Medicine, Omaha, NE; ⁴Creighton University School of Medicine, Omaha, NE; ⁵Medical College of Wisconsin, Milwaukee, WI; ⁶University of California-San Francisco, San Francisco, CA; ⁷Chicago Medical School, North Chicago, IL; ⁸Armed Forces Medical College, Pune, India. (Tracking ID #2199024)

BACKGROUND: Cardiovascular disease (CVD) & cancer are the leading causes of morbidity and mortality. We sought to assess any association present between the two in a nationally representative sample.

METHODS: We utilized data from National Health & Nutrition Examination Survey (NHANES) 1999–2010 database. Patients were divided into cancer positive & cancer negative groups based on self-reported cancer history. Patients were excluded if they were <18 years of age and if no response for cancer history was captured. Multiple imputations were used for missing values. Baseline characteristics, prevalence of angina, coronary artery disease (CAD) & congestive heart failure (CHF), and history of myocardial infarction (MI) and stroke were compared between the two groups.

RESULTS: A total of 32,428 patients with complete data were included in final analysis. On univariate analysis, patients with self-reported history of cancer were found to have higher prevalence of angina, CAD, CHF and history of MI and stroke [table]. However, on multivariable logistic regression, no independent association was found after adjusting for age, gender, race, total cholesterol, HDL, LDL, systolic blood pressure, smoking status, diabetes mellitus and body mass index.

CONCLUSIONS: In this large nationally representative sample, patients with history of cancer had higher prevalence of CVD disease. However, a direct association between history of cancer and CVD disease is not established after correcting for CVD risk factors.

Odds ratio for prevalence of cardiovascular events in patients with history of cancer

	Angina	Coronary artery disease	Heart failure	Myocardial infarction	Stroke
Univariate odds ratio and 95% confidence interval	2 . 7 9 (2.40 to 3.25)*	2.84 (2.5 to 3.25)*	2 . 7 9 (2.41 to 3.24)*	2.85 (2.50 to 3.25)*	2 . 7 5 (2.39 to 3.17)*
Univariate p-value	< 0.001*	< 0.001*	< 0.001*	< 0.001*	< 0.001*
Adjusted odds-ratio and 95% confidence interval	1 . 2 3 (0.89 to 1.69)	1.04 (0.78 to 1.38)	1 . 1 8 (0.85 to 1.64)	1.07 (0.81 to 1.42)	1 . 1 5 (0.85 to 1.56)

PREVENTING DIABETES IN PRIMARY CARE: PROVIDERS' PERSPECTIVES ABOUT THE VALUE OF DIAGNOSING AND TREATING PREDIABETES Namratha R. Kandula; Margaret R. Moran; Joyce W. Tang. Northwestern University, Chicago, IL. (Tracking ID #2191304)

BACKGROUND: Seventy-nine million people in the U.S. have prediabetes, and within 3 years, 11 % of these individuals will go on to develop type 2 diabetes mellitus (DM). Current guidelines recommend screening for prediabetes and DM, but population-based studies show that only 10 % of patients with prediabetes are aware of their diagnosis. Primary care is potentially an ideal setting for identifying patients with prediabetes and educating them about how to reduce their risk for DM. However, little is known about primary care providers' (PCPs') perspectives on DM prevention. We investigated PCPs' perspectives about the value of diagnosing and treating prediabetes in primary care.

METHODS: This study was a part of a qualitative investigation of patient and PCP experiences with and perspectives on DM prevention. Fifteen primary care providers (14

physicians and one nurse practitioner) were recruited from 2 primary care clinics using emailed recruitment letters. We conducted in-depth interviews using a semi-structured interview guide. The guide was designed to elicit PCPs' values, preferences, knowledge, experience, and approach to DM prevention. The study team developed a coding guide a priori that was iteratively refined while reviewing the first set of interviews. Digital audio files of the interviews were transcribed verbatim. Transcripts were coded and analyzed utilizing template analysis. All interviews were coded by at least 2 members of the study team (NK, MM, or JT). All coding and qualitative analysis was performed using NVivo qualitative data analysis software (QSR International Pty Ltd. Version 10, 2012) to organize the data.

RESULTS: We identified three major themes related to the value of identifying prediabetes in primary care: 1) Providers said that a diagnosis of prediabetes was a "wake-up call" for patients and an important opportunity to educate and intervene. For example, "I think it is good for people to know **now**, before they have diabetes. Some providers are of the mindset, 'oh I don't want to scare the patient, they don't actually have diabetes.' I don't agree with that. I think that changes made earlier so we can prevent are helpful, rather than coming in and finding their A1c is 8 or 9 and they really have diabetes and then they have to go on medication." 2) Other PCPs felt that focusing on prediabetes was potentially a waste of resources because the scientific evidence did not show that finding and treating prediabetes prevented serious, long-term complications, such as heart attack, kidney failure, or death. These PCPs felt that resources should be focused on patients who already had DM or on treating established cardiovascular risk factors. 3) Another key theme was that the importance of DM prevention varied by patient. For patients with few or no comorbidities, a prediabetes diagnosis was seen as a concrete way to motivate patients to lose weight; in contrast, providers perceived that the diagnosis of prediabetes may add less value for patients with multiple co-morbidities. A provider said, "he (the patient) is very complicated, and so given his other medical issues, I was trying to figure out whether to even bring up the issue of prediabetes with him. I don't even know that I want to give him one more thing to think about. I honestly didn't even mention it." Several providers also voiced the belief that prediabetes was a public health or societal problem that could not be effectively treated in primary care. PCPs voiced frustration that patients generally did not have access to intensive, evidence-based lifestyle interventions, such as the Diabetes Prevention Program: "So, I think it's all well and good, but it just doesn't match my reality. If I could write a script for 'do lifestyle therapy as they prescribed with 7 % of body weight,' as easily as I can write a prescription for Metformin, and people would actually do it, and their insurer would pay for it or it would be affordable, I would do that every time, but I can't even get out the door on most of these things."

CONCLUSIONS: We identified substantial variation among PCPs' perspectives about DM prevention. The value of diagnosing and educating patients about prediabetes was influenced by several factors: PCPs' belief that this was an opportunity to motivate lifestyle change, PCPs' prioritization of other cardiovascular risk factors, how providers interpreted the science behind DM prevention, patient comorbidities, and patient access to effective lifestyle interventions. Efforts to increase DM prevention screening in primary care should focus on improving PCPs' ability to easily refer patients to low-cost, evidence-based lifestyle interventions, and should consider approaches that help target DM prevention towards patients who are most likely to benefit (e.g., those with few co-morbidities).

PRIMARY CARE ACCESS BEFORE AND AFTER MEDICAID EXPANSION UNDER THE AFFORDABLE CARE ACT Renuka Tipirneni²; Karin V. Rhodes⁴; Rodney A. Hayward^{1,2}; Richard L. Lichtenstein¹; Elyse Reamer^{3,2}; Matthew M. Davis². ¹U. Michigan, Ann Arbor, MI; ²University of Michigan, Ann Arbor, MI; ³University of Michigan Medical School, Ann Arbor, MI; ⁴University of Pennsylvania, Philadelphia, PA; ⁵University of Michigan School of Public Health, Ann Arbor, MI. (Tracking ID #2195650)

BACKGROUND: The Patient Protection and Affordable Care Act (ACA) provides for expansion of health insurance coverage to millions of Americans, but availability of health care services for the newly insured remains uncertain. This study examines primary care appointment availability and wait times for new Medicaid and privately insured patients before versus after implementation of Medicaid expansion in Michigan.

METHODS: We conducted a simulated patient ("secret shopper") study, in which trained research staff called a stratified proportionate random sample of primary care practices (N=295) to request a new patient appointment before (March 2014) and after (July-August 2014) Medicaid expansion implementation in Michigan on April 1, 2014. The sampling frame included clinics that care for adult patients, such as internal medicine or family medicine clinics, because the working age population is the target group gaining coverage under the ACA. For clinics that accepted new Medicaid patients, we used simulated patient calls to assess wait times for appointments (difference in calendar days between call and appointment dates). Clinics were called twice during each data collection period, once by a simulated patient with Medicaid and once by a simulated patient with private insurance.

RESULTS: During the study period, nearly 350,000 adults enrolled in Medicaid expansion health plans in Michigan, representing 33 % of the state's previously uninsured non-elderly adult population. Compared with the period immediately before Medicaid expansion, appointment availability for new Medicaid patients increased from 49 to 55 % (absolute difference +6 %, 95 % CI +1.2 to +9.1 %, $p=0.005$) while availability for new privately insured patients decreased slightly from 88 to 86 % (absolute difference -2 %, -0.1 to -4.0 %, $p=0.01$). When offered an appointment, median wait times for both new Medicaid and new privately insured patients increased slightly after expansion, but these changes were not statistically significant (8 to 12 days for Medicaid, $p=0.15$; 7 to 11 days for private, $p=0.13$).

CONCLUSIONS: During a period of rapid insurance coverage expansion, primary care appointment availability for new Medicaid patients improved and wait times remained reasonable to ensure access to primary care. Follow-up data collection (next scheduled for March 2015) will indicate whether access to primary care will endure as new patients enter the system under Medicaid expansion.

PRIMARY CARE PROVIDERS IN NEW MEXICO ARE CONCERNED ABOUT IMPLEMENTING LOW-DOSE CT LUNG CANCER SCREENING Richard Hoffman¹; Andrew Sussman¹; Robert Rhyné¹; Christina Getrich²; Kathryn L. Taylor³; Shiraz I. Mishra¹. ¹University of New Mexico School of Medicine, Albuquerque, NM; ²University of Maryland, College Park, MD; ³Georgetown University, Washington, DC. (Tracking ID #2190737)

BACKGROUND: Lung cancer is the leading cause of cancer death in the United States. Cancer control efforts have traditionally focused on stopping or preventing tobacco use, because tobacco contributes to over 80 % of lung cancer deaths. Unfortunately, screening with chest x-rays (CXR) and/or sputum cytology has not been proven effective in reducing lung cancer mortality. However, the National Lung Screening Trial (NLST) recently found that three rounds of annual screening with low-dose computed tomography (LDCT) significantly reduced the risk of lung cancer death in heavy smokers ages 55 to 74 compared to annual CXR screening. Consequently, guidelines issued by organizations such as the U.S. Preventive Services Task Force (USPSTF) and the American Cancer Society (ACS) now recommend screening high-risk smokers with LDCT. Because translating research results to routine practice is challenging, we characterized the knowledge, attitudes, and beliefs of primary care providers about implementing LDCT screening.

METHODS: We conducted qualitative in-depth, semi-structured interviews with providers practicing in New Mexico clinics for underserved minority populations. Using a purposeful sampling approach, we identified rural and urban clinicians who primarily see Hispanic patients meeting criteria for LDCT screening. We conducted audio-taped interviews from February through September 2014 that focused on the providers' tobacco cessation efforts; lung cancer screening practices; perceptions of NLST results and guideline recommendations; and attitudes about decision-making. Investigators iteratively reviewed transcripts to create an initial coding structure; transcripts were then imported into NVivo10, a qualitative data analysis program, for final coding.

RESULTS: We reached thematic saturation after interviewing 10 primary care providers practicing in urban ($n=6$) or rural ($n=4$) settings; 8 practiced at Federally Qualified Health Centers. All promoted smoking cessation; a few screened with CXR though none with LDCT. Not all were aware of NLST results or current guideline recommendations. They viewed study results skeptically, particularly the 95 % false-positive rate, the absolute mortality benefit of only 3/1000, the high proportion of academic sites, and the small proportion of minority participants. The NLST results were not seen as providing sufficient evidence to justify the USPSTF guidelines; providers were also generally wary of new cancer screening guidelines given the controversies over prostate and breast cancer screening recommendations. Providers were uncertain whether New Mexico had the necessary infrastructure to support high-quality screening, and worried about access barriers and financial burdens for rural, underinsured populations. While recognizing that the Affordable Care Act provides first-dollar coverage for screening tests, providers expressed concern about the potentially prohibitive out-of-pocket costs for subsequent diagnostic testing and procedures. Providers noted the complexity of discussing benefits and harms of screening and surveillance and believed that it would be challenging to

support low-literacy patients in making informed decisions. Some questioned allocating resources to screen older smokers rather than to target smoking cessation and prevention interventions for the young.

CONCLUSIONS: Providers were not well informed about NLST trial results and screening guidelines, but raised many concerns about the feasibility and appropriateness of implementing LDCT screening, particularly in a state with limited health care resources. Effective screening programs will need to educate providers and patients to support informed decision making and to ensure that high-quality screening can be efficiently delivered in community practice.

PROMOTING PROPER UTILIZATION OF EARLY DETECTION TECHNOLOGY IN THE ACUTE CARE SETTING Graham Lowenthal; Patricia C. Dkys; Stuart R. Lipsitz; Catherine Yoon. Brigham and Women's Hospital, Boston, MA. (Tracking ID #2191446)

BACKGROUND: If utilized properly, patient monitoring systems designed for early detection and alerting of clinical decompensation may contribute to better quality of care, length of stay, and healthcare cost outcomes.^[1,2] In January of 2013, an early detection system was implemented on all adult medical-surgical beds in an Eastern Massachusetts acute care hospital. The purpose of this study was to identify barriers to implementation of the early detection system and to develop strategies to maximize proper utilization. References: 1) Brown H, Terrence J, Vasquez P, Bates DW, Zimlichman E. Continuous monitoring in an inpatient medical-surgical unit: a controlled clinical trial. *Am J Med.* 2014 Mar;127(3):226-32. 2) Slight SP, Franz C, Olugbile M, Brown HV, Bates DW, Zimlichman E. The return on investment of implementing a continuous monitoring system in general medical-surgical units. *Crit Care Med.* 2014 Aug;42(8):1862-8.

METHODS: We established a committee of stakeholders (physicians and nurse champions), researchers, and vendor partners. This committee hosted regular meetings to identify barriers that could impede successful use of the system. We developed strategies for overcoming each identified barrier, using a Plan Do Study Act (PDSA) framework, a cyclical model for developing, testing, adjusting, and retesting improvement approaches.^[3] In order to test each strategy, we established goals and process measures, and reported out on progress during our next meeting. We measured overall progress by tracking use of the system and response times to system alerts. After gathering feedback, we adjusted our approach by revising preexisting goals or setting new ones. References: 3) Patient Safety—Quality Improvement [Internet]. Durham (NC): Department of Community and Family Medicine, Duke University Medical Center. 2014-. Part A, What is quality improvement?; [cited 2015 Jan 5]; [about 3 screens]. Available from: http://patientsafetyed.duhs.duke.edu/module_a/methods/pdsa.html

RESULTS: The barriers we identified as limiting successful implementation of the early detection system, and strategies we developed to overcome them, are included in Table 1. Units made numerous improvements as new barriers were identified and strategies to work through them were developed and tested. We found that the strategies we implemented led to more frequent, and more correct, use of the technology. Monthly mean response times to system alerts improved between January and November of 2014. Overall monthly mean response times decreased from 88 (range: 17 to 362) to 51 (range: 2 to 157) minutes. Cardiac alert responses improved from 93 (range: 17 to 312) to 35 (range: 2 to 84) minutes. Respiratory alert responses decreased from 87.5 (range: 28 to 362) to 53 (range: 9 to 157) minutes. Communication of the system also improved, especially within the electronic health record and multidisciplinary rounds. Regular teaching sessions have contributed to greater awareness of and familiarity with using the system and features. Attitudes toward accepting and using the system were more positive as well. Staff members became increasingly more enthusiastic about achieving goals and more engaged in discussion of utilization and planning next steps.

CONCLUSIONS: Our Plan Do Study Act framework was effective for overcoming barriers to proper utilization of early detection technology in the acute care setting. Since implementing the PDSA methodology, we have seen continuous improvement in system use and alert response times. Our PDSA model was successful overall, but each individual unit exhibited varying levels of progress using the strategies we developed. Some units excelled with the system, while others repeatedly struggled to improve practice and response times. We will continue using our PDSA framework to support proper system utilization and to decrease unit response times.

Table 1: Identified Barriers to Proper Utilization of Early Detection Technology, and Strategies Developed to Overcome Them

Identified Barriers	Strategies Developed to Overcome Barriers
Inadequate Training/Education	<ul style="list-style-type: none"> ● Kickoff Event, emphasizing the system's importance and proper utilization ● Regular Didactic and Hands-on Teaching sessions for promoting awareness of and familiarity with using system and features
Lack of Physician Involvement	<ul style="list-style-type: none"> ● Integrated system reporting and scripted discussion into multidisciplinary rounds ● Physician peer counseling on use of system
Inability to See Device's Value	<ul style="list-style-type: none"> ● Reviewed recent "saves" (device's detection of early patient decompensation that alerted staff to intervene and prevent worsening/emergency health problems) during champions meetings to promote perceived value
Clinical Workflow Challenges	<ul style="list-style-type: none"> ● Involved physicians and nurse champions in identifying workflow challenges and solutions ● Physicians and nurse champions led practice redesign efforts
Alarm Fatigue	<ul style="list-style-type: none"> ● Educated staff on proper alerts management ● Implemented protocol enabling nurses to change device settings within specified limits to reduce unnecessary alerts
Pagers ("Just one more thing to carry")	<ul style="list-style-type: none"> ● Multiple methods of receiving alerts give staff option to carry pagers or regularly check status boards in halls ● Response times are continuously monitored and feedback is provided to help each unit determine whether to continue with, or reevaluate, current practice
Lack of Communication	<ul style="list-style-type: none"> ● Alerts being integrated into nurses' phones ● Incorporated system reporting into EHR to keep staff up-to-date at shift change ● Champions share content of committee meetings with units ● Partnership with vendor to address challenges
Multiple Conflicting Priorities	<ul style="list-style-type: none"> ● Reaffirmed and aligned leadership support at every level of the organization, from top to bottom (Hospital Leadership → Unit Leadership → Staff RNs → Multidisciplinary Team)

PSYCHOLOGICAL SYMPTOMS AND RELIGIOSITY IN PATIENTS WITH VENTRICULAR ASSIST DEVICES: A COHORT STUDY Himali Weerahandi¹; Nathan Goldstein²; Laura P. Gelfman²; Ulrich Jorde³; James N. Kirkpatrick⁴; Judith Marble⁵; Yoshifumi Naka⁶; Sean Pinney¹; Mark S. Slaughter⁷; Emilia Bagiella¹; Deborah D. Ascheim¹. ¹Icahn School of Medicine at Mount Sinai, New York, NY; ²Icahn School of Medicine at Mount Sinai, New York, NY; ³Montefiore Medical Center, Bronx, NY; ⁴Hospital of the University of Pennsylvania, Philadelphia, PA; ⁵University of Pennsylvania, Philadelphia, PA; ⁶Columbia University, College of Physicians and Surgeons, New York, NY; ⁷Jewish Hospital Louisville, Louisville, KY. (Tracking ID #2196096)

BACKGROUND: Ventricular assist devices (VADs) are increasingly used to treat heart failure (HF) patients with advanced disease. While these devices have been shown to improve survival and quality of life in patients with advanced HF, there are little data exploring the psychological symptoms of these patients, and there have been no studies examining religiosity in this patient population.

METHODS: Patients were enrolled in this cohort study immediately before or after VAD implant to determine baseline prevalence of symptoms of patients, and then followed at regular intervals for up to 21 months after VAD placement to determine how these symptoms change over time. Patients were eligible for the study if they were age 21 and older, had a planned LVAD implant or had an LVAD implanted within 6 months, were fluent in English, had a caregiver or family member who was willing to be enrolled (for outcomes not shown), and had consistent and reliable access to a phone. Outcomes related to religion were obtained through structured patient interviews. Depression and anxiety were assessed with PROMIS SF8a questionnaires. The panic disorder, acute stress disorder (ASD) and post-traumatic stress disorder (PTSD) modules of the Structured Clinical Interview for the DSM (SCID) were also used. Generalized estimating equations (GEE) were used to examine relationship of scores to time.

RESULTS: Eighty-seven patients were enrolled at four clinical sites; mean age was 57.7, and 29.3 % were African-American. The indications for VAD placement were bridge to transplant (40.2 %), destination therapy (49.3 %) and unknown (10.3 %). At the end of the study period, 6.9 % of the patients died and 16.7 % received a cardiac transplant. Mean religiosity score was as high as 9.4 (SD 0.9) out of 10 (at 3 months post implant; range over time: 5.8–9.4). They also rated that their medical team supported their spiritual needs to a moderate extent. However, the relative risk of these patients receiving pastoral care services while in the hospital was 0.14 (SD 0.4). Mean depression t-scores were 51.9 (SD 8.5) pre-implantation, and 43.9 (SD 6.4) at 12 months post-implantation. A GEE model demonstrated that the score decreased by 0.8 points at each time interval post LVAD implantation ($p=0.04$). Mean anxiety t-scores were 54.0 (SD 10.7) pre-implantation, and 42.4 (SD 9.4) at 12 months post-implantation. A GEE model demonstrated that the score decreased by 2.09 points at each time interval going forward ($p<0.001$). Only 2 patients met criteria for panic disorder after implantation, and these patients' symptoms resolved over time. No patients met criteria for ASD or PTSD.

CONCLUSIONS: This study demonstrated that these patients were fairly religious and felt that the medical team supported their spiritual needs, even though they rarely received pastoral services in the hospital. In addition we found that anxiety and depression decreased over time for patients implanted with a VAD. There was also a low incidence of ASD and PTSD, and panic disorder. Anxiety also improved over time. Undergoing a major procedure may produce anxiety or other psychological harm. However, our study demonstrates that the VAD implantation does not appear to cause or worsen these outcomes. The incidence of panic disorder is lower than in both the general population and the general heart failure population. This may be because we selected a group of patients that have a known caregiver, which may affect the prevalence of psychiatric disorders. This finding warrants further investigation. Given that religion is important source of support to these patients, increasing access to religious services while hospitalized could improve the quality of care.

PULLING TEAMS TOGETHER: INTERPROFESSIONAL TEAMWORK AND THE CHALLENGES FACED BY HOSPITALS, PROVIDERS, AND PATIENTS

Benjamin J. Chesluk¹; Elizabeth C. Bernabeo²; Siddharta Reddy²; Lorna A. Lynn¹; Brian Hess¹; Thorsten Odhner¹. ¹ABIM, Philadelphia, PA; ²American Board of Internal Medicine, Philadelphia, PA. (Tracking ID #2199320)

BACKGROUND: Interprofessional teamwork is a basic component of healthcare; physicians and other providers need to directly and indirectly coordinate and collaborate with each other to care for patients. However, this necessary coordination and collaboration often depends primarily on the diligence of providers, who must exercise their own individual skills in teamwork to reach across professional boundaries and overcome systemic challenges. Ethnography has proved a useful method of studying healthcare teams in practice; previous ethnographic research has focused on information systems and teamwork in settings where teams are well-defined (such as ORs). Additional research is needed to define what teamwork means and how it is achieved in other contexts, particularly for groups such as hospitalist physicians, for whom teamwork is a core competency, with distinct challenges.

METHODS: We conducted ethnographic fieldwork with a sample of 4 hospitalists in 3 hospitals in a single US metropolitan area. Sites and participants were selected to represent a range of practice types and settings (academic/non-academic; urban/suburban; large research / small community hospital). This entailed close observation in practice over the course of approximately 7 days with each physician, for a total of 160 h of data collection. Fieldwork was led by a team led by a PhD cultural anthropologist with extensive experience in observing healthcare providers; other team members provided expertise in medicine, public health, psychology, and usability research. We recorded detailed fieldnotes describing observations and conversational interviews with providers in context. We conducted qualitative, iterative analysis of all data using the constant comparative method, during and after fieldwork, to identify themes and illustrative quotes and incidents. We also presented a preliminary analysis to providers at the fieldsites, which allowed for refinement of the analysis to incorporate informants' perspectives.

RESULTS: Hospital providers work in conditions that often undermine effective teamwork in a variety of reasons: geographically scattered patients, unreliable information systems and ordering processes, fragmented care teams, and lack of consistent formal support for effective teamwork. These conditions can pose threats to the timeliness, efficacy and safety of the care that patients receive, especially at transition points when patients or patient information must move between departments within the hospital or between the hospital and other institutions. Providers must exercise of a great deal of individual effort to mitigate these challenges; individuals may innovate ways to improve their teamwork, but these are not typically tested or shared, even with close collaborators. Beyond the burden on providers, these conditions can pose serious problems for patients and their family members, who may need to play a critical, active role in coordinating their own care to make up for the system's shortcomings. However, these expectations put on

patients and family members are rarely clearly stated; they may not be aware of their role on their own care team, or fully able to fulfill that role.

CONCLUSIONS: Expectations for the practice of effective teamwork and how to overcome common challenges must be acknowledged and taught. Systems for sharing information and coordinating care within and between institutions, and mechanisms for identifying and resolving conflicts within members of the care team, must be strengthened. Expectations for the roles that care providers, patients and family members play must be clarified and made explicit, and support in fulfilling these roles must be provided by healthcare providers and the organizations within which they work.

QUALITY OF END-OF-LIFE CARE PROVIDED TO PATIENTS WITH DIFFERENT LIFE-LIMITING CONDITIONS IN THE VETERANS HEALTH ADMINISTRATION Melissa W. Wachterman³; Corey Pilver⁴; Dawn Smith⁵; Stuart R. Lipsitz⁶; Mary Ersek^{2,5}; Nancy L. Keating^{1,6}. ¹Harvard Medical School, Boston, MA; ²University of Pennsylvania School of Nursing, Philadelphia, PA; ³VA Boston Healthcare System, Jamaica Plain, MA; ⁴VA Boston Healthcare System, Boston, MA; ⁵Philadelphia VA Medical Center, Philadelphia, PA; ⁶Brigham and Women's Hospital, Boston, MA. (Tracking ID #2191203)

BACKGROUND: Historically, patients with cancer have been the primary focus of efforts to improve end-of-life (EOL) care; however, with the aging of the U.S. population, high quality EOL care for patients with other life-limiting conditions is increasingly important. There is an emerging set of quality measures in EOL care (such as palliative care consultation and bereaved family evaluation of care), but little is known about the relative quality of EOL care across different life-limiting conditions. Our objective was to evaluate the quality of EOL care provided to patients with different life-limiting conditions within the nation's largest healthcare system, the Veterans Health Administration (VA). Quality of EOL care was measured using the validated Bereaved Family Survey and several chart-based measures.

METHODS: We contacted the next of kin of all 57,342 Veterans who died in one of the 146 VA hospitals or long-term care facilities nationwide during 2010–2012. Our final sample included 33,768 Veteran decedents for whom we received a completed Bereaved Family Survey (response rate 58.9 %). We categorized Veterans as having one of six life-limiting conditions: end-stage renal disease (ESRD), cancer, cardiopulmonary failure (congestive heart failure and chronic obstructive pulmonary disease), dementia, frailty, and other causes. Chart review-based quality measures included: 1) palliative care con-

sultation in the last 3 months of life; 2) death in the intensive care unit (ICU); and 3) do-not-resuscitate (DNR) status at the time of death. Survey-based quality measures included families' reports of: 1) excellent care in the last month of life and 2) frequent uncontrolled pain in the last month of life. We used multivariate logistic regression to compare these EOL quality measures for patients with different life-limiting conditions, controlling for demographic factors and medical comorbidity. We then generated adjusted proportions based on these multivariate adjusted models. All analyses were weighted to account for survey non-response, yielding estimates representative of the full population of Veterans dying in VA facilities.

RESULTS: Among 33,768 Veteran decedents, 6.0 % of decedents' life-limiting condition was ESRD, 44.0 % cancer, 26.0 % cardiopulmonary failure (CHF and COPD), 4.4 % dementia, 11.1 % frailty, and 8.5 % other causes. The cohort was 97.9 % male, 75.2 % non-Hispanic white, with a mean age of 74.1. As shown in the Table, life-limiting condition was significantly associated with all chart review-based and survey-based outcomes (adjusted $P < .001$). The adjusted proportion of patients receiving a palliative care consult was highest among cancer patients (69.8 %) and dementia patients (61.5 %), while less than half of patients with ESRD, cardiopulmonary failure, and frailty received such consults. The adjusted proportion of patients dying in the ICU was lowest among cancer patients (16.1 %) and dementia patients (11.0 %), while about one-third of patients with ESRD, cardiopulmonary failure, and frailty died in the ICU. The adjusted proportion of patients with a DNR order at death was highest among cancer patients (94.6 %) and dementia patients (93.5 %), compared to 87–88 % for other conditions. The adjusted proportion of family members reporting that care in the last month of life was excellent was highest among those of patients with cancer (57.7 %) and dementia (59.2 %) and lowest among patients with ESRD (53.8 %) and cardiopulmonary failure (53.5 %).

CONCLUSIONS: Quality of EOL care, both in terms of objective measures and family-reported quality, varied by life-limiting condition and was generally highest for dementia and cancer patients, and lowest for patients with CHF, COPD, and ESRD, independent of demographic factors and medical comorbidity. Patients with CHF, COPD, and ESRD were significantly less likely than patients with cancer or dementia to be seen by palliative care, to have a DNR order, and to receive excellent care in the last month of life according to family, and were more likely to die in the ICU. These findings suggest that expanding the scope of palliative care and high-quality EOL care for patients with CHF, COPD, and ESRD should be a priority for both clinicians caring for patients at the end of life and policymakers.

Outcome	ESRD	Cancer	Cardiopulmonary Failure	Dementia	Frailty	Adjusted P-value
Weighted % of sample	6.0	44.0	26.0	4.4	11.1	NA
Chart Review Quality Measures(Adjusted %)						
Palliative consult	48.8	69.8	47.5	61.5	47.1	<.001
Death in the intensive care unit	35.6	16.1	33.9	11.0	30.4	<.001
DNR order at death	87.9	94.6	87.0	93.5	87.7	<.001
Bereaved Family Survey Quality Measures(Adjusted %)						
"Excellent care" in last month of life	53.8	57.7	53.5	59.2	55.5	<.001
Frequent uncontrolled pain	46.7	49.1	45.3	39.8	44.1	<.001

"Other causes" (8.5 % of sample) omitted from table. All proportions are adjusted for age, race, sex, survey respondent's relationship to decedent, and number of comorbidities. P-values are for overall association between life-limiting condition and each outcome after adjustment.

QUALITY OF LIFE, FUNCTIONAL STATUS, AND PAIN OVER TIME IN PATIENTS WITH VENTRICULAR ASSIST DEVICES: A COHORT STUDY Himali Weerahandi¹; Nathan Goldstein²; Laura Gelfman²; Ulrich Jorde³; James N. Kirkpatrick⁴; Judith Marble⁵; Yoshifumi Naka⁶; Sean Pinney¹; Mark S. Slaughter⁷; Emilia Bagiella¹; Deborah D. Aschheim¹. ¹Icahn School of Medicine at Mount Sinai, New York, NY; ²Icahn School of Medicine at Mount Sinai, New York, NY; ³Montefiore, Bronx, NY; ⁴Hospital of the University of Pennsylvania, Philadelphia, PA; ⁵University of Pennsylvania, Philadelphia, PA; ⁶Columbia University, College of Physicians and Surgeons, New York, NY; ⁷Jewish Hospital Louisville, Louisville, KY. (Tracking ID #2188070)

BACKGROUND: Ventricular assist devices (VADs) are used to treat advanced heart failure (HF) patients both as a bridge to cardiac transplantation and for those ineligible for transplantation. These devices have been shown to improve survival, but to our knowledge, there is limited data on pain control in this patient population. In addition, the literature on quality of life and functional status over time is limited to small studies.

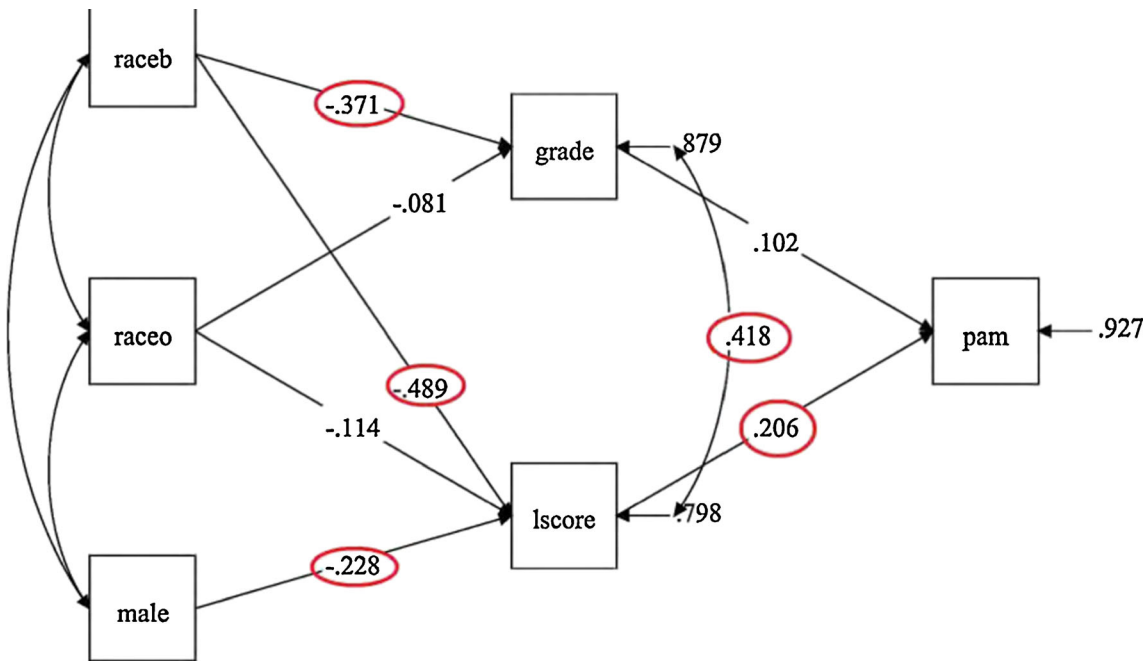

METHODS: A 4-center cohort study of patients with VADs was performed. Patients were enrolled immediately before or after VAD implant to determine baseline symptoms of patients and then followed at regular intervals for up to 21 months after VAD placement to determine how these characteristics change. Patients were eligible for this study if they were aged 21 and older, and were fluent in English, had a caregiver or family member who was willing to be enrolled (for outcomes not shown), and had consistent and reliable access to a phone. The Brief Pain Inventory (BPI), a 23-item questionnaire, was used to assess pain. The Kansas City Cardiomyopathy Questionnaire (KCCQ), a 23-item questionnaire covering 5 domains (physical function, symptoms, social function, self-efficacy, and quality of life) was used to assess quality of life and health status. The Katz Independent Activities of Daily Living questionnaire was used to assess functional status. Generalized estimating equations (GEE) examined relationship of scores to time.

RESULTS: Eighty-seven patients were enrolled in this study; mean age was 57.7, 21.8 % were women, and 29.3 % were African-American. The mean BPQ score was 2.4 (SD 2.4) out of 10 (with 10 representing worst pain) before implantation, 3.7 (SD 2.9) immediately after implantation, and 2.0 (SD 2.5) 12 months after implantation. A GEE model using time to predict pain score demonstrated that the score decreased by 0.32 points at each time interval going forward ($p = .002$). Mean BPQ score representing how much pain interferes with activity was 3.7 (SD 3.9) out of 10 (with 10 representing worst pain) before implantation, 2.9 (SD 3.2) immediately after implantation, and 0.2 (SD 0.4) at 12 months

after implantation. A GEE model using time to predict pain score demonstrated that the score decreased by 0.43 points at each time interval going forward ($p<0.0001$). KCCQ summary scales demonstrated improvement with time. A GEE model using time to predict score demonstrated that the overall summary score increased by 3.38 points at each time interval going forward ($p=.0003$). Katz IADL summary scores also demonstrated improvement over time. A GEE

model using time to predict score demonstrated that the summary score decreased by 1.2 points at each time interval going forward ($p<0.0001$).

CONCLUSIONS: This study demonstrated that VAD implanted patients experienced improved pain, quality of life, health status and functional status over time. These data may be useful in helping patients in decision making when considering whether VAD implantation may meet their goals of care.

QUALITY OF REPORTING OF RANDOMIZED CONTROLLED TRIAL ABSTRACTS AMONG LEADING GENERAL MEDICINE JOURNALS: A REVIEW AND ANALYSIS Meredith A. Hays³; Kevin M. Douglas¹; Mary Andrews⁴; Ramey L. Wilson⁴; Lynn Byars²; David M. Callender⁵; Patrick G. O'Malley². ¹USUHS, Potomac, MD; ²Uniformed Services University, Washington, DC; ³WRNMMC, Kensington, MD; ⁴Walter Reed National Military

Medical Center, Bethesda, MD; ⁵Walter Reed National Military Medical Center, Washington, DC. (Tracking ID #2194050)

BACKGROUND: The Consolidated Standards of Reporting Trials (CONSORT) for Abstracts statement was designed to improve reporting of Randomized Controlled Trial (RCT) abstracts, allowing readers to quickly assess the validity and applicability of the

trial results. CONSORT was endorsed by the top five high-impact general medicine journals (ranked by the reported ISI impact factor of 2014). Our primary goal was to determine adherence to the CONSORT guidelines by these journals.

METHODS: We conducted a descriptive, cross-sectional study of RCT abstracts published between 2011 and 2014 in the five highest-impact general medicine journals. Abstracts were assessed for adherence to a 19-item checklist based on the CONSORT for Abstract reporting guidelines. After establishing inter-rater agreement using 30 RCT abstracts published prior to 2011, an author (KD) not involved in abstract scoring searched PubMed to identify up to 100 of the most recent RCTs published between January 1, 2011 and December 1, 2014 in each journal. A collaborator not involved in abstract scoring or data analysis ensured that reviewers were blinded to the journal of publication by removing PMID, journal name, author names, and journal-specific subheadings from study abstracts. Study abstracts were randomly ordered using a computer-generated sequence and divided among the three reviewers (MA, MH, RW). Each abstract was scored by a single reviewer using the 19-item checklist. Proportion of abstracts adherent to each checklist item was calculated for the entire sample and for the abstracts published in each journal. Chi-square tests of homogeneity were used to test the hypothesis that the proportion of abstracts adherent to checklist items was homogeneous across journals.

RESULTS: Mean inter-rater agreement among the three reviewers for checklist items was 84 % in the pre-study run-in. Search results yielded 466 study abstracts (100 from J1, 66 from J2, 100 from J3, 100 from J4, 100 from J5), three of which were later excluded as they were not RCTs. Analysis of all scored items in the 463 abstracts showed an overall adherence of 67 % (95 % CI, 0.66–0.68) to the CONSORT guidelines. Adherence was lowest for descriptions of methods of allocation concealment (8 %, 95 % CI, 0.06–0.10) and random sequence generation (19 %, CI 95 %, 0.15–0.23) and highest for clear interpretations of the trial (99 %, 95 % CI, 0.98–1.00), clear statements of trial objectives (96 %, 95 % CI, 0.94–0.98), and reporting of trial registration data (96 %, 95 % CI, 0.94–0.98). Adherence rates displayed substantial heterogeneity among journals. J3 had the highest overall adherence rate (78 %, 95 % CI, 0.76–0.80) while J1 had the lowest (55 %, 95 % CI, 0.53–0.57).

CONCLUSIONS: Among the five highest-impact general medical journals there is variable and overall suboptimal adherence to CONSORT for Abstract reporting guidelines of randomized trials, with substantial differences between individual journals. Specific areas in need of improvement include reporting of allocation concealment and random sequence generation. Interventions to systematically standardize the reporting of abstracts at the journal manuscript processing level could enhance the reliability and quality of abstract reporting of clinical trial results.

QUALITY OF TOBACCO TREATMENT IN HOSPITALS—SYSTEM-LEVEL AND PATIENT-LEVEL PREDICTORS OF GAPS IN CARE Ellie Grossman¹; Jenny Chen¹; Alissa R. Link²; Binhuan Wang²; Scott Sherman³. ¹NYU School of Medicine, New York, NY; ²New York University, New York, NY; ³VA New York Harbor HCS, New York, NY. (Tracking ID #2199135)

BACKGROUND: Identification and treatment of patients who smoke is a priority for hospitals. Hospitalization may be a key 'teachable moment' for enhancing behavior change, when patients must undergo enforced abstinence from cigarettes and may also be particularly concerned about their health. We aimed to describe care for smokers at two urban safety-net hospitals and determine patient and system characteristics associated with higher-quality care.

METHODS: As part of a randomized controlled trial of post-discharge smoking cessation interventions, we assessed care for smokers at two large hospitals in New York City. Adult patients were eligible for study inclusion if they: smoked at least one puff of a cigarette in the past 30 days; spoke English, Spanish, or Mandarin; were not incarcerated or in police custody; were not pregnant or breastfeeding, and had a U.S. phone number. Study participants provided sociodemographic information via in-person questionnaires administered at enrollment. Study staff reviewed participants' electronic medical records (EMR) for information about type of inpatient unit, history of medical or psychiatric illnesses, and tobacco treatment received. Outcomes of interest were: receipt of bedside counseling, prescription of nicotine replacement therapy (NRT) in hospital and patient acceptance of it, and prescription of NRT on discharge.

RESULTS: We enrolled 1618 participants. Mean age was 48 years (SD 13.4); 35 % were Hispanic, and 69 % were non-white race. Twenty-nine percent had Medicaid, and 17 % were uninsured. Fifty-two percent had a high-school diploma, GED, or less. Twenty-one percent were born outside the United States. Thirty-nine percent were hospitalized on an inpatient psychiatric unit at the time of study enrollment. Seventeen percent had coronary artery disease, and 60 % had an alcohol or substance use disorder documented in the EMR. Study participants smoked an average of 12.4 cigarettes per day, and had smoked for an average of 26.6 years. Eighty-eight percent received some type of counseling to support smoking cessation in the hospital (as documented in the EMR), 44 % were prescribed NRT during hospitalization, and 79 % of participants accepted the NRT more

than half of the days it was prescribed. Eighteen percent of participants were prescribed smoking cessation medication on discharge. Patients on inpatient psychiatric units were more likely to receive bedside counseling (odds ratio (OR) 1.53, 95 % confidence interval (CI) 1.004–2.33). Patients who smoked more cigarettes per day prior to admission (OR 1.05, 95 % CI 1.04–1.06 for each additional cigarette per day), were born in the United States (OR 1.39, 95 % CI 1.02–1.89), were on an inpatient psychiatric unit (OR 2.80, 95 % CI 2.12–3.69), and were at the VA site (OR 1.44, 95 % CI 1.10–1.90) were more likely to be prescribed NRT in hospital. However, patients who had less education, were non-Hispanic white, were on non-psychiatric units, and were at the non-VA site were more likely to accept most of the NRT prescribed. Patients who smoked more cigarettes per day (OR 1.03, 95 % CI 1.02–1.04 for each additional cigarette per day) and were at the VA site (OR 2.76, 95 % CI 1.71–4.45) were more likely to be prescribed NRT on discharge.

CONCLUSIONS: Although rates of bedside counseling (as documented in the EMR) are high, there is significant room for improvement in rates of prescribing NRT in hospital and on discharge—with quality differences between hospitals, between units within hospitals, and between patients. Further study is needed to understand how hospital systems and clinician behavior can be improved to boost quality of care for all patients.

RACIAL AND ETHNIC DIFFERENCES IN HEALTH BEHAVIORS AMONG PREGNANT AND POSTPARTUM WOMEN Ashley M. Harris¹; Nymisha Chilukuri²; Meredith West³; Janice L. Henderson⁴; Shari Lawson⁴; Sarah Polk⁴; David M. Levine¹; Wendy L. Bennett¹. ¹Johns Hopkins Hospital, Baltimore, MD; ²Johns Hopkins University School of Medicine, Baltimore, MD; ³Johns Hopkins School of Medicine, Baltimore, MD; ⁴Johns Hopkins Bayview Medical Center, Baltimore, MD. (Tracking ID #2194807)

BACKGROUND: Obesity is increasingly prevalent among young and minority women, increasing the risk for both pregnancy-related, and chronic metabolic, hypertensive and cardiovascular diseases. Obesity rates vary by race and ethnicity with minority women at highest risk, yet data on racial/ethnic differences in health behaviors is conflicting. Understanding women's health behaviors, as well as perceived barriers and facilitators for positive dietary lifestyle changes, will inform outpatient interventions to target those at highest risk. Our objectives were to assess racial and ethnic differences in health behaviors among a racially diverse group of pregnant and postpartum women.

METHODS: We conducted a cross-sectional study of 247 women who were pregnant or within one year of delivery, of which 212 women were Hispanic (31 %), Black (44 %) or White (25 %). They were recruited from 4 hospital-based outpatient clinics and completed a self-administered survey that assessed health behaviors. Main outcomes were fast food frequency and sugar sweetened beverage intake. Secondary outcomes were the relationship between socioeconomic factors and the outcomes, as well as barriers and facilitators to healthy behaviors. We used multivariate logistic regression analyses to evaluate the association between race/ethnicity and health behaviors, after adjusting for relevant socio-demographic factors. We used descriptive statistics and bivariate analyses to evaluate secondary outcomes. We performed a sensitivity analysis to evaluate the effect of obesity status (BMI <30 vs BMI ≥30) on the relationship between race/ethnicity and fast food frequency.

RESULTS: Black women, when compared with Hispanic and White women, were less likely to be married (52.6 % vs 85.7 and 79.6 %, $p < 0.0001$), and more likely to be under age 30 (80 % vs 63.5 and 42.6 %, $p < 0.0001$), and unemployed (33.7 % vs 20 % and 16.7 %, $p < 0.0001$). Black women (60 %) were more likely than Hispanic (38 %) or White (37 %) women to eat fast food 1 or more times/week ($p = 0.03$). Similarly, Black women (68 %) were more likely to drink one or more cans of sugar sweetened beverages per week than Hispanic (52 %) or White (52 %) women, but the results were not statistically significant ($p = 0.06$). In adjusted analyses, Black women had 2.4 increased odds of fast food intake ≥ once weekly, when compared with White women ($p = 0.03$). Hispanic women were equally likely to eat fast food as White women (OR = 1.10, $p = 0.83$). There were no significant differences in sugar sweetened beverage intake between the racial/ethnic groups. In the sensitivity analysis, there were no significant differences between the racial groups in the BMI ≥30 subgroup. In the subgroup with BMI <30, Black women had 4.7 greater odds of fast food intake one or more times a week, when compared with White women ($p = 0.01$). There were no significant differences between Hispanic and White women (OR = 1.39, $p = 0.36$) in this subgroup. In terms of barriers to healthy eating, 37.6 % of women named family/personal preference as a barrier, followed by access to healthy, affordable foods (25.7 %) time constraints (22.0 %), and knowledge (14.8 %). For facilitators, 34.8 % of women named internet related activities, followed by educational activities such as guided shopping (30.00), group activities such as social support group (18.8) and stress reduction seminar (17.4).

CONCLUSIONS: Pregnant and postpartum Black women have increased odds of fast food intake one or more times per week when compared to White and Hispanic women, with a stronger association in the non-obese subgroup of women. These data suggest that nutritional counseling around fast food should be targeted to all obese women, and to

Black women, regardless of BMI. Despite the lack of significant differences in sugar sweetened beverage consumption by race/ethnicity, intake was high across all 3 groups, suggesting the need for interventions to improve this health behavior among high risk women.

RACIAL AND ETHNIC DISPARITIES IN HEALTHCARE AMONG WOMEN IN THE VA: A SYSTEMATIC REVIEW Andrea Carter¹; Sonya Borrero^{1, 2}; Charles Wessel¹; Bevanne Bean-Mayberry³; Donna L. Washington³; Jennifer Corbelli¹. ¹University of Pittsburgh, Pittsburgh, PA; ²VA Pittsburgh Healthcare System, Pittsburgh, PA; ³VA Greater Los Angeles Healthcare System, Los Angeles, CA. (Tracking ID #2194054)

BACKGROUND: Women, including those from racial and ethnic minority groups, are a rapidly growing segment of patients who seek care in the Veterans Affairs (VA) Healthcare System, yet many questions regarding their health care experiences and outcomes remain unanswered. Numerous studies have documented racial and ethnic disparities in healthcare among male veterans and among non-veteran women, but potential disparities among female veterans have not been systematically studied. We aimed to identify and summarize existing work on racial and ethnic healthcare disparities among female VA users and to identify areas in which research efforts should be focused to address the largest and most important gaps in the literature.

METHODS: We conducted a systematic review of the literature on racial and ethnic disparities in healthcare among female patients in the VA Healthcare System. We selected studies that met the following criteria: 1) were conducted within the VA Healthcare System, 2) reported data on females only, 3) reported data on utilization or quality of health care services, 4) stratified data by patient race or ethnicity, and 5) were published in a peer-reviewed source. A health sciences librarian developed and translated systematic literature searches using Mesh, Emtree, and the American Psychological Association (APA) Thesaurus of Psychological Index Terms. We identified studies by searching PubMed, EMBASE, and APA PsycINFO on June 30, 2014. Our search identified 4065 references. After duplicate citations were removed, 2591 citations were screened, and 2446 citations were eliminated based on title or abstract. The remaining 145 full-text citations were reviewed, 9 of which met the inclusion criteria.

RESULTS: The 9 studies that examined racial and ethnic disparities in health care among female VA users assessed the following healthcare domains: contraception provision/access ($n=3$), treatment of low bone mass ($n=1$), hormone therapy ($n=1$), utilization of mental health or substance abuse related services ($n=2$), trauma exposure and utilization of various VA services ($n=1$), and satisfaction with primary care ($n=1$). Six were retrospective cohort studies, one was a cross-sectional survey, and two were combination cohort and survey studies. Overall, six of nine studies showed evidence of a significant racial or ethnic difference (Table 1).

CONCLUSIONS: In contrast to the wealth of literature examining racial and ethnic healthcare disparities both among male veterans and women in non-VA settings, only nine studies have been published that examine disparities specifically among women in the VA Healthcare System. Many areas of women's health where racial and ethnic disparities have been shown to exist in non-VA settings have not yet been examined within the VA, including obtaining cervical cancer screening, early prenatal care, mammograms, and annual preventive visits[1]. The results of this systematic review demonstrate that there is an unmet need both to further identify and subsequently reduce or eliminate racial and ethnic disparities among female VA-users. Addressing this unmet need will inform our national agenda of eradicating of health disparities. [1] Kaiser Family Foundation. Putting Women's Health Care Disparities on the Map. 2009.

Table 1

First Author Year	Outcome(s)	Evidence of significant racial/ethnic difference?
Kazerooni 2014	No evidence of racial disparity in adherence to hormonal contraception.	No
Borrero 2013	Hispanic women are more likely than Caucasian women to experience gaps between refills of hormonal contraception. Hispanic women and African-American women receive fewer months of contraceptive coverage than Caucasian women.	Yes
Borrero 2012	Hispanic and African American women are less likely than Caucasian women to have documented receipt of any contraception. African American women are more likely than white women to use one of the most effective methods of contraception such as intrauterine device, implant, or surgical sterilization.	Yes

(continued)

Haskell 2008	African American and Hispanic women are more likely than Caucasian women to discontinue hormone therapy.	Yes
Grubaugh 2008	No evidence of racial disparity in manifestation or severity of psychopathology or in use of VA health care services or disability benefits.	No
Bean-Mayberry 2006	No evidence of racial disparity in satisfaction with primary care clinic.	No
Wei 2003	African-American women are less likely than Caucasian women to receive anti-resorptive drugs for treatment of low bone mass.	Yes
Bosworth 2000	No evidence of disparity in obtaining mental health services. African American women want a mental health referral more frequently than Caucasian women.	Yes
Ross 1998	Native American women are more likely than Caucasian women to receive formal alcohol treatment.	No

RACIAL AND ETHNIC DISPARITIES IN MENTAL HEALTH VISITS AND EXPENDITURES FOR CHILDREN AND YOUNG ADULTS: A NATIONAL STUDY Lyndonna M. Marrast²; David Himmelstein^{1, 3}; Steffie Woolhandler^{1, 3}. ¹City University of New York School of Public Health, New York, NY; ²Hofstra North Shore LIJ School of Medicine, Kew Gardens, NY; ³Harvard Medical School, Cambridge, MA. (Tracking ID #2198370)

BACKGROUND: The United States has the world's highest incarceration rate. Blacks and Latinos account for the majority of inmates. A substantial proportion of inmates are mentally ill, and prisons and jails are now the largest mental health institutions in many states. Prior studies have found that minorities have less access to various healthcare services. We assessed racial and ethnic disparities in mental health care for children and young adults, groups at high risk for criminal justice system involvement.

METHODS: We analyzed data from the 2006–2012 Medical Expenditure Panel Survey (MEPS), a nationally representative survey that collects data on healthcare utilization and expenditures. We limited our analysis to white, black, and Latino children under 18, and youths age 18–34. Using t-tests, we compared the mean number of visits to outpatient mental health providers (any visit to a psychiatrist or psychologist, as well as visits to social workers for psychotherapy or mental health counseling). In addition, we examined visits to any outpatient clinician at which (1) psychotherapy/mental health counseling was delivered; (2) “mental health care” was coded as the principal reason for the visit; or (3) substance abuse counseling was delivered. We also analyzed emergency department visits and inpatient admissions for psychiatric diagnoses. Using linear regression we assessed racial and ethnic differences in mental health care utilization controlling for gender, region, poverty level, insurance and mental health status.

RESULTS: Black and Latino children made 39 and 46 % fewer visits to psychiatrists; 67 and 67 % fewer visits to psychologists, and 40 and 80 % fewer visits, respectively, to social workers for mental health care compared to white children ($p<0.05$ for all comparisons). Similarly, comparison of white youth to minorities show that Black and Latino youth made 47 and 65 % fewer visits to psychiatrists; 80 and 80 % fewer visits to psychologists; and 83 and 88 % fewer visits, respectively, to social workers for mental health care ($p<0.05$ for all comparisons). Minority children and youth also had fewer outpatient visits for mental health services to outpatient clinicians overall. Expenditures for mental health-related outpatient care followed similar patterns. For instance, per capita mental health psychiatry expenditures for white children were 62 % higher than for Black children. Analyses controlling for gender, region, poverty level, insurance and mental health status yielded similar results. Findings on substance abuse counseling, emergency department visits and psychiatric hospitalizations showed variable differences.

CONCLUSIONS: Minority children and youth receive markedly less mental health care than their white counterparts. These disparities appear greater than for most other health services, and may be a reflection of institutional racism that contributes to the excess incarceration of minority youth.

RACIAL DISPARITIES IN PATIENT ACTIVATION: EVALUATING THE MEDIATING ROLE OF HEALTH LITERACY WITH PATH ANALYSES Kendrick B. Gwynn^{1, 5}; Michael Winter²; Howard Cabral²; Michael S. Wolf⁴; Lori Henault⁵; Katie Waite⁵; Timothy Bickmore³; Michael Paasche-Orlow¹. ¹Boston University School of Medicine, Boston, MA; ²Boston University School of Public Health, Boston, MA; ³Northeastern University, Boston, MA; ⁴Northwestern University, Chicago, IL; ⁵Boston Medical Center, Boston, MA. (Tracking ID #2176220)

BACKGROUND: Patient activation, a person's ability to manage his or her own health has been shown to be lower in African Americans than whites. The etiology of this relationship has not been elucidated. As health literacy has been linked both to race and patient activation it may be a mediator of racial disparities in patient activation. The aim of this study was to use path analysis methods to determine if health literacy mediates the relationship between race and patient activation.

METHODS: We performed a secondary analysis of data from a randomized control trial to promote walking in elderly, urban, minority patients using path analysis. Patients with cognitive impairment, depression and high risk of falls were excluded. Patient activation was measured with the Patient Activation Measure. Health literacy was measured with the short Test of Functional Health Literacy in Adults. Path analysis was used to evaluate the mediation of race on patient activation through different variables. Several models were tested for best fit including direct and indirect effects of age, level of education, sex, depression, number of comorbidities for their effects on patient activation.

RESULTS: The 263 participants had a mean age of 71.3; 51 % female; 63 % African American; 51 % high school education or less. Across all models significant mediation paths were identified from African American race to lower patient activation through health literacy. This relationship remained significant throughout alternative model testing for combinations including: education; age; sex; depression; and level of comorbidity. The best-fit model included an indirect effect of sex on patient activation through health literacy indicating that the mediation effect of health literacy on patient activation was most profound for African American males. The relationship between health literacy and patient activation was also significantly related to comorbidities such that health literacy had a bigger influence on patient activation for participants with a higher number of comorbidities than for those with a lower number of comorbidities. No significant direct effect was shown between race and patient activation in any of the models.

CONCLUSIONS: The relationship between African American race and lower patient activation was fully mediated by health literacy. Future interventions to improve race disparities in patient activation need to be targeted at improving health literacy and removing unneeded complexity from health systems.

Model of best fit: Path from race and gender to patient activation goes through health literacy. Significant effects are circled.

RACIAL/ETHNIC DIFFERENCES IN DESTINATION EMERGENCY DEPARTMENTS FOR ACUTE CARE Amresh D. Hanchate^{1, 2}; Michael Paasche-Orlow²; William E. Baker³; Sophia Dyer³; Chen Feng²; James Feldman³. ¹VA Boston Healthcare System, Boston, MA; ²Boston Medical Center/Boston University School of Medicine, Boston, MA; ³Boston University School of Medicine, Boston, MA. (Tracking ID #2197883)

BACKGROUND: Several studies have identified high levels of clustering of minority patients in a small number of hospitals; 5 % of hospitals cared for nearly half of all

admissions for elderly minority patients. Other studies have reported that worse quality of inpatient care for minority patients. Different pathways and factors likely affect "choice" of hospitals. For patients with acute conditions an important pathway is the emergency department (ED) where care is initiated. Do patients of different race/ethnicity residing in the same area arrive at the same ED? Our hypotheses were that, for patients living in the same area, likelihood of admission to a given ED varies by race/ethnicity, and the main destination hospitals for minorities and Whites are likely to differ in quality characteristics.

METHODS: Using comprehensive administrative data from Massachusetts (2010–11), we identified all ED visits among adults 18 or older for selected 26 AHRQ Clinical Classification System (CCS) admission conditions, including non-specific chest pain, AMI, congestive heart failure, asthma, chronic obstructive pulmonary disease, acute cerebrovascular disease, epilepsy and hip fracture. Limiting the study to Massachusetts residents, and using residence zip code as the location indicator, we defined the expected probability of being admitted to a given ED as the proportion of all patients from that zip code admitted to that ED. Under the null hypothesis of similar probability by race/ethnicity, we calculated expected number of ED visits by hospital for each race/ethnic group from each zip code based on total ED visits. Aggregating the patient counts from all zip codes, we then obtained the ratio of observed to expected number of patients (O/E) by race/ethnicity, along with the 95 % confidence interval (CI) using 1000 bootstrap samples. For each minority group, we identified hospitals with observed admissions more than expected (O/E 95 % CI > 1) as minority-serving hospitals. We compared hospital characteristics between minority-serving and non-minority serving hospitals. To examine sensitivity of findings, we performed similar analysis for ED visits that resulted in inpatient admission.

RESULTS: We identified a total of 767,874 visits to 60 EDs in Massachusetts. The top 5 destination EDs accounted for a larger proportion of the ED visits among minorities (45 % for Blacks and 40 % for Hispanics) than for Whites (20 %). Observed number of patients was significantly larger than expected in 7 hospitals for blacks and 17 hospitals for Hispanics. Seventy-three percent of the 7 black-serving hospitals and 53 % of the 17 Hispanic-serving hospitals were safety net hospitals, compared to 20 % safety net hospitals overall. A similar pattern was found for the subset of ED visits that led to inpatient admission; 4 and 5 hospitals, respectively, were identified as black-serving and Hispanic-serving. Minority-serving hospitals were more likely to be teaching hospitals with larger bed size capacity and admission volume.

CONCLUSIONS: For patients living in the same zip code, we found that the destination EDs for Black and Hispanic patients differed from that for White patients. Future studies need to examine if such differences can be explained by differences in transportation time, clinical condition, or patient preference, or lead to differential patient outcomes.

RANDOMIZED CONTROLLED EVALUATION OF AN INTENSIVE MANAGEMENT PATIENT ALIGNED CARE TEAM (IMPACT) FOR HIGH-NEED, HIGH-COST VETERANS AFFAIRS PATIENTS Donna M. Zulman^{1, 2}; Christine Pal Chee^{2, 2}; Stephen C. Ezeji-Okoye³; Jonathan G. Shaw^{1, 3}; James S. Kahn^{3, 1}; Steven Asch^{1, 2}. ¹Stanford University, Stanford, CA; ²VA Palo Alto, Menlo Park, CA; ³VA Palo Alto, Palo Alto, CA. (Tracking ID #2198452)

BACKGROUND: Healthcare systems are increasingly adopting intensive management primary care interventions to optimize care and contain costs for high-need, high-cost (HNHC) patients. Few of these programs, however, have been studied in randomized controlled trials, raising concern that observed decreased costs are driven by regression to the mean rather than by the programs themselves. An intensive management quality improvement intervention was offered to a random sample of Veterans Affairs (VA) HNHC patients, providing an opportunity for a rigorous controlled study.

METHODS: In 2013, the Palo Alto VA launched a quality improvement program for HNHC patients to augment the VA's patient centered medical home (Patient Aligned Care Team, or PACT) with Intensive management (ImPACT). ImPACT's multidisciplinary team offered patients enhanced access, chronic disease management, support during health deteriorations, and social work and recreation therapy. Patients were eligible for ImPACT if their VA health care costs or risk for hospitalization were in the top 5 % for the facility, they were outpatients for over half of the eligibility period, and they were not enrolled in another VA intensive management program. Among 583 eligible patients, 150 randomly selected individuals were invited to enroll in ImPACT; the remaining ImPACT-eligible patients received standard PACT care and served as a control group. We evaluated changes in total health care costs (including intervention costs), hospital admissions, and emergency department visits among ImPACT and PACT patients, excluding those who died or moved away before the intervention began ($n=38$), across a 16-month baseline and 17-month follow-up period. We performed an intention-to-treat analysis within a difference-in-differences framework. In secondary analyses, we estimated the effect of the intervention on patients who actively participated in ImPACT using randomization as an instrument for participation. We also conducted stratified analyses to examine the influence of age, comorbid mental health and medical conditions, and baseline risk for

hospitalization. We assessed changes in satisfaction with VA care using ImPACT patients' responses to the Patient Satisfaction Questionnaire at baseline and 6 months after enrollment.

RESULTS: Two-thirds of invited patients ($n=101$) enrolled in ImPACT, 87 % of whom remained actively engaged at 9 months. In intention-to-treat analyses, changes in average monthly costs between the baseline and follow-up periods did not differ significantly between ImPACT and PACT patients. Modest, but non-statistically significant, greater cost reductions were observed for certain subpopulations in ImPACT (Table). Rates of medical/surgical hospitalizations and emergency department visits declined at similar rates in both groups. Secondary analyses accounting for patient participation revealed similar, non-statistically significant, patterns for cost and utilization. Among 48 ImPACT patients who responded to baseline and follow-up surveys (55 % response rate among engaged participants), there were significant increases in general satisfaction with VA care ($p<0.05$) and satisfaction with communication ($p<0.05$).

CONCLUSIONS: Intensive management for HNHC individuals did not achieve greater reductions in costs or acute care utilization compared with standard patient-centered medical home care but resulted in significant improvements in patient satisfaction among participants. Given the rapid spread of these models, understanding organizational context is important. Settings with existing medical homes and population-based management strategies may not achieve cost benefits.

Change in average monthly costs among ImPACT patients, relative to ImPACT-eligible patients receiving standard care

	n	Mean	Standard Error
All Patients	545	-101	(614)
Heart Failure, Diabetes, or COPD diagnosis	306	-754	(763)
No mental health diagnosis	165	-246	(1184)
Age under 65 years	276	-922	(998)
Hospitalized in 6 months pre-enrollment	197	-198	(1315)
High-risk and hospitalized in 6 months pre-enrollment	171	-657	(1343)

RANDOMIZED CONTROLLED TRIAL OF A DECISION AID WITH TAILORED FRACTURE RISK TOOL DELIVERED VIA A PATIENT PORTAL Joan Neuner¹; Marilyn M. Schapira²; Alicia J. Smallwood¹. ¹Medical College of Wisconsin, Milwaukee, WI; ²University of Pennsylvania, Philadelphia, PA. (Tracking ID #2200195)

BACKGROUND: Decision aids have been shown to improve a number of measures of shared-decision making, but are rarely implemented in routine primary care practice. We aimed to adapt and evaluate a tailored fracture prevention decision aid, delivered via a patient portal for "just in time" use with bone mineral density test results.

METHODS: The decision aid (DA) was adapted from an earlier AHRQ decision aid using international IPDAS standards. It included general information about osteoporosis, a personalized risk estimate based on the FRAX model, summary of medication risks and benefits (prescription and nonprescription) and an elicitation of values. The DA was iteratively pilot tested by seven patients for completeness and usability within a portal. Primary care internal medicine and family medicine patients in three clinics affiliated with a large academic center (aged ≥ 55 , spoke and read English fluently and without evidence of dementia) who were enrolled in an institutional PHR (Epic's MyChart), had completed a bone mineral density exam (BMD), and were diagnosed with osteoporosis or osteopenia were offered participation in the study. After internet-based consent, eligible patients were randomized to receive the decision aid or a link to a general aging website; telephone-based help from a research assistant was available if needed. Results of the decision aid were made available to primary care internal medicine and family medicine physicians. Patient outcome measures included pre- and post-decision aid 10-item decisional conflict scale (DCS, 0-100, lower scores=less conflict), 10 knowledge questions and 10 questions examining the usefulness of the DA. The same outcome measures, along with questions about the DA's influence upon discussions with the patient's PCP, were also measured at 3 months; 44 % of the sample has completed that study phase. Physicians were also asked if reviewing bone density test information affected the length of any followup visit with the patient and if the decision aid had any effect on their team's workload.

RESULTS: Fifty patients of 18 PCPs had a median age of 79 years; 96 % were Non-Hispanic white; 86 % had attended at least some college. Patients randomized to the decision aid were more likely to report that they had made a decision (65%vs. 36 %, $p<.01$), had a greater increase in knowledge, $p=0.015$, and a greater reduction in overall decisional conflict (29.7 vs 8.0, $p=.002$). Decisional conflict subscale results were similar (table). All patients who received the decision aid were able to negotiate their computer

and the decision aid website, but required help understanding their BMD test results in order to use the FRAX-based personalized risk calculator. Among patients who received the decision aid, 52 % reported (on a 5-point scale) that the DA prepared them to make a better decision "quite a bit" or "a great deal" 79 % reported that the DA helped them think about how involved they want to be in this decision "quite a bit" or "a great deal", and 69 % reported that the DA helped prepare them for their follow-up visit with their doctor. Among patients who have completed 3-month follow-up, most reported not having met with their doctor regarding their BMD test and thus had not had the opportunity to talk about whether/how their bone density test and decision aid results influenced recommendations about fracture reduction strategies. Most of the physicians also reported not having seen the patient at the time of the three month follow-up survey; they did not report any effect of the decision aid on out-of-office workload.(eg additional emails via the portal).

CONCLUSIONS: A fracture reduction decision aid for patients through a patient portal improved knowledge and key measures of quality of decision-making. Patients were generally successful at using their computer and the internet to negotiate the DA, but required help completing FRAX-based risk calculator, and often did not see physicians back to discuss results. Patient portals may offer an important opportunity to engage patients, but future research should investigate how best to incorporate DAs into care workflows to maximize shared decision-making.

RATES OF HEPATITIS A AND HEPATITIS B VACCINATION IN AN URBAN, PRIMARY CARE-BASED HEPATITIS C CLINIC Michelle P. Clermont²; Sangeetha Dayalan³; Shelly-Ann Fluker²; Lesley Miller¹. ¹Emory University, Atlanta, GA; ²Emory University School of Medicine, Atlanta, GA; ³WellStar Cobb Medical Group, Austell, GA. (Tracking ID #2196390)

BACKGROUND: Patients with hepatitis C who become infected with hepatitis A or B are at risk of accelerated progression to cirrhosis and fulminant hepatic failure. Thus, vaccination against hepatitis A and B for all susceptible hepatitis C patients is recommended. However, studies have shown that rates of vaccination remain low, especially in the primary care setting. The Liver Clinic at Grady Memorial Hospital is a primary-care based clinic that provides comprehensive care for underserved patients with hepatitis C. Rates of hepatitis A and B vaccination in the Liver Clinic were previously found to be comparable to other specialty clinics, but vaccination was not universal. We were interested in seeing whether vaccination rates would be higher in a cohort of Liver Clinic patients treated with a protease inhibitor-based antiviral regimen.

METHODS: A retrospective chart review was performed on 42 consenting patients with chronic hepatitis C treated with telaprevir or boceprevir between 2011 and 2013. Data were abstracted on frequency of serologic testing for hepatitis A and B, hepatitis A and B immunity status, and vaccination receipt. Hepatitis A immunity was defined as a positive hepatitis A total antibody. Hepatitis B immunity was defined as the presence of either a positive hepatitis B core antibody or a positive hepatitis B surface antibody.

RESULTS: Immunity status to hepatitis A and B was checked in 100 % of patients. Forty-eight percent of patients were potentially susceptible to hepatitis A, and 74 % of patients were potentially susceptible to hepatitis B. The rate of documented, completed vaccination for hepatitis A among those susceptible was 55 % and for hepatitis B was also 55 %. Of note, an additional 12 % of patients received partial hepatitis A vaccination but did not complete the series and an additional 17 % of patients received partial hepatitis B vaccination without completing the series.

CONCLUSIONS: The rates of vaccination for hepatitis A and B in patients with chronic hepatitis C on antiviral therapy in our primary care-based hepatitis C clinic were significantly higher than reported for primary care practices, and comparable to some specialty

practices. Reasons for sub-optimal vaccination rates are multi-factorial and include lack of time, failure on the part of the physician to remember to inquire about or order the vaccinations, unknown immunity status, patients' fears or misconceptions about vaccination and failure on the part of the patient to follow up to complete a vaccination series. Solutions addressing each of these will be necessary to improve vaccination rates in the future. Potential solutions include use of electronic medical record for tracking vaccination status, improving physician training to counsel patients, and creating patient registries for more accurate patient vaccination schedules.

RATIONALE, FACILITATORS, AND BARRIERS TO COLORECTAL CANCER SCREENING AMONG A RACIAL AND ETHNIC DIVERSE POPULATION

Crystal T. Doan¹; Vanessa Ramirez-Zohfeld¹; M. Rosario Ferreira¹; Nancy C. Dolan¹; Jonathan M. Radosta²; William L. Galanter³; Alfred Rademaker¹; Kenzie A. Cameron¹.

¹Northwestern University, Chicago, IL; ²University of Illinois Hospital and Health Sciences System, Chicago, IL; ³University of Illinois at Chicago, Chicago, IL. (Tracking ID #2197956)

BACKGROUND: Colorectal cancer (CRC) remains a leading cause of death in the United States; yet screening rates remain suboptimal, particularly in socioeconomically disadvantaged and racial/ethnic minority groups. Previous studies often have assessed barriers to CRC screening, but facilitators to screening are less well explored. Furthermore, more exploration is needed in a longitudinal setting regarding such barriers to and facilitators of CRC screening. Our objective is to describe rationale, facilitators and barriers to CRC screening (stool card and colonoscopy) reported by a population of average risk, 50–75 year-old, racial/ethnic minority patients 6 months following a non-acute general internal medicine visit.

METHODS: Data were extracted from a larger study designed to promote CRC screening among racial/ethnic minority patients at seven federally qualified health centers and one academic health center in a large, urban area (Chicago, Illinois). English and Spanish-speaking patients ages 50–75 years who had participated in a trial designed to increase screening recommendation and completion for CRC participated in an interviewer-administered telephone survey 6 months after their clinic visit. Qualitative responses about barriers and facilitators to screening and future screening intentions were analyzed by content and constant comparative analysis. Responses to open-ended questions were unitized, generally delineated by conjunctions or punctuation. Based on a preliminary review of the unitized responses, coders developed a set of mutually exclusive and exhaustive categories. Responses were double-coded; disagreements were resolved by discussion.

RESULTS: Among 538 eligible patients, 239 patients completed an interviewer-administered survey 6 months after their physician visit (response rate: 44.4 %). The mean age was 58.2 years (SD=6.4); 77.8 % were female; 43.7 % identified themselves as Hispanic/Latino, and 54.0 % as Non-Hispanic Black; 29.7 % reported 0–6 years of education, 45.6 % reported 7–12 years of education and 23.8 % had 13 or more years of education. Almost one-third of patients (29.3 %) reported being uninsured. At 6 months post-clinic visit, self-reported screening rates for colonoscopy within the past 6 months were 14.6 %, 7.1 % for stool tests (FOBT and FIT), and 2.1 % reported an unspecified CRC screening. Primary reasons for undergoing a colonoscopy included: physician recommendation, desire for wellness/health, desire for reassurance, and perceived susceptibility due to age. Additional reasons identified by participants completing stool tests included that they could not afford a colonoscopy and/or perceived stool tests as less invasive. Few participants screened by either colonoscopy or stool tests were able to identify any specific facilitators to completion, those who did identified their own desire for reassurance, and physician recommendations as the primary facilitators. Participants screened via colonoscopy identified barriers related to the preparation, challenges with scheduling and general fear, although overall few barriers were expressed. Participants who reported completing stool tests also identified a lack of barriers to screening. Barriers to colonoscopy among those unscreened included fear, missing appointments, medical comorbidities, competing family priorities, and lack of insurance and/or time; barriers to completing stool tests included lack of time and forgetting to return the test. Of the participants who remained unscreened, 65.4 % reported intending to complete CRC screening within the next year. Their rationale for screening completion was similar to that identified among those who had completed screening. A novel barrier identified among participants reporting no intention to complete CRC screening was that of embarrassment; other reasons identified as impeding completion were similar to the barriers previously identified.

CONCLUSIONS: Barriers identified among our participants are similar to those reported in other studies, suggesting the continued need for healthcare providers and systems to address issues such as fear, and stressing the importance of CRC screening in cancer prevention, even when faced with competing priorities and medical comorbidities. Of interest is that even among those participants who had completed screening, few were able

to express any specific patient facilitators. Therefore, in addition to ensuring barriers to screening are consistently addressed at patient, provider and system levels, implementing and communicating the presence of facilitators (e.g., patient navigators, transportation services, appointment reminders), is crucial to increasing CRC screening completion among this population.

REDESIGNING RESIDENT CONTINUITY CLINIC: RESULTS OF A PRE-INTERVENTION SURVEY Rachel Jantea; Raquel Buranosky; Deborah M. Simak; David M. Elnicki. University of Pittsburgh School of Medicine, Pittsburgh, PA. (Tracking ID #2198477)

BACKGROUND: Continuity clinic is a longitudinal patient experience for internal medicine residents required by the Accreditation Council for Graduate Medical Education. Traditionally, residents spend 1/2 day per week in continuity clinic, regardless of clinical rotation. Because residents must perform their usual inpatient rotation duties in addition to clinic, they may spend clinic time on inpatient responsibilities or vice versa. This may inadvertently blunt the educational value of continuity clinic or create a resentful view of ambulatory medicine. Because alternative continuity clinic models exist, we conducted a needs assessment of our current traditional model.

METHODS: Electronic surveys were distributed to residents and preceptors at 3 clinic sites in an internal medicine residency program in June 2014. Survey items were open-ended questions and 5 point Likert scale responses to statements about continuity clinic. Some questions were specific to residents or preceptors; most were asked of both groups. Responses to questions asked of both groups were compared with t-tests. Open-ended responses underwent thematic analysis.

RESULTS: Sixty-four percent of residents and 71 % of preceptors responded. Residents reported being distracted by inpatient issues in clinic, estimating on average 16.7 % of clinic time was spent on inpatient issues. Preceptors agreed with this, but to a significantly higher degree (3.59 vs. 4.27, $p=0.004$). Only a minority of residents felt they had sufficient time in clinic to prepare for appointments (38 % residents) and address their patients' problems (32 % residents). Residents and preceptors agreed there was sufficient time for educational conferences during clinic, but to different degrees (3.33 vs. 3.85, $p=0.029$). Residents felt they spent enough time in clinic to be available for appointments, while preceptors disagreed to a significant degree (3.60 vs. 2.85, $p<0.001$). Residents and preceptors agreed residents saw an adequate number of patients overall, but to different degrees (3.90 vs. 3.27, $p=0.003$). Residents reported their patient continuity was excellent, but estimated continuity with only 50 % of their patients. Residents were generally pleased with their clinic experience, rating it 75/100 (100 was ideal), and anticipated spending approximately 50 % of their future practices in outpatient settings, regardless of specialization. On thematic analysis, areas of resident dissatisfaction were time constraints and inpatient distractions while in clinic, poor patient continuity, and insufficient ambulatory exposure.

CONCLUSIONS: While residents are generally pleased with their continuity clinic experiences, these results revealed several areas for improvement. Residents and preceptors agree that residents are distracted by inpatient issues during clinic. Residents spend substantial clinic time performing inpatient responsibilities, which may explain why they perceive insufficient time for clinic duties and educational conferences. Residents believe they spend enough time in clinic to be available for appointments and report excellent continuity, while preceptors generally disagree. This may suggest a difference in clinical practice expectations with important implications, since residents anticipate half their future practices will be ambulatory. Based on these results, we converted to a 50/50 continuity clinic model, where residents alternate between inpatient and outpatient/elective rotations. In this model, residents attend clinic one full day per week during outpatient months only. We hoped this would minimize inpatient distractions during clinic.

REGIONAL TRENDS IN LONG-TERM ACUTE CARE HOSPITAL USE IN TEXAS Anil N. Makam¹; Ethan Halm²; Oanh K. Nguyen²; Jie Zhou³; Yong-Fang Kuo³; Timothy A. Reistetter³; Kenneth J. Ottenbacher³; James S. Goodwin³. ¹UT Southwestern, Dallas, TX; ²UT Southwestern Medical Center, Dallas, TX; ³University of Texas Medical Branch at Galveston, Galveston, TX. (Tracking ID #2196305)

BACKGROUND: There is significant regional variation in the use of long-term acute care hospitals (LTCH), even within states such as Texas that have a relatively abundant supply. We sought to assess whether increased LTCH use is occurring in regions that already have a relatively high use to begin with, suggesting that further increases may result in potentially inappropriate use among individuals with lower acuity of illness who may be better served in alternative post-acute care sites.

METHODS: We evaluated trends of LTCH utilization by the hospital referral regions (HRR) among Texas beneficiaries with continuous enrollment in Medicare Parts A and B from 2002 to 2011 using 100 % Texas Medicare data. Analyses for 23 HRRs were stratified by tertiles of baseline LTCH use (lowest, middle, and highest). We estimated the interaction terms between year and tertile of baseline LTCH use in 2002 using linear regression, accounting for clustering of data by HRR. Utilization is reported per 100,000 Medicare beneficiaries.

RESULTS: Overall, LTCH utilization increased in Texas from 689 patients per 100,000 beneficiaries in 2002 to 782 patients in 2011. From 2002 to 2011, HRRs in the lowest tertile of baseline LTCH use had increased LTCH utilization by 211 % from 190 patients to 591 patients and HRRs in the middle tertile had increased LTCH utilization by 43 % from 473 patients to 675 patients; whereas HRRs in the highest tertile had decreased LTCH utilization by 21 % from 915 patients to 719 patients ($p < 0.001$; **Figure**). The absolute difference between the trends of the lowest and highest HRR tertiles during the 9-year period was 597 patients per 100,000 beneficiaries (95 % CI, 289 to 904, $p < .001$).

CONCLUSIONS: LTCH utilization has increased in the HRRs in Texas with the least utilization at baseline, suggesting that the increased use of LTCHs may be appropriate to care for an aging population recovering from prolonged and/or critical illnesses. Additional work examining trends and patterns in demographic and clinical characteristics of the patients with an LTCH hospitalization is needed.

REGIONAL VARIATION IN HOME HEALTH CARE REFERRALS AT HOSPITAL DISCHARGE: RESULTS FROM THE 2012 NATIONAL INPATIENT SAMPLE Christine D. Jones²; Heidi Wald³; Rebecca S. Boxer³; Frederick A. Masoudi³; Robert E. Burke¹; Roberta Capp³; Adit A. Ginde³. ¹Denver VA Medical Center, Denver, CO; ²University of Colorado, Denver, Aurora, CO; ³University of Colorado, Denver, CO. (Tracking ID #2197874)

BACKGROUND: Referrals to home health care (HHC) at hospital discharge increased by 61 % between 2001 and 12. The contributing factors to this rapid growth are unknown. We sought to describe patient- and hospital-level factors associated with home health care (HHC) referrals at hospital discharge.

METHODS: Cross-sectional, retrospective cohort analysis of hospital discharges contained in the 2012 National Inpatient Sample (NIS). The NIS is a weighted, nationally-representative sample of inpatient discharges in the U.S. We included all non-elective admissions for adults 18 years of age or older who survived hospitalization and were discharged to home; we excluded discharges for maternal/neonatal and psychiatric diagnoses. Our primary outcome was HHC referral at discharge, which was compared to discharges home without a HHC referral. We evaluated regional variation using the census division for the discharging hospital. We used logistic regression to evaluate patient- and hospital-level factors associated with HHC referrals and included all statistically significant variables from bivariate analyses. The All Patient Refined Diagnosis Related Group (APR-DRG) Severity of Illness measure was used to measure loss of function. The APR-DRG incorporates both primary and secondary diagnoses, age, procedures, and considers combinations of factors in assigning 5 categories ranging from minor to extreme loss of function.

RESULTS: Five hundred twenty-six thousand three hundred thirty-three hospitalizations ended with a referral for HHC at the time of discharge (18.2 % of 2.9 million total hospitalizations in 2012). Patients with hospitalizations ending in a HHC referral were older (69.9 vs. 57.6 years), women (58.7 vs. 52.8 %), white (72.1 vs. 66.7 %), Medicare beneficiaries (72.8 vs. 44.1 %), had extreme loss of function (9.7 vs. 3.0 %), and had more chronic conditions (6.9 versus 5.0 conditions; p values for all comparisons < 0.05). HHC referrals at discharge were more likely to occur in certain census divisions, including New England (7.4 % HHC referral vs. 4.2 % without HHC referral) and Middle Atlantic (18.1 vs. 14.6 %) divisions (p value < 0.05 for both comparisons). The top 3 primary diagnoses (by AHRQ Clinical Classifications Software codes) associated with HHC referral were Heart Failure (7 % of HHC discharges), Sepsis (6.3 %), and Pneumonia (4.8 %); the top 5 associated with no HHC referral were Cardiac Dysrhythmia (3.9 % of non-HHC discharges), Pneumonia (3.9 %), and COPD/Bronchiectasis (3.4 %). In multivariable logistic regression, HHC referrals for discharged patients were more likely in: older patients (OR 1.41 for each 10 year increase in age, 95 % CI 1.40–1.42); women (OR 1.24, 95 % CI 1.23–1.25); APR-DRG moderate loss of function (OR 1.54, 95 % CI 1.52–1.57), major loss of function (OR 2.39, 95 % CI 2.23–2.44), or extreme loss of function (OR 3.29, 95 % CI 3.18–3.39), compared to no loss of function; patients with comorbid metastatic cancer (OR 1.78, 95 % CI 1.74–1.83); and in census divisions including New England (OR 2.52, 95 % CI 2.20–2.89), Middle Atlantic (OR 1.62, 95 % CI 1.48–1.78), South Atlantic (OR 1.30, 95 % CI 1.20–1.41), and East North Central (OR 1.27, 95 % CI 1.17–1.39) compared to the Pacific division (referent). HHC referrals were less likely in patient discharges with: a primary payer listed as self pay (OR 0.30, 95 % CI 0.28–0.32), no charge (OR 0.31, 95 % CI 0.26–0.37), private (OR 0.75, 95 % CI 0.73–0.76), or Medicaid (OR 0.79, 95 % CI 0.77–0.81) compared to Medicare; and patient addresses in rural counties were less likely to receive a referral compared to central (i.e. urban) counties (OR 0.81, 95 % CI 0.76–0.86). We found similar results in a sensitivity analysis performed only among patient discharges with Medicare insurance.

CONCLUSIONS: Nearly 1 in 5 patient discharges to home are referred for HHC services. Although several factors associated with HHC referrals might be expected, surprisingly large regional variation of HHC referrals by census division was present even after adjusting for demographics and co-morbidities. It is unclear if regional variability in HHC referrals reflects a higher prevalence of functionally impaired, older adults in areas such as New England or if other characteristics, including penetrance of HHC agencies and region-specific differences in provider decision-making about HHC referrals at discharge might also be important. Further evaluation of factors that contribute to regional HHC referral variability should be completed given the rapid growth of HHC referrals at hospital discharge.

REINTEGRATION OF VETERANS AFTER DEPLOYMENT-RELATED MILD TRAUMATIC BRAIN INJURY Edward C. Shadiack²; Drew Helmer^{2, 3}; David P. Graham¹. ¹Michael E. DeBakey VAMC, Houston, TX; ²VA-NJHCS, East Orange, NJ; ³Rutgers University - New Jersey Medical School, Newark, NJ. (Tracking ID #2180940)

BACKGROUND: Veterans of wars in Iraq and Afghanistan returned home after their deployments and experienced challenges reintegrating in civilian social and civic activities. Difficulty with reintegration has been attributed to mild traumatic brain injury (mTBI), experienced by approximately 15 % of these Veterans. We evaluated the association between mTBI and reintegration using the Community Reintegration of Injured Service Members (CRIS) instrument. The CRIS instrument assesses participation as conceptualized in the World Health Organization International Classification of Functioning, Disability and Health and was developed for use with veterans. We hypothesized that mTBI will be independently associated with the extent of participation as measured by the CRIS.

METHODS: This was a retrospective analysis of 93 Veterans who completed a detailed TBI evaluation and full CRIS instrument. Other domains (instruments) evaluated included: alcohol use (AUDIT), pain (BPI), depression (CES-D), environmental barriers to function (CHIEF), and testing effort (WMT). The Neurobehavioral Symptom Inventory (NSI) detected clusters of affective, somato-sensory, and cognitive symptoms. Primary analyses included evaluation of bivariate associations between possibly confounding factors and CRIS subscales of Extent of Participation, Perceived Limitations in Participation, and Satisfaction with Participation. Three hierarchical linear regressions were evaluated, with each CRIS subscale score as the dependent variables. Each hierarchical linear regression involved three steps: entering demographics, then comorbid conditions and finally mTBI status. Secondary hierarchical linear regression analyses evaluated the NSI symptom cluster scores to explore a symptom-based approach to the relationship between mTBI symptoms and reintegration. Demographics were entered in step 1, the three NSI symptom clusters in step 2, mTBI status in step 3.

RESULTS: The mTBI and non-TBI groups did not differ regarding age, ethnicity, marital status, years of education, or number of deployments (all $p > 0.05$), although the mTBI group had higher comorbidity and symptom ratings than the non-TBI group. For the

primary analyses of comorbid conditions, TBI did not independently contribute additional explanatory information. However, lower Extent of Participation was associated with greater depression, alcohol use, and pain interference ratings. Results were similar for Perceived Limitations and Satisfaction ratings. Secondary analyses of symptoms also demonstrated that mTBI had no additional explanatory information. The NSI Affective Cluster was the sole significant predictor for Extent of Participation. Results were similar for Perceived Limitations and Satisfaction.

CONCLUSIONS: While mTBI is associated with reintegration as measured by the CRIS, this relationship disappears after controlling for comorbid conditions, such as depression and chronic pain. Similarly, when controlling for affective symptoms, an independent effect of mTBI disappears. These findings imply that a historical report of mTBI, in and of itself, does not significantly affect extent of community reintegration as measured by the CRIS instrument. Instead, affective symptoms and pain do. mTBI may serve as a marker for greater likelihood, and need for evaluation of, depression, affective symptoms, and pain.

CRIS—Extent of Participation Subscale—Primary Analysis

Variable	Beta(Standardized)	Standard Error	p-Value

RELATIONSHIP BETWEEN NUMBER OF OUTPATIENTS WITH DIARRHEA AND LOCAL NOROVIRUS OUTBREAK Yuichi Takahashi; Naoto Matsuda; Akihiro Inui; Tomohiro Hosoda; Hiromizu Takahashi; Fujiko Morita; Kazutoshi Fujibayashi; Hirohide Yokokawa; Yuki Uehara; Toshio Naito. Juntendo University School of Medicine, Bunkyo, Japan. (Tracking ID #2199911)

BACKGROUND: Norovirus infection is one of the most important infectious disease and occasionally fatal in the infection of infants and the elderly. Every year, high incidence of norovirus infection has been observed in Japan, and each prefecture report the norovirus incidence. However, there are no reports for the smaller city or town level, and we do not have any method for detecting local epidemic of norovirus infection. For primary care setting, local factors to diagnose norovirus are required. If locally centered hospital can provide the alert for local clinics, the information must be useful for regional primary care provider. The aim of the present study was to develop a simple method for detection of local norovirus outbreak.

METHODS: This cross-sectional study was conducted at the Department of General Medicine Juntendo University School of Medicine, Tokyo from November 1st 2013 to March 31st 2014. Participants were outpatients with diarrhea who were agreed to participate in this study and who could perform norovirus test at our center during the mentioned period above. Norovirus positive results were determined if one of RT-PCR or immunochromatography (IC) test showed positive result. RT-PCR and IC test was performed according to the manufacture instruction. Number of patients with diarrhea and number of norovirus-positive patients were evaluated every 2 weeks. "Epidemic" was defined based on the alert of Survey of infectious gastroenteritis by Tokyo Metropolitan Infectious Diseases Surveillance Center Receiver operating characteristic (ROC) curve analysis was performed to determine the optimal cutoff values of numbers of outpatients with diarrhea for detecting the local norovirus outbreak.

RESULTS: Ninety-seven diarrheal outpatients were analyzed during the period. The maximum number of diarrheal outpatient in 2 weeks was 18 in a period of 1st to 15th December 2013. Maximum prevalence of norovirus was 88 %. More than 75 % prevalence of norovirus was shown from the 1st December 2013 to the 31st January 2014. The

optimal numbers of patients cutoff values derived from the ROC analysis was 15 patients during 2 week. The sensitivity and specificity under these cutoff values were 75 and 100 % respectively. The areas under the ROC curve (AUC) for local norovirus outbreak was 0.95. ($p < 0.01$)

CONCLUSIONS: Our study suggested that the epidemic of norovirus infection was inferred from the number of diarrheal outpatients at our hospital. More than 15 patients in 2 weeks might be a simple indicator of local norovirus outbreak. Counting outpatients with diarrhea was useful to predict a local norovirus outbreak of norovirus and may have a potential to contribute for prevention of infection in the community.

RELAXATION RESPONSE AND RESILIENCY TRAINING AND ITS EFFECT ON RESOURCE UTILIZATION James Stahl; John W. Denninger; Darshan H. Mehta; Roberta Goldman; Herbert Benson. Massachusetts General Hospital, Swampscott, MA. (Tracking ID #2195783)

BACKGROUND: A lack of psychological and physical resilience in response to stress drives a great deal of health care utilization. Health care expenditures on mental health disorders were estimated at over \$80 billion/year and were the third largest source of healthcare expenditures after heart disease and cancer; each of which have their own stress burden. Stress influences physiology and the course of disease. Its successful management is part of wellness for the individual and may help us better manage our healthcare resources. The objective of this study was to estimate the consequences on healthcare utilization of mind-body training, specifically, the Relaxation Response and Resiliency program (3RP).

METHODS: A retrospective database analysis was conducted exploring the resource utilization of all patients receiving 3RP through the MGH Benson-Henry Institute from 1/12/2006 to 7/1/2014. In the analysis, we compared resource utilization during the year prior to the 3RP to the year following the training. Patients' resource utilization was captured using the Research Patient Data Registry, a centralized data warehouse comprising all administrative and clinical databases for the Partners Healthcare System. The control group was comprised of patients matched to the intervention group by age, ethnicity, and gender and was three times the size of the intervention group. The intervention, 3RP, is an integrated program of meditation, cognitive behavioral therapy, yoga tools focused on developing skills to promote the voluntary application of the relaxation response and the mitigation of triggers for the stress response. Both study arms were further stratified by the encounter type: clinical, imaging, laboratory and procedural as well as by class of the chief complaint: e.g., Cardiovascular, Musculoskeletal, and Neurologic. Standard statistical methods were used including t-test, ANOVA and regression where appropriate. JMP 11 (SAS product) was used for the statistical analysis.

RESULTS: At one year follow up for the 3RP group ($n=4455$), total utilization decreased by a relative reduction of 61 % [53.46 to 30.47 billable encounters/year (be/yr)] ($p < .0001$) though still remained almost 2 times as high as the control group (15.32 be/yr). Clinical encounters decreased by 59 % [39.96 to 23.21 be/yr] ($p < .0001$), imaging and lab encounters by 66 % [11.52 to 5.72 be/yr] ($p < .0001$), procedures by 41 % [2.15 to 1.69 be/yr] ($p < .006$). Reductions by clinical category were greatest for patients with renal chief complaints, 91 % [199.91 to 16.29 be/yr] ($p = .06$), and least for endocrinologic complaints, 47 % [32.48 to 17.2 be/yr] ($p = .009$). Emergency department visits among the intervention group decreased from 4.5/year to 1.5/year ($p < .0001$) after the intervention, making their utilization of this resource indistinguishable from the control group ($n=13149$) at 1 year.

CONCLUSIONS: Mind body interventions in general and 3RP in specific have the potential to substantially reduce healthcare utilization at relatively low cost. Such interventions are likely to be useful in population supported self-care and may potentially help reduce the healthcare's demand curve, further study is called for,

RESULTS FROM NEXT-D: DOES A DISEASE SPECIFIC HEALTH PLAN REDUCE INCIDENT DIABETES DEVELOPMENT AMONG A NATIONAL SAMPLE OF WORKING-AGE ADULTS WITH PRE-DIABETES? Tannaz Moin^{2, 4}; Jinnan Li³; O. Kenrik Duru³; Susan Ettner³; Norman Turk³; Lindsay Kimbro³; Abigail M. Keckhafer⁵; Robert H. Luchs⁵; Sam Ho⁵; Carol Mangione¹. ¹David Geffen School of Medicine at UCLA, Los Angeles, CA; ²David Geffen School of Medicine at ULCA, Los Angeles, CA; ³UCLA, Los Angeles, CA; ⁴VA Greater Los Angeles, Los Angeles, CA; ⁵UnitedHealthCare, Minneapolis, MN. (Tracking ID #2198946)

BACKGROUND: Pre-diabetes affects one in three US adults. About 30 % of affected individuals will progress to diabetes over 3–4 years. We hypothesized that the Diabetes Health Plan (DHP), which reduces cost-sharing for lifestyle interventions and metformin for persons with either pre-diabetes or diabetes, is associated with lower rates of progression from pre-diabetes to diabetes

METHODS: We conducted a retrospective, intent-to-treat analysis using 2009–13 insurance claim and laboratory data from employer groups contracting with UnitedHealth Care to purchase either the DHP or a standard health plan. We ran an employer-level propensity model to find groups offering standard plans most comparable to those offering the DHP. Time to diabetes development was calculated as the days from January 1, 2010 until development of diabetes, over a 4-year timeframe. Kaplan-Meier methods and a log-rank test were used to test unadjusted differences between employees in the DHP versus standard plans. Employee-level, multivariate Cox regressions were estimated to identify predictors of diabetes progression.

RESULTS: We analyzed data from 15,734 continuously enrolled patients with pre-diabetes ($N=1299$ from 9 employers offering the DHP; $N=14,435$ from 219 employers offering standard plans). Mean time to develop diabetes was 948 days ($SD=8.3$). Employees who were older, less affluent, obese, Hispanic, African-American, or Asian developed diabetes at a faster rate regardless of the health plan.

CONCLUSIONS: We found no significant difference in time to diabetes development for employees in groups with and without the DHP (HR 1.06, 95 % CI 0.94–1.20). These results suggest that reduced cost sharing for metformin and lifestyle interventions for those with known pre-diabetes may not prevent development of diabetes. Alternatively, it is possible that the increased follow-up and testing among DHP plan enrollees relative to those with a standard benefit may have led to greater detection of diabetes and biased our findings to the null.

RESULTS FROM NEXT-D: PROMOTING BREAST CANCER SCREENING IN A DIABETES/PRE-DIABETES SPECIFIC HEALTH PLAN Q. Kenrik Duru¹; Norman Turk¹; Susan Ettner^{1, 1}; Tannaz Moin²; Jinnan Li¹; Abigail M. Keckhafer³; Robert H. Luchs³; Charles Chan³; Neil Steers¹; Carol Mangione^{1, 1}. ¹UCLA, Los Angeles, CA; ²UCLA/VA Greater Los Angeles, Los Angeles, CA; ³UnitedHealthcare, Minneapolis, MN. (Tracking ID #2196155)

BACKGROUND: The Diabetes Health Plan (DHP) reduces cost-sharing for medications and physician visits, and facilitates access to disease management and telephonic coaching for patients with pre-diabetes or diabetes. While the primary focus of the plan is reducing incident diabetes and/or improving diabetes-related outcomes, the DHP is also designed to encourage other healthy behaviors such as cancer screening. As part of the Natural Experiments for Translation in Diabetes (NEXT-D) multicenter network, we evaluated whether employer purchase of the DHP was associated with higher mammography rates among eligible female employees.

METHODS: Using a quasi-experimental design, we conducted a retrospective, intent-to-treat, employer-level analysis of 2010–13 administrative claims and laboratory data from employer groups contracting with UnitedHealth Care to purchase either the DHP or a standard health plan. We ran an employer-level propensity model to find control employer groups most comparable to those that purchased the DHP. We defined diabetes in both the DHP and control groups based on the presence of at least one 250.xx ICD-9 claim, any A1c value ≥ 6.5 %, or use of any antidiabetic medication other than metformin. We defined pre-diabetes based on the absence of any 250.xx ICD-9 claims, having at least one 790.21 or 790.22 claim, or any A1c value 5.7–6.4 %, fasting plasma glucose value of 100–125 mg/dl, or oral glucose tolerance test value of 140–199 mg/dl. Our primary outcome was at the employer level, measuring the percentage of female enrollees 50–64 years of age who had a screening mammogram during the 2 years after DHP implementation (or a similar time frame for the control employers). We also examined mammography rates for this group using a 3-year follow-up period. While mammography recommendations are controversial for women between 40 and 49 years of age, we also examined mammography rates for women 40–64 years of age over the same study windows. Among DHP employers, the analyses included all women of eligible age regardless of whether or not they were actually enrolled in the DHP. We applied inverse propensity weighting to the comparison samples, to adjust for inter-group differences. We expressed results at the Average Treatment Effect on the Treated (ATET). All analyses were conducted using STATA 13.

RESULTS: We analyzed data from 26,810 women 50–64 years of age with diabetes or pre-diabetes who were continuously enrolled for 3 years ($N=1282$ from 9 employers offering the DHP; $N=25,528$ from 240 employers offering standard plans). The expanded sample of women 40–64 years of age with diabetes or pre-diabetes who were continuously enrolled for 3 years included 1628 women in the 9 DHP employers and 31,910 women in the 240 employers offering standard plans. In weighted analyses using the 2 year follow-up study window, the predicted percentages of having a mammogram were 60.8 % without DHP purchase and 67.8 % with DHP purchase, for women aged 50–64 years ($+7.0$, $p=0.01$). Among women aged 40–64, the predicted percentages were 62.8 % without DHP purchase and 68.0 % with DHP purchase ($+5.2$, $p=0.07$). In weighted analyses using the 3 year follow-up study window, the predicted percentages of having a

mammogram were 68.7 % without DHP purchase and 73.7 % with DHP purchase, for women aged 50–64 years ($+5.0$, $p=0.09$). Among women aged 40–64, the predicted percentages were 73.0 % without DHP purchase and 76.5 % with DHP purchase ($+3.5$, $p=0.14$).

CONCLUSIONS: Employer purchase of the Diabetes Health Plan (DHP), a disease-specific plan for patients with diabetes or pre-diabetes, was associated with an increase in mammography rates among women 50–64 years of age over the first 2 years of plan implementation when compared to employers that did not purchase the DHP. These findings suggest that messaging and encouragement about general preventive care may be effective even within a disease-specific health plan targeting individuals with high-risk conditions, and may inform the design of similar plans in the future.

RETROSPECTIVE REVIEW OF RESISTANT CRYPTOCOCCAL MENINGITIS IN IMMUNOCOMPROMISED HOSTS Hachem Nasri¹; Sarah Kabbani¹; Melhim Bou Alwan²; Albert Anderson¹; Nadine Rouphael¹. ¹Emory University, Atlanta, GA; ²West Georgia Health, Lagrange, GA. (Tracking ID #2196047)

BACKGROUND: Cryptococcosis, caused by an environmental yeast *Cryptococcus neoformans*, occurs predominantly in immunocompromised individuals. While cryptococcosis is now more effectively treated with anti-fungal agents, the mortality rates for cryptococcal meningitis remains significant, and resistance to first line maintenance therapy, particularly fluconazole, has been reported. However, predictors of fluconazole resistance and outcomes remain underreported.

METHODS: A retrospective chart review was done on all patients admitted with cryptococcal meningitis, who had susceptibility testing performed on their cerebrospinal fluid (CSF) specimens, between 2001 and 2011, at Emory University affiliated hospitals and the Grady Health System in Atlanta, Georgia. We report a descriptive analysis of the patients' demographics, clinical and laboratory characteristics, and their outcomes. A univariate analysis for the predictors of fluconazole resistance, central nervous system (CNS) complications and mortality is reported.

RESULTS: A total of 35 patients were identified, 13 (37.1 %) of which had fluconazole resistance ($MIC > 8$). Eighty percent were males with African-American predominance (80 %), and the median age was 37 years. Furthermore, 80 % of the patients were HIV positive, while the rest were solid organ transplant recipients, except for one patient without a known immunocompromising condition. Subsequent recurrence of cryptococcal meningitis was more likely in HIV patients compared to solid organ transplant patients (p -value 0.0366). Overall, there was a statistically significant increase in fluconazole resistance in patients who had a history of prior azole use (OR 10.12, CI 2.04–50.15). Patients with fluconazole resistance and those with a high CSF cryptococcal antigen load (> 512) were more likely to have CNS complications (p -values 0.023 and 0.0358, respectively). On the other hand, patients who received voriconazole or high dose fluconazole (≥ 800 mg) for maintenance therapy showed a trend towards lower CNS complications, although not statistically significant (43 vs. 22 %). No increased risk of mortality was found with fluconazole resistance, however patients who received voriconazole or high dose fluconazole for maintenance therapy were more likely to survive (p -value 0.0195).

CONCLUSIONS: This retrospective study shows that immunocompromised patients with cryptococcal meningitis who have a history of prior azole exposure are more likely to develop fluconazole resistance and subsequent CNS complications; voriconazole or high dose fluconazole, however, are associated with lower CNS complications and a trend towards lower mortality. In addition to limited sample size, only cases where fluconazole susceptibility testing was performed on CSF samples were included in this study, thus no firm conclusions can be made on the effect of fluconazole resistance on mortality. Although this study shows an association between azole exposure and subsequent CNS complications, additional studies are required to further investigate the morbidity and mortality associated with fluconazole resistance in cryptococcal meningitis, to determine when it is appropriate to request susceptibility testing, and to evaluate its cost-effectiveness.

RISK OF PERIPHERAL NEUROPATHY IN PATIENTS INITIATING THALIDOMIDE OR LENALIDOMIDE FOR MULTIPLE MYELOMA: A PROPENSITY SCORE-MATCHED COHORT STUDY Jing Luo¹; Joshua Gagne²; Jerry Avorn³; Aaron Kesselheim¹. ¹Brigham and Women, Boston, MA; ²Division of Pharmacoepidemiology and Pharmacoeconomics, Brigham and Women's Hospital / HMS, Boston, MA; ³Harvard Medical School, Boston, MA. (Tracking ID #2200711)

BACKGROUND: In recent years, thalidomide and lenalidomide have become preferred agents in chemotherapy for multiple myeloma. Lenalidomide is a chemical derivative of thalidomide and is believed to have greater efficacy and a more favorable side-effect

profile, particularly with respect to the occurrence of peripheral neuropathy, though there is limited information from direct comparative trials. Thalidomide will soon be generic, while patent-protected lenalidomide costs about \$160,000/year. We performed an observational study to assess the comparative risk of peripheral neuropathy and death in a large population of typical myeloma patients receiving routine care.

METHODS: We identified patients with multiple myeloma who initiated lenalidomide or thalidomide within a large national health insurance claims database. We used propensity scores to match initiators on a large number of potential confounders, including age, sex, comorbidities, and other drugs comprising patients' initial treatment regimens. We followed patients from first use of either drug until censoring, defined as: development of a pre-specified clinical outcome, end of study (December 31, 2013), treatment discontinuation (plus 90 days), initiation of the other study drug, stem cell transplant, or bortezomib use during follow-up. The primary clinical outcome was a new diagnosis of peripheral neuropathy; secondary clinical outcomes were a new prescription of a medicine to treat neuropathic pain or death. Cox proportional hazards regression was used to estimate hazard ratios (HR) and 95 % confidence intervals (CI).

RESULTS: We identified and propensity-score matched 838 thalidomide initiators to the same number of lenalidomide initiators. Among new users of thalidomide, 76 (9 %) developed peripheral neuropathy during 487 person-years of follow-up. Among new users of lenalidomide, 114 (14 %) developed neuropathy during 444 person-years. Lenalidomide was associated with a higher rate of peripheral neuropathy (HR 1.67, 95 % CI:1.25–2.23), and a higher risk of being prescribed a medication to treat neuropathic pain (HR 1.46, 95 % CI:1.16–1.84), but a reduced risk of death (HR 0.56, 95 % CI:0.36–0.86). When we varied the duration of follow-up in sensitivity analyses, HRs were materially unchanged.

CONCLUSIONS: This study of 1676 treatment-naïve myeloma patients found that incident peripheral neuropathy may be more common for lenalidomide users than previously suspected. However, if confirmed, the survival advantage seen with lenalidomide would far outweigh this risk.

RISK STRATIFICATION METHODS AND PROVISION OF CARE MANAGEMENT SERVICES IN COMPREHENSIVE PRIMARY CARE INITIATIVE PRACTICES Ashok Reddy^{2,3}; Laura L. Sessums^{1,3}; Tim Day³; Jonathan Fried³; Bruce Finke³; Asaf Bitton³. ¹USUHS, Washington, DC; ²University of Pennsylvania, Philadelphia, PA; ³Center for Medicare & Medicaid Innovation, Baltimore, MD. (*Tracking ID #2197498*)

BACKGROUND: Risk-stratified care management strategies are key to the development of population health management capabilities in primary care practices. The goal of risk-stratified care management is to align the limited resources of a practice to patients most in need of these services. Evidence on the typology and utility of different patient risk stratification methods at the practice level, and their association with care management services, is limited. The Comprehensive Primary Care initiative (CPC) is a large-scale, multi-state, multi-payer test of a new primary care payment and practice transformation model developed by the Center for Medicare and Medicaid Innovation. One key component of CPC is directed at implementing practice-wide risk-stratified care management. We conducted an analysis of the risk stratification methods CPC practices initiated in the first year of the program and evaluated the association between the type of risk stratification methodology and the provision of care management services.

METHODS: CPC practices reported on their risk stratification strategy at the end of the first year of the initiative (2013). We used a modified Grounded Theory approach to analyze CPC practices' responses to a qualitative question on methods used for risk stratification of their patient population. Two members of the research team reviewed a random sample of 20 responses to identify concepts and categories in the data. Through consensus, risk stratification typologies were developed and applied to categorize the risk stratification methodology in 493 CPC practices. CPC practices also reported quantitative data on the number of patients in the highest two risk strata that resulted from the risk stratification of their population and the number of patients in those two strata who received care management services. Based on the data we determined the overall proportion of high-risk patients who received care management. With available practice level data on practice size, medical home recognition, ownership type, meaningful use (stage 1) providers, and geographical area (state and rural/urban), we used a generalized linear equation, controlling for the above practice level characteristics, to test if risk stratification methodology was associated with the overall proportion of high-risk patients who received care management.

RESULTS: All 493 practices submitted risk stratification methodology reports. CPC practices reported using four major methods to risk stratify their patient populations: payer claims/electronic health record (13 %), publicly available clinical algorithm (31 %), practice-developed algorithm (44 %), clinical intuition (11 %) (<1 % of practices did

not report). The average percentage of high-risk patients who received care management in CPC practices was 39 % (SD 36 %). The percentage of high-risk patients who received care management differed by risk stratification method: clinical intuition (50 %), payer claims/electronic health records (43 %), practice-developed algorithm (37 %), and publicly available clinical algorithm (36 %). In our primary analysis, after adjusting for practice level characteristics, we found the following statistically significant result: practices that chose to risk-stratify using clinical intuition had a 12 percentage point higher rate (95 % CI, 1–24 %, P-value 0.04) in the overall percentage of high-risk patients receiving care management when compared to practice-developed clinical algorithm.

CONCLUSIONS: Our findings offer some of the first insights into the ways practices implement risk stratified care management while undergoing rapid primary care transformation linked to payment reform. A key challenge for primary care practices is implementing population health management with limited resources: First, the financial resources to spend on commercial risk stratification software and second, the time needed to implement claims or clinical algorithms to identify high-risk patients. We find practices using clinical intuition, potentially the fastest and cheapest strategy to implement, provided care management to the highest proportion of their high-risk patients.

RISKY BUSINESS: EVALUATION OF PHYSICIAN ADHERENCE TO NEW ACC/AHA CHOLESTEROL GUIDELINES FOR DIABETIC PATIENTS

Siddharth Sheth¹; Trisha A. Miller; Kathana D. Mehta; Deborah M. Simak; David C. Demoise; Gary Tabas. University of Pittsburgh Medical Center, Pittsburgh, PA. (*Tracking ID #2196663*)

BACKGROUND: In November 2013, the American College of Cardiology/American Heart Association (ACC/AHA) published new cholesterol guidelines to reduce atherosclerotic cardiovascular risk. Focus shifted from achieving specific LDL targets to identifying high-risk patients with atherosclerotic cardiovascular disease (ASCVD), diabetes, or primary dyslipidemia. An ASCVD calculator estimating 10-year risk for myocardial infarction or stroke was created to stratify statin intensity (moderate- vs. high-intensity) based on a clinically validated 7.5 % cutoff and specific statin benefit categories. In diabetic patients, statins are recommended for all individuals aged 40–75 years, with the intensity determined by 10-year risk. Our study assessed both attending and resident physician prescribing practices in diabetic patients to determine knowledge of and adherence to the new cholesterol guidelines.

METHODS: We retrospectively reviewed the charts of diabetic patients cared for in a general internal medicine residency/faculty practice. Inclusion criteria included diabetics over 21 years old who had been evaluated by a clinic physician within the year prior to project initiation. In total, 255 patients were included. Baseline data were collected using EMR generated diabetes compliance reports. We compared actual statin prescriptions to ACC/AHA recommended statin medication and dose at both 8 months (June 2014) and 12 months (November 2014) following release of the new guidelines. A seven question de-identified survey was administered to providers to evaluate knowledge of new ACC/AHA guidelines.

RESULTS: Baseline characteristics of the 255 patients are summarized in Table 1. Patients were predominantly female (54 %), African American (61 %), and active or former smokers (56 %). Average A1c was 7.8 % and blood pressure was well-controlled. Average ASCVD risk score was 23.2 % with 89 % of patients requiring high intensity statin. Comparing June and November 2014 data, there was no statistical difference in the percent of patients on any statin (74 vs. 76 %, $p=0.68$) or those on the correct intensity (37 vs. 41 %, $p=0.40$). We also compared prescribing practices of attending and resident physicians and found no statistical difference between the two groups for percent of diabetic patients on any statin ($p=0.76$) or correct intensity statin ($p=0.52$) in July 2014. Similar non-significant differences were observed between groups in November 2014. In a survey of 34 physicians, 88 % responded that their statin prescribing practice was based on the 2013 ACC/AHA guidelines and 85 % used the ASCVD risk calculator 'often'. However only 50 % correctly answered two vignettes that assessed knowledge of the new guideline recommendations, including statin choice and intensity.

CONCLUSIONS: Our study is the first that we know of to assess knowledge of and adherence to the ACC/AHA cholesterol guidelines in a resident/faculty clinic practice. While physicians in the study effectively prescribed statins for diabetic patients, they were less successful at correctly selecting statin intensity, particularly when higher intensity was required. Our survey results suggest this suboptimal prescribing practice may be due to a knowledge gap. Furthermore, only minimal prescribing improvements were seen over time suggesting persistent lag time between guideline release and their incorporation into clinical practice. Lastly, we found no differences in prescribing practices between faculty and residents indicating poor adherence to guideline recommendations regardless of the level of physician experience.

Baseline Characteristics of Diabetic Patients

ROLE-MODELING COST-CONSCIOUS CARE—A NATIONAL EVALUATION OF FACULTY AT TEACHING HOSPITALS IN THE UNITED STATES

Mitesh Patel^{1, 4}; Darcy Reed¹; Cynthia D. Smith⁵; Vineet M. Arora². ¹Mayo Clinic, Rochester, MN; ²University of Chicago Medical Center, Chicago, IL; ³University of Pennsylvania, Philadelphia, PA; ⁴Philadelphia VA Medical Center, Philadelphia, PA; ⁵American College of Physicians, Philadelphia, PA. (Tracking ID #2196655)

BACKGROUND: Little is known about how well faculty at teaching hospitals role-model behaviors consistent with cost-conscious care. The objective of this study was to evaluate whether faculty at teaching hospitals in the United States (US) role-model cost-conscious care and whether role-modeling is impacted by the presence of a formal residency curriculum in cost-conscious care.

METHODS: Data on internal medicine resident perceptions of faculty behaviors were obtained from responses to a questionnaire administered during the Internal Medicine In-Training Examination in October 2012 (response rate: 83.7 %). Data on internal medicine program director perceptions of faculty behaviors were obtained from responses to a cost-consciousness questionnaire administered electronically in August 2012 (response rate: 70.5 %). To evaluate a more comprehensive assessment of faculty behaviors, resident and program director perceptions data were merged to match residents with the director of their residency program. The study sample included 12,623 paired responses from residents and their program directors. The main outcome measure was the perception of faculty role-modeling cost-conscious care. Multivariate logistic regression models were fit to the outcome variable using paired survey responses from US internal medicine residents and their program directors, adjusting for resident, program director, and residency program characteristics. Sensitivity analyses were performed by independently evaluating the model using the outcome measure as only perceptions of internal medicine residents and only perceptions of internal medicine program directors.

RESULTS: Among 253 residency programs, 37 (14.6 %) had a formal curriculum in cost-conscious care, 127 (50.2 %) did not but were working on it, and 89 (35.2 %) did not have a curriculum. A higher proportion of residents (52.7–54.7 %) than program directors (39.4–44.7 %) agreed that faculty consistently role-model cost-conscious care. Only one-fourth of the time (23.0–26.7 %) did the resident and their program director both agree. In the adjusted model, presence of a formal curriculum in cost-conscious care did not have a significant impact on perceptions (odds ratio [OR], 1.04; *P*=0.91). Higher odds of agreement were found among residency programs that were community-based (OR, 3.20; *P*<0.01), community-based, university-affiliated (OR, 1.80; *P*=0.02) and located in the South (OR, 2.09; *P*=0.02). Compared to US medical school graduates, higher odds of agreement were found among residents who trained at foreign medical schools (OR, 1.39; *P*=0.03). These findings were supported by

sensitivity analyses evaluating perceptions of residents and program directors independently.

CONCLUSIONS: The majority of residents and program directors reported that faculty at US teaching hospitals were not consistently role-modeling cost-conscious care. Presence of a formal curriculum in cost-conscious care did not impact perceptions. Future efforts should focus on placing more emphasis on faculty development and combining curricular improvements with institutional interventions to adapt the training environment.

ROUTINE INPATIENT HCV SCREENING OF 4582 BABY BOOMERS: LOWER HCV PREVALENCE BUT MORE ADVANCED DISEASE IN NEWLY DIAGNOSED MEXICAN-ORIGIN HISPANICS

Barbara J. Turner^{1, 2}; Barbara S. Taylor^{1, 2}; Joshua T. Hanson^{1, 2}; Poornachand Veerapaneni²; Yuanyuan Liang^{1, 2}. ¹University of Texas Health Science Center at San Antonio, San Antonio, TX; ²UT Health Science Center at San Antonio, San Antonio, TX. (Tracking ID #2195842)

BACKGROUND: Guidelines now recommend one-time Hepatitis C virus (HCV) screening of all baby boomers (born 1945–1965). National surveys report that Hispanics are less likely to have HCV infection than non-Hispanic whites (NHW) or blacks and, among Hispanics, persons from Puerto Rico are more likely to be infected than those of Mexican origin. Given these data, regions of the country with majority Mexican-origin populations might place lower priority on implementing HCV screening. In a prospective cohort of primarily Mexican-origin baby boomers admitted to a South Texas hospital, we examined the association of race-ethnicity and other demographic characteristics with HCV infection and, for chronic HCV, with hepatocellular carcinoma (HCC) or cirrhosis on imaging studies.

METHODS: A prospective cohort of never screened baby boomers admitted to a safety net hospital in San Antonio was screened for eligibility (birth year 1945–65, no prior HCV diagnosis or prior HCV test, not admitted to psychiatry, and no metastatic cancer) using an electronic medical record algorithm from 12/1/2012 to 9/30/2014 and followed through 12/10/2014. Anti-HCV antibody (anti-HCV) and reflex HCV RNA were performed on eligible patients with opt out consent. Anti-HCV positive (+) patients received inpatient counseling and outpatient case management for linkage to primary and specialty HCV care. Logistic regression models examine the association of age, gender, self-reported race-ethnicity, and insurance status with three outcomes: anti-HCV +, HCV RNA + (chronic HCV), and cirrhosis or likely HCC on imaging by liver ultrasound or CT scan.

RESULTS: Of 4582 unique patients screened for HCV, the mean age was 57.0 (SD 5.7) 56.7 % men, 58.4 % Hispanic (Mexican-origin), 33.3 % NHW, 5.2 % Black, 3.1 % Asian/other and 45.1 % uninsured. Of screened patients, 316 (6.9 %) were anti-HCV +, of whom 287 (91 %) received HCV RNA testing. HCV RNA was detected in 175 (61.0 %) indicating chronic HCV (3.8 % of all screened patients). Adjusted odds of anti-HCV+ were significantly higher for men but reduced for increasing age and Hispanics or Asian/other race compared with NHW (Model 1, Table). Age had the only significant association with HCV RNA+ (Model 2) with lower odds for increasing age. Of chronically infected patients, 125 (71 %) had an imaging study and 60 (48 %) were reported to have cirrhosis or HCC. Increasing age and Hispanic ethnicity were associated with significantly higher odds of cirrhosis/HCC; notably Hispanics were over three-fold more likely to have advanced disease than NHW/Asian/other. Across all models, uninsured persons had higher odds of these outcomes but did not reach statistical significance.

CONCLUSIONS: In this prospective cohort, Hispanics of primarily Mexican-origin had lower prevalence of anti-HCV but over 3-fold greater odds of advanced disease on imaging than NHW. These data reinforce the value of HCV screening in Hispanics of Mexican origin despite their having a lower prevalence of HCV.

Associations of Patient Demographic Characteristics with HCV Screening Results and Advanced Liver Disease on Imaging

SATISFACTION WITH HEALTH CARE AMONG PATIENTS NAVIGATED FOR PREVENTIVE CANCER SCREENING Emilia A. Hermann²; Steven J. Atlas¹; Jeffrey M. Ashburner¹; Sanja Percec-Lima¹. ¹Massachusetts General Hospital, Boston, MA; ²Perelman School of Medicine University of Pennsylvania, Philadelphia, PA. (Tracking ID #2198829)

BACKGROUND: The Affordable Care Act includes provisions that support population health management activities as part of fostering accountable care organizations. The use of patient navigation (PN) for vulnerable patients may help ensure that population-based interventions, such as preventive cancer screening, improve equity of care. In a large, diverse academic primary care network, we implemented a PN program as part of a visit-independent, population management system for comprehensive cancer screening in vulnerable patients. As part of a randomized control trial (RCT) comparing PN to usual care for patients at increased risk for non-adherence to screening, we surveyed patients about satisfaction with overall medical care and in intervention patients with the PN program. Little is known about patient perception and satisfaction with this novel type of PN and whether it may influence patient satisfaction with overall medical care.

METHODS: The RCT took place from April to December 2014. This study began in October 2014. Introductory letters about the survey were sent in batches of 80 per week to equal numbers of randomly selected patients in the control and PN (intervention) arm. In order to best capture patient satisfaction with PN, patients were only asked to participate in this study if they had contact with a navigator after July 2014. No remuneration was provided for participation. Patients were then contacted by phone 1 week after the introductory letter was mailed and asked to complete the PSQ-18 "Short-form Patient Satisfaction Questionnaire" (PSQ-18: scores range from 18 to 90). Patients in the intervention (PN) group were also asked to complete the "Satisfaction with Interpersonal Relationships with Navigator" (PSN-I), a validated instrument with scores that range from 9 to 45. We compared patient satisfaction with overall medical care between the two study arms, as measured by the PSQ-18, using a two-sample t-test. In the PN (intervention) patients, we also evaluated the relationship between patient satisfaction with PN (as measured by PSN-I) and their satisfaction with overall medical care (as measured by PSQ-18) using a linear regression model.

RESULTS: There were 792 patients in the PN arm and 820 in the control arm. Phone surveys are ongoing with completion expected by the end of February 2015. As of January 1, 2015, 126 of 400 patients (31.5 %) agreed to participate and completed the survey (66 intervention and 60 control). Among patients not agreeing to participate, 233 (58.3 %) could not be contacted (134 intervention and 140 control) and 41 (10.3 %) were contacted but declined (14 control, 27 intervention). Respondents had a mean age of 57.6 years, most were female (60.4 %) and white (79.8 %), and 50 % had commercial health insurance. There was no difference in age, gender, race, primary language, or type of insurance among intervention and control group respondents. Patients who were contacted by a PN in the intervention group had higher satisfaction with their overall medical care compared to control patients (mean PSQ-18: 71.8 vs. 67.8, $p=0.002$). The average PSN-I score among the 66 intervention respondents was 38.1 (SD: 6.2). To evaluate the relationship between satisfaction with patient navigation and overall satisfaction with medical care, a regression model evaluating the relationship between PSN-I score and PSQ-18 score among intervention patients demonstrated a positive association ($R^2=0.2194$, p -value <0.001). However, only 22 % of the PSQ-18 score variation is explained by PSN-I scores.

CONCLUSIONS: Among patients at increased risk of non-adherence for preventive cancer screening, those randomized to a PN intervention had higher overall satisfaction with medical care. For intervention patients, there was positive relationship between higher PN satisfaction scores and higher general satisfaction scores. This study suggests that systematically addressing patient-identified barriers to care using PN may improve patient perception of health care overall.

SEEKING EMERGENCY CONTRACEPTION IN DENVER, COLORADO: A HEALTH IMPACT ASSESSMENT Alia Moore²; Dr. Carol Stamm⁴; Laura Borgelt⁴; Dan Topp¹; Rachel Blumhagen³; Leanne Rupp¹; Christine Gilroy². ¹The Colorado Health Foundation, Denver, CO; ²University of Colorado Anschutz Medical Campus, Denver, CO; ³University of Colorado Denver, Aurora, CO; ⁴University of Colorado, Aurora, CO. (Tracking ID #2190499)

BACKGROUND: Emergency contraception (EC)—a progestin-only pill that reduces the risk of pregnancy by delaying or inhibiting ovulation—is important for comprehensive reproductive health. Brand-name Plan B One-Step has been available over the counter without age restrictions since June 2013; generic medications have been widely available since February 2014. EC is a very effective medication when taken correctly, although recent European research suggest reduced efficacy in heavier women. Previous studies

have identified various barriers to EC access, including ethical objections and propagation of outdated information. Our study aimed to evaluate potential barriers to EC access within the Denver area.

METHODS: A female resident posing as a 190-lb woman called 118 Denver pharmacies seeking EC. Using a predetermined script, the resident inquired about EC availability and location (over the counter or behind it), cost, age restrictions, ID requirements and weight considerations. Data was input into a RedCap database and analyzed using descriptive statistics and Fisher's exact testing.

RESULTS: Ninety-three percent (110/118) of phone calls were successful. 23/110 (20.91 %) pharmacies had complete access, defined as in-stock and on-the-shelf without ID requirements; none of these were independent. 17/110 (15.45 %) pharmacies had no EC in stock, 7/17 (41.18 %) of which never carry it. 26/110 (23.64 %) pharmacies keep generic EC behind the counter. Mean cost of Plan B: \$48.61; mean cost of generic EC: \$40.83. 54/110 (49.09 %) inaccurately reported age restrictions or ID requirements for any form of EC. Only 19/110 (17.27 %) pharmacies were aware of potentially reduced EC efficacy in heavier women. Of these 19, 3 (15.79 %) offered alternative forms of EC.

CONCLUSIONS: Pharmacy employees were forthcoming with EC information, but demonstrated significant knowledge gaps regarding age restrictions and current research. This study suggests that timely, comprehensive and ongoing EC education for both pharmacists and pharmacy technicians may help overcome these barriers and encourage accurate patient counseling.

SELF-DIRECTED LEARNING AMONG INTERNAL MEDICINE RESIDENTS: A QUALITATIVE STUDY USING GROUNDED THEORY Adam P. Sawatsky; John T. Ratelle; Sara Bonnes; Jason Egginton; Thomas J. Beckman. Mayo Clinic, Rochester, MN. (Tracking ID #2196264)

BACKGROUND: Self-directed learning (SDL) is a process in which individuals take the initiative, with or without the help of others, in diagnosing their learning needs, formulating goals, identifying resources for learning, choosing learning strategies, and evaluating learning outcomes. SDL overlaps many of the Accreditation Council for Graduate Medical Education core competencies and is woven into the language of practice-based learning and improvement, including evaluating one's own knowledge, setting learning goals, incorporating formative evaluation feedback into practice, and using scientific evidence. Previous qualitative studies reveal that residents recognize the importance of SDL but frequently experience difficulty with the application of SDL. While previous studies have guided the development of SDL curricula, significant gaps remain in our understanding of the practice of SDL by residents. Our goal was to build a theory to explain the process of SDL within the residency training environment and to better understand the role that faculty members and residency programs play in the promotion and support of resident SDL.

METHODS: We used grounded theory to build a theoretical framework for understanding SDL during internal medicine residency training at the Mayo Clinic in 2014. The investigators have experience in qualitative research in medical education and have teaching roles in the residency program. We conducted focus groups of internal medicine residents, with separate focus groups for first-year and for upper-level residents to avoid power differentials. We developed the focus group guide through reviewing the literature, brainstorming, pilot-testing, reviewing with a panel of experts, and constantly comparing with acquired focus group data. A trained facilitator with experience in focus group moderation and with no connection to the residency program moderated the focus groups. The primary investigator served as note-taker. Focus groups were transcribed verbatim and the data was de-identified prior to analysis. Using a grounded theory approach, the analytic process involved reflection throughout the process of data collection. Team members reviewed transcripts from five serial focus groups using open coding and analytic memos to identify important themes and guide subsequent focus group discussions. Using constant comparison, we developed axial codes that were applied to each transcript. We refined the axial codes through open coding to identify new, emerging themes. We developed a theoretical model for the process of SDL which was refined over time until theoretical saturation was achieved.

RESULTS: We conducted five focus groups of 36 residents, with an average of 7 residents per group. SDL was triggered by problem that uncovered a learning need and then continued through setting goals, identifying content and resources, applying knowledge, and self-evaluation. The main trigger for SDL was patient care, but additional triggers included faculty, peer discussions, other-directed learning, news sources, push notifications and exam questions. There were several major themes that affected the process of SDL, including 1) motivations, 2) barriers and activators, 3) context, and 4) the role of external feedback and faculty support. SDL was driven by internal motivations (personal interest, desire to be a good physician) and external motivations (passing exams, "looking stupid" to others). The main barriers were time, amount of information to learn and not knowing how to focus learning. Activators included time for learning and thought,

and the provision of optimal resources. The context included program structure and culture, the structure of rotations and the social context of learning. Residents were clear about the crucial role of feedback from faculty members, peers, patients, and other sources to inform each step in the process of SDL, including self-evaluation. The residency program and individual faculty members were critical in guiding residents through the process of SDL, providing input at every step of the SDL process. Residents expressed that faculty members must understand a resident's specific learning need and goals within a specific context to effectively guide their SDL. Finally, residents preferred "collaborative self-directed learning" to being asked "why don't you look that up," with faculty modeling SDL to residents through working with the resident to seek answers to clinical questions.

CONCLUSIONS: To our knowledge, this represents the first study to present a theory of SDL among residents. Our theory delineates a process that evolves from the identification of learning need to the self-evaluation of learning, and there are multiple influences to this process, including motivations for learning and barriers to SDL. Ultimately, this model may serve to cultivate learning environments that optimize SDL and competency-based assessment in resident education.

SHARED DECISION MAKING DURING INPATIENT ROUNDS: OPPORTUNITIES FOR IMPROVEMENT IN PATIENT ENGAGEMENT AND COMMUNICATION Stephanie M. Harman¹; Poonam Hosamani¹; Lisa Shieh¹; Eric Huynh¹; Stephanie Rennke²; Bradley Monash³; Patrick Yuan⁴; Joan F. Hilton³; Rebecca Blankenburg²; Debbie S. Sakai¹; Ian Chua¹; Adeena Khan³; Lijia Xie³; Jason Satterfield⁴. ¹Stanford University, Stanford, CA; ²Stanford University School of Medicine, Palo Alto, CA; ³UCSF, San Francisco, CA; ⁴University of California, San Francisco, San Francisco, CA. (Tracking ID #2198113)

BACKGROUND: Shared decision-making (SDM) has been shown to be an important tool for improving patient engagement and health care outcomes. Evidence indicates that patients are both willing and able to engage in SDM with their providers. Despite the demonstrated value of SDM across disciplines, little is known about the extent of SDM occurring in general inpatient settings. We sought to quantify the presence of key SDM behaviors during morning rounds on general pediatrics and internal medicine services at two academic hospitals.

METHODS: We completed an IRB-approved cross-sectional study of inpatient ward rounds on pediatric and internal medicine services at two large academic hospitals over a

12-week period. Twelve physicians trained to use a validated observation tool, the Rochester Participatory Decision-Making Scale (RPAD) a 9-item survey, observed the occurrence of SDM behaviors on inpatient rounds. Mean scores across all RPAD items were calculated, and performance across medicine and pediatrics services was compared using t-tests.

RESULTS: A total of 32 teams (16 medicine, 16 pediatrics), 89 ward rounds (47 medicine, 48 pediatrics), and 268 unique patient encounters (127 medicine, 141 pediatrics) were observed. The overall performance in pediatrics trended higher than in medicine (mean total RPAD score of 4.27 vs. 3.60, $p < 0.001$, scores range 0.5–9.0, Figure 1). The most frequently observed behaviors across all services included: explaining the clinical issue or nature of the decision and matching medical language to the patient's level of understanding. The least frequently observed behaviors included checking understanding of the patient's point of view, examining barriers to follow-through with the treatment plan, and asking if the patient has any questions (Figure 2).

CONCLUSIONS: Opportunities exist to improve patient care and health outcomes by strengthening SDM on rounds through checking understanding of the patient's perspective, examining barriers to follow-through with the treatment plan, and asking if the patient has questions.

SHARED DECISION-MAKING DURING INPATIENT ROUNDS: DISSIMILAR YET CORRELATED PERSPECTIVES OF PATIENTS/GUARDIANS AND PHYSICIAN OBSERVERS Stephanie Rennke²; Bradley Monash^{2, 5}; Rebecca Blankenburg¹; Patrick Yuan³; Stephanie M. Harman⁴; Joan F. Hilton³; Debbie S. Sakai¹; Ian Chua¹; Eric Huynh⁴; Poonam Hosamani⁴; Adeena Khan²; Lisa Shieh⁴; Lijia Xie²; Jason Satterfield³. ¹Stanford University School of Medicine, Palo Alto, CA; ²UCSF, San Francisco, CA; ³University of California, San Francisco, San Francisco, CA; ⁴Stanford University School of Medicine, Stanford, CA; ⁵Pediatrics, UCSF, San Francisco, CA. (Tracking ID #2197867)

BACKGROUND: Educating and empowering patients to actively participate in their own care through shared decision-making (SDM) can improve patient satisfaction as well as health outcomes. Prior work has led to the development and validation of tools to assess the quality of key SDM behaviors, predominantly in the outpatient setting. Using a validated instrument, we sought to compare patient and physician perception of specific SDM behaviors as they occurred on inpatient rounds.

METHODS: We conducted a cross-sectional study of inpatient ward rounds on pediatric and internal medicine services at a large academic center over a 12-week period. Twelve physicians trained to use a validated observation tool (the nine-item Rochester Participa-

tory Decision-Making Scale (RPAD)) observed the occurrence of specific SDM behaviors on inpatient rounds, and scored each item (0=absent, 0.5=weak, 1=strong). We assessed patient/guardian perception of the quality of each of the nine items using a patient survey adapted from the RPAD. Research assistants blinded to the RPAD scores approached English-speaking patients/guardians after rounds to complete the surveys. We used t-tests to compare the scores of each item as assessed by the physician observers and patients/guardians.

RESULTS: SDM behaviors by physicians were collected for 115 unique patient encounters (44 medicine, 71 pediatrics) on 15 rounding teams (6 medicine, 9 pediatric) during 49 ward rounds (20 medicine, 29 pediatrics). Of the 115 patients, 40 (35 %) were administered patient-perspective RPAD surveys. Patients scored their physicians higher on average, by 32 % (2-sided paired t-test, $p=0.004$), compared with the scores given by physician observers. However, excluding Item 1, patients' and clinicians' assessments were high correlated, showing they identified strengths and weakness similarly ($r=0.68$; Figure).

CONCLUSIONS: Patients/guardians perceive the quantity and quality of shared decision-making on rounds more favorably than physician observers do; however, they identify similar strengths and weaknesses in the shared decision-making process.

Comparison of patient/guardian and physician observer assessment of shared decision-making on rounds

- 1=MD clearly explained medical issue or decision to be made
- 2=MD discussed alternatives or uncertainties
- 3=MD checked for patient agreement with plan
- 4=MD examined barriers to follow through with treatment plan
- 5=MD provided opportunity for patient to ask questions to ensure understanding
- 6=Patient understood what MD was saying
- 7=MD asked if patient had any questions
- 8=MD asked open-ended questions
- 9=MD checked own understanding of patient's point of view

SHOULD PRIMARY CARE PHYSICIANS REMAIN MORE INVOLVED IN THE CARE OF PATIENTS WITH ADVANCED CHRONIC KIDNEY DISEASE?

Raquel Greer¹; Patti Ephraim¹; Neil R. Powe²; Bernard G. Jaar¹; Michael J. Choi¹; Felicia Hill-Briggs¹; Edward Kraus¹; Courtney Cook¹; LaPricia Lewis-Boyer¹; Luis Gimenez¹; Joseph K. Melancon⁴; L. Ebony Boulware³. ¹Johns Hopkins Medical Institutions, Baltimore, MD; ²University of California San Francisco, San Francisco, CA; ³Duke University, Durham, MD; ⁴George Washington University, Washington, DC. (Tracking ID #2198874)

BACKGROUND: Greater co-management between primary care physicians and nephrologists in chronic kidney disease (CKD) care is increasingly encouraged. Primary care physicians often have longer established relationships with patients with CKD compared to nephrologists, and may serve as a more trusted source for medical advice

and decision-making support. However, nephrologists most often deliver the majority of CKD care with insufficient continuity or collaboration with patients' primary care physicians. The extent to which patients with advanced, progressive CKD prefer to rely on their primary care physicians for medical advice is unknown.

METHODS: As part of the Talking about Living Kidney Donation (TALK) study, a randomized controlled trial of educational and behavioral interventions to improve consideration of living kidney transplantation, we assessed via the baseline questionnaire the extent to which patients with advanced, progressive CKD from Baltimore area nephrology practices reported they relied on their primary care physicians for medical care and advice rather than their nephrologist or other providers: "Between your kidney doctor, your primary care doctor, and your other doctors, which doctor do you most heavily rely on for care of your medical problems and for medical advice?" Using multivariate logistic regression, we also identified independent predictors of patients' primary reliance of their

primary care physician for care and advice compared to other physicians, adjusting for patients' demographics (age, race, and sex); CKD severity; duration and frequency of nephrology care; trust in medical care; and their perception of their nephrologists' patient centeredness.

RESULTS: Among 112 patients with advanced, progressive CKD (mean age 58 years), 58 % were female, 48 % were African American, and 82 % were high school graduates. The majority (69 %) of patients had Stage 4 CKD with a mean estimated glomerular filtration rate of 26.5 ml/min/1.73 m² and most (62 %) had been under nephrology care for at least 2 years. Patients most frequently reported they relied most heavily on their primary care physician for care and advice (46 %), while fewer reported they relied on all their physicians fairly equally (27 %), mostly on their nephrologist (21 %), or mostly with another provider (6 %). After adjustment for all other variables, patients receiving shorter duration nephrology care (51 % less than 2 years, 49 % 2–4 years, and 33 % five or more years, *p* for trend=0.03) or making less frequent visits to their nephrologists (56 % at least once a year, 52 % at least every 3 months, and 22 % at least every 2 months, *p* for trend=0.01) were more likely to rely mostly on their primary care physician for care and advice. Patient age, race, CKD severity, trust in medical care, or perception of nephrologists' patient centeredness were not associated with their likelihood of seeking care or advice from primary care physicians.

CONCLUSIONS: Despite being in nephrology care for prolonged time periods, the majority of patients with advanced, progressive CKD continue to rely heavily on their primary care physician for medical care and advice. While primary care physicians often become less involved in CKD care as patients near end-stage renal disease and prepare for renal replacement therapy, our results reinforce efforts to increase primary care physician involvement and improve nephrologists' and primary care physicians' collaboration in advanced CKD care.

SIBLINGS HISTORY IS A STRONGER PREDICTOR OF TYPE 2 DIABETES THAN PARENTAL HISTORY Gautam A. Deshpande^{2, 3}; Sachiko Ohde¹; Osamu Takahashi². ¹St. Luke's Life Science Institute, Tokyo, Japan; ²St. Luke's International University, Chuo-ku, Japan; ³University of Hawaii, Honolulu, HI. (Tracking ID #2196945)

BACKGROUND: Type 2 diabetes mellitus (T2DM) affects an approximate 387 million individuals worldwide, with an estimated prevalence of 11 % in the United States by 2035. Identification of at-risk individuals by primary care physicians may play an important role in disease prevention. While family history is a well-established risk factor for the development of T2DM, the details of this risk, including age at diagnosis in family members, remain unclear. This study aims to assess the risk of development of T2DM in apparently healthy individuals by relationship to parents and siblings with T2DM, as well as by age at which family members were diagnosed.

METHODS: This was a retrospective open cohort study of apparently healthy individuals presenting to an annual health screening clinic located in metropolitan Japan (St. Luke's International Hospital, Tokyo, Japan) between 2005 and 2010. Individuals without a previous history of DM, and taking no medications which might modify glucose levels, were included in the study and followed at return visits. At each visit, all patients completed a comprehensive screening questionnaire on new medical diagnoses, family history, and lifestyle habits. Newly diagnosed T2DM was the primary outcome; independent variables included first-degree family members with DM and age at DM diagnosis. Logistic regression models were built for those with newly diagnosed T2DM, comparing data based on parental and sibling DM history, and age at DM diagnosis, as well as stratifying data by BMI of index cases.

RESULTS: Of 52,820 individuals included, 1510 (2.9 %) developed T2DM during the study period (mean age, 53.8±11.1 years; 981 (65 %) male). Six thousand four hundred sixty-seven (12.2 %) patients had a parental history of DM, with 4.2 % reporting a maternal history of DM. Six hundred eighty-nine (1.3 %) reported a sibling with DM, among whom 7.9 % developed T2DM. Logistic regression, adjusted for age, gender, and baseline BMI, revealed an increased risk of T2DM with any family history (OR 1.79; 95%CI 1.57–2.04) though a maternal history (OR 1.89; 95%CI 1.57–2.28) was associated with more robust risk than a paternal history (OR 1.42; 95%CI 1.21–1.67); risk was unchanged with early age at parental diagnosis. A sibling with T2DM was most strongly associated with development of disease (OR 2.50; 95%CI 1.89–3.30), a risk further increased if the sibling was diagnosed at <50 years old (OR 3.07; 95%CI 2.20–4.27). Strength of association regarding sibling history remained intact even among those at normal weight after stratification by BMI.

CONCLUSIONS: Our data corroborate previous findings associating risk of T2DM with parental, especially maternal, DM history. In contrast to previous reports, however, personal risk of developing T2DM was more robustly associated with having a sibling with T2DM, compared to either parent. In contrast to parental history, which does not appear to be affected by age at diagnosis, T2DM risk increases substantially if the disease is diagnosed earlier in a siblings' life (prior to age 50). Adding virtually no further time to the already busy clinical encounter, asking about sibling, in addition to parental, family history may lead to more optimal identification of those at risk for T2DM.

SMOKING CESSATION INTERVENTIONS FOR URBAN HOSPITAL PATIENTS: A RANDOMIZED COMPARATIVE EFFECTIVENESS TRIAL Scott Sherman⁴; Alissa R. Link¹; Erin Rogers³; Paul Krebs^{3, 1}; Joseph A. Ladapo¹; Donna Shelley¹; Yixin Fang¹; Binhuan Wang²; Ellie Grossman¹. ¹NYU School of Medicine, New York, NY; ²New York University, New York, NY; ³VA NY Harbor Healthcare System, New York, NY; ⁴VA New York Harbor HCS, New York, NY. (Tracking ID #2198537)

BACKGROUND: Hospitalization is an under-appreciated window of opportunity to promote smoking cessation, particularly given a higher prevalence of smoking among hospitalized patients and the time of enforced abstinence and heightened vulnerability. Prior studies with hospitalized smokers have primarily been efficacy studies, with narrowly defined populations. We attempted to enroll every smoker admitted to two "safety net" hospitals into a post-discharge cessation intervention.

METHODS: We conducted a comparative effectiveness trial, as part of the NIH-funded Consortium of Hospitals Advancing Research on Tobacco (CHART). At two public hospitals in New York City (Bellevue Hospital Center and VA New York Harbor Healthcare System), we approached every person admitted who was identified as a smoker (based on admission notes). Inclusion criteria were: smoked cigarettes in the past 30 days; spoke English, Spanish, or Mandarin; had a U.S. phone number; not discharged to an institution where follow-up or smoking was limited (e.g., jail, nursing home); and not pregnant or breastfeeding. At discharge, participants were randomized to a) multi-session telephone counseling from study staff (*n*=804) or b) referral to the state Quitline for proactive outreach and counseling (*n*=814). We sent nicotine replacement therapy to participants who did not receive cessation medications on discharge. Our pre-specified primary outcome was self-reported abstinence (30-day point prevalence) at 6 months. For follow-up, we reached 69 % of participants at 2 months and 68 % at 6 months.

RESULTS: Of 18,797 patients identified as current smokers between July, 2011 and April, 2014, 3047 (16 %) were discharged before being approached, 3273 (17 %) were not current smokers, 4026 (21 %) had no US phone number, 2831 (15 %) were ineligible for other reasons and 3983 (21 %) refused participation. One thousand six hundred eighteen (9 %) participants enrolled in the study (71 % at Bellevue, 29 % at the VA). Approximately one quarter of participants were either homeless or in unstable housing, 60 % had a history of substance abuse or dependence, 43 % reported current hazardous drinking and half had a psychiatric diagnosis other than substance abuse. Including only patients reached for follow-up, the rate of abstinence was higher in the intensive counseling arm than the Quitline arm at 2 months (29.0 vs. 20.7 %; OR 1.56, 95 % CI 1.18–2.07) and 6 months (37.4 vs. 31.3 %; OR 1.31, 95 % CI 1.02–1.69). Results were similar using an intention to treat analysis. Participants in either arm who received at least one counseling call were much more likely to quit than participants who did not receive any calls (40.0 % vs. 26.5 %; OR 1.85, 95 % CI 1.41–2.42). This was not true for NRT—there was no difference in the abstinence rate between people who reported having used NRT and those who did not report using it.

CONCLUSIONS: At urban safety net hospitals, intensive counseling was more effective than referring to the state Quitline, but long-term abstinence was excellent in both groups. Many patients were not eligible for enrollment, despite minimal exclusion criteria. Either intervention would be feasible for any hospital.

SOCIAL NEEDS AND CARDIOVASCULAR RISK SCORES IN THE HEALTHY COMMUNITY NEIGHBORHOOD INITIATIVE—A COMMUNITY-ACADEMIC PARTNERSHIP IN SOUTH LOS ANGELES Arleen F. Brown³; D'Ann Morris⁶; Keith Norris¹; Katherine L. Kahn³; Ibrahima Sankare³; Keyonna M. King³; Roberto Vargas³; Aziza L. Wright²; Felicia U. Jones²; Homero del Pino⁷; Courtney Porter⁶; Dennishia Banner²; Rachelle Bross⁴; Nell Forge⁷; Orwilda L. Pitts⁷; Lujia Zhang⁵; Stefanie D. Vassar¹; Sitaram Vangala¹; Li-Jung Liang¹; Loretta Jones². ¹University of California Los Angeles Division of General Internal Medicine and Health Services Research, Los Angeles, CA; ²Healthy African American Families, Los Angeles, CA; ³UCLA, Los Angeles, CA; ⁴UCLA Clinical and Translational Science Institute, Harbor-UCLA Medical Center and Los Angeles Biomedical Research Institute, Torrance, CA; ⁵UCLA David Geffen School of Medicine, Los Angeles, CA; ⁶Los Angeles Urban League, Los Angeles, CA; ⁷Charles R. Drew University, Los Angeles, CA. (Tracking ID #2174127)

BACKGROUND: Behavioral, clinical, and public health efforts to improve awareness and management of cardiovascular disease (CVD) have had limited success in reducing disparities. Community-partnered participatory research (CPPR) to understand both clinical and social needs may result in more effective community-level risk reduction efforts.

The Healthy Community Neighborhood Initiative (HCNI) is a multifaceted community-initiated CPPR study to understand and reduce health and health care disparities in a bi-ethnic, under-resourced community in South Los Angeles.

METHODS: To better understand clinical needs, social needs, and available resources in the community, the HCNI developed and fielded protocols for in-home interviews (in English or Spanish) and clinical and laboratory examinations. The interview included questions about clinical characteristics, health status, health behaviors, use of health services, unmet need for social services, and neighborhood characteristics, including social cohesion. The service needs score was developed by the community partners, who identified modifiable social service needs that could be addressed by community agencies. The score was an unweighted sum of self-reported unmet needs related to childcare, employment, education, housing, neighborhood safety, emergency response, food sufficiency, legal advice, criminal justice, and health care. The social cohesion score, modified from the Project on Human Development in Chicago Neighborhoods, assessed the strength of social networks in the community. For each participant, we constructed 10-year 1) American College of Cardiology/American Heart Association and 2) Framingham CVD risk profiles. We constructed linear regression models for each log-transformed risk score, adjusted for age, sex, ethnicity, education, insurance, unmet social service needs, and social cohesion.

RESULTS: Of the 206 participants enrolled, 71 % were female and 29 % male, 75 % were African American and 25 % Latino, mean was age 44.6 years (SD=15.9), and 23 % had not graduated from high school. Participants reported a mean 3.4 (SD=2.8) unmet social service needs (range=0–10), rated neighborhood social cohesion a mean 2.6 (SD=0.7; range 1–5) and 38 % reported fair or poor health. Mean total cholesterol was 160 mg/dl (SD=35) for men and 178 mg/dl (SD=47) for women; mean HDL cholesterol was 49.8 mg/dl (SD=19.1) for men and 60.1 mg/dl (SD=17.4) for women; mean systolic blood pressure was 126 mmHg (SD=20) for men and 126 mmHg (SD=21) for women; and 24 % currently smoked, 23 % had hypertension treated with medications, and 14 % had a diagnosis of diabetes. In the multivariable analyses, for both CVD risk scores, older age, male sex, and each point on the unmet social service needs score were associated with higher CVD 10-year risk ($p<0.005$ for each). (Table)

CONCLUSIONS: Unmet need for social services, as defined by partners from community-based agencies, was associated with significantly higher 10-year risk (using both the Framingham and ACC/AHA equations) after adjustment for other traditional biologic and clinical risk factors. The HCNI community-academic partnership has developed an effective strategy for understanding modifiable clinical and social influences on CVD risk and will continue to collaborate to develop novel risk reduction interventions that are feasible and acceptable within this community.

Biologic and Social Influences on CVD Risk Scores—Multivariable Linear Regression Models*

Variable	Framingham (N=185): Adj		ACC/AHA (N=185): Adj

SOCIOECONOMIC STATUS AND RISK OF HEMORRHAGE DURING WARFARIN THERAPY FOR ATRIAL FIBRILLATION: A POPULATION-BASED STUDY

Alex M. Cressman^{1, 2}; Erin M. Macdonald¹; Zhan Yao¹; Tara Gomes^{1, 3}; Michael Paterson¹; Peter C. Austin¹; Moira K. Kapral^{1, 2}; Muhammad M. Mamdani^{1, 3}; David N. Juurlink^{1, 2}. ¹Institute for Clinical Evaluative Sciences, Toronto, ON, Canada; ²University of Toronto, Toronto, ON, Canada; ³St. Michael's Hospital, Toronto, ON, Canada. (Tracking ID #2152814)

BACKGROUND: In patients prescribed warfarin therapy for atrial fibrillation, higher socioeconomic status is associated with superior anticoagulant control. However, the extent to which this influences the risk of hemorrhage is unknown.

METHODS: We conducted a population-based study of patients aged 66 years or older with atrial fibrillation who commenced treatment with warfarin between April 1, 1997 and March, 31 2012. We ascertained socioeconomic status using neighbourhood level income quintiles. We followed patients for up to five years of continuous warfarin therapy, censoring on the first of drug discontinuation, mortality, or the end of the study period. We used Cox proportional hazards models to identify the association between income and hospitalization for hemorrhage. In a secondary analysis, we examined the association between income and fatal hemorrhage.

RESULTS: Among 166,742 patients with atrial fibrillation who commenced treatment with warfarin, 16,371 (9.8 %) were hospitalized for hemorrhage. After extensive multivariable adjustment, we observed an association between risk of hemorrhage and socioeconomic status, with those in the lowest income quintile facing an increased risk relative to those in the highest quintile (adjusted hazard ratio [HR] 1.17; 95 % CI 1.12 to 1.23). We also observed an association between socioeconomic status and fatal hemorrhage, with an increased risk of death in those in the lowest income quintile relative to those in the highest quintile (adjusted HR 1.27; 95 % CI 1.10 to 1.47).

CONCLUSIONS: In patients who commence warfarin therapy for atrial fibrillation, lower socioeconomic status is a risk factor for hemorrhage and mortality from hemorrhage. This factor should be considered when initiating and monitoring warfarin therapy.

Figure 1. Cumulative incidence of hemorrhage over time, by income quintile

SPECIALIST AWARENESS OF THE VA PATIENT-CENTERED MEDICAL HOME Jessica L. Zuchowski³; Alexis K. Huynh³; Susan E. Stockdale³; Lisa S. Meredith²; Antonio E. Robles^{3, 6}; Philip Roos^{5, 6}; Lisa V. Rubenstein^{1, 2}; Kristina M. Cordasco^{4, 3}. ¹GLA VA, North Hills, CA; ²RAND Corporation, Santa Monica, CA; ³US Dept of Veterans Affairs, North Hills, CA; ⁴VA Greater Los Angeles Healthcare System/UCLA, Los Angeles, CA; ⁵VA Loma Linda Healthcare System, Loma Linda, CA; ⁶Loma Linda University, Loma Linda, CA. (Tracking ID #2196239)

BACKGROUND: The Patient-Centered Medical Home (PCMH) model is a dominant trend in US healthcare delivery. A major PCMH focus is care coordination between the medical home and the specialist “medical neighborhood”. In 2010, the VA began transforming its primary care services into the PCMH model, called Patient Aligned care Teams, or “PACT”. Little is known about VA specialists’ awareness of PACT. We measured specialist-reported familiarity with the PACT model and assessed variations in familiarity in relationship to specialist characteristics.

METHODS: We conducted an online cross sectional survey of all VA specialist providers in Southern California and Southern Nevada. We asked specialists: “PACT stands for Patient Aligned Care Teams and is being implemented in facilities throughout VA as part of VA’s national mandate for redesigning its healthcare system. How familiar are you with the PACT initiative described above?” Specialists responded using a 4-point Likert scale (“I have never heard of PACT apart from in this survey;” “I have heard of PACT, but am not very familiar with it;” “I am somewhat familiar with PACT;” “I am very familiar with PACT”). We stratified specialists by type (medical, surgical, mental health, and other specialists); whether or not the specialist reported having a primary focus on any specific patient population in their work (e.g., geriatrics, women’s health, HIV/AIDS, homeless); employment status (full time or part time); and number of years employed by VA. We examined specialists’ responses overall and within each stratum. All analyses were weighted for non-response and performed in SAS 9.3.

RESULTS: Of the 1530 specialists invited to participate, 380 (25 %) responded. Specialist familiarity with PACT varied by specialist group: of the four categories of specialists, mental health specialists were most familiar with PACT, and surgical specialists were least familiar (25 and 70 % reporting not very familiar or never heard of PACT, respectively; p-value <0.0001). Specialist familiarity with PACT varied by employment status: specialists who were employed by the VA full-time were most familiar with PACT and those employed by the VA part-time were least familiar (32 and 70 % reporting not very familiar or never heard of PACT, respectively; p-value <0.0001). There was a significant trend toward specialist familiarity with PACT varying by the presence of a primary focus on any patient population: specialists reporting any patient population focus in their work were more familiar with PACT than those without a population focus (30 and 45 % reporting not very familiar or never heard of PACT, respectively; p-value=0.0542). There were no significant differences in specialist familiarity with PACT by the average number of years working in the VA.

CONCLUSIONS: Specialist familiarity with PACT varied significantly by specialist group, employment status, and population-based focus. Full achievement of PCMH goals will require high levels of communication and care coordination between the PCMH and the VA medical neighborhood. These results suggest the need for a systematic approach toward engaging specialists in PACT, including efforts to specifically target: surgical specialists, part-time specialists, and specialists without any patient population focus for additional education and engagement with primary care.

SPECIALTY PHYSICIANS’ BELIEFS ABOUT MEDICAID PATIENTS Meredith A. Niess¹; Irene V. Blair²; Arthur Davidson^{3, 4}. ¹University of Colorado, Aurora, CO; ²University of Colorado Boulder, Boulder, CO; ³Denver Health, Denver, CO; ⁴University of Colorado School of Medicine, Aurora, CO. (Tracking ID #2190781)

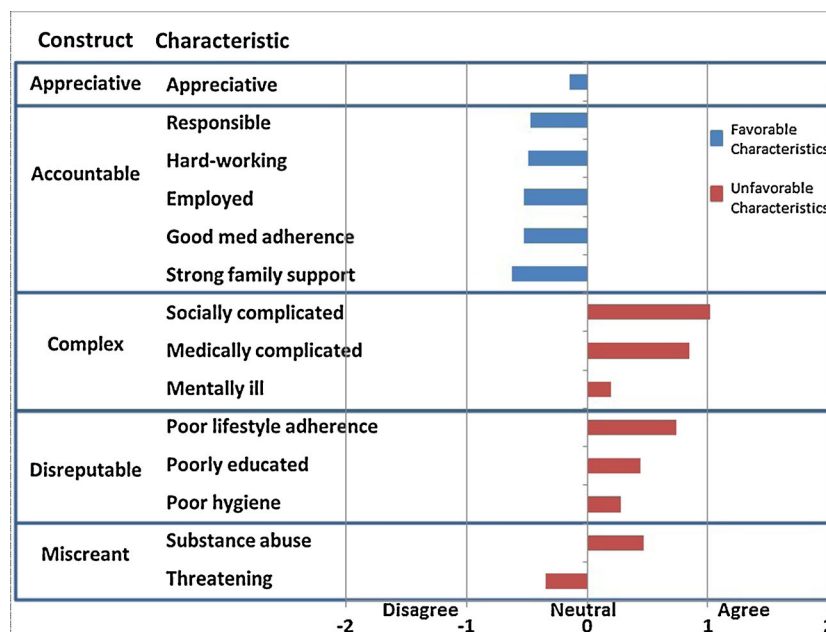

BACKGROUND: Medicaid is the largest health insurance provider in the United States, insuring more than 1 in 5 Americans annually. Nationally more than

30 % of office-based practices do not accept any Medicaid patients. Low acceptance of Medicaid is attributed nearly exclusively to inadequate reimbursement rates. Unfavorable perceptions about Medicaid patients may exacerbate this access gap, but are minimally described in existing literature. This survey of specialists describes their beliefs about Medicaid patients.

METHODS: We surveyed 1600 randomly selected Colorado Medical Society specialist members in April-June of 2014 via mail and email. Primary care physicians, hospitalists, pediatric specialists, and emergency physicians were excluded, along with retirees and trainees. Using a 5-point Likert-scale (strongly disagree to strongly agree) we assessed endorsement of 14 potential characteristics of “the typical adult Medicaid patient.” Our primary outcome was a composite belief score that combined respondent ratings such that a positive composite score=a favorable view of Medicaid patients and a negative score=an unfavorable view. We examined associations between the composite score and both respondent characteristics and their practice characteristics, retaining significantly associated variables in a multivariable regression model. Retained variables included years of practice experience, independent versus large employer practices, effect of productivity on individual income, and type of specialty practice. Using factor analysis, we identified distinct belief constructs underlying the clustering of respondents’ answers on the 14 characteristics. Our research team applied titles to these underlying belief constructs.

RESULTS: Eight hundred four of 1600 eligible physicians returned the survey with data on key variables, yielding a 50 % response rate. Respondents were predominantly male (74 %), white non-Hispanic (82 %), in practice for <20 years (53 %), and had ownership interest in their practice (72 %). Eighty-six percent of respondents had an unfavorable view of Medicaid patients on the composite belief score. Univariate analysis revealed significant associations between an unfavorable composite belief score and 10–20 years in practice, independent practice (versus large employer practice), higher income dependence on productivity, surgical or hospital-based specialty types (versus medical or ob/gyn), higher average specialty salary, and fewer Medicaid patients seen daily. In multivariable analysis, unfavorable beliefs remained significantly associated with independent practice, higher income dependence on productivity, and surgical or hospital-based specialty types. Factor analysis revealed 4 underlying constructs and a single item characteristic describing Medicaid patients: accountability, complexity, disreputability, miscreant, and appreciative (Figure 1). Respondents predominantly agreed with all unfavorable belief constructs and disagreed with all favorable belief constructs about Medicaid patients (Figure 2), consistent with the overall unfavorable beliefs found with the composite score.

CONCLUSIONS: Overall, specialty physicians in Colorado have an unfavorable view of Medicaid patients. These negative beliefs potentially affect both access to care and quality of care for Medicaid patients. Existing analysis of the Medicaid specialty access gap may oversimplify the cause as reimbursement. Policymakers may need to address negative beliefs about Medicaid patients to shrink the access gap.

Respondents’ description of a typical Medicaid patient.

	Belief Construct (from factor analysis)	% respondents agree	% respondents disagree	% neutral or non-response
Unfavorable	Complex	82%	8%	10%
	Disreputable	69%	13%	19%
	Miscreant	41%	31%	28%
Favorable	Accountable	13%	74%	13%
	Appreciative	28%	36%	37%

Respondent rates of agreement with belief constructs about Medicaid patients

SPECTRUM OF BREAST DISEASE AT RWANDA'S FIRST NATIONAL CANCER REFERRAL CENTER, JULY 2012-DECEMBER 2013 Lydia E. Pace¹; Jean-Marie Vianney Dusengimana³; Vedaste Hategekimana⁴; Hamissy Habineza³; Jean Bosco Bigirimana³; Neo Tapela^{1, 3}; Cadet Mutumbira⁴; Egide Mpanumusingo⁴; Nancy L. Keating^{2, 1}; Jane E. Brock¹; Susan Lester¹; Nzayisenga Ignace³; Deborah Dillon¹; Lawrence Shulman^{5, 1}; Tharcisse Mpunga⁴. ¹Brigham and Women's Hospital, Boston, MA; ²Harvard Medical School, Boston, MA; ³Partners in Health, Butaro, Rwanda; ⁴Ministry of Health, Butaro, Rwanda; ⁵Dana-Farber Cancer Institute, Boston, MA. (Tracking ID #2197897)

BACKGROUND: Programs to facilitate earlier diagnosis of breast cancer among patients with breast symptoms are urgently needed in low-and-middle-income-countries (LMICs). Understanding the presentations and distribution of breast diseases encountered in the early stage of a cancer program can guide clinical algorithms for evaluation of patients with breast concerns, and is important for resource allocation and quality improvement efforts. Prior to 2012, cancer services in Rwanda were extremely limited, and no facility had a breast clinic equipped to comprehensively evaluate and treat breast disease. We describe the spectrum of breast conditions evaluated in the breast clinic at Butaro Cancer Center of Excellence (BCCOE), Rwanda's first national cancer referral center, during its first 18 months.

METHODS: Using the electronic medical record, a list of all patients presenting with a breast concern to the oncology program's breast clinic from July 1, 2012-December 31, 2013, was compiled. We reviewed paper medical records to determine patients' evaluation and diagnosis. We excluded patients who had been diagnosed elsewhere with cancer and referred for management.

RESULTS: Among the 353 patients who presented with a breast concern during the 18 month study period, the median age was 41 (range 11–83) and 98 % were female. On exam, 289 (82 %) had a breast mass, 29 (8 %) had lymphadenopathy or another abnormality, 20 (6 %) had a normal exam, and 15 (4 %) had no initial exam documented. Biopsies were taken in 79 % of cases with abnormal exam findings. Among 168 breast cancers, 35 (21 %) were Stage I or II, 77 (46 %) were Stage III, and 51 (30 %) were Stage IV at diagnosis; for 5 (3 %), the stage was not documented. Among patients with a mass, 160 (55 %) had breast cancer, 105 (36 %) had benign disease, 6 (2 %) had non-breast cancers (including lymphoma and metastatic melanoma), and 18 (6 %) had no clearly documented diagnosis in the record. Among benign masses that were biopsied ($n=82$), proliferative mass-forming lesions including fibroadenomas were most common ($n=36$; 44 %), followed by non-proliferative mass-forming lesions ($n=19$; 23 %), inflammatory lesions ($n=9$; 11 %), changes related to pregnancy or lactation ($n=5$; 6 %), non-specific pathologic findings ($n=5$; 6 %), and normal breast tissue ($n=8$; 10 %). For half of patients with a documented mass but unknown diagnosis ($n=9$), biopsy was recommended but not performed or a pathology result was not found.

CONCLUSIONS: Following the opening of Rwanda's first national cancer referral center, more than half of patients presenting with an undiagnosed breast mass had breast

cancer, and most breast cancers were Stage III or IV at diagnosis. This is a much higher breast cancer detection rate than has been reported in other settings in Africa, though the breast cancer stage distribution is similar. As awareness of breast cancer and the availability of services increase, it will be important to monitor and describe changes in the relative proportions of benign and malignant disease at BCCOE, as well as the breast cancer stage distribution. Our findings will help inform innovative strategies in rural primary care facilities to allow efficient and effective evaluation and triage of women with breast complaints, assuring timely and earlier stage diagnoses.

STABILITY IN HEALTH LITERACY ASSESSMENTS OVER A THREE YEAR PERIOD AMONG OLDER ADULTS Laura M. Curtis; Rachel O'Connor; Michael S. Wolf. Northwestern University, Chicago, IL. (Tracking ID #2199184)

BACKGROUND: Numerous studies have found strong associations between older age and limited health literacy in cross-sectional analyses, suggesting age-related decline in the ability to manage one's health. However, few studies have examined health literacy performance prospectively, and not merely as a test-retest assessment of measures. We sought to examine changes in performance across time on the three most common health literacy measures and determine whether performance declines more rapidly after age 65.

METHODS: Adults between the ages of 55 and 74 receiving care at either an academic general internal medicine ambulatory care clinic or one of five federally qualified health centers in Chicago, Illinois were recruited for a National Institute of Aging study. Structured interviews including the Test of Functional Health Literacy (TOFHLA), the Rapid Estimate of Adult Literacy in Medicine (REALM), and the Newest Vital Sign (NVS) were completed by 560 patients at two time points 3.2 (SD=0.4) years apart. Changes in total scores from baseline to follow-up were calculated for each of the measures and decline was tested using paired t-tests. Differences in change scores were compared between participants who were less than 65 and 65+ at baseline using two-sample t-tests. Change scores were then modeled with age (<65 vs. 65+) as the main independent variable of interest, controlling for baseline health literacy score, gender, race, education, income, number of chronic conditions, and amount of time between interviews.

RESULTS: Participants had a mean (SD) age of 63(5.4) years at baseline, 69 % were female, 56 % White, and 38 % African American. Baseline literacy levels differed depending on the test, with 26 % having limited literacy on the TOFHLA (total score < 75), 22 % on the REALM (total score < 61), and 49 % on the NVS (total score < 4). Total scores decreased but not significantly for the TOFHLA (-0.22 (8.07), $p=0.53$) and NVS (-0.07 (1.38), $p=0.21$), while increasing slightly for the REALM (0.23 (3.29), $p=0.11$). TOFHLA scores did significantly decrease among participants age 65 and older at baseline (Mean change (SD) -1.14 (8.17), $p<0.05$) and differed significantly from those less than 65 (Mean change (SD) 0.33 (7.98), $p=0.04$). However, the two age groups performed similarly on the REALM and the NVS. In multivariable models, TOFHLA scores declined more significantly in those 65 and older compared to those less than 65 (β

−2.43, 95 % Confidence Interval (CI) −3.80, −1.06, $p=0.001$). No significant differences between the two age groups were found in literacy scores measured using the REALM or the NVS (β −0.11, 95 % CI −0.66, 0.44, $p=0.70$; β −0.21, 95 % CI −0.44, 0.02, $p=0.07$, respectively).

CONCLUSIONS: Performance on health literacy measures overall did not decline significantly during the 3 year follow-up period in this cohort, however participants over 65 years of age demonstrated significantly poorer performance on the TOFHLA. While the extent of decline may still be subtle, such detriment over time is similar to what has consistently been seen in older patients' fluid cognitive abilities. Future studies should further investigate with greater precision changes in health literacy among elderly persons. Such investigations could directly justify and inform the development of interventions that could mitigate decline in health literacy and subsequent self-management skills.

STAFF ROLES ON PRIMARY CARE TEAMS ARE FAILING TO ALIGN WITH PHYSICIANS' EXPECTATIONS AND NEEDS

Karleen Giannitrapani³; Alison Hamilton⁴; Alexis K. Huynh⁵; Susan E. Stockdale²; Lisa V. Rubenstein¹. ¹GLA VA, North Hills, CA; ²Greater Los Angeles VA Healthcare System, Sepulveda, CA; ³UCLA / VA GLA, Los Angeles, CA; ⁴US Department of Veterans Affairs, Los Angeles, CA; ⁵Veterans Affairs, Sepulveda, CA. (Tracking ID #2196596)

BACKGROUND: The VA has implemented a patient-centered medical home (PCMH) model called Patient Aligned Care Teams (PACT). In PACT, primary care staff including Registered Nurses (RNs), Licensed Practical Nurses (LPNs), Health Techs and Clerks are assigned to interdisciplinary working groups called "teamlets" which support a primary care provider (PCP) in caring for a consistent panel of patients. With the aim of shifting tasks off of PCPs, PACT staff roles have been expanded to include top-of-license tasks. We sought to identify challenges associated with this role expansion on PACT teamlets.

METHODS: We conducted interviews to assess the experiences of teamlet members during early PACT implementation. A strata sampling approach captured teamlet members in each of four PACT roles: PCPs (Physicians, Nurse Practitioners, and Physician Assistants), RNs, clinical associates including LPNs and Health Techs, and Clerks. With the aid of a semi structured interview guide we assessed 1) how teamlet members were informed about their PACT roles and responsibilities, and 2) how these roles affected professional dynamics in the teamlets. Interviews were recorded, transcribed, and analyzed using team-based, consensus-driven, content analysis techniques

RESULTS: Seventy-nine members of PACT teamlets from six VA clinics in Southern California including PCPs ($n=29$), RNs ($n=18$), LPNs ($n=20$), and clerks ($n=12$) participated in interviews. We identified three interdisciplinary coordination failures that inhibit non-PCP teamlet members from fully assuming the PACT roles and responsibilities that would best support their PCPs. First, we identified insufficient coordination between medicine (PCP) and nursing leadership about staff roles, with inconsistent understandings across leaders about the responsibilities of the non-PCP teamlet members (e.g., RNs). "Nursing leadership needs to talk to physician leadership—it's frustrating sometimes because my provider will come back from a meeting [with Physician Leadership] and we'll say we were told this by our nursing leadership and they [Providers] were told we would do something totally different [RN]. Second, we found that PCPs were not consistently informed about the parameters of the non-PCP teamlet members' roles, and therefore often asked these individuals to engage in tasks that were not approved by their direct line supervisors. "A nurse will say, "Well, I want to do this for you, but at the same time we were told we're really not supposed to do this for you." And so I [the PCP] say, "Well, I'm the physician here. I'm making a clinical decision. I tend to feel that I'm placing the RN or the LVN in a quandary in a sense that, okay, who do I follow, my nursing leader or my doctor." [PCP] This contributed to the third coordination failure, which was that the parameters set by non-PCP supervisors often did not align with the needs of the PCPs. PCPs expressed frustration that their needs were not being accommodated within the expanded non-PCP roles. "The issue here is defining the roles... frustration comes from the fact that they're [the nurses] are not getting laws or mandates from their leadership that would best suit physician's desires." [PCP]

CONCLUSIONS: PCPs need to be informed about the parameters of non-PCP staff roles as well as have a mechanism to provide input about the parameters. This would enable staff roles to better align with providers' expectations and needs. Implementing role changes for staff working on primary care teams requires interdisciplinary coordination. Our findings thus lend support to interdisciplinary leadership approaches to implementation of the primary care patient centered medical home.

STATIN-USERS' MORAL HAZARD IN DIET MAY BE AN AMERICAN PHENOMENON

Sachiko Ohde¹; Gautam A. Deshpande³; Osamu Takahashi^{2, 1}. ¹St. Luke's Life Science Institute, Tokyo, Japan; ²St. Luke's International Hospital, Tokyo, Japan; ³St. Luke's Life Science Institute, Chuo, Japan. (Tracking ID #2180254)

BACKGROUND: A recent report of US adults by Sugiyama et al. analysing NHANES data showed a significant increase in calorie and fat intake, as well as BMI, among statin users compared to nonusers¹. Hypothesizing that this moral hazard among statin users may be specific to the U.S., we analysed BMI change over time in statin users versus non-users in an apparently healthy Japanese screening population using longitudinal data.

METHODS: Data included all individuals presenting for health screening at St. Luke's International Hospital Center for Preventive Medicine (Tokyo, Japan) at least twice between 2005 and 2010. Patients were stratified into two groups based on self-reported statin use. Linear random effects models with random intercepts (initial BMI value), adjusted for age, gender, and statin use by year were used to derive parameters describing BMI progression.

RESULTS: Of 60,181 apparently healthy Japanese adults (mean baseline age, 46.8 years, SD 12; 49.5 %, female), 2368 patients were prescribed a statin on their first visit. Mean baseline BMI of statin users and non-users were 23.8 (SD 3.5) and 22.4 (SD 3.3), respectively. BMI decreased by an estimated 0.06 kg/m² (95 % CI: −0.07 to −0.04, $p<0.001$) per year among statin users, while only decreasing 0.007 kg/m² (95 % CI: −0.01 to −0.004, $p<0.001$) per year among non-users (Table 1).

CONCLUSIONS: Statin-users' moral hazard in diet appears to be absent in a Japanese health screening population. Where the phenomenon occurs, adoption of standardized screening programs that offer targeted patient intervention may be effective for promoting optimal behavioral changes to supplement pharmacotherapy.

Linear random effects models for yearly change in BMI, adjusted for age and gender

STOP THE PRESSES? A SURVEY OF INFORMATION AND LEARNING PREFERENCES AMONG GENERAL INTERNISTS IN THE INFORMATION AGE

Bradley H. Crotty¹; Vineet M. Arora⁷; Leslie V. Dunne⁴; Kevin Hwang⁵; Neil Mehta²; Alexander K. Smith⁶; Richard M. Frankel³. ¹Beth Israel Deaconess Medical Center, Brookline, MA; ²Cleveland Clinic Lerner College of Medicine of Case Western Reserve University, Cleveland, OH; ³Indiana University School of Medicine, Indianapolis, IN; ⁴SGIM, Alexandria, VA; ⁵The University of Texas Medical School at Houston, Houston, TX; ⁶University of California, San Francisco, San Francisco, CA; ⁷University of Chicago Medical Center, Chicago, IL. (Tracking ID #2199226)

BACKGROUND: General internists have a daunting task of keeping up with new medical advances given the rise in biomedical publications and the time demands of clinical practice. In addition to becoming aware of new research, they must also assess its applicability to patient care in their practice. Clinical colleagues can one another with information and appraisals of new data, which may be helpful for physicians in sifting through medical publications. In the modern Internet era, online social networks may help physicians filter information relevant to their practice based upon what their peers are reading and recommending. However, social networks may be relatively 'noisy' and inundate physicians with irrelevant information. With the goal of improving the delivery of high-value information to physicians and as part of an AHRQ grant to the Society of General Internal Medicine (SGIM), we sought to understand how general internists gather and appraise information, and their preferred information channels.

METHODS: This was a cross-sectional survey of the physician membership ($n=3619$) of SGIM from March to December, 2014. We asked physicians about their confidence in staying abreast of new medical information, their strategies for ongoing learning, their preferred information channels, and what steps are necessary before they adopt new information into practice. We stratified based on training status, specialty, and self-reported technology adoption tendencies. Respondents were asked how they would like to receive information in a free-text question, and responses were coded. Differences in continuous variables were assessed by Wilcoxon Rank-Sum tests and in categorical variables by Chi-Square tests.

RESULTS: Four hundred seventy-eight physicians responded for an estimated response rate of 13 %. Attending physicians represented 82 % of respondents, while trainees represented 18 %. Seventy percent of physicians reported finding it difficult to keep up with new medical information, though 92 % make deliberate efforts to stay up to date. Topical reviews of information, professional conferences, and conversations with peers were the most highly rated sources of information (table). E-mail is still a common way physicians wish to be alerted of new practice-changing information, with 52 % of respondents mentioning e-mail within their free-text response. Professional conferences and practice peers were valuable sources of information. Most avoided online social networks for information, though trainees rated slightly them more preferable than did attending physicians. For reading information in depth, attending and training physicians preferred printed journals/articles over computer-based web browsers, mobile phones and tablets. However, early adopters of technology marginally

preferred web over print (37 vs 36 %). Before deciding to change their practice, physicians preferred to have guidelines, and 52 % of trainees ranked these as most important factor (mean rank 1.8/5) when adopting new knowledge compared with 36 % of attendings (mean rank 2.1) ($p<0.01$). However, many also wished to review the primary article (mean rank 2.6 and 2.3 for trainees and attending respectively, $p=0.06$).

CONCLUSIONS: Despite regular efforts to stay apprised of new medical information, most general internists in this sample found it difficult to keep up. Reliance on guidelines, topic updates, and e-mail alerts may signify an increasing reliance on pre-digested data in this fast-paced information age. Interestingly, print was the most highly ranked medium for reading in-depth overall, and a very close second to the web among early adopters of technology. Generalists were not fond of either professional or personal online social networks for learning about new information, despite placing a high value on their "offline" social networks. This may be due to either a separation of work/personal personae online, an unfavorable signal to noise ratio, or other factors. Interventions that provide synopses and context to busy generalists, with links to the primary articles, may help better disseminate new knowledge. Despite the increasing trend for journals to abandon print media, print media is considered the most best source for in-depth reading. Engaging peers and reputable colleagues in spreading this information may be synergistic. These insights will be used to design an intervention to improve delivery of medical information to SGIM members.

STRENGTHENING INFORMATION EXCHANGES IN RESIDENT SIGN-OUTS: THE ROLES OF RESPONSIBILITY AND ACCOUNTABILITY Soo Hoon Lee^{3, 1}; Dale A. Fisher²; Wei-Ping Goh⁴; Heidi Mah⁴; Phillip Phan^{1, 2}. ¹Johns Hopkins University, Baltimore, MD; ²Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore; ³Old Dominion University, Norfolk, VA; ⁴National University Hospital, Singapore, Singapore. (Tracking ID #2192647)

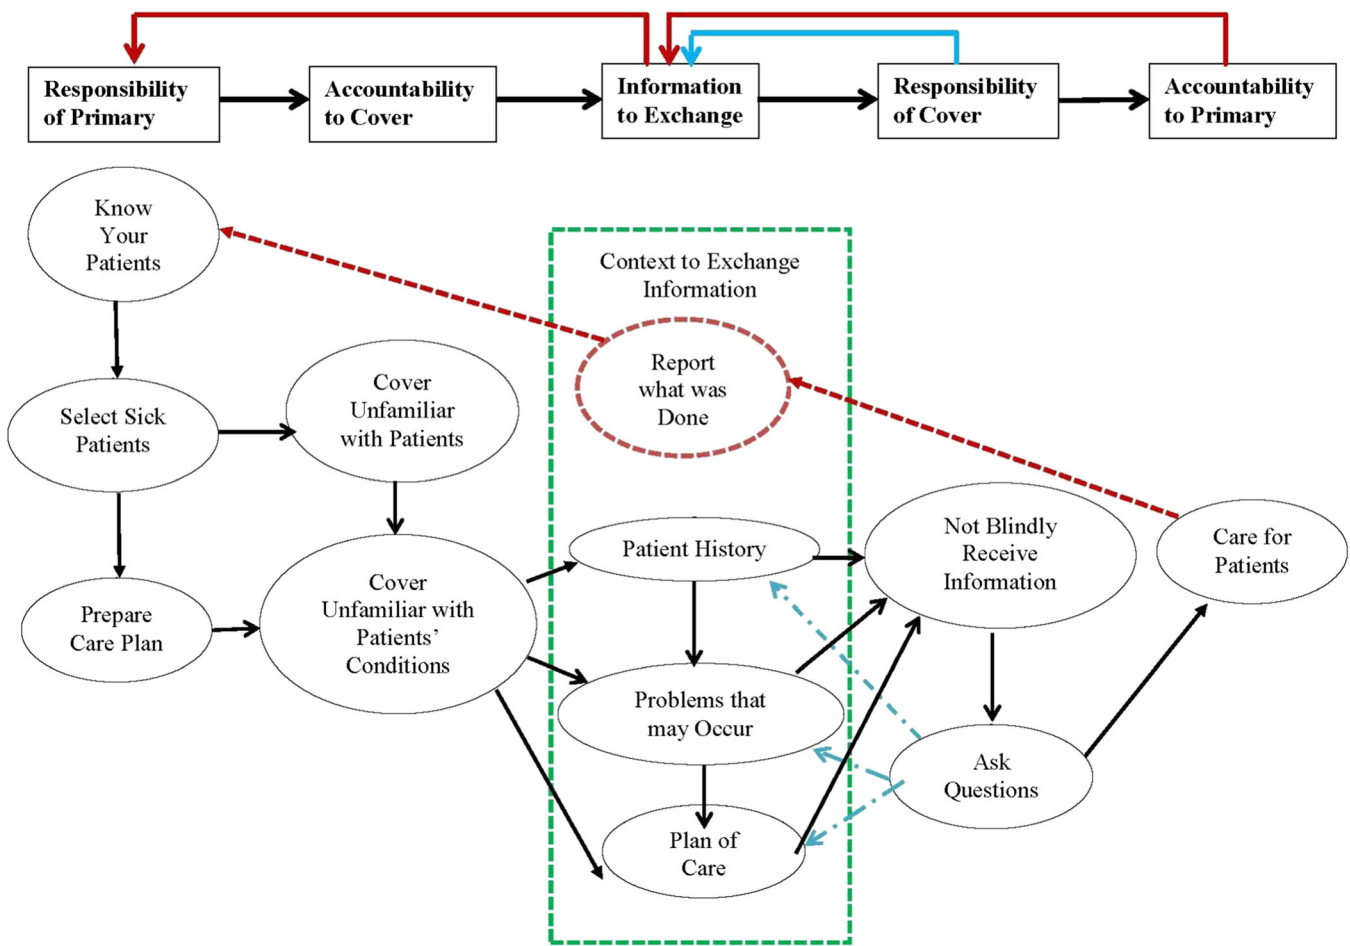

BACKGROUND: Sign-out is critical to the transition of patient care between shifts. The literature on sign-outs focuses on information exchange with little attention to other dimensions, such as the transfer of responsibility and accountability. We hypothesize that a process view linking the transfer of responsibility and accountability to information exchange is better for understanding how sign-outs relate to clinical outcomes.

METHODS: Design. A qualitative study using one-on-one semi-structured interviews, archival data, and observations. Setting. A 1100-bed tertiary academic hospital in Singapore. Prior to November 2011, sign-outs to six night coverage residents were ad hoc. Eight sentinel events between 2008 and 2010 identified sign-outs as a root cause of risk, leading to a 2.5-day Rapid Improvement Event on sign-outs in November 2011 with staff participation from every level and department. Intervention. A formal sign-out protocol with a minimum data set for information exchange, protected time and location, senior physician supervision, and prioritization of patients by acuity (tiering) for type of sign-out (face-to-face, phone, text, or none by decreasing levels of acuity). Data. In

December 2012, we conducted 60-min interviews with residents, registrars, a clinical director, and a hospital vice-president from General Medicine, Pediatrics, Cardiology, and Anesthesiology. We followed up with archival data and direct observations to validate the interview information. In June 2013, we conducted a second round of interviews to track protocol implementation. Analysis. We analyzed audio-taped interview transcripts according to guidelines by Strauss and Corbin (1990). We used in-vivo open coding to identify and categorize initial concepts in the data. We used axial coding to identify second order themes from the first order conceptual categories. We then extracted overarching dimensions by grouping the second order themes. We did this iteratively, using different starting points in the data until we reached theoretical saturation, to ensure convergence.

RESULTS: While the formal sign-out protocol facilitated efficient information exchange, primary residents took personal responsibility to identify high-risk patients that needed vigilance at night and held themselves accountable to provide thoughtful plans of care to night coverage residents in order to facilitate the tiering decision. In turn, night coverage residents took personal responsibility to ask questions about the plans of care since they had not previously seen those patients. Figure 1 illustrates the structure of the data.

CONCLUSIONS: Until a more efficient (e.g., electronic) handover system is established to facilitate sign-outs for large numbers of patients to a small team of night coverage, tiering patients seemed an optimal method to increase patient safety at night. This system fostered a formal process of information exchange that gave rise to explicit two-way transfers of responsibility and accountability between primary and coverage residents. The net result was increased confidence of night coverage residents to care for patients at night.

STRIVING TOWARD TEAM-BASED CONTINUITY: COVERAGE ARRANGEMENTS IN VHA ACADEMIC PRIMARY CARE CLINICS AND IMPLICATIONS FOR MEDICAL HOME URGENT ACCESS AND CONTINUITY METRICS Jane Forman²; Claire H. Robinson¹. ¹VA Ann Arbor Health Care System, Ann Arbor, MI; ²VA HSR&D, Ann Arbor, MI. (Tracking ID #2199898)

BACKGROUND: Improving timely access to primary care while maintaining continuity with the patient's primary care provider (PCP) is an important goal of patient-centered medical homes (PCMH). In the Department of Veterans Affairs (VA) medical home initiative, Patient Aligned Care Teams (PACT), care is provided by a dedicated team, including PCPs, nurses, and administrative staff. To promote quality improvement, VA has set key metrics for same-day visit requests with the patient's assigned PCP (access), and the proportion of visits completed with the patient's assigned PCP (continuity). One hundred twenty of approximately 900 VHA primary care clinics are located in academically-affiliated medical centers, and have a dual mission of providing patient care and training resident PCPs in the medical home model. Because all resident PCPs (and many staff PCPs) in academic clinics are available to provide clinical care on a part-time basis, these clinics must provide coverage for their patients when they are not in clinic, and face special challenges in meeting metrics based on in-person visits with the patient's assigned PCP compared to smaller, community-based non-academic clinics. There has been no national study to date aimed at understanding how academic primary care clinics provide coverage for same-day requests when a patient's resident PCP is not in clinic, and implications for access and continuity and its measurement.

METHODS: As part of a multi-site quality improvement project, we conducted semi-structured telephone interviews with members of Primary Care clinic leadership involved with residency programs at 19 VHA academic medical centers across 16 of 21 Veterans Integrated Service Networks (VISNs). Interviews took place from December 2013

through October 2014 and lasted approximately 1 h. All interviews were audio recorded and transcribed verbatim. Participation in the project was completely voluntary. We created comprehensive, structured summaries from the interview transcripts, and conducted matrix analysis to identify themes and patterns across sites. We used NVivo v.10 to organize and manage our data.

RESULTS: Almost all sites took a team-based approach to coverage for same-day visit requests, usually prioritizing either the absent resident's attending PCP or another resident of that attending (both of which count toward meeting the continuity metric), then another resident or PCP on the same team, then any resident or PCP, either on another team or in a walk-in/urgent care clinic. The degree of formality and organization of coverage arrangements varied, from having a detailed algorithm for schedulers in the electronic scheduling system to simply hoping a team resident would be available. Success with implementing team-based urgent access depended on the predictability of resident and attending schedules, ability to have attendings and their residents in clinic at the same time, availability of open visit slots, and scheduler knowledge of preferred coverage arrangements. University affiliates largely controlled resident schedules, and coverage was generally more complex at sites with part-time attendings who had their own patient panels. Successful coverage arrangements that promoted both continuity of care and teaching missions included resident "micro-PACTs" with dedicated RN, LPN, and clerk staff, creating multidisciplinary practice partner triads, pairing up residents on opposite ambulatory and inpatient blocks, and having mid-level providers as part of the team and coverage algorithm. Most interviewees said academic clinic could not meet metrics as currently designed; however, some sites reported that the metrics had had some positive consequences, such as scheduling residents and their attendings to be in clinic together more often. Sites uniformly recommended a transition to team-based urgent access and continuity metrics that provided more flexibility in defining a team. Some sites emphasized inclusion of groups of residents and attendings, almost all sites would include RNs, and one site would include extended team members such as clinical pharmacists. Team-based

metrics were thought to be a better fit with on-the-ground efforts to provide urgent access and continuity, to incentivize team-based care as envisioned in the PACT model, and to improve resident training in team-based care.

CONCLUSIONS: Team-based urgent access and continuity metrics are currently being developed by VA, and may encourage creative coverage arrangements in academic clinics that improve continuity and care quality, and that are more congruent with the interdisciplinary team-based care at the heart of the PCMH model. Designers of PCMH performance measures should take into account the constraints imposed on academic clinics by residency programs, and allow the flexibility that these clinics need to both meet patient-centered care goals and provide rich trainee education in continuous team-based care.

STRONGER ALCOHOL POLICIES LINKED TO LOWER ALCOHOLIC CIRRHOSIS MORTALITY RATES IN THE UNITED STATES Scott E. Hadland^{1, 2}; Ziming Xuan³; Jason G. Blanchette³; Timothy Heeren³; Timothy S. Naimi^{4, 3}. ¹Boston Children's Hospital, Boston, MA; ²Harvard Medical School, Boston, MA; ³Boston University School of Public Health, Boston, MA; ⁴Boston University School of Medicine, Boston, MA. (Tracking ID #2193589)

BACKGROUND: Stronger alcohol policies have been linked to decreased alcohol consumption and binge drinking in the United States. We examined the relationship between the strength of states' alcohol policies and alcoholic cirrhosis mortality rates.

METHODS: To quantify the alcohol policy environment in each state, we used the Alcohol Policy Scale (APS), a validated assessment of alcohol policies across 50 states and Washington DC. The APS combined ratings on the efficacy and implementation of 29 policies nominated by a Delphi panel of policy experts from a range of disciplines, including law, epidemiology, psychology, sociology, and economics. Examples of policies incorporated into a state's APS score included alcohol taxes, retail price restrictions, and hours of sales regulations, among other policies. The theoretical range of the APS score

was 0 to 100, with high APS scores representing strong alcohol policy environments. State-level APS scores for each year between 1999 and 2008 were related to age-adjusted alcoholic cirrhosis death rates obtained from the US Centers for Disease Control and Prevention for each year between 2002 and 2011, based on a 3-year lag between policies and their associated mortality rates. We used Poisson regression with robust sandwich standard error estimates to account for state-level clustering. We also stratified analyses by census region to examine geographical differences in the association between APS and mortality. Analyses adjusted for state-level race/ethnicity, college education, insurance status, household income, religiosity, policing rates, and level of urbanization.

RESULTS: Across states from 1999 to 2008, the mean APS score was 41 (range, 23 to 66), and increased over the study period (mean APS in 1999, 38; mean APS in 2008, 42; $p < 0.001$). The mean age-adjusted alcoholic cirrhosis mortality rate across the US from 2002 to 2011 was 4.7 deaths per 100,000 per year (95 % confidence interval [CI], 4.2–5.3) with a range of 2.5 (Pennsylvania) to 10.3 (New Mexico). Alcoholic cirrhosis mortality rates were associated with the proportion of individuals of American Indian / Alaska Native ancestry in a state ($r^2 = 0.319$; $p < 0.001$). Overall, higher APS scores were significantly associated with lower alcoholic cirrhosis mortality among the entire population (adjusted incidence rate ratio [IRR], 0.89 per 10-point increase in APS score; 95 % CI, 0.82–0.97), and among females (adjusted IRR, 0.82; 95 % CI, 0.82–0.97) but not males (adjusted IRR, 0.94; 95 % CI, 0.87–1.01). However, significant variation was found by geographical region: for females, higher APS scores were significantly associated with lower mortality in the Northeast geographical census region (adjusted IRR, 0.39; 95 % CI, 0.25–0.61) but not in the Midwest, South, or West; for males, higher APS scores were significantly associated with lower mortality in the Northeast (adjusted IRR, 0.71; 95 % CI, 0.60–0.84) and the West (adjusted IRR, 0.83; 95 % CI, 0.70–0.99), but not in the Midwest or South.

CONCLUSIONS: Stronger state-level alcohol policy environments are associated with lower alcoholic cirrhosis mortality. Future studies should scrutinize this relationship to determine the direction of causality of this relationship, and delineate which alcohol policies are most protective.

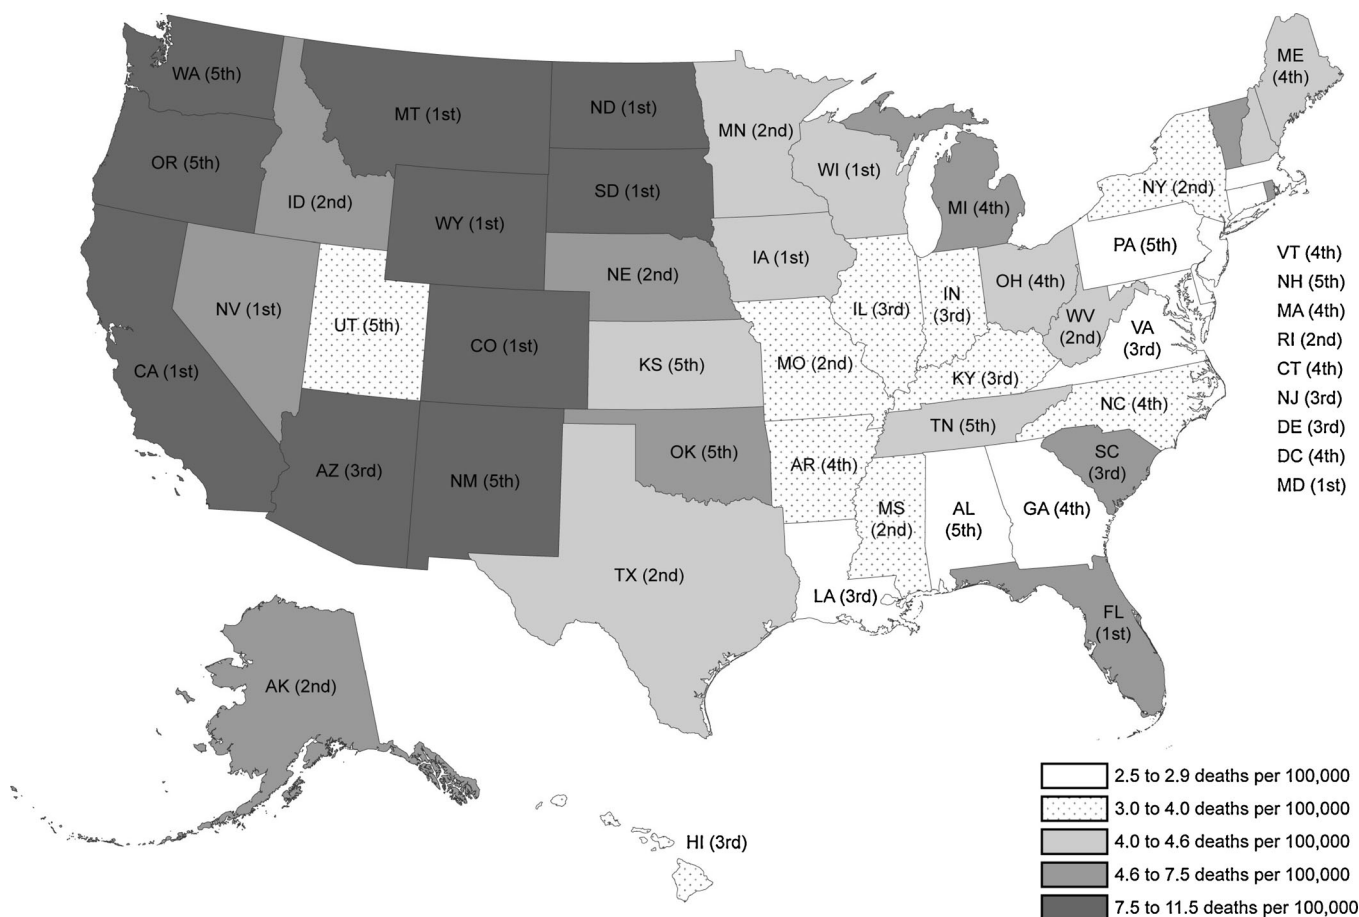

FIGURE: Overall state age-adjusted alcoholic cirrhosis mortality rates and associated alcohol policy scale (APS) score quintiles. Mortality rates are from 2010 to 2011 and alcohol policy scale scores are from 2008 to introduce a 3-year lag between APS score and associated mortality. Darker shading indicates higher mortality, as indicated in the legend. The 1st quintile corresponds to the lowest APS scores (weakest policy environments); 5th quintile, the highest (strongest policy environments).

SUBSTANCE USE IN A POPULATION-BASED SAMPLE OF OLDER HOMELESS ADULTS Matthew A. Spinelli¹; Claudia Ponath¹; Lina Tieu¹; Emily E. Hurstak¹; David Guzman¹; Margot Kushel¹ University of California, San Francisco, San Francisco, CA. (Tracking ID #2190894)

BACKGROUND: The median age of the homeless population is rising, with half of homeless adults 50 and older. Homeless adults have higher rates of substance use disorders (SUDs) than non-homeless adults, but, in the general population, rates of SUD decrease with age. Rates of SUD in older homeless adults have not been well described.

METHODS: We conducted purposive population-based sampling of homeless individuals aged 50 and older in Oakland, CA from homeless encampments and recycling centers, homeless shelters and low-cost meal programs ($n=350$). Inclusion criteria included: English speaking, age 50 or over, homeless at recruitment based on the Homeless Emergency Assistance and Rapid Transition to Housing (HEARTH) criteria, and able to give informed consent. An initial interview included questions about demographics, health status, substance use and alcohol use and treatment. We used questions derived from the Addiction Severity Index (ASI) to capture lifetime use, and the WHO's Alcohol Use Disorders Identification Test (AUDIT) and the WHO's Alcohol, Smoking, and Substance Involvement Screening Test (ASSIST) to measure current use. We measured depression using the Center for Epidemiologic Studies Depression Scale (CES-D; score ≥ 15) and for PTSD the Primary Care PTSD Screen (PC-PTSD; score ≥ 50). We used descriptive statistics to analyze substance use.

RESULTS: Among 350 participants, 77.1 % were male, 29.1 % were ages 50–54, 33.4 % were ages 55–59, 25.4 % were ages 60–64 and 12.0 % were ages 65 and older. The majority (79.7 %) was African-American, 10.9 % were non-Hispanic white and 4.6 % were Hispanic. Depression and PTSD were present in 53.3 and 32.6 % respectively. Over half (55.1 %) reported fair or poor health. In the 180 days prior to interview, 46 % were principally unsheltered, 25.1 % used shelters, 16.3 % lived unstably with family and friends, and 12.3 % were recently homeless. At-risk cocaine use was more common among African Americans, with 48.0 % having at-risk use compared to 21.0 % of non-Hispanic whites ($p=0.001$), while at-risk amphetamine use was more common among non-Hispanic whites, with 31.6 % having at-risk use compared to 4.3 % of African Americans ($p<0.0001$). Men were more likely than women to have at-risk alcohol use, 28.0 % versus 16.2 % ($p=0.03$). At-risk illicit drug use declined by age group, with 77.5 %, 59.8 %, 60.7 %, and 54.8 % reporting at-risk use for ages 50–54, 55–59, 60–64 and 65+ respectively ($p=0.005$). At-risk alcohol use did not demonstrate a statistically significant decline. Fewer than a third (31.1 %) of participants with current at-risk alcohol use had ever accessed treatment, while 51.8 % of participants with current at-risk non-alcohol drug use had ever received treatment.

CONCLUSIONS: Despite the older age distribution, substance use disorders (SUDs) are common among older homeless adults, with proportions similar to those seen in previous studies of the overall homeless population. We found that rates of at-risk illicit substance use were lower with increasing age in our sample, which could reflect a survival effect or changing behavioral patterns with advancing age. In contrast, rates of alcohol use remained high throughout all age strata we studied. This may reflect the overall poor access to alcohol treatment observed in our sample. Despite the aging of the population, SUDs remain a key health concern in homeless populations. Substance use treatment programs should take into account the needs of older homeless individuals, who may face additional barriers to treatment and health risks of continued use.

At-risk substance use

Substance	Current at-risk use % (moderate or greater severity)
Alcohol	25.8
Any illicit drug	64.6
Cocaine	43.1
Opioid	12.9
Amphetamine	8.0
Cannabis	39.1
Sedative	2.5
Hallucinogen	1.4
Inhalant	1.2

SUSPICION OF CANCER CLINIC: A POTENTIAL MODEL FOR FACILITATING OUTPATIENT CANCER DIAGNOSIS IN UNDERSERVED PATIENT Safina Hossain²; Amir Mehrvarz Sarshekah¹; Sarah Mougalian⁴; Meghan Karuturi³; Alex Zarzour³; Alyssa Rieber³; Jennifer Swails¹. ¹University of Texas at Houston, Houston, TX; ²University of Texas at Houston, League City, TX; ³MD Anderson Cancer Center, Houston, TX; ⁴Yale School of Medicine, New Haven, CT. (Tracking ID #2199182)

BACKGROUND: Patients with concerning findings for malignancy experience significant stress while awaiting final diagnosis, and delayed diagnosis may contribute to disparities in cancer survival among underserved patients. Innovative practice models aimed at these high-risk patients may improve clinical outcomes and reduce cost. The suspicion of cancer clinic (SOCC) was started in May 2013 to address this need after data showed that average time to outpatient diagnosis of a new malignancy within our system was 70 days, with 94 days until the first oncology appointment. Excess cost to the system from unnecessary hospitalization and ER visits was estimated at \$723,445 over 20 weeks. One year after implementation of the clinic, we aimed to determine whether this specialized outpatient suspicion of cancer clinic expedited evaluation in patients eventually diagnosed with cancer.

METHODS: This retrospective chart review was conducted on 100 patients between November 2013 and December 2014 at the Lyndon Baines Johnson (LBJ) Hospital SOCC and compared to a historical control group of 104 patients diagnosed with cancer in 2011. Time, in days, from presentation with abnormal signs and symptoms to evaluation at LBJ medical oncology clinic was measured. Patients with cancer diagnosed at an outside hospital, previously diagnosed cancer within HCHD, or with no established diagnosis at time of chart review were excluded from final data analysis.

RESULTS: After exclusion criteria were applied, 42 patients in the SOCC group and 56 patients in the control group were included in the analysis. Most patients were excluded due to diagnosis outside of our healthcare system. The SOCC decreased the mean time from presentation to oncology appointment by 42 days ($P=0.001$, 95 % CI 16.2 to 69.9). The groups differed significantly with respect to the type of cancer diagnosed. SOCC patient primarily had lung (21.4 %) and upper GI (14.3 %) malignancy, but the control group was primarily composed of breast cancer (32.1 %) and colorectal cancer (19.6 %).

CONCLUSIONS: The SOCC significantly reduced time from presentation to oncology appointment compared to a historical control group in the Harris County Health District. A potential confounder is the differing proportions of each cancer between the groups (e.g., higher proportion of breast cancer diagnosis in the control group). Benefits that could be derived from expediting the process of cancer diagnosis in the outpatient setting include earlier stage of cancer diagnosis, earlier treatment initiation, reduction in healthcare disparities and cost reduction in cancer diagnosis. Similar studies of a larger size are needed to further validate the benefit of such a specialized clinic, as well as cost-effectiveness studies.

SUSTAINABILITY OF A TAILORED BEHAVIORAL INTERVENTION TO IMPROVE HYPERTENSION CONTROL: OUTCOMES OF A RANDOMIZED CONTROLLED TRIAL Maria Antonia Rodriguez²; Jennifer P. Friedberg³; Binhuan Wang¹; Yixin Fang¹; Sundar Natarajan^{2, 1}. ¹New York University, New York, NY; ²VA New York Harbor Healthcare System, New York City, NY; ³VA New York Harbor Healthcare System, New York, NY. (Tracking ID #2201363)

BACKGROUND: The efficacy of blood pressure (BP) lowering through medication, diet, and exercise is established. Recent national guidelines recommended blood pressure (BP) control goals of systolic BP [SBP] <130 mm Hg and diastolic BP [DBP] <80 mm Hg in diabetes or kidney disease, or SBP <140 mm Hg and DBP <90 mm Hg in all others. However, a substantial proportion of patients with hypertension continue to have uncontrolled BP. While behavioral interventions can lower BP, little is known about their sustainability when the intervention ends. We previously reported on the effect of a tailored behavioral intervention to lower BP at 6 months. Here, we report on a key prespecified goal, assessing sustainability of the intervention at 12 months, i.e., 6 months after stopping the intervention.

METHODS: We conducted a three-arm, randomized controlled trial to evaluate the effectiveness of two active interventions, 1) a tailored stage-matched intervention (SMI) based on the Transtheoretical Model and 2) a non-tailored health education intervention (HEI) to improve BP control through six monthly telephone calls focusing on diet, exercise and medication adherence. Each was compared to a usual care (UC) group where participants did not receive phone counseling. Participants were Veterans with repeated uncontrolled BP, despite antihypertensive drug treatment for ≥ 6 months. BP measurements were taken at baseline, 6 months (immediately after the intervention period) and 12 months (6 months post-intervention). Generalized estimating equations (GEE) with logistic link function was fitted to analyze the repeated BP measures (at both 6 months and 12 months), adjusting for baseline BP control. Similarly, GEE was used to analyze the continuous SBP measurement with repeated measurements at both 6-month and 12-month, adjusting for baseline SBP. These GEE analyses utilized all available data, taking into account the correlations among

repeated measures. Finally, McNemar test was applied to evaluate the null hypothesis of no change in BP control from baseline to 12 months within each arm, ie, if the proportion of participants with BP under control from baseline to 12 months changed within SMI, HEI, and UC, respectively.

RESULTS: We enrolled and randomized 533 participants with repeated uncontrolled BP into the SMI, HEI and UC groups. There were no differences between groups at baseline. At 12-month follow-up, the proportion of SMI, HEI and UC with BP under control were 61.84 %, 60.13 %, and 52.23 %. Compared to UC, SMI participants were 1.8 times more likely to have BP under control between 6 and 12 months (OR 1.8, 95 % CI: 1.27, 2.66), and HEI participants were 1.5 times more likely to have BP under control (95 % CI: 1.01, 2.12). The adjusted analyses for SBP levels indicate that the mean effect of SMI was 2.80 mmHg (95 % CI: -5.33, -0.26) lower than UC ($p=0.0306$), while the mean effect of HEI compared with UC was 2.56 mmHg (95 % CI: -5.54, +0.42,) lower ($p=0.0918$). To evaluate the robustness of our findings, we tested the null hypothesis of no change in BP control from baseline to 12 months within each arm and found that there was 19.23 % improvement in the proportion with controlled BP for SMI ($p<.0001$), 19.57 % for HEI ($p<.0001$) and 7.60 % for UC ($p=.15$).

CONCLUSIONS: We found that both a telephone-delivered tailored SMI and a non-tailored HEI resulted in improved BP control at 12 months, with SMI having a greater proportion under control. SMI also led to a significant lowering in SBP at 12 months while HEI led to a non-significant lowering in SBP. Depending on needs and resources available, decision makers can choose either SMI or HEI to improve BP control rates of patients with repeated uncontrolled hypertension. This could be an important new approach to improve BP control, particularly in settings where Telehealth or Patient Centered Medical Home is being implemented.

SYSTEMATIC REVIEW AND META-ANALYSIS OF INHALED TOXICANTS FROM WATERPIPE AND CIGARETTE SMOKING Brian A. Primack¹; Mary Carroll²; Patricia M. Weiss¹; Alan Shihadeh⁴; Ariel Shensa¹; Steven Farley¹; Michael J. Fine²; Thomas Eissenberg⁶; Smita Nayak⁵. ¹University of Pittsburgh, Pittsburgh, PA; ²VA Pittsburgh Healthcare System, Pittsburgh, PA; ³Squirrel Hill Health Center, Pittsburgh, PA; ⁴American University of Beirut, Beirut, Lebanon; ⁵Swedish Center for Research and Innovation, Seattle, WA; ⁶Virginia Commonwealth University, Richmond, VA. (*Tracking ID #2198875*)

BACKGROUND: Waterpipe tobacco smoking (WTS) is an emerging trend worldwide. In the US, usage rates are increasing not only among youth and college students but also among adults in the greater community. Because up to half of WTS users do not use other forms of tobacco, it exposes many individuals who may otherwise not have been exposed to tobacco combustion products. Although waterpipe tobacco smoke is known to contain many toxicants found in cigarette smoke, such as tar, nicotine, and carbon monoxide (CO), estimates vary as to the relative smoke volumes and toxicant loads. Therefore, to inform clinical education, interventional programming, and public health policy, we conducted a systematic review and meta-analysis to provide pooled estimates of relative toxicant exposures for WTS compared with cigarette smoking.

METHODS: We designed and reported this study using the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA). We included all studies that: (1) reported a controlled laboratory or natural environment study designed to mimic human tobacco consumption; (2) quantified the mainstream smoke of a single cigarette and/or single WTS session; and (3) reported smoke volume, nicotine, tar, and/or CO. In 2013 we conducted searches of OvidSP MEDLINE, Embase, Scopus, TOXLINE, Science Citation Index Expanded, BIOSIS Previews, and the Cochrane Library. Search strategies tailored to each individual database were developed by a professional research librarian. Reference lists of included studies were hand-searched to identify additional relevant articles. Two researchers independently reviewed all retrieved articles to identify studies meeting eligibility criteria. Two different researchers abstracted key quantitative information for meta-analysis, including measurement of smoke volume in liters, and nicotine, tar, and CO in milligrams. We developed structured spreadsheets to facilitate complete and accurate data collection. We then conducted meta-analyses to calculate summary estimates for the inhalation of each unique toxicant for each mode of tobacco consumption (waterpipe and cigarette). After performing meta-analyses, we used the established method of Fieller to calculate the ratio of each inhaled toxicant for a single waterpipe session compared with a single cigarette and the 95 % confidence interval of that ratio.

RESULTS: Regarding selection criteria, interrater reliability was high (98 % agreement, Cohen's $\kappa=0.83$). For the few initial disagreements, reviewers easily achieved consensus upon brief discussion. All specific numbers (toxicant amounts) included in meta-analyses
