CASE: We present a 21 year old female from Ecuador with history of chronic hepatitis and atypical presentation of HELLP syndrome 2 years ago, who was first admitted with jaundice and progressively worsening liver function tests. Viral hepatitis serologies were negative. Liver biopsy at the time showed chronic active hepatitis, erythrophagocytosis and congestion. She was started on prednisone for presumed autoimmune hepatitis and was discharged. She presented a few days later with fever, hematochezia and fulminant liver failure. A bleeding scan localized the site to cecum and rectosigmoid colon and she underwent embolization. This was complicated by ischemic colitis, prompting a hemicolectomy with ileostomy. Due to her clinical presentation of pancytopenia, hepatosplenomegaly, persistent fevers, elevated Epstein-Barr virus (EBV) and biopsies of liver and bone marrow showing hemophagocytosis, she was diagnosed with secondary HLH. She was treated with intravenous corticosteroids and Rituximab; however, she failed to respond to therapy. Her hospital course was complicated by multiple episodes of spontaneous gastrointestinal bleeding and refractory coagulopathy despite numerous transfusions of platelets, fresh frozen plasma and cryoprecipitate. She underwent multiple endoscopies with clipping of small bowel vessel bleeding. Repeat laboratory tests for autoimmune and infectious etiologies were unremarkable except for markedly elevated EBV PCR studies (251,000 copies) and CMV (431 copies). After a prolonged hospital course, she ultimately developed urosepsis and expired shortly thereafter

DISCUSSION: Hemophagocytic lymphohistiocytosis (HLH) or hemophagocytic syndrome (HPS) is a rare, life-threatening and aggressive condition which leads to progressive multi-organ failure due to an unregulated immune response to extreme inflammation. There is a congenital form primarily seen in children and secondary form, seen in children and adults. Both forms are characterized by fevers, hepatosplenomegaly and bi or tri-lineage cytopenias. The key to success in treating HLH is an early diagnosis, which is a challenge given the rarity of the syndrome, variable clinical presentation and lack of specific clinical and laboratory findings. While the pathophysiology of secondary HLH remains unclear, the disease pattern is attributed to a cytokine storm leading to overactivation of antigen-presenting cells and upregulation of T cell immunity, causing end organ damage. Diagnostic criteria is met if at least five out of eight criteria are met. These include fever, splenomegaly, at least bi-lineage cytopenia, hypertriglyceridemia and/or hypofibrinogenemia, hemophagocytosis in bone marrow, spleen, CSF or lymph nodes, decreased or absent NK-cell activity, elevated ferritin and elevated soluble IL-2 receptor levels. Supportive evidence includes cerebral symptoms with moderate pleocytosis and/or elevated protein, elevated transaminases, bilirubin and lactate dehydrogenase. Without treatment, prognosis is poor and often fatal with mortality of 18–24 % in EBV related HLH. Treatment should include an early referral to hematology and evaluation for possible triggers in stable patients. Current treatment recommendations for HLH include intravenous corticosteroids and etoposide along with intrathecal therapy for those with CNS disease. Better responses may be seen with rituximab for EBV-related HLH. Due to the aggressive nature of secondary HLH, rapid escalation of treatment is necessary and consideration of hematopoietic stem cell transplant is sometimes necessary within hours to days of presentation. HLH is a rare entity in adults and outcomes are poor without early recognition; we recommend consideration of this disease in the setting of persistent hepatitis, fevers, refractory cytopenias and global inflammation.

SEPSIS DUE TO LISTERIA BACTEREMIA AS INITIAL PRESENTATION OF HODGKIN LYMPHOMA Jin Xu; Dhruvatej Boddupalli; Sarah Apgar. Yale School of Medicine, New Haven, CT. (Tracking ID #2199075)

LEARNING OBJECTIVE #1: Recognize the association between listeriosis and underlying malignancy.

LEARNING OBJECTIVE #2: Review the importance of excisional lymph node biopsy for the diagnosis of Hodgkin lymphoma.

CASE: A 53-year-old man with past medical history of heavy alcohol use presented to the emergency room with a 1-month history of worsening fatigue, night sweats, daily high fevers, and 20-lb weight loss over 3 months. He was treated empirically by his primary care physician with amoxicillin/clavulanic acid 1 week prior to admission without

improvement. Physical exam was significant for temperature 102.9 °F, heart rate 110 beats per minute, splenomegaly, and bilateral axillary and inguinal lymphadenopathy. Initial laboratory testing was notable for sodium 129 mmol/L, hemoglobin 7.7 g/dL, aspartate transaminase (AST) 49 U/L, alanine transaminase (ALT) 50 U/L, sedimentation rate 120 mm/hr, C-reactive protein 234 mg/L, ferritin 2950 ng/mL, otherwise normal basic chemistries and normal white blood count and platelets. Computed tomography (CT) revealed splenomegaly to 14.2 cm, mediastinal and axillary lymph nodes up to 1.2 cm in diameter, and abdominal (paracaval and paraaortic) lymph nodes up to 3 cm in diameter. Within 24 h of admission, blood cultures returned positive for *Listeria monocytogenes*, and treatment was initiated with intravenous (IV) ampicillin and gentamicin. Soon after the initiation of antibiotics, the patient complained of a severe headache, associated with high fevers, tachycardia, and meningeal signs. Cerebrospinal fluid (CSF) revealed 1100 cells/uL with 92 % granulocytes, glucose 54 mg/dL and protein 93 mg/dL. CSF cultures for bacteria, fungi and acid-fast bacteria as well as viral studies were all negative. Headache and meningeal signs improved with treatment for presumed *Listeria* meningitis, however the patient continued to spike high fevers daily. Further evaluation of his lymphadenopathy with CT-guided core tissue biopsy of the retroperitoneal lymph nodes revealed fibrous adipose tissue with mixed inflammatory cell proliferation. Bone marrow biopsy revealed hypercellular marrow but no evidence of a malignant process. Positron emission tomography (PET) was performed to help guide further diagnostic testing, which confirmed intensely hypermetabolic lymph nodes, most notable in the right axilla, mediastinum and retroperitoneum. Excisional lymph node biopsy of two axillary lymph nodes revealed classic Hodgkin lymphoma. Chemotherapy was subsequently initiated with resolution of fevers.

DISCUSSION: This case illustrates an example of sepsis due to *Listeria monocytogenes* and presumed *Listeria* meningitis in a patient with undiagnosed Hodgkin lymphoma. *Listeria monocytogenes*, a gram-positive facultative anaerobic rod, is well-known to affect immunocompromised patients. There are multiple case reports in the literature of *Listeria* bacteremia or meningitis found in patients with previously known immunosuppressive states, including leukemias and lymphomas. Our patient, however, was an unusual case in whom listeriosis was the initial presentation of underlying Hodgkin lymphoma. Systemic listeriosis carries a high mortality rate if not recognized early, and should be considered and empirically treated in patients with suspected underlying malignancy, especially if evidence of meningitis is present. This case further underscores the importance of excisional lymph node biopsy for the diagnosis of Hodgkin's lymphoma. Although this patient's largest lymph nodes were in the retroperitoneum, CT-guided core biopsy of these lymph nodes was not diagnostic. Excisional biopsy of the smaller axillary lymph nodes revealed the diagnosis of Hodgkin lymphoma.

SEROTONIN SYNDROME INDUCED BY THE COMBINATION OF LAMOTRIGINE, ARIPIRAZOLE AND COCAINE Anupam Kotwal¹; Sarah L. Cutrona². ¹University of Massachusetts, Worcester, MA; ²University of Massachusetts Medical School and Meyers Primary Care Institute, Worcester, MA. (Tracking ID #2193948)

LEARNING OBJECTIVE #1: Recognize the clinical features and management of Serotonin syndrome

CASE: A 24 year old female with a history of bipolar disorder was admitted for nausea, dizziness and jitteriness that started after intentional ingestion of 4 gm of lamotrigine and 80 mg of aripiprazole, in addition to cocaine abuse. Physical examination revealed diaphoresis, tachycardia, bilateral horizontal nystagmus, and bilateral lower extremity hyperreflexia with inducible patellar and ankle clonus. Laboratory studies were remarkable for mildly elevated liver enzymes that normalized within 24 h. Urine was positive for codeine, cocaine and lamotrigine. Blood levels of lamotrigine and aripiprazole drawn on the date of admission were within normal limits. She was diagnosed with Serotonin syndrome (SS) with severity classified as mild. Lamotrigine and Aripiprazole were discontinued, and Lorazepam was given for symptomatic management. During the hospital stay, her tachycardia, nystagmus, clonus and hyperreflexia resolved within 48 h. Her symptoms of nausea, dizziness, jitteriness and diaphoresis also resolved. This was followed by initiation of Divalproex and Risperidone for her psychiatric condition. On follow up, she continued to abuse cocaine, but did not develop similar clinical features.

DISCUSSION: SS is a potentially life-threatening condition associated with increased serotonergic activity in the central nervous system (CNS). It is characterized by mental status changes, autonomic hyperactivity and neuromuscular abnormalities along a spectrum ranging from mild to severe. Using the Hunter criteria, diagnosis is established if the patient has taken a serotonergic agent and meets any one of the following criteria: spontaneous clonus; inducible clonus plus agitation or diaphoresis; ocular clonus plus agitation or diaphoresis; tremor plus hyperreflexia; hypertonia plus temperature above 38°C plus ocular clonus or inducible clonus. Differential diagnoses include anticholinergic poisoning, malignant hyperthermia, neuroleptic malignant syndrome and sympathomimetic toxicity. SSRIs are perhaps the most commonly implicated medications

associated with this syndrome. Our patient developed features of SS after the ingestion of higher than prescribed doses of Lamotrigine and Aripiprazole, in addition to cocaine abuse. None of these agents have strong serotonergic activity by themselves, and the blood levels of lamotrigine and aripiprazole in our patient were within normal limits. However, these agents do have some effect on serotonin neurotransmission. Lamotrigine has a weak inhibitory effect on 5-HT₃ receptor, Aripiprazole is a partial agonist at 5-HT_{1A} receptor and an antagonist at serotonin reuptake transporter, and Cocaine increases the release and inhibits the reuptake of serotonin at the synaptic cleft. An extensive literature search on PubMed did not yield any case description of SS induced by these agents alone or in combination. Also, Micromedex and Epocrates do not list this syndrome as an adverse effect for any of these agents. To conclude, the pharmacokinetic and pharmacodynamic interactions between Lamotrigine, Aripiprazole and Cocaine can lead to increased CNS serotonergic activity. Hence, SS should be considered in a patient who takes these medications and demonstrates even subtle features of neuromuscular hyperactivity. Management includes discontinuation of the offending agents, supportive care and benzodiazepines for symptom control, with serotonin antagonists being a last resort.

SEVERE CHOLESTATIC JAUNDICE LEADING TO AN UNFORESEEN DIAGNOSIS Andrew Whipple¹; Steve Abshagen²; Timothy Schubert¹. ¹Western Michigan University Homer Stryker M.D. School of Medicine, Kalamazoo, MI; ²Portage Gastroenterology, Portage, MI. (Tracking ID #2194853)

LEARNING OBJECTIVE #1: Consider AL amyloidosis in patients presenting with cholestatic jaundice of unknown etiology.

LEARNING OBJECTIVE #2: Recognize that severe hepatic involvement resulting in cholestatic jaundice is considered to be a pre-terminal sign in AL amyloidosis.

CASE: A 72 year old female presented with a 2 month history of progressive pruritis, jaundice, and diarrhea. She also admitted to fatigue and a 30 pound weight loss over the preceding 6 months, but otherwise denied abdominal pain, melena, or alcohol use. Her past medical history included hypertension and well controlled diabetes mellitus type 2 and a previous 45 pack-year smoking history. Initial labs were remarkable for total bilirubin 11.3 mg/dL, alkaline phosphatase 479 U/L, and liver enzymes twice the upper limit of normal. Ultrasound demonstrated increased echogenicity of the liver, a 1.3 cm sludgeball in the gallbladder, and no biliary dilatation. Hepatobiliary scan and endoscopic ultrasound were both unremarkable. Liver biopsy subsequently revealed amyloidosis with amorphous, eosinophilic deposits predominately within the portal areas, surrounding and compressing the bile ducts and intra-hepatic blood vessels. Further laboratory workup resulted in a final diagnosis of AL (primary) amyloidosis.

DISCUSSION: AL amyloidosis is characterized by abnormal immunoglobulin light chains with subsequent organ deposition and dysfunction. Up to 70 % of systemic amyloid cases demonstrate hepatic involvement, and typical findings include hepatomegaly and elevated alkaline phosphatase. While hepatic involvement in AL amyloidosis is common, the overall clinical significance of this is mild or often absent. In two published series of primary AL-type amyloidosis, Kyle et al. reported the incidence of an elevated serum total bilirubin level to be between 4 and 8 %. More precisely, the presence of clinical jaundice resulting from severe intrahepatic cholestasis is even less common, and seen in less than 3 % of cases. This is an important distinction to make, as the presence of jaundice carries a particularly poor prognosis and considered to be a pre-terminal sign from hepatic involvement in amyloidosis. In fact, analysis by Gertz et al. suggested an elevated total bilirubin > 3 mg/dL correlated with an average 1.8 month life expectancy, and 80 % of reported patients died within 6 months after the onset of clinical jaundice. The cholestasis seen with amyloidosis is related to direct compression of intrahepatic bile ducts by amyloid deposits in the portal area and sinusoidal spaces. A low threshold for liver biopsy at the onset of suspicion for amyloidosis can provide early diagnosis so aggressive treatment, or palliative options can be offered. Our case serves as a reminder of the variable presentations of amyloidosis, which includes intrahepatic cholestasis, and that the presence of jaundice is indicative of an extremely poor prognosis.

SEVERE COBALAMIN DEFICIENCY DISGUISED AS MICROANGIOPATHIC HEMOLYTIC ANEMIA Gagandeep Cheema. Henry Ford Hospital, Royal Oak, MI. (Tracking ID #2198926)

LEARNING OBJECTIVE #1: Recognize the rare hematological presentations of severe B12 deficiency.

CASE: A 27-year-old female with no prior past medical history presented with non-specific complaints of malaise, fatigue, dizziness, and nausea. Her history was significant for exposure to both Ciprofloxacin and Nitrofurantoin in the preceding weeks for a UTI. Her initial evaluation revealed severe pancytopenia with a Hemoglobin of 4.8 g/dL and a platelet count of 53 K/uL. Her physical exam and vital signs were unremarkable, except for pallor. Further workup was suggestive of severe hemolysis, with an elevated LDH of

4476 IU/L and low haptoglobin of <8 mg/dL. The peripheral blood smear showed schistocytes and fragmented red blood cells, compatible with microangiopathic hemolytic anemia (MAHA). The patient was started on steroids for suspected autoimmune hemolytic anemia. However, Coombs test was negative, and her hemoglobin responded appropriately to multiple transfusions of packed red blood cells, therefore steroids were discontinued. An extensive hematological workup eventually revealed severe B12 deficiency with positive intrinsic factor antibodies. The patient was treated with subcutaneous B12 injections and had near normalization of her hematological indices within 3 weeks of initiating treatment.

DISCUSSION: RBC fragmentation and destruction associated with severe vitamin B12 deficiency is a relatively rare and underreported phenomenon. It is attributed to ineffective erythropoiesis leading to intramedullary hemolysis. This type of “pseudo-thrombotic microangiopathy” is commonly misdiagnosed and treated as TTP. One small retrospective study has found that the pseudo-thrombotic microangiopathy has been associated with lower reticulocyte counts and higher LDH levels than true TTP, as was seen in our case.

SEVERE MYELOSUPPRESSION SECONDARY TO ACCIDENTAL DAILY METHOTREXATE Bharat Rao; Shahzaib Nabi; Rohit Gulati; Michael H. Lazar. Henry Ford Hospital, Detroit, MI. (Tracking ID #2189080)

LEARNING OBJECTIVE #1: Early recognition and treatment of methotrexate toxicity and associated myelosuppression.

LEARNING OBJECTIVE #2: Importance of medication reconciliation in patient care.

CASE: A 67-year-old Hispanic female presented with a 5-day history of bleeding sores from her mouth, pain on swallowing, watery diarrhea, and fatigue. She has a history of breast cancer diagnosed and treated 10 years ago with lumpectomy, chemotherapy, and radiation. She also has a significant history of psoriasis and diabetes mellitus type 2. She has no personal or family history of autoimmune diseases, leukemia, or lymphoma. She reported taking an unknown medication for psoriasis. On exam, she was febrile and tachycardic. She had erosions of lips with associated bleeding and oral ulcerations. Her abdominal exam revealed mild diffuse tenderness but no hepatosplenomegaly. Lab work revealed pancytopenia that decreased progressively to WBC 0.4 billion cells/L (ANC 0), hemoglobin 6.6 g/dL, and platelet count 17 billion/L. Other remarkable initial labs included elevated transaminases (AST 183 U/L, ALT 157 U/L). The initial differential diagnosis included acute leukemia, drug induced pancytopenia, and infectious processes. Broad-spectrum antibiotics were initiated during admission for neutropenic fever. Initial infectious work-up was negative. Further hematologic labs revealed normal iron studies and vitamin B12 level, low reticulocyte count and low folate (4.7 ng/ml). She underwent a bone marrow biopsy, which revealed marked trilineage hypoplastic bone marrow without definitive evidence of lymphoproliferative disease. She did receive blood transfusions given low hemoglobin. On day five the patient's family brought her medications along with her pillbox. It was discovered she was prescribed methotrexate 10 mg weekly. However, on inspection of her weekly pillbox, she was noted to have a methotrexate tablet for each day. A presumptive diagnosis of methotrexate toxicity was given. She was immediately initiated on intravenous folic acid treatment. Methotrexate level was ordered on day five of admission, and returned <0.10 umol/L; however this was several days after her last exposure. Given she still had diarrhea and persistent fevers, a CT abdomen was ordered to rule out enterocolitis; it revealed cholelithiasis, with mild fat stranding surrounding the gallbladder. This was followed by a HIDA scan with findings consistent with acute cholecystitis. She also had urinalysis that was positive for ampicillin-resistant and vancomycin-resistant enterococcus. Clostridium difficile testing was negative during admission. Although she was clinically asymptomatic from gallstones at the time of imaging, it was decided to pursue cholecystostomy placement in light of her neutropenia and persistent fevers. Her antibiotic coverage was changed to cefepime and metronidazole for cholecystitis, and daptomycin for the enterococcus. In addition, the decision was made to administer her granulocyte-colony stimulating factor. During her clinical course, she showed gradual symptomatic improvement and her blood counts increased. Upon follow-up with hematology as an outpatient, her blood counts had normalized and she was reportedly doing well.

DISCUSSION: Methotrexate has been used as a treatment of psoriasis for many years and is generally prescribed as a low dose taken weekly. Generally, severe side effects are rare when taken as prescribed and with folic acid supplementation. This case highlights several clinical clues to identifying methotrexate toxicity including stomatitis, GI symptoms, fatigue, fever and transaminitis. However, it is important to recognize that fever should not be solely attributed to drug induced toxicity, and that infectious etiologies should be ruled out. Her labs showed low folate secondary to methotrexate's antagonist effect on dihydrofolate reductase and replacement is one of the mainstays of overdose treatment. Myelosuppression, as in this case, can be fatal and treatment should focus on rapid identification and treatment of an underlying etiology, empiric antibiotic coverage for neutropenic fever, supportive transfusions as needed, and consideration of granulocyte stimulating factors. Moreover, one of the most important learning points in this case is that

a thorough medication review including efforts to identify unknown medications or non-traditional medications might lead to an earlier diagnosis. It is also important to ensure patient understanding of medication doses and frequency upon prescribing in order to prevent severe adverse events like in this case.

SEVERE PULMONARY HYPERTENSION FROM CHRONIC, UNTREATED POLYMYOSITIS WITHOUT INTERSTITIAL LUNG DISEASE Benjamin Barbash²; David M. Levine²; Natalie K. Levy¹. ¹NYU School of Medicine, Bellevue Hospital, New York, NY; ²New York University School of Medicine, New York, NY. (Tracking ID #2196353)

LEARNING OBJECTIVE #1: Describe the natural history of polymyositis

LEARNING OBJECTIVE #2: Formulate a differential diagnosis for shortness of breath in patients with polymyositis

CASE: A 68 year-old female with hypertension, osteoporosis, and polymyositis (PM) presented with two weeks of severe shortness of breath at rest. Eight years prior she developed quadriceps weakness, which gradually progressed such that she became bed-bound 3 years prior. PM was diagnosed by a neuromuscular specialist 7 months prior, after deltoid muscle biopsy demonstrated degenerative muscle fibers without inclusions, consistent with chronic PM. Daily high-dose prednisone was started 6 months prior to admission, but the patient was subsequently lost to follow-up. Her exam revealed 95 % saturation on 4 L oxygen with rapid, shallow breaths, accessory muscle use, 1/5 bilateral proximal muscle strength, and 5/5 distal muscle strength. TTE demonstrated moderate-to-severe pulmonary hypertension (PH), severe right ventricular dilatation, preserved LVEF, and no anatomic defects or shunting. Chest CT and V/Q scan showed no thromboembolic disease and no interstitial lung disease (ILD). Right heart catheterization demonstrated pulmonary artery pressure 68/19 mmHg, wedge pressure 12 mmHg (no vasodilator response). Sleep study ruled out OSA. FEV1 was 0.55 L, FVC 0.69 L, FEV1/FVC 79 %, DLCO 3.7 mL/mmHg/min (normal is 15.8 mL/mmHg/min), and mean inspiratory pressure -17cmH2O (normal range -65cmH2O to -95cmH2O). Labs showed normal serum ESR, CRP, CPK, aldolase, negative antibodies to Jo-1, scl70, anti centromere, SSA, SSB, RNP, and smith. ANA and dsDNA were both weakly positive (1:40 [nucleolar] and 11 IU/mL, respectively). A trial of mycophenolate mofetil and prednisone provided no symptomatic improvement. Physical therapy and overnight bilevel offered minimal symptomatic relief.

DISCUSSION: Our case highlights the natural history of PM and the importance of maintaining a broad differential for SOB. PM is an idiopathic inflammatory myopathy characterized by proximal skeletal muscle weakness. Diagnostic criteria vary but generally rely on clinical (symmetric proximal weakness), laboratory (elevated CK, aldolase, or liver enzymes), electromyographic (irritable myopathy), radiographic (MRI with muscle inflammation), and histologic (inflammatory infiltration) criteria. Patients are diagnosed with definite, probable, or possible PM based on the number of criteria met. Our patient regrettably represents the natural history of untreated PM: proximal muscle inflammation and weakness that progresses to severe debilitation and non-viable muscle tissue. Active disease is treated with steroids and/or immune modulator therapy. However, therapy has limited value in longstanding disease, as in our patient. To our knowledge, this is the first account of PH secondary to PM without the presence of ILD. While the association of PH with various connective tissue diseases (particularly scleroderma) is well known, knowledge of PM-induced PH is limited. Two other cases with ILD have been described, while 8 additional patients with overlap of PM-dermatomyositis and PM-Sjogrens have been reported. The differential diagnosis for PH generally includes 5 groups: pulmonary arterial hypertension, PH secondary to left heart disease, PH due to lung disease, PH from chronic thromboembolic disease, and PH due to unclear multifactorial mechanisms. As our patient lacked significant left heart disease and unclear pulmonary dysfunction, she required PFTs, V/Q scan, polysomnography, autoimmune testing, and cardiac catheterization to rule out all but the last of these groups, leaving PM the cause of her PH. While the pathophysiology of PM-induced PH without ILD is not well understood, we postulate that diaphragmatic weakness causes poor lung expansion, atelectasis, and chronic hypoxemia, with ensuing PH. Our case illustrates the importance of early recognition of PM and is the first account of PM-induced PH in the absence of ILD.

SEVERE THROMBOCYTOPENIA CAUSED BY NASH Gen Yamada²; Christine Kwan^{1, 2}. ¹Teine Keijinkai Hospital, Arlington, TX; ²Teine Keijinkai Hospital, Sapporo, Japan. (Tracking ID #2199817)

LEARNING OBJECTIVE #1: Recognize that severe thrombocytopenia can be caused by nonalcoholic steatohepatitis (NASH)

CASE: A 39-year-old Asian woman is transferred for possible splenectomy. She initially visits her primary care physician 5 weeks ago with gingival bleeding and purpura for which blood tests show platelet counts <2000 /L and slightly elevated liver function tests.

Bone marrow biopsy is consistent with idiopathic thrombocytopenic purpura for which she is given prednisolone for 10 days with partial response, so splenectomy is considered. She also reports slight appetite loss, but other review of systems is within normal limits (WNL). Past medical history includes diabetes mellitus II (DMII) on sitagliptin and miglitol and fatty liver on ursodeoxycholic acid. The patient has no known drug or food allergies. She does not smoke, drink, or use recreational drugs. Her father also has DMII. On physical examination, the patient's body mass index is 34.6 kg/m². Her vital signs include temperature 36, blood pressure 134/68, heart rate 78, respiratory rate 12, and oxygen saturation 99 % room air. Head and neck exam shows no nasal or gingival bleeding. Her abdomen is soft, obese, non-distended, and non-tender with positive bowel sounds; spleen and liver exams are limited. She has no abdominal wall vascular collaterals or shifting dullness. Skin exam reveals ecchymosis at venipuncture sites and erythematous papules on her face. The rest of her exam is WNL. Labs, including complete blood counts, chemistries, and coagulation panel, are WNL except platelet 17,000/mcL, HbA1c 7.8 %, GGTP 91 IU/L, and prothrombin activity 74.3 %; copper is not measured. Hepatitis B/C and human immunodeficiency antibodies are negative. Peripheral blood smear shows no abnormalities. After platelet transfusions, abdominal ultrasound shows a fatty liver and enlarged spleen; computed tomography (CT) confirms an 11 × 16 cm enlarged spleen with renal-splenic collaterals. Upper gastrointestinal endoscopy shows no abnormalities. Given the differential diagnosis of cirrhosis from NASH, the patient undergoes splenectomy and liver biopsy, which shows hepatic steatosis, inflammation, and fibrosis, consistent with NASH (Matteoni classification type 4/nonalcoholic fatty liver disease (NAFLD) activity score 4). After splenectomy, her platelet count recovers to >200,000 /mcL.

DISCUSSION: Risk factors for NAFLD, the most common liver disease in the world, include DMII, dyslipidemia, and obesity. It can be divided into non-NASH and NASH, which is more likely to develop cirrhosis. NAFLD patients are usually asymptomatic, but some NASH patients develop fatigue, malaise, abdominal pain, and hepatomegaly (18 %), in addition to signs/symptoms of cirrhosis. Lab data may show increased AST, ALT, and ferritin. While this patient's liver biopsy shows NAFLD, she has no alcohol use; other causes of secondary hepatic steatosis, such as hepatitis virus, medications, and Wilson's disease, are less likely. She is thus diagnosed with NASH cirrhosis. Severe thrombocytopenia (<50,000 /mcL) is rare in cirrhotic patients, and only 1 % need transfusion. The mechanism is due to increased pooling of platelets in the enlarged spleen and decreased liver production of thrombopoietin. The most common cause of thrombocytopenia in outpatients is due to liver disease (58 %), and the prevalence of NAFLD is increasing. Recently, NAFLD accounts for 75 % of chronic liver disease; NASH can thus cause severe thrombocytopenia due to cryptogenic cirrhosis like the above patient.

SHORTNESS OF BREATH IN PREGNANCY Megha Prasad. Mayo Clinic, Rochester, CA. (Tracking ID #2199455)

LEARNING OBJECTIVE #1: –To understand the presentation and management of peripartum cardiomyopathy

LEARNING OBJECTIVE #2: –To avoid premature closure when evaluating a common, nonspecific chief complaint

CASE: Our patient is a 27 year old lady G1P0 female at 39 weeks gestation who presented to the Emergency Department with a 2 week history of cough, insomnia, shortness of breath and palpitations. She had been seen at local clinic and her shortness of breath was thought to be secondary to her fullterm pregnancy. When the patient presented to our emergency department, physical examination revealed regular, rapid rate, 3/6 holosystolic murmur, inspiratory wheezing, as well as bibasilar crackles. EKG demonstrated sinus tachycardia, Q waves in leads I and AVR and right axis deviation. Chest X ray was significant for marked enlargement of cardiac silhouette with increased opacity over the heart suggestive of pericardial effusion. Echo revealed left ventricular enlargement and generalized hypokinesis with an LVEF of 20 % as well as mild mitral and tricuspid valve regurgitation. CT Chest ruled out pulmonary embolism, and demonstrated moderate cardiomegaly with a moderate sized pericardial effusion as well as a small right pleural effusion. Cardiac magnetic resonance imaging ruled out any underlying myocarditis. The patient was diagnosed with peripartum cardiomyopathy in light of her clinical history and imaging findings. The patient was saturating 90 % on 2 L of oxygen. She was induced to accelerate delivery, however as respiratory distress worsened, she required emergency cesarean section. She was diuresed acutely with intravenous furosemide, and continued on oxygen. As her condition stabilized, carvedilol and digoxin were initiated. The patient was also anticoagulated with heparin, and then warfarin due to her high risk of thromboembolism in light of her low ejection fraction, and inherent postpartum clotting risk. The patient's moderate sized pericardial effusion was drained via pericardiocentesis and the patient recovered appropriately with her home medications which included warfarin, carvedilol, lisinopril and furosemide. Bromocriptine, traditionally used to treat hyperprolactinemia, has been recently recognized as having benefit in peripartum cardiomyopathy. The medication is associated with a significant risk of venous thromboembolism however. Risk and benefits of bromocriptine initiation were carefully reviewed. The

decision was made to not use bromocriptine due to increased risk of venous thromboembolism. The patient returned home and was followed in heart failure clinic for resolution of symptoms. She regained normal cardiac function on repeat echocardiogram, and her ejection fraction improved in the postpartum period. She did not require placement of implantable cardiac defibrillator.

DISCUSSION: Our patient represents an unusual presentation of peripartum cardiomyopathy. Significant pericardial effusion is a rare complication of peripartum cardiomyopathy and is generally associated with an underlying autoimmune process such as myocarditis, ruled out by Cardiac MRI in our patient. Furthermore, while the etiology of peripartum cardiomyopathy is unknown, several studies have suggested underlying viral illness as a precipitant. Our patient's history of sick contact and viral URI prior to presentation may provide an explanation for her condition. Our case also highlights the importance of risk benefit analysis when treating a postpartum patient. The patient was discharged on warfarin for anticoagulation in light of her reduced ejection fraction and risk of thromboembolism. The need for thrombosis prophylaxis outweighed the tangible risks of postpartum hemorrhage as well as the contraindication to breastfeeding. Furthermore, despite recent advances in peripartum cardiomyopathy noted with bromocriptine use, we did not administer bromocriptine. When evaluating patients in the peripartum period, symptoms of shortness of breath and chest pain should be carefully considered and peripartum cardiomyopathy should be ruled out. Patients with peripartum cardiomyopathy have a good prognosis if managed appropriately in the outpatient setting. Also, it is important to maintain a wide differential when managing common chief complaints. Premature closure may lead to missed diagnoses, as in this patient, who was dismissed as having shortness of breath due to her pregnancy several times before undergoing complete evaluation. Other important causes of shortness of breath to be aware of in a pregnant female include pulmonary thromboembolism and spontaneous coronary artery dissection. Pregnant women with new onset symptoms of shortness of breath should undergo thorough evaluation to rule out lifethreatening causes such as these.

SIGNIFICANCE OF UP-SLOPING ST-SEGMENT DEPRESSION WITH TALL POSITIVE T-WAVE Naoki Misumida; Akihiro Kobayashi. Beth Israel Medical Center, New York, NY. (Tracking ID #2196314)

LEARNING OBJECTIVE #1: Identify up-sloping ST-segment depression as a possible sign of ongoing ischemia in patients with suspected acute coronary syndrome

CASE: A 91-year-old woman with a history of coronary artery disease status post stent placement presented with chest pain lasting for 4 h. Chest pain was constant, pressure sensation, non-radiating, and located in her left chest. Her blood pressure was 134/73 mmHg, pulse rate was 111 /min, respiratory rate was 18 /min, and oxygen saturation was 96 % on 2 L of oxygen via nasal cannula. The patient had bilateral basilar crackles without jugular venous distention or leg edema. Chest X-ray revealed mild pulmonary vascular congestion. Electrocardiogram revealed sinus tachycardia and up-sloping ST-segment depression with tall positive T waves in anterior leads, which were new when compared to her previous electrocardiogram. Patient was diagnosed with non-ST-segment elevation acute coronary syndrome and treated with heparin infusion and antiplatelet therapy. The laboratory tests revealed an elevated troponin I of 64 µg/ml. Troponin was further elevated to 116 µg/ml 4 h later. The patient was subsequently taken to an urgent cardiac catheterization, which showed a total occlusion of the left circumflex artery. She underwent percutaneous coronary intervention with stent placement. The patient suffered from large myocardial infarction and became persistently hypotensive despite extensive treatments including pharmacologic therapy and intra-aortic balloon pump. Patient's cardiac function did not recover and the patient died on day nine because of cardiogenic shock.

DISCUSSION: The present case illustrated the significant diagnostic value of up-sloping ST-segment depression in risk stratification in patients with non-ST-segment elevation acute coronary syndrome. Up-sloping ST-segment depression has not been historically considered to represent ischemia, as it is often observed in patients with tachycardia. Indeed, the current guideline for the diagnosis of myocardial infarction includes only horizontal and down-sloping ST-segment depression. Several recent studies, however, reported that up-sloping ST-segment depression, especially when accompanied with tall T waves, may represent ongoing ischemia of left anterior descending artery or left circumflex artery territories. In the present case, up-sloping ST depression was caused by a total occlusion of left circumflex artery. The interpretation of an electrocardiogram is the central part of the management of acute coronary syndrome. High-risk patients, those with significant electrocardiographic change or positive cardiac biomarker, will receive greater benefit from an early invasive strategy. Therefore, early recognition of ischemic ST-segment change is crucial to guide the further management including the timing of coronary angiogram and revascularization, and the choice of pharmacologic agents. In conclusion, up-sloping ST depression may represent ongoing ischemia in patients with acute coronary syndrome, though this finding can also be seen in patients with

tachycardia. Identifying up-sloping ST-segment depression as a possible sign of ongoing ischemia will allow internists to provide appropriate care, including a timely referral for invasive treatment, to patients with suspected acute coronary syndrome.

SLOW AND STEADY WINS THE RACE Cecilia Berardi; Darlene LeFrancois. Montefiore Medical Center, Bronx, NY. (Tracking ID #2194006)

LEARNING OBJECTIVE #1: Recognize atrial flutter presentations in elderly populations

LEARNING OBJECTIVE #2: Manage arrhythmias in patients with history of left ventricular outflow obstruction

CASE: A 90 year-old female experienced the sudden onset of palpitations and chest tightness causing her to gasp for air on the morning of admission while she was getting out of the shower. The patient's past medical history was significant for known left ventricular concentric hypertrophy with a small hyperdynamic left ventricle and a severe outflow gradient with systolic anterior motion (SAM) of the mitral valve documented previously in the setting of diuretic use, hypertension on daily metoprolol and benazepril, and hyperlipidemia on atorvastatin. The patient's presenting blood pressure was 154/107 mmHg, heart rate 132 bpm, her oxygen saturation was 95 %, she was afebrile. Her physical exam was significant for rales at the lung bases but no peripheral edema. Electrocardiogram revealed a regular QRS complex; due to the fast rate, p waves were difficult to detect and the rhythm was initially interpreted as sinus tachycardia. Cardiac enzymes were normal, as was pro-BNP. The patient was given two liters of normal saline and continued on metoprolol but subsequently experienced a reduction in blood pressure. Metoprolol 5 mg was given twice with no change in rate or rhythm. After adenosine 6 mg transiently slowed the ventricular rate, atrial flutter was noted on telemetry with a heart rate of 125 bpm in a 2:1 atrioventricular (AV) conduction pattern. Enoxaparin was started and successful electrical cardioversion was performed after a trans-esophageal echo showed normal left atrium size with no thrombus. The patient's symptoms improved and she was discharged on long-term anticoagulation and amiodarone.

DISCUSSION: Atrial flutter is characterized by a rapid atrial depolarization at a rate of approximately 300 bpm and a regular ventricular rate of about 150 bpm, when in its typical 2:1 AV nodal conduction pattern. The EKG shows absence of p waves with a sawtooth pattern in leads II, III, and aVF. The incidence increases markedly with age. In elderly patients, especially treated with beta-blockers such as ours, atrial flutter can present with a slower atrial rate and can also demonstrate a 1:1 conduction pattern across the AV node, which may be confused with sinus rhythm. Therefore, it is important to study the EKG closely in these patients in order to recognize underlying arrhythmias. The hemodynamic effect of atrial flutter on the left heart is an increase in the mean left atrial pressure, a reduction in the left ventricular end-diastolic pressure, with a subsequent decrease in systolic blood pressure, and increase in diastolic pressure. In patients with preexisting mitral disease and left ventricular remodeling, SAM and consequent worsening of left ventricular outflow tract (LVOT) obstruction frequently occurs with supraventricular arrhythmia. Furthermore, atrial flutter, regardless of the presence of SAM, can precipitate LVOT obstruction through decreased left ventricular filling and therefore decreased ventricular pressure otherwise necessary to counteract the outflow tract obstruction. Typical complaints include palpitations, fatigue, lightheadedness, and shortness of breath. Less frequently patients refer significant dyspnea, angina, hypotension, anxiety, presyncope. In patients with LVOT obstruction, for the above hemodynamic reasons, atrial flutter is poorly tolerated and is more likely to present with severe symptoms. As such, in elderly patients with history of mitral valve disease and LVOT obstruction, it is challenging yet vitally important to recognize atrial flutter, or any other supraventricular arrhythmias. Restoration and maintenance of sinus rhythm with cardioversion and antiarrhythmics is essential in this patient population in order to optimize cardiac function and minimize symptoms.

SNAP, CRACKLE, STROKE Christina Molumby; Jabraan Pasha. University of Oklahoma—Tulsa, Tulsa, OK. (Tracking ID #2157847)

LEARNING OBJECTIVE #1: Recognize vertebral artery dissection as a cause of stroke especially in patients younger than 45 years old.

LEARNING OBJECTIVE #2: Recognize neck manipulation, even self-manipulation, as a risk factor for vertebral artery dissection.

CASE: A 41-year-old female presented with a complaint of headache, nausea, vomiting, dizziness, and peripheral vision loss from her left eye since the day before admission. She stated that she had been "clumsy" and struggled to walk without falling. Vital signs were within normal limits. On physical exam, the patient had homonymous hemianopsia on the left. She had an ataxic gait and positive Romberg sign. There was no focal neurological deficit. Her initial CT scan of her head showed an infarction involving the right cerebellar hemisphere. CTA head and neck and MRI brain showed right vertebral artery dissection

from V2 to V3, right cerebellar infarction, right parietal infarction, and right occipital infarction. PT, PTT, and INR were all within normal limits. A hypercoagulability panel, including cardiolipin antibody and lupus anticoagulant, was all within normal limits. The patient had never had a chiropractic adjustment. However, she would routinely vigorously over-rotate her neck until she heard a "pop" sound. She admitted to doing this in both directions of rotation several times a day on a daily basis. She was discharged with high dose aspirin therapy, a statin, and Depakote for her headaches and was advised to stop twisting her neck.

DISCUSSION: The annual incidence of vertebral artery dissection is estimated to be between 1 and 1.5 per 100,000 and may account for 20 % of strokes in patients younger than 45.^{1,2} Many case reviews have been done in an attempt to determine causality between spinal manipulation and stroke. One such study that found that patients younger than 45 with vertebral artery dissection were 5 times more likely to have visited a chiropractor in the month before the incident compared to an age matched control group.³ Another case-controlled study concluded that spinal manipulation is independently associated with vertebral artery dissection.⁴ However, causality was never established. The incidence of spontaneous vertebral artery dissection is low. However, it is emerging as a cause of new onset strokes in patients under the age of 45. More study is needed to establish a causal relationship between spinal manipulation and dissection. Suspicion for vertebral artery dissection may be increased if the patient has a history of any neck manipulation. References 1. Redekop GJ. SOFOSBUVIR INDUCED ANEMIA: AN IMPORTANT SIDE EFFECT OF A NOVEL HEPATITIS C MEDICATION Tina P. Kapadia; Alfred Burger. Mount Sinai Beth Israel, New York, NY. (Tracking ID #2199197)

LEARNING OBJECTIVE #1: Review the adverse effects associated with a novel Hepatitis C medication, Solvadi (Sofosbuvir).

LEARNING OBJECTIVE #2: Emphasize the importance of medication reconciliation.

CASE: A 68 year old male with a history of AIDS (CD4 238 cells/mL in June 2014) on HAART, chronic Hepatitis C, Hepatitis B, COPD, CKD stage III, and active IV drug abuse presented with a chief complaint of generalized weakness of one month duration. His symptoms were associated with exertional dyspnea of the same duration. Review of systems was negative for fever, chills, chest pain, palpitations, syncope, orthopnea, lower extremity swelling, melena, BRBPR, or hematemesis. On admission, the patient was afebrile, tachycardic to 118, normotensive and saturating normally on room air. Physical exam was significant for a thin, elderly, chronically ill appearing male, with pale sclerae. Labs demonstrated a hemoglobin of 5.5 g/dL, MCV 96.3 fL, decreased from 11.1 g/dL 11 weeks prior to admission. Anemia work up revealed a negative FOBT, absolute reticulocyte index of 1 %, and normal B12, folate, iron and hemolytic studies, however these were obtained post-transfusion. Labs ordered to evaluate common viral causes showed Parvovirus B19 IgM 0.1, IgG 0.5, CMV PCR <200 copies/mL, and negative EBV heterophile Antibody screen. The patient's HIV Viral load was 55 copies/mL. Upon further investigation, the patient had recently been initiated on treatment for his chronic Hepatitis C. Collateral information from his primary care physician identified the regimen as a combination of Ribavirin and Solvadi (Sofosbuvir). With the assistance of hematology consult service, the patients drop in hemoglobin was attributed to the initiation of these medications. The patient required blood transfusions to improve his anemia and was advised to discontinue these medications.

DISCUSSION: We present here an interesting case of drug induced anemia from a novel Hepatitis C medication. Sofosbuvir (Solvadi) was recently approved for treatment of Hepatitis C in 2013. Since its approval, Sofosbuvir has been the point of much debate. Due to its cost, and the debate it has raised, this new, efficacious drug has likely been utilized less frequently than fully indicated. The current estimated prevalence of Hepatitis C is 1 % of the US population. Treatment of hepatitis can reduce morbidity and mortality from cirrhosis and hepatocellular carcinoma. Sofosbuvir will likely be more commonly included into treatment regimens in the near future. Functioning as an oral nucleotide analog, Solvadi inhibits the HCV RNA polymerase enzyme. The common side effects have not been widely discussed and encountered by many providers due to its slow adoption into clinical use. The most common adverse effects identified in clinical trials of patients who were on a regimen of Solvadi, Peg-Interferon, and Ribavirin were fatigue, headache, nausea, insomnia, and anemia. Approximately 20 % of patients experienced these side effects. Twenty-three percent of patients on this three drug combination had a change in hemoglobin to less than 10 g/dL, and 2 % of patients were noted to have hemoglobin of less than 8.5 g/dL. This was greater in the three drug combination, than in

drug regimens of Ribavirin and Peg-Interferon (14 and 2 % respectively), and Solvadi and Ribavirin (6 and 1 % respectively). Anemia is a common problem faced in the hospital setting and can require an extensive work up. This case reminds us that accurate medication reconciliation is a pivotal part of the clinical picture. High discrepancy rates in medication reconciliation are a well-known obstacle in the inpatient setting, and can play a significant role in preventing drug-disease and drug-drug interactions. This case shows the profound impact this new medication, initially absent from the patient's medication reconciliation, had on the diagnosis and treatment for this patient.

SPINAL EPIDURAL ABSCESS PRESENTING AS PARAPLEGIA AND DISSEMINATED SEPTIC ARTHRITIS IN AN IMMUNOCOMPETENT ADULT Jeremiah Stromich²; Adrian P. Umpierrez De Reguero¹; Pinky Jha³. ¹Froedtert & the Medical College of Wisconsin, Milwaukee, WI; ²Medical College of Wisconsin, Waukesha, WI; ³medical college of wisconsin, Milwaukee, WI. (Tracking ID #2198631)

LEARNING OBJECTIVE #1: Recognize an atypical presentation of a spinal epidural abscess (SEA)

LEARNING OBJECTIVE #2: Learn about the diagnosis and management of SEA

CASE: A 57 year old male with a past history of hepatitis C (treated with PEG-Interferon), hypertension, and gout presented with 1 week of bilateral hand edema, pain and erythema affecting multiple joints (right wrist, left first and second MCP, left shoulder and bilateral hips). He was initially treated by his PCP with Prednisone for a presumed gout flare. The ED drew blood cultures and consulted Orthopedic surgery for aspiration of the right wrist both of which later revealed Methicillin Sensitive *Staphylococcus Aureus* (MSSA). He denied any trauma, IV drug use, back pain and fevers. His initial neurological exam had no focal deficits. He was admitted and started on Vancomycin and Zosyn. The following day he underwent incision and drainage of his right wrist and left thumb IP joint. The third day of hospitalization, infectious disease was consulted and recommended a TEE and a WBC scan. The TEE was negative for valvular vegetations and the WBC scan showed increased uptake involving the right wrist and hip, left AC joint, elbow, thumb and ankle. On hospital day four, cultures grew MSSA and he was switched to Nafcillin. He developed lower extremity paralysis and hypoaesthesia as well as urinary retention which he felt began soon after admission. A spinal MRI with contrast demonstrated a T2 to T8 anterior SEA, L5 SEA, septic arthritis involving L4-L5 and L5-S1 facet joints, left psoas muscle abscess measuring 3.1×1.5 cm. Neurosurgery and Interventional Radiology were consulted but felt surgical intervention was not warranted given the extent, location and duration of the patient's symptoms. He developed complete paraplegia, urinary retention, bowel incontinence and drastically reduced sensation below his umbilicus. He later recalled a left hip injection 3 months ago as well as a history of lower back injections which he believes were facet joint. The patient was discharged to a long term acute care facility and follow up in Infectious Disease clinic 6 weeks after discharge revealed increased lower extremity sensation with some movement but continued inability to walk, urinary retention and bowel incontinence. A repeat MRI showed resolution of the T2-T8 SEA.

DISCUSSION: Here we report a case of MSSA SEA that progressed to paraplegia. SEA is a localized collection of pus between the dura mater and the vertebral column and the most common isolate is *S. aureus*. The classic triad presentation of SEA is back pain, fever and neurologic deficits but this triad occurs in about 13 % of patients which contributes a delay in diagnosis. Majority of cases will present with back pain (70–90 %) and fever (60–70 %); however our patient did not. Risk factors for SEA are impaired immune status, IV drug abuse, instrumentation of the spinal column and a source of infection. Numerous reports have demonstrated lumbar facet joint septic arthritis as a rare cause of SEA from local extension into the epidural space. The gold standard diagnostic test for a SEA is MRI with contrast but CT myelography can be substituted in centers without MRI or when MRI is contraindicated. Radionuclide studies have more sensitivity than radiographs but remain non-specific and carry a high false negative rate as seen in our patient. Studies suggest that the more chronic the infection and the use of antibiotics may contribute to a higher false negative rate. Given this less specificity and higher false negative rate, radionuclide scans are not recommended for routine use in diagnosing spinal infections. The treatment of choice is both surgical intervention with decompression and drainage of the SEA with antibiotics for at least 4–6 weeks. Empiric antibiotic coverage should include an anti-staphylococcal agent and aerobic gram negative bacilli (i.e. third generation cephalosporin or carbapenems). Blood and cultures from the SEA should be obtained, preferably before the initiation of antibiotics, but treatment should not be delayed in unstable patients. A delay in diagnosis can lead to a delay in treatment and the development of paraplegia, estimated at 34 % at time of presentation. The more severe or prolonged the neurological symptoms the poorer the prognosis. Surgery is not likely to be a therapeutic option in patients who have experienced paraplegia for longer than 36 h. The most severe complications of SEA include irreversible paralysis, which affects anywhere from 4 to 22 % of patients and mortality, estimated at 5 to 30 %. Given the

significant morbidity and mortality, SEA should be considered in any patient with acute onset neurological deficits.

SPINLED OUT OF CONTROL: A RARE, AGGRESSIVE FORM OF LUNG CANCER Randy Chung¹; Jeffrey T. Bates^{1, 2}. ¹Baylor College of Medicine, Houston, TX; ²Michael E. DeBakey VA Medical Center, Houston, TX. (Tracking ID #2191314)

LEARNING OBJECTIVE #1: Recognize pulmonary sarcomatoid tumor as a clinically aggressive subtype of non-small cell lung cancer.

LEARNING OBJECTIVE #2: Identify the clinicopathologic features of sarcomatoid carcinoma of the lung.

CASE: The patient is a 79-year-old man with a 40 pack-year smoking history who presented with progressive right hip pain. During the 2 months prior to his admission, he noted generalized fatigue, poor appetite, and an unintentional weight loss of 20 lb. Two weeks prior to admission, he began experiencing a constant pain in his right hip which radiated down his leg. He did not have fever, chills, low back pain, bladder incontinence, numbness or tingling. Physical examination was notable for diminished breath sounds over the left upper lung field and decreased strength of his right lower extremity secondary to pain. A chest x-ray showed a large left apical pleural-based mass. A subsequent computed tomography (CT) scan of the thorax revealed a 7.3-cm left upper lobe mass invading the chest wall. A biopsy confirmed a high-grade spindle cell neoplasm consistent with sarcomatoid carcinoma. A positron emission tomography (PET) scan showed metastatic lesions to the right iliac wing, ascending colon, and left supraclavicular lymph nodes. Given his poor functional status, the patient was deemed not to be a candidate for surgery or chemotherapy; he opted for palliative radiation therapy to his right hip.

DISCUSSION: Pulmonary sarcomatoid carcinoma (PSC) is a rare histologic subtype of non-small cell lung cancer (NSCLC), accounting for less than 1 % of all lung malignancies. PSCs are defined as poorly differentiated NSCLCs that contain a sarcomatous component or sarcoma-like element. Five subtypes are recognized by the World Health Organization: spindle cell carcinoma, giant cell carcinoma, pleomorphic carcinoma, carcinosarcoma, and pulmonary blastoma. The patients are usually male with a history of moderate to heavy tobacco consumption; mean age at diagnosis is between 65 and 75 years. PSCs commonly present as large (mean 7 cm) solitary peripheral masses with predilection for the upper lobes of the lung. Compared to other histologic subtypes, PSC behaves in an aggressive manner and tends to be a predictor of poor prognosis. In one retrospective study, the 5-year survival for PSC patients was 24.5 % compared with 46.3 % for NSCLC patients. Limited evidence currently exists supporting any particular treatment strategy. While surgical resection is likely associated with improved outcomes in early stage disease, several case series suggest high rates of resistance to conventional first-line chemotherapy.

STONES, BONES AND GROANS FOLLOWING COSMETIC SILICONE INJECTIONS Matthew Stuart. Montefiore Medical Center, New York, NY. (Tracking ID #2199289)

LEARNING OBJECTIVE #1: Understand the pathophysiology of hypercalcemia as a result of granulomatous disease

LEARNING OBJECTIVE #2: Review the anti-inflammatory effects of tetracyclines as an alternative to corticosteroids

CASE: A 38 year-old male to female transgender woman was admitted for 2 days of fever, nausea, malodorous urine and lower back pain. The patient has a history of chronic hypercalcemia, nephrolithiasis, recurrent urinary tract infections, and silicone injections to the buttocks and breasts. On exam, she had an ulceration of her right breast draining serosanguinous fluid, bibasilar rales, and two buttocks ulcers draining purulent fluid. Routine laboratory analysis revealed a hemoglobin of 11.6 g/dL, normal white blood cell count, calcium of 12.6 mg/dL, and albumin of 3 g/dL. Patient was found to have a slightly decreased parathyroid hormone (PTH) of 9 pg/mL, normal vitamin D 1,25 OH (calcitriol), decreased vitamin D 25-OH of 8 ng/mL, normal parathyroid hormone related protein, and elevated angiotensin converting enzyme of 98 U/L. CT of the pelvis revealed extensive and infiltrative granuloma formation in the buttocks and upper thighs from prior free silicone injections. Review of prior skin biopsies revealed areas of necrotic tissue with calcifications and acute inflammation. The patient had previously been treated with corticosteroids, however was unable to tolerate the steroids due to palpitations and tachycardia. The patient was treated instead with doxycycline.

DISCUSSION: Granulomas are a rare complication of silicone injections for cosmetic procedures. This is especially true in the transgender population. Multiple case reports have identified granulomatous reactions to free silicone injections, occasionally resulting in hypercalcemia. Although the pathophysiology of granuloma formation is unknown, it has been postulated that T-cell activation and release of cytokines, primarily tumor necrosis factor alpha, promote granuloma formation.

Hypercalcemia is a known complication of granulomatous disorders. In healthy patients, the conversion of vitamin D 25-OH to calcitriol is normally mediated by 1-hydroxylase in the proximal tubule of the kidney. This process is regulated by parathyroid hormone and the serum phosphate concentration. In patients with sarcoidosis and other granulomatous diseases, an elevated level of 1-hydroxylase has been demonstrated in activated macrophages. This results in an increased conversion of vitamin D 25-OH to calcitriol. Increased serum calcitriol results in increased intestinal absorption of calcium and in increased bone resorption. This process is independent of PTH regulation. Corticosteroids have been shown to inhibit the calcitriol synthesis by activated macrophages. However, due to our patient's inability to tolerate glucocorticoids, she was treated with doxycycline. The anti-inflammatory effects of tetracyclines have been studied in multiple cutaneous and autoimmune diseases and can be classified as indirect or direct. The indirect activity is based on the anti-bacterial effect of tetracyclines resulting in decreased neutrophil chemoattractants released by the bacteria. The direct effect is related to the ability of tetracyclines to inhibit leukocyte chemotaxis and to inhibit protein kinase C, which is believed to be a key enzyme involved in signal transduction and control of inflammation in granulomatous disease. It is important for physicians and patients to understand the unintended, unforeseen, long-term complications of elective cosmetic procedures. Further, larger randomized clinical trials are needed to evaluate the anti-inflammatory effects of tetracyclines in clinical practice.

STONES, BONES, GROANS, AND PSYCHIATRIC OVERTONES: TREATING A YOUNG PATIENT WITH HYPERCALCEMIA OF MALIGNANCY DUE TO METASTATIC EWING'S SARCOMA Farrell Tobolowsky. University of Texas at Houston, Houston, TX. (Tracking ID #2199724)

LEARNING OBJECTIVE #1: To recognize the poor prognosis in a cancer patient with hypercalcemia

LEARNING OBJECTIVE #2: To treat a patient with hypercalcemia of malignancy

CASE: C.H. is a 21 year-old male with a past medical history of Ewing's Sarcoma of the left thigh (diagnosed in 2012 with lung metastases) who presented from jail with shortness of breath, chest pain, back pain, and confusion. Patient stated that he was having these symptoms but was unable to communicate extensively. According to the nurse practitioner at the jail, patient was acting unusual that morning in the county jail clinic, and it was thought to be secondary to his pain medications. C.H. was then referred to the emergency department where he was found to be tachycardic to the 130's with a temperature of 100.5°, respiratory rate of 32, and oxygen saturation of 91 %. Patient refused a non-rebreather mask and was put on 6 l of oxygen. He was unable to give a full history and provide a complete review of systems. On physical exam, C.H. was found to be oriented to place and person, had bilateral crackles upon auscultation of the lungs, and a wound on the left upper thigh that appeared to have granulation tissue and minimal purulent drainage. Initial laboratory studies showed hypercalcemia with a calcium level of 16.8 and a creatinine of 2.9 (baseline of 0.8). Intact parathyroid hormone was low at 5.3. Leukocyte count was within normal limits. However, due to the patient's fever and altered mental status, he was commenced on broad spectrum antibiotics for possible hospital acquired pneumonia. Treatment of hypercalcemia was commenced with normal saline, calcitonin, and pamidronate. CT abdomen/pelvis showed new metastases to the liver, spine, pelvis, and ribs as well as increased lung metastases. The patient received multiple packed red blood cell transfusions as the metastases were hemorrhagic. Blood and urine cultures continued to remain negative for growth. Antibiotics were eventually discontinued once infection was deemed unlikely. After having a goals of care discussion with the patient and the palliative care team, comfort measures were initiated, and the patient passed away 12 days after admission.

DISCUSSION: C.H. presented with many of the typical symptoms of hypercalcemia such as bone pain, confusion, lethargy, and abdominal pain, which are usually seen with a calcium above 12 mg/dl. Severe hypercalcemia is classified as a value above 15–16 mg/dl. If a patient who has cancer presents with elevated calcium, it signifies a very poor prognosis, and approximately 50 % of these patients die within 30 days. This is correlated to advanced tumor burden in an individual and occurs in 20 to 30 % of patients with cancer during the course of their disease. Further, the patient's hypoxia on presentation can be explained by his extensive lung metastases, and the patient's acute renal failure is most likely due to calcium deposition in the kidneys. As the patient's intact parathyroid hormone was found to be low, the increased calcium was most likely due to malignancy rather than primary hyperparathyroidism. Hypercalcemia associated with cancer can be due to four different mechanisms. Most commonly, humoral hypercalcemia can occur due to systemic secretion of PTHrP, which causes increased bone resorption and the kidney to retain more calcium. The other mechanisms include: local osteolytic hypercalcemia from bone resorption in areas near the malignant cells in the marrow (likely in our case), secretion of an active form of vitamin D by lymphomas, and rarely, ectopic parathyroid hormone produced by tumors to cause release of bone calcium. Osteolysis is likely in our

case as the tumor has metastasized further to bone, and PTHrP secretion is less common in a primary Ewing's Sarcoma. Regardless of the mechanism, the current literature illustrates that the treatment of hypercalcemia of malignancy is with intravenous fluids, calcitonin, bisphosphonates, steroids, and in some cases, loop diuretics. Calcitonin acts the most rapidly; however, it is only effective for 2–3 days. Bisphosphonates may take days to work, yet the effects can last weeks to months. Fluids should be utilized at a rate of 200 to 500 cc/hour and act immediately to increase calcium excretion from the kidney. Loop diuretics should not be utilized in patients with severe metabolic derangements or until rehydration is achieved. These treatments help to decrease the calcium to normal limits for 1 to 3 weeks while treatment is initiated for the cancer. In C.H.'s case, the calcium returned to normal with treatment, yet the cancer was already metastatic and hemorrhagic throughout the body; therefore, the mainstay of treatment became palliative. Recognizing that hypercalcemia was indicative of advanced disease, even in a cancer with a typical survival rate of over 50 %, led the team to obtain further imaging in order to realize the poor prognosis of this young patient.

STOWAWAY: SCHISTOSOMIASIS AS A RARE CAUSE OF CHRONIC DIARRHEA IN THE UNITED STATES Yihan Yang²; Tao Liu²; Sheldon Campbell¹; Abhay J. Dhond². ¹Yale School of Medicine, New Haven, CT; ²YNHH, New Haven, CT. (Tracking ID #2194139)

LEARNING OBJECTIVE #1: Evaluate patients with chronic diarrhea

LEARNING OBJECTIVE #2: Recognize and manage patients with schistosomiasis

CASE: A 30 year old male immigrant from Brazil without travel since 2003 presented with a 1.5 year history of diarrhea. The diarrhea initially occurred ten times a day but had decreased to five times daily at presentation. Bowel movements were watery with occasional blood, associated with lower abdominal cramping. His diarrhea and abdominal pain were not related to oral intake. He denied any fevers, chills, night sweats, weight loss, decreased appetite, oral ulcers, nausea, vomiting, joint or muscle aches, rash, recent travel or hiking, or any antibiotic exposure prior to onset of diarrhea. He had no significant medical or surgical history and was not on any medications. Family history was significant for a paternal grandfather with unknown GI cancer in his 50s. He had a ten pack-year smoking history and occasional marijuana use. He denied alcohol use or IVDU. Currently unemployed, he previously worked in construction. On exam he was afebrile, BP 101/63, HR 62. He had no oral lesions and his heart and lung exam was normal. His abdomen was notable for mild tenderness to palpation in the lower quadrants bilaterally with hyperactive bowel sounds but no organomegaly. A rectal exam revealed brown, guaiac negative stool. There was no lymphadenopathy. Laboratory testing revealed normal chemistries, mild normocytic anemia of chronic inflammation, no eosinophilia, normal LFTs, amylase, lipase and TSH negative stool culture, ova and parasites, fecal leukocytes, transglutaminase IgA, *C. difficile* antigen, HIV, and Quantiferon Gold positive FOBT and minimally elevated ESR of 21. CT abdomen and pelvis 7 months prior to presentation showed no colitis or other abnormalities. Repeat O&P was negative. Given history of bloody diarrhea with positive FOBT, anemia, and ongoing diarrhea, he was referred for colonoscopy. Two nodules were found within the sigmoid colon and biopsied. Pathology revealed colonic schistosomiasis with surrounding eosinophilic colitis. Testing for concomitant *Strongyloides* infection was negative. He was treated with Praziquantel 40 mg/kg divided into two doses. His diarrhea and abdominal pain resolved completely.

DISCUSSION: Chronic diarrhea is defined as the presence of loose stools for greater than 4 weeks. Common causes in the United States include lactose intolerance, celiac disease, inflammatory bowel disease, irritable bowel syndrome and chronic infections. Assessment of the history should include diarrhea characteristics, associated symptoms, and exposures to help narrow the differential into three classic categories: watery (secretory or osmotic), inflammatory, or fatty. Laboratory tests should include serum electrolytes, CBC with differential, thyroid and liver function studies, fecal occult blood, fecal leukocytes/lactoferrin/calprotectin, ova and parasites, ESR, CRP, and antitissue transglutaminase IgA. Inconclusive diagnosis, weight loss, bloody diarrhea or persistent diarrhea despite therapy should prompt endoscopic evaluation. Pertinent features of this case included the patient's emigration from Brazil 11 years prior, bloody diarrhea, abdominal pain unassociated with food intake, presence of anemia and mildly elevated ESR concerning for inflammatory or chronic infectious etiology. While schistosomiasis is common in the patient's native country of Brazil, we found only eight published reports of colonic schistosomiasis in the US on PubMed search. Schistosomiasis is a helminthic parasitic disease affecting an estimated 200 million people worldwide with high morbidity and mortality in Sub-Saharan Africa, Southeast Asia, and South America. Acute infection can present with fevers, chills, myalgia, abdominal pain, diarrhea, and hepatosplenomegaly. Chronic infection can cause portal hypertension, splenomegaly, colonic polyps with bloody diarrhea, pulmonary hypertension and glomerulonephritis. Diagnosis can be made through stool O&P, serology, or tissue biopsy. Praziquantel 40–60 mg/kg taken in divided doses over 1 day is first line therapy. Our patient was atypical as his symptoms began eleven years after possible exposure in Brazil, and he lacked "classic" positive O&P and

elevated eosinophils, likely due to a low parasite burden. This case demonstrates that long-lived infections, like schistosomiasis, should remain on the differential for patients with chronic diarrhea and remote travel to or from endemic areas.

SUBMUCOSAL LESIONS PRESENTING WITH RECTAL BLEEDING—ENDOMETRIOSIS IN THE GASTROINTESTINAL TRACT

Fahd Jowhari¹; Pearl Behl²; Sean Pritchett³. ¹Queen's University, Kingston, ON, Canada; ²University of Toronto, Toronto, ON, Canada; ³Belleville General Hospital, Belleville, ON, Canada. (Tracking ID #2196515)

LEARNING OBJECTIVE #1: Recognize intestinal endometriosis as an important cause of rectal bleeding in the adult female.

LEARNING OBJECTIVE #2: Include intestinal endometriosis in the differential for undiagnosed sub-mucosal lesions in the adult female's GI tract.

CASE: A 46-year-old female presented with a 4-week history of irregular bowel movements and hematochezia. There was no associated abdominal pain, nausea/vomiting, hematemesis, coffee ground emesis, or melena. There were no fevers, chills, weight loss (some weight gain), history of travel or sick contacts. Family history was negative for colon cancer, celiac disease or Inflammatory Bowel Disease (IBD). Her past medical history was unremarkable with no prior surgeries or endoscopies/colonoscopies. She was on no medications. She had been a lifelong non-smoker and non-drinker and had no drug allergies. Examination was unremarkable with no palpable masses or areas of tenderness in the abdomen. DRE was unremarkable. Basic laboratory investigations and inflammatory markers were all normal. With non-contributory labwork and physical exam findings, an elective colonoscopy was performed. Two large submucosal lesions were found (30 cm & 40 cm from the rectum) and appearances were most in keeping with GIST tumors. Deep biopsies were taken and pathologies revealed normal colonic mucosa, muscularis mucosa and superficial submucosa, with no neoplastic spindle cell lesions present. CT imaging of the abdomen/pelvis was unremarkable & the submucosal lesions could not be seen on imaging. Given the persistence of symptoms & focally identified lesions on colonoscopy, our patient underwent a repeat colonoscopy for landmarking of the submucosal lesions, and a subsequent left hemi-colectomy & end anastomosis for resection of lesions. Pathologies from the resected specimen interestingly revealed extensive endometriosis characterized by variably sized columnar-lined glands cuffed by endometrial-type stroma, extending from the sub-mucosa to the mesentery. The diagnosis was supported by immunohistochemistry (positive ER immunostain with CD10 reactivity). The appendix (resected) also showed evidence of endometriosis, and the anastomotic margins were histologically normal. The patient did very well post-operatively. Her bowel movements became regular and formed, with no evidence of further lower GI bleeds.

DISCUSSION: Endometriosis occurs in 6 to 10 % of the general female population. Its presence in the GI tract has been reported in several case reports with the sigmoid colon and rectum being the two most common sites, followed by the ileum, ileocecal area, appendix & anterior rectal wall. Establishing a diagnosis of intestinal endometriosis is often a diagnostic challenge as none of its symptoms are pathognomonic, and even though the symptoms should physiologically be worse cyclically with menses, this is not always the case. The disease is primarily diagnosed in premenopausal women, but can also occur in postmenopausal women as endometrial implants may cause a fibrotic reaction in the muscle of the affected bowel wall even after cessation of ovarian function. Presenting symptoms are often non-specific and may include unexplained digestive problems, tenesmus, per-rectal bleeding, bloating, constipation, diarrhea, and pain. Pain can be epigastric, abdominal, pelvic or rectal with the symptoms varying depending on the location, depth of invasion, adnexal adhesions, and the presence of a consequential partial or complete bowel obstruction. Endoscopic diagnosis of intestinal endometriosis is challenging, as most lesions do not infiltrate the gastrointestinal mucosa; and therefore radiological modalities such as CT scans, MRI or trans-vaginal ultrasonography may be helpful in diagnosis. Luminal findings suggestive of endometriosis range from eccentric wall thickenings, polypoid lesions, endometrioid heterotopias of the mucosa, and gross surface nodularities/ulcerations. Rates of histological confirmation of the diagnosis seem to be highest in cases with surface nodularities, with inconclusive results seen in most other cases. Management involves symptom control and maintaining fertility. This is achieved primarily from surgical resection of all visible endometriosis (via laparoscopic bowel resection, or segmental bowel resection depending on disease extent). Hormonal therapies may improve symptoms in the short term but they do not improve fertility. In summary, the diagnosis of intestinal endometriosis can be challenging. However, it is prudent to consider this in the differential diagnosis of sub-mucosal GI lesions, especially in a premenopausal patient presenting with vague abdominal symptoms including pain, irregular bowel movements or bleeding from the GI tract. Cyclical bowel symptoms with menstruation, along with historical evidence of menometrorrhagia, infertility and dyspareunia should point one in the direction of intestinal seeding; however, the absence of these should not deter one from considering the diagnosis.

SUGAR RUSH: KETOSIS PRONE DIABETES Lika E. Targan; Marie Brubacher. Beth Israel Deaconess Medical Center, Boston, MA. (Tracking ID #2196611)

LEARNING OBJECTIVE #1: Recognize the presentation and epidemiology of ketosis prone diabetes

LEARNING OBJECTIVE #2: Review the management of ketosis prone diabetes

CASE: A 52 year old African American gentleman with no known medical problems presented to the ICU after being found unconscious in his home. Laboratory analysis revealed pH 7.05, bicarbonate 10, anion gap of 30, blood sugar >1500, and ketonuria. He was treated for diabetic ketoacidosis (DKA) per hospital protocol. His anion gap closed, his mental status improved, and he was switched to a long acting insulin regimen once he was able to tolerate PO intake.

DISCUSSION: The diabetes categories we commonly know classify diabetes as Type I or Type II. Type I diabetic patients have autoimmune destruction of pancreatic beta cells, require life-long insulin therapy, and are prone to develop DKA. Patients with Type II diabetes develop insulin resistance, but are generally not considered to be at risk for DKA. However, there is a group of patients who present with DKA, but do not require long-term insulin therapy. These patients fall into the group called Ketosis Prone Diabetes (KPD). KPD is classically a syndrome of obesity, unprovoked ketoacidosis, reversible β -cell dysfunction, and near-normoglycemic remission. The underlying mechanism for beta cell dysfunction in this group not well defined. KPD is most common among African Americans and Hispanics. These patients with KPD have clinical features of Type II diabetes: They are obese, have a strong family history of diabetes, a low prevalence of autoimmune markers, and no association with HLA. Intense management with insulin results in an improvement in beta cell function and many patients are ultimately able to discontinue insulin therapy. The system of classification that most accurately predicts the need for insulin treatment 12 months after presentation with DKA is known as the A β system. This system classifies diabetics into 4 groups: 1) A+ β -: Autoantibodies present, beta cell function absent. 2) A+ β +: Autoantibodies present, beta cell function present. 3) A- β -: Autoantibodies absent, beta cell function absent. 4) A- β +: Autoantibodies absent, beta cell function present. A- β patients are the largest KPD subgroup and most commonly present with DKA, yet clinically behave as type II diabetes. Management requires the immediate treatment of DKA and subsequent close outpatient follow up for monitoring and assessment of the ability to discontinue insulin or intensify therapy. The natural history of KPD after the initial episode of DKA depends upon the presence of autoantibodies and beta cell reserve. Beta cell reserve is the key determinant of long-term glycemic control and dependence. Patients should be discharged on insulin therapy, regardless of the presumed phenotype of the KPD. Ultimately, assessment of beta cell reserve and autoimmunity, by measuring C-peptide levels and presence of antibodies, can help predict the clinical course. In clinical practice it is not always feasible to accurately assess beta cell functional reserve and beta cell autoantibodies based on cost restraints and assay availability. In general practice, the insulin dose can be gradually reduced, if ultimately possible, with monitoring of serum glucose and serum and urine ketones.

SUPERIOR MESENTERIC ARTERY SYNDROME: AN ACUTE ANGLE CAUSING CHRONIC ABDOMINAL PAIN Oluwaseun Shogbesan; Anene Ukaigwe; Adetokunbo F. Oluwasanjo; Anthony Donato. Reading Health System, West Reading, PA. (Tracking ID #2196282)

LEARNING OBJECTIVE #1: Recognize the role of angiography in evaluating chronic postprandial pain

LEARNING OBJECTIVE #2: Recognize the key clinical features of Superior Mesenteric Artery syndrome

CASE: A 44-year-old woman presented to her primary care office with a 3-year history of moderate to severe postprandial abdominal pain associated with nausea, post prandial vomiting, anorexia and 60-lb weight loss. Weight loss preceded the onset of abdominal pain, but then became progressive and unintentional. Significant past medical history included multiple abdominal surgeries, migraine headaches, depression and anxiety disorder. Physical examination revealed a hemodynamically stable but thin woman with body mass index of 19 kg/m². Abdominal and other examinations were unremarkable. Laboratory tests, including liver functions, electrolytes, creatinine, TSH, complete blood count were normal. Ultrasonography revealed a previous cholecystectomy and no hepatic or pancreatic lesions. Computed tomography scan of the abdomen and pelvis excluded mass lesions and obstruction. Esophagogastroduodenoscopy with biopsy showed esophagitis, and chronic active H. pylori gastritis. Her duodenum was grossly and microscopically normal. Colonoscopy was unremarkable. She completed triple H. pylori antibiotic therapy. Given her psychiatric history, the possibility of an eating disorder was explored and she was referred for psychiatric evaluation. A CTA of the abdomen and pelvis ordered to evaluate for a possible vascular etiology showed an aortomesenteric distance of 5.5 mm (Normal: 10 mm-28 mm), and aortomesenteric angle of 12° (Normal: 33-65°). Mild

distention of the proximal duodenum to 31 mm was also noted with compression of the distal portion of the duodenum to a diameter of 14 mm (Normal: 24 mm). A diagnosis of Superior Mesentery Artery (SMA) syndrome was made and she was referred to surgery for further management. She is presently being evaluated for a duodenojejunostomy bypass

DISCUSSION: Chronic abdominal pain is an extremely common complaint in the primary care setting. Although often functional, high value, cost-conscious care supports recognizing the key clinical features of abdominal pain due to vascular anomalies and the clinical presentations in which the use of Computed Tomography Angiography (CTA) is appropriate. Chronic postprandial abdominal pain can result from anatomical distortion of the superior mesenteric artery as seen in Superior Mesentery Artery (SMA) syndrome. SMA syndrome is characterized by postprandial epigastric pain, nausea and vomiting that relieves the pain, and weight loss which further aggravates the condition. This syndrome should be considered in patients with significant weight loss presenting with acute or chronic proximal bowel obstruction, especially when an extensive workup is otherwise negative. A CT scan may show signs of bowel obstruction, but in some cases like ours, it may be normal. The demonstration of an aortomesenteric angle less than 25° and an aortomesenteric distance less than 8 mm, with compression of the distal duodenum on CTA supports the diagnosis of SMA syndrome. Gaining lost weight is recommended; surgical procedures to correct anatomic obstruction are often indicated.

SYNCOPE IN THE YOUNG AND HEALTHY: A CASE REVISITED Camille Clarke. ¹Cambridge Health Alliance, Cambridge, MA; ²Harvard Medical School, Boston, MA. (Tracking ID #2199119)

LEARNING OBJECTIVE #1: Appreciate syncope in the presentation of pulmonary embolism

LEARNING OBJECTIVE #2: Review the pathophysiology of syncope in pulmonary embolism and clinical clues that can help distinguish these presentations from other less fatal etiologies

CASE: A 30 year old Caucasian female with no known medical history presented following two syncopal episodes. She felt lightheaded while walking then lost consciousness and fell twice. She admitted to not eating since the prior evening but denied any symptoms during the episode and was in her normal state of health. She formerly smoked but quit 8 years before and denied any alcohol or drug use. Her family history was significant for fainting episodes in her father and her only medication was oral contraceptives. On presentation her vital signs were normal. Physical exam revealed a normal cardiac and neurological examination with some transient light-headedness when changing position. Initial workup showed normal urinalysis, complete blood count, cortisol, prolactin, vitamin B12 and thyroid levels. She had mild hyponatremia on basic metabolic panel but a clear chest x-ray and normal EKG. On the night of admission, she reported feeling dizzy while ambulating to the bathroom and was noted to be tachycardic on telemetry. She denied any other symptoms during this episode. Morning vitals were unremarkable and physical examination near identical except for a split S2 murmur in her left upper sternal border. Repeat EKG revealed new T wave inversions in leads 3, V1-3, so ECHOCardiogram was obtained which showed a normal ejection fraction but severely enlarged left ventricle and elevation of the right ventricular systolic pressure. Troponin and BNP levels were obtained and elevated. Emergent computed tomography pulmonary angiography revealed large obstruction in the distal main pulmonary segment of right and left main pulmonary arteries causing right ventricular strain for which she underwent successful thrombolysis.

DISCUSSION: Pulmonary embolism is a frequent cause of death with wide clinical variations. Obstruction of the branches of the pulmonary trunk precipitates severe hypoxia and obstruction of this blood flow to the lungs can cause dyspnea, hemoptysis and pleuritic pain. This classic triad however, is rare, and several cases of pulmonary embolism discovered on autopsy were unsuspected before death. Syncope, though a common presenting complaint, can be an important symptom of this fatal event. It is often a result of impaired filling and reduced cerebral flow perfusion secondary to right heart failure from acute obstruction. Cardiac biomarkers can be used as a prognostic factor for patients with pulmonary embolism. Transient changes can be seen on EKG with classic S1Q3T3 pattern or T wave inversions in leads V1-3. In the case of our patient, her troponin and BNP were elevated demonstrating significant left ventricular dysfunction with acute right ventricular overload and there were marked variations of her EKG pattern. Though she did not have alarming risk factors and subsequent hypercoagulable studies were negative timely identification of this condition was imperative. With unexplained or 'idiopathic' presentations of syncope pulmonary embolism should be suspected as prompt diagnosis and treatment can be life-saving.

SYSTEMIC ALLERGIC REACTION TO INSULIN LISPRO IN AN INSULIN NAIVE TYPE 2 DIABETES PATIENT Divya Akshintala²; Manajyoti Yadav¹. ¹University of Illinois College of Medicine, Peoria, IL; ²University of Illinois College of Medicine at Peoria, Peoria, IL. (Tracking ID #2191341)

LEARNING OBJECTIVE #1: Recognize the potential for allergic reactions to recombinant human insulin

LEARNING OBJECTIVE #2: Consider other forms of insulin in such patients as hypersensitivity to one type does not preclude the use of other types of insulin

CASE: A 43-year-old male presented to the ED with confusion, abdominal pain, nausea and vomiting. Patient reported one month history of generalized weakness, polyuria and poor vision. He had no significant past medical history. His father had diabetes. Physical examination revealed tachycardia. Patient was lethargic, but oriented. Abdominal exam was remarkable for diffuse tenderness. All other systems were within normal limits. Initial laboratory studies were consistent with hemoconcentration and leukocytosis. The anion gap was high and ketones were detected in urine. Blood glucose level was markedly elevated. A diagnosis of diabetic ketoacidosis was made and an insulin drip and crystalloid infusion was started. With above management the ketoacidosis resolved over time. Patient was then started on a regimen of basal insulin glargine and mealtime insulin lispro. With the first few doses of insulin lispro patient started having generalized itching and skin flare reactions all over his body. He also had lip and palate swelling, without any respiratory distress. These symptoms were noted serially just after the insulin lispro injections. Insulin lispro was held, and the patient was treated symptomatically. Patient's symptoms dramatically improved after stopping insulin lispro. The expert opinion of an endocrinologist was sought. Patient was given NPH insulin and he did not have any further similar reactions. He was discharged home with no symptoms, on NPH insulin.

DISCUSSION: This case illustrates the potential for systemic type I hypersensitivity reactions with the use of insulin lispro and the importance of early clinical identification of the reaction. Although such reactions to different types of insulin are rare (Insulin Lispro ~ 1 %), they are predictable. The reaction can be in response to insulin itself, or to the various components in the mixture such as zinc, protamin and preservatives such as phenol or glycerol. Hypersensitivity to one type of insulin does not preclude the use of other types. Other forms of insulin must be considered and may provide successful treatment options in situations where insulin use is warranted.

TAKE TWO! AN UNEXPECTEDLY AGGRESSIVE COAGULASE NEGATIVE STAPHYLOCOCCUS Jien Shim; Rachel Solomon; Lindsay Gottlieb. Mount Sinai Medical Center, New York, NY. (Tracking ID #2196150)

LEARNING OBJECTIVE #1: Recognize *Staphylococcus lugdunensis* as a virulent species causing native valve endocarditis

LEARNING OBJECTIVE #2: Identify signs and symptoms of endocarditis in a young, healthy patient presenting in an ambulatory setting

CASE: A 31 year-old woman presented to resident clinic with progressive fatigue and myalgias for one month. Prior to the onset of symptoms, she had been very active working as a college instructor and running five miles daily. Her function had become increasingly limited by anorexia, weakness, fevers, chills, myalgias, and right hip pain. Her medical history included anemia and a heart murmur since childhood. She denied intravenous drug use. In clinic, she was well appearing and afebrile, with a blood pressure of 86/62 mm Hg, heart rate 104 beats-per-minute, and a 2/6 systolic ejection murmur loudest at the apex. Labs revealed hemoglobin of 8.5 g/dL, leukocytosis to 18,400/uL (86 % neutrophils), thrombocytosis to 696,000/uL, Erythrocyte Sedimentation Rate 99 mm/hr, and C-Reactive Protein (CRP) 36.3 mg/L. The patient was called in for follow-up but did not come. One month later, she returned unable to stand or ambulate due to pain in her right hip and profound weakness. On transfer to the hospital for admission, labs showed persistent leukocytosis, anemia and CRP 108 mg/L. Transesophageal echocardiogram revealed rheumatic heart disease, severe mitral regurgitation, and a moderately sized mitral valve vegetation. Blood cultures grew coagulase-negative staphylococcus within 15 h of incubation, confirming a diagnosis of infective endocarditis. CT pelvis and MRI of the brain later revealed multiple embolic foci including a 6 cm right external iliac artery thrombus, left-sided parietal lobe infarcts, and a mycotic aneurysm of the left MCA. On hospital day two, cultures speciated *Staphylococcus lugdunensis*.

DISCUSSION: *Staphylococcus lugdunensis* is a coagulase negative species that was first described in 1988. Although it is only responsible for about 1 % of cases of infective endocarditis (IE), it is aggressive in its course and associated with high rates of embolic complications and mortality. Notably, as in our patient, *S. lugdunensis* IE most commonly involves native valves (77 % of known cases) and usually causes left-sided infections (particularly mitral valves). *S. lugdunensis* is commonly found on human skin and is rarely a contaminant in cultures. In most patients, infections are community acquired and in many, as in ours, the site of entry remains undetermined. Importantly, *S. lugdunensis* (unlike other coagulase-negative *Staphylococcus* species (CoNS) which typically cause more indolent presentations of IE characterized by low rates of complications and mortality) is noted to behave similarly to *S. aureus* in its pathogenicity and mortality rates. Specifically, high rates of valve destruction, abscess formation, acute heart failure, and peripheral emboli yield overall mortality rates as high as 50–70 % (vs. 16 % in IE

caused by other CoNS). More recent studies, however, suggest that early surgical intervention and appropriate antibiotic therapy are associated with mortality rates closer to 20 %. Given the aggressive course and high mortality rates associated with *S. lugdunensis* IE in patients with native valves, physicians must maintain a high index of suspicion and CoNS in culture must be taken seriously. Our patient presented with nonspecific systemic symptoms, heart murmur, and elevated inflammatory markers. Blood cultures were not drawn. A 1 month delay in her diagnosis allowed for valvular destruction requiring open heart surgery for mitral valve repair and propagation of septic emboli causing stroke, thromboembolism, and mycotic aneurysm formation. Following a 3 week hospital-stay, she returned home to complete an 8-week course of nafcillin-rifampin. Her mycotic aneurysm remains under surveillance and she is slowly recovering strength.

TAKING NOTE OF THE LYMPH NODES Marce E. Abare; Darlene LeFrancois. Montefiore Medical Center, Bronx, NY. (Tracking ID #2199307)

LEARNING OBJECTIVE #1: Recognize the clinical manifestations and epidemiology of AIDS-related lymphomas

LEARNING OBJECTIVE #2: Formulate an appropriate differential and diagnose the etiology of hypotension in an immunocompromised patient

CASE: A 54 year-old woman with AIDS reported a month of worsening fatigue and weight loss (documented 15 lbs in 1 month). She had developed sternal dysphagia and odynophagia to solids, increasing anorexia, and intermittent diarrhea. Her history was notable for inconsistent adherence to HAART, HCV cirrhosis Childs class B, hypertension on 3 oral agents, and active polysubstance use. On physical exam, she was oriented but lethargic, falling asleep mid-sentence. She was febrile at 101.0 and hypotensive to 63/37 (BP 1 month prior 80/49). The extremities were cool with equal distal pulses; lungs clear; the abdomen soft with 5 cm mildly tender splenomegaly and no fluid wave; neurologic exam nonfocal. There was normal cardiac function on bedside ultrasound. Labs revealed LDH 167 (100–190), CD4 77/14 % (prior nadir 167 1.5 years prior, 255 4 months earlier), WBC 8.5, Hgb 8.7 g/dl, BUN/Cr 27/2.1, albumin 2.1, lactic acid 3.8 (0.6–2.2). CT abdomen revealed a cirrhotic liver and retroperitoneal lymphadenopathy measuring 3.6×2.4 cm. Due to persistent hypotension despite IV hydration, she was admitted and received a short course of pressors, dexamethasone, and antibiotics. An infectious workup was negative. Random cortisol and response to ACTH were normal. Esophageal candida was identified on endoscopy; dysphagia improved with treatment. After further fluid repletion BP stabilized but fever persisted. On hospital day 7, diffuse large B-cell lymphoma was found on biopsy of a retroperitoneal lymph node. The patient was treated as an outpatient with 2 cycles of reduced dose R-CHOP for stage III C-MYC positive DLBCL but expired just prior to cycle 3 for unknown reasons.

DISCUSSION: Hypotension among immune compromised patients is a commonly encountered clinical problem with a wide differential, often leading to intensive investigation and broad empiric therapies. Among patients exhibiting signs of end-organ dysfunction—altered mental status, metabolic acidosis, oliguria—distinguishing among hypovolemic, cardiogenic and distributive types of shock and identifying their underlying cause must happen in concert with resuscitation. In our case, hypovolemia emerged as a leading etiology in light of the subacute to chronic symptomatology (anorexia, dysphagia, diarrhea, fever) that resulted in decreased oral intake and increased GI and insensible losses. Her underlying chronic conditions (cirrhosis, malignancy, and HIV) also yielded poor intravascular retention of fluids and reduction in vascular resistance. Furthermore, prior failure to modify her anti-hypertensive regimen in the ambulatory setting caused a significant component of iatrogenic hypotension. Our findings did not substantiate other diagnostic hypotheses including sepsis, endocrine dysfunction, or cardiac pump failure, allowing prompt discontinuation of inappropriate therapies and targeted treatment of her underlying conditions, including candida esophagitis and DLBCL. Our patient's history was most striking for its indolent progression and the presence of classic B symptoms, defined as fever >38 degrees C, unintentional weight loss >10 % over 6 months, and drenching night sweats. Due to impaired cellular immunity, HIV positive patients are predisposed to developing malignancy. Overall, 25–40 % of HIV infected individuals will be diagnosed with cancer in their lifetimes, 10 % of which are non-Hodgkin's lymphoma (NHL). Because the clinical presentation of AIDS-related lymphoma is variable, the internist must maintain a high level of suspicion. In a recent case series of HIV infected patients with fever of unknown origin, NHL was the underlying cause in 6 to 14 % of cases. Compared to disease in the seronegative population, AIDS-related lymphoma presents with more frequent B symptoms, more advanced disease (stage III or IV), aggressive subtypes (DLBCL, lymphoblastic or Burkitt's), and extranodal involvement commonly affecting the GI tract, bone marrow, and liver, although any site can be involved. In addition to constitutional symptoms patients may exhibit painless adenopathy, a variety of minor biochemical and hematologic abnormalities (unexplained anemia, leukopenia, thrombocytopenia), and hyperuricemia. As many as half of cases of NHL present with elevated LDH. Diagnosis requires biopsy of nodal

tissue. Therapy strategies include chemotherapy, immunotherapy and HAART. Our patient's profound hypotension was a result of fluid loss from the combined effects of multiple chronic conditions including occult malignancy—a diagnosis uncovered after initial diagnostic and therapeutic maneuvers failed to explain the fever or account for the adenopathy. The case illustrates that in patients with advanced HIV presenting with nonspecific systemic symptoms, AIDS-related lymphoma must be investigated.

TAKOTSUBO CARDIOMYOPATHY ASSOCIATED WITH SPONTANEOUS PNEUMOTHORAX Shawn Potteiger; Paras Karmacharya. Reading Health System, Reading, PA. (Tracking ID #2200126)

LEARNING OBJECTIVE #1: Recognize spontaneous pneumothorax as a cause of Takotsubo cardiomyopathy.

LEARNING OBJECTIVE #2: Differentiate Takotsubo cardiomyopathy from acute coronary syndrome (ACS) as these have different management.

CASE: An 80 year-old male presented to the emergency department with sudden onset left sided chest pain, shortness of breath and diaphoresis. On physical examination, the patient was afebrile and tachypneic. There were decreased breath sounds on auscultation of the left lung field. Chest radiograph revealed a large left-sided tension pneumothorax with mediastinal shift to the right side. EKG showed non-specific ST segment changes with an initial troponin I of 0.16 ng/mL (normal <0.01). Emergent chest tube placement was performed with improvement of symptoms. Serial troponins were drawn with an increase of troponin I to 2.58 ng/mL. Transthoracic echocardiogram demonstrated new left ventricular dysfunction with an ejection fraction of 33 %. Subsequent cardiac catheterization revealed no significant stenosis, and left ventriculography revealed apical ballooning and akinesis. His condition rapidly improved over the next 2 days and he was discharged home.

DISCUSSION: Takotsubo cardiomyopathy, also known as “broken heart syndrome”, is an uncommon mimicker of acute coronary syndrome (ACS) characterized by EKG changes and positive cardiac biomarkers without evidence of coronary artery stenosis on cardiac catheterization. It has classically been described occurring after intense emotional stress. However, it has also been reported to be associated with several clinical problems, such as subarachnoid hemorrhage, pheochromocytoma and Guillain-Barre syndrome. Although the exact mechanism of ventricular dysfunction is unclear, coronary spasm and catecholamine cardiotoxicity have been implicated. Our case demonstrates an unconventional presentation of takotsubo cardiomyopathy precipitated by a spontaneous pneumothorax which has rarely been described in the literature. ST segment changes persisted even after resolution of pneumothorax and coronary angiography did not reveal any coronary spasm. We suggest that left ventricular dysfunction in our patient was induced by altered catecholamine levels (elevated plasma noradrenaline) caused by the sudden underlying stress of spontaneous pneumothorax acting as an underlying stressor. Furthermore, recognition of this condition was important as the treatment and prognosis (95 % with complete recovery in 4–8 weeks) completely differ from ACS.

TB OR NOT TB, THAT IS THE QUESTION! Nanditha N. Malakkla; Chandramohan Meenakshisundaram. Saint Francis Hospital, Evanston, IL. (Tracking ID #2199437)

LEARNING OBJECTIVE #1: To recognize the clinical manifestations of tuberculous effusion and to discuss diagnosis.

CASE: A 61 yo previously healthy Asian male came in with SOB and dry cough since past 2 days. A week prior, he had URI symptoms for which he was prescribed amoxicillin. Chest Xray at that visit revealed right sided pleural effusion and therapeutic thoracentesis was done. He also mentioned 10 pound weight loss in the last 2 weeks and night sweats. He denied hemoptysis, fever, recent travel or sick contacts. He had a 20 pack year history of smoking, but quit 10 years ago. On examination, right supraclavicular lymph node was palpable; lung examination was significant for decreased breath sounds in the right base and dullness to percussion. CT scan of chest showed areas of ground glass opacity in the right lung, right hilar lymph node, pleural-based soft tissue thickening with calcifications on right, and multiloculated moderate to large sized pleural effusion involving the right lung extending to the right lung apex. Repeat thoracentesis was done, which showed highly lymphocytic effusion with elevated ADA suggestive of TB. Quantiferon gold later came back positive. He was started on treatment for tuberculosis.

DISCUSSION: Tuberculosis (TB) is still one of the top three deadly diseases in developing countries with 1.7 million deaths recorded in 2009. Tuberculous pleural effusions occur in up to 30 % of patients with tuberculosis and is the second most common form of extrapulmonary tuberculosis (TB) after lymphatic involvement. Tuberculous pleural effusions can occur with either reactivation disease or primary tuberculosis. Tuberculous pleural effusions are unilateral in majority of cases occurring more frequently on the right side than the left (55 versus 45 %), and are typically small to moderate in size. Patients with tuberculous pleural effusion present with acute febrile illness with nonproductive

cough (94 %) and pleuritic chest pain (78 %), night sweats, chills, weakness, dyspnea, and weight loss. Sputum smear and sputum culture remain the 'gold-standard' techniques for diagnosis of TB. Tuberculosis is the most common cause of pleural effusion in developing countries but it is difficult to diagnose due to its paucibacillary nature: positive cultures are seen in less than 25 % of HIV-negative cases. Diagnostic evaluation of pleural effusion in the setting of suspected tuberculous pleuritis begins with thoracentesis. The pleural fluid is generally exudative with protein concentration >3.0 g/dL and lactate dehydrogenase level commonly exceeding 500 IU/L. Cultures are positive in <30 % of cases. Pleural biopsy is needed when there is moderate to high suspicion for TB and pleural fluid evaluation is not diagnostic. Host immune factors provide greater diagnostic accuracy, including levels of IFN- γ and Adenosine Deaminase (ADA) both of which have >95 % specificity and sensitivity. Treatment includes a four-drug regimen. Therapeutic thoracentesis can be performed in patients with large, symptomatic effusions. With appropriate therapy, most patients defervesce within 2 weeks; in most cases, pleural fluid is resorbed within 6 weeks, but residual pleural thickening can occur.

THE BALLET DANCER'S BACK PAIN Patrick L. Dantzer. University of Pittsburgh Medical Center, Pittsburgh, PA. (Tracking ID #2198795)

LEARNING OBJECTIVE #1: Recognize the differential diagnosis for lower back pain in a young adult

LEARNING OBJECTIVE #2: Recognize and diagnose ankylosing spondylitis

CASE: A 22-year-old previously healthy female ballet dancer presented with chronic lower back pain. The patient developed insidious, progressive lower back and buttock pain beginning one year prior. The pain began on the left side but later alternated from left to right. It was aggravated by movement while dancing and improved, though did not remit, with rest. After initially attributing her symptoms to muscular strains, she was evaluated by an orthopedic specialist and diagnosed with a stress fracture of the sacroiliac (SI) joint based on a bone scan showing increased tracer uptake along the left SI joint. With rest and ibuprofen, the patient's symptoms continued to wax and wane. During an acute flare, she underwent magnetic resonance imaging (MRI) of her spine which revealed bilateral left worse than right sacroiliitis, as well as possible bony erosions, and she was continued on ibuprofen. Her symptoms continued along a relapsing/remitting course until she presented to our office for emergency room follow-up of an acute flare. Physical examination demonstrated reduced lumbar flexion by Schober's test, tenderness to palpation over the bilateral SI joints, and positive Patrick's/FABER test. History, physical, and prior imaging studies raised the concern for spondyloarthritis, specifically ankylosing spondylitis (AS). Laboratory testing revealed erythrocyte sedimentation rate (ESR) 60, C-reactive protein (CRP) 7, and HLA-B27 positivity, all consistent with AS. She was referred to rheumatology where a diagnosis of AS was confirmed. She was started on indomethacin with marked improvement in her symptoms and inflammatory markers, and she was able to resume her dance regimen.

DISCUSSION: AS is the most common variant of spondyloarthritis, a family of chronic inflammatory disorders of the axial skeleton. AS is manifested by pain of the lower back/buttocks secondary to sacroiliitis and progressive stiffness of the spine secondary to fibrous bridging of the spinal joints and discs. Symptoms may be limited to the axial skeleton, as seen in our patient, but the disease may also involve the hips, shoulders, and peripheral joints, in addition to extraarticular manifestations, including uveitis, inflammatory bowel disease, and psoriasis among others. It classically presents in the third decade of life with an estimated 2–3:1 male predominance. AS is a clinical diagnosis made based upon a combination of symptoms and clinical, laboratory, and imaging findings. A patient with chronic back pain (at least 3 months) beginning before age 45 should obtain an anterior-posterior plain radiograph of the pelvis to examine the SI joints. A diagnosis of AS can be made if the imaging meets criteria for sacroiliitis. Pertinent lab findings to support a diagnosis of AS include HLA-B27 positivity and elevated acute phase reactants (CRP/ESR), both of which were seen in our patient. While imaging findings are critical to diagnosing AS, negative plain films do not rule out other forms of spondyloarthritis. In the absence of plain film changes, findings suggestive of spondyloarthritis include inflammatory type back pain (onset before the age of 40 years, insidious onset, improvement with exercise, no improvement with rest, and pain at night), heel pain (enthesitis), dactylitis, uveitis, family history of spondyloarthritis, inflammatory bowel disease, alternating buttock pain, psoriasis, asymmetric arthritis, positive response to NSAIDs, and elevated acute phase reactants. Lower back pain is a frequent chief complaint in a variety of clinical settings, and among these patients it is believed that AS and other forms of axial spondyloarthritis compose roughly 5 %. The differential diagnosis of spondyloarthritis includes acute or chronic mechanical back pain, fibromyalgia, diffuse idiopathic skeletal hyperostosis (DISH), vertebral compression fracture, SI joint infection, osteitis condensans ilii, and erosive osteochondrosis and Schmorl's nodes. Our patient's diagnosis was likely delayed due to several factors including female sex, pain worsening rather than improving with exercise, inconsistent improvement with NSAIDs, and attribution to another plausible cause (musculoskeletal injury).

THE CARDIAC EFFECTS OF HYPOTHYROIDISM Rehaan Shaffie; Lauren Shapiro. Montefiore Medical Center, Bronx, NY. (Tracking ID #2200213)

LEARNING OBJECTIVE #1: Recognize the importance of hypothyroidism as a cause of pericardial effusion.

LEARNING OBJECTIVE #2: Appreciate the physical exam findings of tamponade.

CASE: A 43 year old woman presented to the emergency department with two days of diaphoresis and lightheadedness. She had a past medical history of hypertension, hypothyroidism, and uterine fibroids. On further questioning, she reported fatigue progressing over several months associated with exertional dyspnea, decreased exercise tolerance and bilateral leg swelling. Physical exam showed distended jugular veins, tachycardia, and distant heart sounds. Electrocardiogram showed sinus tachycardia with left ventricular hypertrophy and lateral T wave inversions. Chest x-ray showed an enlarged cardiac silhouette and was otherwise unremarkable. Based on the physical exam and chest x-ray, pulsus paradoxus was measured and exceeded 20 mmHg. Echocardiography was notable for prominent pericardial fluid, right ventricular collapse, respiratory variation across the tricuspid valve, and a plethoric inferior vena cava. Her TSH was 159 microU/mL and free T4 was 0.55 ng/dL. She was treated acutely with emergent pericardiocentesis and drainage of 1450 ml of chylous fluid. She had been non-adherent with her home thyroid supplementation. She was restarted on levothyroxine supplementation with improved symptoms.

DISCUSSION: The differential for pericardial effusion is varied, including pericarditis, inflammatory disorders, hypothyroidism, malignancy, and infection. Hypothyroidism is an uncommon cause of pericardial effusion. Literature review revealed primarily case reports without prevalence data. As illustrated by this patient, even profound hypothyroidism can be clinically subtle, allowing effusion to be met with compensation until the point of near medical emergency. Typical cardiovascular manifestations of hypothyroidism include decreased heart rate and contractility leading to decreased cardiac output, and an increase in peripheral vascular resistance. As in this patient, the development of effusion reverses those changes, and she presented tachycardic with orthostatic hypotension. These findings, in conjunction with gradually progressive fatigue, decreased exercise tolerance, dyspnea, and the physical exam, suggest worsening underlying hypothyroidism. Physical exam findings of effusion include Beck's triad: hypotension, muffled heart sounds and jugular venous distention; as well as pulsus paradoxus. Pulsus paradoxus can be measured by inflating a blood pressure cuff until the Korotkoff sounds are absent, and then gradually deflating until the sounds are heard intermittently during expiration. This first pressure signifies the highest expiratory pressure. The cuff is then deflated until both Korotkoff sounds are heard. A difference between these pressures of above 10 mmHg is abnormal and suggests tamponade. With adequate clinical suspicion, diagnosis can be made by echocardiogram. As in this patient, pericardial effusion due to hypothyroidism is also characterized by fluid that has a high protein and cholesterol content. Emergent treatment is indicated in the presence of cardiac tamponade, and includes either needle decompression or surgical intervention. Typically, hypothyroid pericardial effusion manifests less dramatically, and can instead be managed medically, via titration of exogenous thyroid hormone.

THE CASE OF THE MISSING BAND: A DECEPTIVE CLONE Minghao Liu; Danit Arad. Montefiore Medical Center, Bronx, NY. (Tracking ID #2198487)

LEARNING OBJECTIVE #1: Recognize the limitations of serum protein electrophoresis (SPEP) in detecting multiple myeloma.

LEARNING OBJECTIVE #2: Diagnose light chain myeloma, an uncommon variant of multiple myeloma.

CASE: A 66 year-old man presented with 6 months of migratory body aches, slowed walking and 20-pound weight loss. Exam was benign with no neurological deficits and no focal pain. Labs revealed hemoglobin 10.5 g/dL, creatinine 1.2 mg/dL and normal erythrocyte sedimentation rate, creatine kinase, thyroid stimulating hormone, prostate-specific antigen and liver tests. Serum protein electrophoresis (SPEP) showed hypogammaglobulinemia with no monoclonal protein (M protein). He was admitted 6 weeks later for intractable back pain and found to have creatinine 3.9 mg/dL, random urine protein-to-creatinine ratio 9.4 and calcium 11.9 mg/dL. There was a soft tissue mass in the L2 vertebral body with epidural extension on MRI. Computed tomography scan obtained prior to interventional radiology-guided fine needle aspiration of this mass incidentally revealed multiple lytic lesions in the spine. Free kappa/lambda ratio was 0.05 and immunofixation showed free lambda. Repeat SPEP showed M protein in the beta region, as did urine protein electrophoresis (UPEP). Atypical plasma cells staining positive for lambda had replaced 90 % of the bone marrow on biopsy.

DISCUSSION: Our patient presented with vague but concerning symptoms that raised suspicion for a variety of etiologies. His initial SPEP was deceptive—it lacked the monoclonal protein band classically associated with a clonal plasma cell disorder.

Therefore, efforts focused on characterizing the spinal mass as the key to diagnosis. Imaging obtained to facilitate the biopsy of this mass showed lytic lesions, which combined with his acute renal failure, heavy proteinuria and hypercalcemia increased suspicion for multiple myeloma. Subsequent tests and bone marrow biopsy confirmed the diagnosis of light chain myeloma, a variant of multiple myeloma. Light chain myeloma comprise up to 20% of all forms of multiple myeloma. Multiple myeloma is the malignant expansion of a clone of plasma cells which infiltrates the bone, suppresses the production of normal blood cells and stimulates osteoclastic activity. These plasma cells produce monoclonal protein in the form of immunoglobulin (unless the cells are nonsecretory), which migrates to a certain region of the agarose gel of the serum protein electrophoresis. This band of identical proteins on gel is represented as a peak on densitometer tracing. The peak usually appears in the gamma region because immunoglobulins tend to settle there due to their size and charge. However, in light chain myeloma only a part of the immunoglobulin is produced—the kappa or lambda light chain. The sole expression of light chains (and lack of heavy chains) may manifest as a decrease in the size of the gamma region (i.e. hypogammaglobulinemia, as seen in our patient). In addition, because of rapid excretion of light chains in the urine, serum concentrations of these proteins may be initially too low to register as a spike on SPEP. Renal failure, which is more common in light chain myeloma than in other forms of multiple myeloma, cause serum concentrations of M proteins to rise, in this case to a detectable level on the second SPEP. For these and other reasons, SPEP is 82% sensitive in detecting a monoclonal peak. More sensitive tests are needed to detect light chain myeloma earlier in its course. Serum immunofixation in addition to SPEP increases the sensitivity to 93% in patients with myeloma. Adding a free light chain assay or urine monoclonal protein study (urine protein electrophoresis or urine immunofixation) increases the sensitivity to 97%. When there is high clinical suspicion for multiple myeloma, SPEP must be sent in conjunction with these other more sensitive tests to detect variants such as light chain myeloma. Because renal failure is more common in light chain myeloma, early detection is crucial. Diagnosing light chain myeloma requires looking beyond the SPEP.

THE COMA YOU CAN'T MIX UP Aimee E. Hiltbold²; Ahmed Mohiuddin¹. ¹Tulane University, New Orleans, LA; ²Tulane University Medical Center, New Orleans, LA. (Tracking ID #2199256)

LEARNING OBJECTIVE #1: 1. Recognize the clinical presentation of myxedema coma.

LEARNING OBJECTIVE #2: 2. Appreciate the pathophysiology and treatment of myxedema coma.

CASE: An 85-year-old woman presents with worsening somnolence and altered mental status. Symptoms began 1 week prior with lethargy progressing to unresponsiveness. Her past medical history is significant for DM, HTN, and paroxysmal Afib. Medications include carvedilol, lisinopril, and amiodarone. Initial vital signs are T: 32, HR: 55, RR: 18, SpO₂: 90% on 5 L NC, and BP: 76/53. Her GCS is 7, and she has an edematous face and tongue, bradycardia, crackles at the lung bases, non-pitting edema of the lower extremities, and brisk reflexes with a diminished return. EKG shows sinus bradycardia with low voltage. CXR demonstrates low lung volumes and a pleural effusion in the LLL. ABG is 7.28/24.6/62.4/11.3/saturating 87% on FiO₂ 36%. Laboratory evaluation reveals Na 156, K 2.2, Cl 135, HCO₃ 9, BUN 31, Cr 2.1, gluc 68, and Ca<5.0, WBC 2.9, Hgb 7.6, plts 131. TSH is >100, and FT4 is 0.35. Cortisol is normal. She is immediately intubated and treated for myxedema coma.

DISCUSSION: Prompt recognition of severe hypothyroidism is important for the practicing internist, as mortality approaches 30–40%. Clinical hallmarks include decreased mental status and hypothermia. Hypotension, bradycardia with low voltage, hyponatremia, hypoglycemia, and hypoventilation are often present. Mucin deposits in subcutaneous tissues cause non-pitting edema of the face, tongue, and extremities. Neurologic manifestations include abnormal reflexes, lethargy, and obtundation. Central depression of ventilatory drive occurs, causing hypoventilation with respiratory acidosis. Up to half of patients exhibit hyponatremia, believed secondary to inability to excrete free water. Because free T₄ regulates thermogenesis, inadequate FT₄ causes hypothermia. Hypoglycemia may be caused by hypothyroidism alone or by concurrent adrenal insufficiency. FT₄ regulates sympathomimetic activity of the cardiovascular system; therefore, low FT₄ is associated with bradycardia, decreased myocardial contractility, low cardiac output, and hypotension. Myxedema coma may be immediately precipitated by an acute event, such as myocardial infarction or infection. It may also present after long-standing hypothyroidism. Certain medications may be implicated in development of myxedema coma, especially amiodarone and lithium. Evaluation of severe hypothyroidism should include examination for a thyroidectomy scar, history of I-131 therapy or hypothyroidism, and a thorough medication review. Before therapy with thyroid hormone and glucocorticoids are administered, lab evaluation for TSH, FT₄, and cortisol should be obtained. Due to the high mortality rate, treatment of myxedema coma is an emergency and should not be delayed. Treatment consists of intravenous FT₄, supportive measures, steroid administration,

and management of coexisting conditions. Stress dose steroids are recommended in light of possible adrenal insufficiency. Caution must be exercised in elderly patients, as rapidly increasing thyroid hormone concentrations can precipitate myocardial infarction or arrhythmias. Some experts recommend concomitant use of T₃, as the biologic activity of triiodothyronine (T₃) is greater, and its onset of action is more rapid than T₄. Endocrinology guidance is helpful in establishing an appropriate treatment regimen.

THE COVERT CULPRIT: TOXIC SHOCK SYNDROME UNMASKING A PRE-DISPOSITION TO IMMUNE SYSTEM DYSREGULATION AND IGG4-RELATED DISEASE Meng Chen; Darya Rudym; Robert Mocharla; Joshua Denson. New York University School of Medicine, New York, NY. (Tracking ID #2194024)

LEARNING OBJECTIVE #1: Diagnose IgG4-related disease (IgG4-RD) in a patient with recurring organ dysfunction following toxic shock syndrome (TSS).

LEARNING OBJECTIVE #2: Recognize IgG4-RD as a cause of autoimmune hepatitis (AIH).

CASE: A 76 year-old woman with a history of hypertension and asthma was admitted for fever. Vitals were significant for a temperature of 102.6 °F (39.2 °C), blood pressure of 85/39 mm Hg, heart rate of 113, and oxygen saturation of 92% on nasal cannula. Multiple blood cultures grew methicillin-sensitive staphylococcus aureus (MSSA). C-reactive protein was also elevated to 371 mg/L. Despite aggressive fluid resuscitation and broad spectrum antibiotics, the patient progressed to septic shock, requiring endotracheal intubation, mechanical ventilation, vasopressor support, and hemodialysis. Laboratory studies revealed a peak white blood cell (WBC) count of $32.1 \times 10^3/\mu\text{L}$, creatinine of 7.2 mg/dL, and liver function tests (LFT) significant for aspartate transaminase (AST) 363 U/L, alanine transaminase (ALT) 97 U/L, and alkaline phosphatase (ALP) 245 U/L. Over the next few weeks, the sepsis resolved, with improving fever trend, WBC count, and LFTs. However, ten days after resolution of sepsis, the patient began having subacute desquamation in nearly all skin surfaces sparing mucosal tissues. In the setting of positive blood cultures for MSSA, the patient's disease progression met all of the CDC criteria for staphylococcal toxic shock syndrome (TSS), including fever >38.9 °C, hypotension, multi-organ involvement, and delayed erythroderma and desquamation. As the patient's desquamation slowly improved, LFTs remained at normal values and creatinine steadily recovered to 1.0 mg/dL. However, five weeks after sepsis resolution, the patient had progressive asymptomatic rise of LFTs to peaks of AST 435 U/L, ALT 117 U/L, ALP 417 U/L, GGT 303 IU/L. Multiple abdominal ultrasounds ruled out structural or vascular abnormalities. Extensive work-up was negative for viral hepatitis, alpha-1-antitrypsin deficiency, Wilson's disease, primary biliary cirrhosis, and systemic lupus erythematosus. However, the patient had positive antinuclear antibodies titer of 1:320 and positive anti-smooth muscle antibody titer of 1:40, indicating likely autoimmune hepatitis (AIH). Additionally, immunoglobulin panel revealed a highly elevated IgG level of 3360 mg/dL, with IgA and IgM in normal range. Due to suspected IgG4-related disease (IgG4-RD), IgG4 level was sent and found to be elevated to 271 mg/dL (normal range 2.4–121 mg/dL), signifying IgG4-RD as the likely etiology of patient's AIH.

DISCUSSION: IgG4-RD is a newly recognized immune-mediated disease, first reported in 2003 as a systemic condition causing extra-pancreatic disorders in patients with autoimmune pancreatitis. However, IgG4-RD remains difficult to diagnose due to its recent identification and its variable pattern that can cause multiple characteristic organ pathologies. These include sialadenitis, interstitial pneumonia, pericarditis, pancreatitis, cholangitis, colitis, nephritis, etc. A number of recent studies have described IgG4-RD causing autoimmune hepatitis. One report concluded that AIH may be divided into either IgG4-related AIH or non-IgG4-related AIH, with the former showing a more marked response to steroid therapy. Additionally, studies have described the link between the IgG4 antibody subclass and TSS, as only IgG1 and IgG4 subclass antibodies have specifically been shown to neutralize the TSS toxin-1. We report here a case of IgG4-RD causing AIH following TSS. Our patient had delayed LFT derangements occurring after LFTs had completely recovered from the initial rise secondary to septic shock. Thus, a second process was suspected, and IgG4-RD causing AIH was diagnosed. It is possible that the patient had an underlying IgG4-RD predisposition, and the immunologic response to TSS caused an overdrive of IgG4 antibody production. This then lead to pathologic IgG4-RD manifested as AIH. Due to IgG4-RD's recent discovery and ongoing characterization, its diagnostic criteria have not been firmly established in the literature. Our patient met the criteria promulgated by Okazaki et al., with elevated IgG4 levels >135 mg/dL and characteristic organ involvement. However, she refused histopathologic analysis of liver and skin and was clinically improved by the time IgG4-RD was suspected. She will be followed closely in our outpatient clinic with recommended steroid therapy and biopsy for any further IgG4-RD exacerbations. Current therapies for IgG4-RD include glucocorticoids and rituximab. The disease generally responds well to steroid therapy, especially if initiated early in the course. Thus, as we come to a better understanding and familiarity with this disease, it is important to consider

IgG4-RD as a treatable etiology of autoimmune hepatitis. Additionally, further elucidation of IgG4-RD pathogenesis is needed, including investigation of TSS as a possible risk factor.

THE DANGER OF NON-STEROIDAL SUPPLEMENTATION IN BODY-BUILDERS Karin Chen¹; Geeta Varghese². ¹Mount Sinai Beth Israel, New York, NY; ²Mount Sinai Beth Israel, First Avenue at 16th Street, NY. (Tracking ID #2200005)

LEARNING OBJECTIVE #1: Recognize the dangers of over-the-counter performance enhancing supplements

LEARNING OBJECTIVE #2: Describe importance of inquiring about supplement use

CASE: A 31 year-old healthy male with no significant past medical history presented to clinic requesting testosterone levels after he initiated performance enhancing supplements. In preparation for his first amateur bodybuilding competition, the patient started the supplement "PharmaFreak Test Freak," under the advisement of his bodybuilding coach. He started the supplement 1 month prior to his clinic visit. He was not taking any prescription medication or other over-the-counter supplements. Social history was significant for tobacco use and the absence of alcohol and illicit drug use. He had no complaints at the time of his visit. Review of systems was positive for increased libido, while all other systems were negative. Physical exam was notable for a muscular build and mild gynecomastia. An extensive dialogue was held with the patient regarding over-the-counter supplements, including discussion about the lack of standardized clinical studies, lack of standardization of dosage and manufacturing because this industry is not regulated. Despite this conversation, his increased libido, and physical exam findings, the patient continued the PharmaFreak Test Freak supplement citing competition preparation. Lab work revealed elevated testosterone levels, subdivided into Free (direct) >50 pg/ml (8.7–25.1 pg/ml), and Total, LC/MS 1670.2 ng/ml (348.0–1197 ng/dL), as well as elevated total estrogens 2130 pg/ml (40–115 pg/mL) and low prolactin 0.4 ng/ml (4.0–15.2 ng/ml). After abnormal labwork returned, the patient was agreeable to cessation of supplement use. The patient is to return to clinic in 3–6 months for re-evaluation and repeat blood work.

DISCUSSION: News headlines frequently highlight exogenous steroid use in professional athletes, but it is not uncommon for young amateur athletes seeking to improve performance and physique to use non-steroidal performance enhancing supplements widely available online and in retail stores. These supplements often contain active ingredients with biological effects, as seen in our patient. The supplement industry remains largely unregulated and ingredients remain vague, both in dosage and manufacturing, from lack of standardization. Furthermore, supplements, like PharmaFreak Test Freak, are often developed from a combination of ingredients with little to no information available regarding drug, dietary, or supplement interaction. Ingredients of PharmaFreak Test Freak include: vitamin B6, magnesium, zinc, "proprietary testosterone support complex," composed of *trigonella foenum graecum* and *tribulus terrestris*, "proprietary DHT support complex," made up of saw palmetto and stinging nettle extracts, and "proprietary estrogen support complex," consisting of hesperidin, apigenin, and resveratrol. This supplement is advertised to boost free and total testosterone, as well as strengthen muscles. In light of recent research about the risks of testosterone supplementation including increased cardiovascular risk, it is even more important to recognize the hidden dangers of over-the-counter performance supplementation, especially in these unregulated forms.

THE DIAGNOSIS AND TREATMENT OF TRACHEOBRONCHOMALACIA: A BREATH OF FRESH AIR Angeline J. Sabol; Adam P. Sawatsky. Mayo Clinic, Rochester, MN. (Tracking ID #2195209)

LEARNING OBJECTIVE #1: Recognize tracheobronchomalacia in a patient with COPD.

LEARNING OBJECTIVE #2: Manage tracheobronchomalacia in a patient with COPD.

CASE: A 76 year-old woman with a diagnosis of severe COPD and Giant Cell Arteritis presented to her primary pulmonologist with increasing cough, dyspnea and a new continuous oxygen requirement. Seven months prior to this presentation, she started to have increased shortness of breath and limitations in her physical activity. Over the next several months, she had several hospitalizations for acute COPD exacerbations with associated dyspnea, wheezing, and chest tightness. Each hospitalization resulted in improved wheezing and chest tightness but continued shortness of breath. Her pulmonary function test 3 months prior to presentation revealed an FEV1/FVC ratio of 40.9 % and an FEV1 of 33 %. She was followed closely by her primary care doctor who continued her on a regimen of salmeterol/fluticasone, albuterol HFA, tiotropium, prednisone 10 mg daily (for Giant Cell Arteritis), and albuterol nebulized solution as needed. Two months prior to presentation she was started on daily azithromycin for its anti-inflammatory properties and her salmeterol/fluticasone was switched to salmeterol alone because of her previous history of pneumonia and the concern for an association between inhaled steroids and

pneumonia. She was hospitalized 1 month prior to presentation for a COPD exacerbation and treated with prednisone taper. She was then seen by her pulmonologist a week prior to presentation and was started on Augmentin and prednisone 40 mg daily for 5 days due to her continued dyspnea and wheezing. Upon presentation, she had resumed her home dose of 10 mg daily. The patient was admitted directly from the pulmonologist office for work-up of her persistent symptoms. CT angiography of the chest was performed which ruled out pulmonary embolism. It demonstrated bilateral bronchial thickening and mild ground glass opacities in the apices, less extensive than predicted by her severe symptomatology. Bronchoscopy with bronchoalveolar lavage was performed on day 3 due to the concern for infection given the CT scan findings. It demonstrated tracheobronchomalacia with approximately 75 % collapse of the posterior membrane in the trachea with expiration, and almost complete collapse in the right and left mainstem bronchi. She was not a candidate for an airway stent as she had closure of the small airways distal to the two main bronchi, limiting its utility. We started her on CPAP therapy in conjunction with her home medications. She did not feel significant relief with the CPAP and it was discontinued. She was discharged without resolution of symptoms, and was recommended physical therapy as an outpatient to maximize her exercise tolerance.

DISCUSSION: COPD is an extremely common disease and is increasing in prevalence in most of the world. Chronic lower respiratory disease is the third most leading cause of death in the United States. This case demonstrates an example of an initial misdiagnosis as a COPD exacerbation and illustrates the importance of thinking of tracheobronchomalacia (TBM) when a COPD exacerbation is not resolving with traditional therapies. The prevalence is unknown, however in a study looking at the relationship between COPD and TBM, 40 % of patients with TBM had COPD. Symptoms described are similar to COPD and include dyspnea, cough, sputum production, and hemoptysis. When there is little symptom improvement with maximal therapy, TBM should be considered. Bronchoscopy is considered the gold standard for the diagnosis, but end-inspiratory and end-expiratory CT scanning and multidetector CT scanning can also be used (1). Management of TBM includes optimization of treatment for the underlying disease and symptom control, including smoking cessation and relaxation techniques (1). NSAIDs, corticosteroids or other immunosuppressants can be tried before procedural-based therapies are initiated. CPAP reduces resistance and improves expiratory flow, however there are no studies demonstrating its long-term efficacy (2). It also can be potentially dangerous in a patient with COPD as it can worsen air-trapping. Stent placement and tracheoplasty are other options, however these are much more invasive. Due to complications of persistent cough, infections, and stent migration, stents are not recommended until other conservative options fail; a temporary stent can be placed and demonstrates symptom improvement (3). 1. THE DISAPPEARING LACTATE: ETHYLENE GLYCOL AND LACTIC ACIDOSIS Molly A. Fisher; Andrea Carter. University of Pittsburgh Medical Center, Pittsburgh, PA. (Tracking ID #2195662)

LEARNING OBJECTIVE #1: To diagnose ethylene glycol toxicity.

LEARNING OBJECTIVE #2: To recognize the difference in lactate run from an arterial blood gas analyzer versus a serum analyzer in a patient with ethylene glycol toxicity.

CASE: MJS is a 76 year old female with no significant past medical history who presented after her family found her unresponsive at home. She was last seen by her family in her usual state of health 6 h prior to arrival and at that time had only been complaining of mild abdominal pain. On arrival to the hospital, she was unresponsive and immediately intubated. Her arterial blood gas (ABG) on arrival showed pH 6.94, PaCO2 20, PaO2 105, and HCO3 4 which indicated a severe metabolic acidosis without appropriate respiratory compensation; lactate run on the blood gas analyzer was 11. Her serum electrolytes on arrival included sodium 142, chloride 111, blood urea nitrogen 19, glucose 203, and measured serum osmolality of 302 which leaves an anion gap of 27 and an osmole gap of 61. Her initial labs also included a white blood cell count 11.4, acetaminophen level 204, and urine toxicology screen positive for opioids and propoxyphene. Electrocardiogram showed sinus bradycardia with a prolonged corrected QT interval (523 ms). CT chest was unremarkable, CT abdomen/pelvis with contrast showed colonic wall thickening and mild stranding indicative of colitis, and CT head was negative for evidence of bleed or large stroke. Ethylene glycol toxicity was suspected, so serum ethylene glycol level was sent and came back elevated at 184. While placing a dialysis catheter and awaiting initiation of dialysis, her lactate run on an ABG analyzer continued to rise and peaked at 22. However, a serum lactate that was drawn at the same time came back at 2.9. She was dialyzed, regained consciousness and full neurologic function, was extubated, and admitted to a suicide attempt by ingestion of ethylene glycol. Her acidemia

resolved with dialysis, she regained kidney function, and she was admitted to a psychiatric hospital for care of her depression.

DISCUSSION: Ethylene glycol toxicity can be difficult to diagnose and if missed on an initial assessment, can be fatal. It is possible to test for ethylene glycol in the serum but it can take several hours to get a result and many hospitals do not have this capability. There are other lab abnormalities that can come back immediately which would indicate that the patient may have ingested ethylene glycol. These include an elevated osmole gap, a lactate that is elevated on the ABG analyzer but not when run from the serum, and crystals in the urine. The osmole gap (OG) is the difference between the measured serum osmolality and the calculated serum molarity. This value will be elevated in any alcohol toxicity. The second indication is a discrepancy in the serum lactate and the lactate run on the blood gas analyzer. Ethylene glycol is metabolized into glycolate, which is chemically similar to lactate. On many blood gas analyzers, the analytical reagent L-lactate oxidase cross-reacts with glycolic acid and glyoxylic acid, and can give a falsely elevated lactate. The last lab abnormality seen is crystals in the urine which come from oxalic acid, another byproduct of the breakdown of ethylene glycol. The crystals can be seen on light microscopy and are usually needle or envelope shaped. Additionally, urine can be examined with a Wood's lamp and if fluorescence is observed, this can indicate the presence of fluorescein which is often added to commercial antifreeze products to help detect radiator leaks. These various ways of detecting ethylene glycol can allow a more prompt diagnosis of ethylene glycol toxicity and should be considered in any patient in which toxic alcohol ingestion is on the differential.

THE ELUSIVE PALINDROMIC RHEUMATISM Julia Manasson; Philip Chuang; Vanessa Charubhum; Angela Hou; Ann Garment. New York University School of Medicine, New York, NY. (Tracking ID #2174493)

LEARNING OBJECTIVE #1: To recognize the pertinent features of palindromic rheumatism, a rare rheumatologic condition.

LEARNING OBJECTIVE #2: To discuss the broad differential of monoarthritis.

CASE: A 59 year-old woman with a history of diabetes presented with 1 day of right shoulder pain. The pain was sudden, severe, and woke her in the night. She denied recent joint trauma. Several hours later she noted swelling around the shoulder and pain radiating to her right elbow and wrist. Ice and naproxen did not offer relief so she came to the hospital. On further history, the patient recalled three additional isolated episodes of monoarticular pain and swelling in her knee, arm, and ankle over the last four years. Each time the pain resolved spontaneously. Family history was remarkable for possible rheumatoid arthritis (RA) in her mother and brother. Review of systems was negative for fevers, weight loss, photosensitivity, rash, dry eyes and mouth, mucosal ulcers, back and neck pain, joint stiffness, and recent gastrointestinal and genitourinary infections. The right shoulder, elbow, and wrist were warm, tender, mildly swollen, and non-erythematous. Range of motion was limited by pain. All other joints were unremarkable. No rashes or tophi were noted. Multiple attempts at arthrocentesis were unsuccessful so fluid could not be aspirated for analysis. Initial labs were significant for a leukocytosis of $18.8 \times 10^9/L$ (87.2 % neutrophils), erythrocyte sedimentation rate (ESR) of 30 mm/h, c-reactive protein (CRP) of 103 mg/L, and a normal uric acid. The diagnoses of trauma, septic arthritis, and crystal arthropathy were initially entertained. However, several days later additional labs resulted in an anti-nuclear antibody (ANA) of 1:80 in a homogenous pattern, rheumatoid factor (RF) of 184 IU/mL, and anticyclic citrullinated peptide antibody (ACPA) greater than 250 units. Hand and foot X-rays showed osteoarthritic changes but no erosive joint damage. Shoulder MRI revealed a 50 % partial thickness supraspinatus tear, thought to be secondary to chronic stress on the joint. Given the patient's multiple presentations of asymmetric acute monoarthritis that resolved with minimal intervention, as well as very elevated RF and ACPA antibodies, she was diagnosed with palindromic rheumatism (PR) and started on low-dose prednisone and ibuprofen with significant improvement in symptoms. She continues to follow with rheumatology.

DISCUSSION: Monoarticular arthritis has a broad differential. Common etiologies include trauma, osteoarthritis, septic arthritis, reactive arthritis, crystal disease, enteropathic arthritis, and hemarthrosis. PR is a rare condition that is often overlooked. It is an idiopathic syndrome that typically presents as recurrent monoarticular or oligoarticular joint inflammation without precipitating factors or systemic symptoms. Inflammation spontaneously resolves, and there is no residual joint damage. Studies show that a significant proportion of patients with PR, especially those with positive RF and/or ACPA antibodies, eventually develop RA or another connective tissue disease. It remains unclear whether PR is a harbinger or simply within the spectrum of RA.

THE HOOK EFFECT: DON'T TAKE THE BAIT! Akshata Moghe; Hoda Kaldas. University of Pittsburgh Medical Center, Pittsburgh, PA. (Tracking ID #219953)

LEARNING OBJECTIVE #1: Assess the possibility of 'hook effect' in case of discrepancies in the clinical picture and laboratory results

LEARNING OBJECTIVE #2: Recognize the clinical and laboratory signs of nephrotic syndrome

CASE: A 76 year old woman with hypertension and Crohn's disease presented with a 1 month history of a 15 lb weight gain, progressive edema, fatigue, decreased exercise tolerance and dyspnea on exertion. Review of systems was significant for dark-colored urine with a musty odor. She denied any fevers, chills, cough, chest pain, palpitations, or orthopnea. Medications included Losartan and Adalimumab; both of which were started 6 months prior to presentation. On physical examination, she was afebrile with a blood pressure of 176/86 mm Hg, heart rate of 75 beats per minute and a respiratory rate of 16 per minute. Her JVP was 7 cm above sternal angle, and she had a loud S2 with gallop on cardiac exam. Lungs were clear to auscultation. She had 3+ pitting edema of her arms and legs, with trace periorbital edema. EKG showed left ventricular hypertrophy and chest x-ray showed clear lungs with mild cardiac enlargement. Initial labs were notable for: BNP 206 pg/ml, albumin 2.7 mg/dl and creatinine 1.4 mg/dl with a baseline of 0.8 mg/dl 9 months prior. Serum cholesterol was 307 mg/dl and LDL was 191 mg/dl. Urine examination revealed protein >1000 mg/dl, albumin 17.6 mg/dl, trace blood, many WBCs and granular casts but no bacteria or eosinophils. Albumin to creatinine ratio was calculated to 81.6. A renal ultrasound was normal.

DISCUSSION: This patient's edema, hypoalbuminemia, proteinuria, hyperlipidemia and fatigue were pathognomonic of nephrotic syndrome. Spot and 24-hour urine collections showed massive proteinuria but, surprisingly, minimal albuminuria. This was in conflict with the diagnosis of nephrotic syndrome and raised the suspicion for a paraproteinemia. However, serum and urine protein electrophoresis did not show monoclonal immunoglobulins; instead there was a large albumin spike on the urine electrophoresis, quite in contrast to the minimal albuminuria. This is suggestive of the 'hook effect,' and a return to the original diagnosis of nephrotic syndrome. The hook effect, also called the prozone effect, is a phenomenon which sometimes occurs in immunoassays wherein a false negative or erroneously low test result is obtained due to extremely high analyte levels. In these assays, an accurate positive result is obtained when antibodies from the patient's serum bind and bridge antigens in the assay leading to immune complex formation and agglutination. However, if antibodies occur in excess, they flood the antigen pool, saturate all binding sites and prevent effective cross-bridging and agglutination. Serial dilutions of the patient's serum often reveal the true results by optimizing the antigen to antibody ratio in the assay. In our patient, the true urine albumin level was calculated to be 1526 mg/dL with a urine protein of 2200 mg/dL. Her 24 h-urine sample actually contained 6 gm albumin and 8.5 gm total protein. Further investigations with a renal biopsy showed minimal change disease. The newly started Adalimumab was thought to be the culprit and was discontinued. There are rare accounts of Adalimumab-induced glomerular disease in the literature. She was started on steroid therapy and is being actively followed on an outpatient basis.

THE IMPORTANCE OF PATIENT EDUCATION AND COMMUNICATION AT HOSPITAL DISCHARGE: A CASE OF RAPID RECOGNITION AND READMISSION FOR GUILLAIN-BARRE SYNDROME AS A RESULT OF THE TEACH-BACK METHOD Ramy Sedhom; Ranita Sharma. Rutgers- Robert Wood Johnson, Staten Island, NY. (Tracking ID #2193631)

LEARNING OBJECTIVE #1: Recognize the transition from hospital to home as a vulnerable period for adverse events.

LEARNING OBJECTIVE #2: Implement the teach-back method at discharge to effectively communicate disease management.

CASE: Physician-patient communication is fundamental to the practice of medicine and is especially important at discharge. However, several studies have demonstrated a disconnect between physician information giving and patient understanding. Despite the recognized importance of a comprehensive discharge summary, it often is not given to patients in a timely manner nor communicated at their literacy level. Thus, absent is critical information about diagnosis, complications, medications, test results and follow-up. We report a case of Guillain-Barre Syndrome (GBS) where effective communication and education at discharge provided for early recognition and timely intervention for this well established sequela of Campylobacteriosis. A 65-year old female with no past medical history was admitted with 4 days of cramping abdominal pain, non-bloody diarrhea (10 episodes/day) and fevers to 101.5. She denied antibiotic use, sick contacts, travel, nausea, vomiting, hemochezia, or melena. She lived alone, and denied smoking, alcohol, or illicit drug use. She presented with a temperature of 99.7 and was not hypotensive or orthostatic. Physical exam revealed dry mucus membranes, hyperactive bowel sounds, and marked tenderness to palpation in the RUQ. Murphy's sign was negative. There was no hepatosplenomegaly. No evidence of ascites or manifestations of chronic liver disease was noted. Stool occult blood testing was negative. Prerenal AKI was suspected with a creatinine 1.3. CBC and hepatic function panel were normal. CT abdomen revealed mesenteric adenitis and right-sided colitis. C. difficile toxin was negative. A diagnosis of Campylobacter infection was made from stool culture. The patient recovered rapidly

with a 5-day course of azithromycin. She left with discharge paperwork and was educated about manifestations of a rare, yet well documented association of a neurologic illness characterized by ascending weakness in her lower extremities and was advised to return if such symptoms were noted. A week later, she developed progressive weakness in her distal lower extremities with difficulty ambulating and fine motor weakness in her hands. She promptly returned to the hospital and requested to be seen by her prior doctors. Preceding campylobacter infection, new ascending paralysis, symmetric areflexia in the lower extremities and CSF albuminocytologic dissociation confirmed the diagnosis of GBS. Sensory symptoms, cranial nerve involvement, respiratory failure or bladder/bowel dysfunction were notably absent. She completed a 1-week course of IVIG with motor function improvement from 2/5 to 4/5 strength in lower extremities at discharge. She regained full function with rehabilitation.

DISCUSSION: In the era of progressively shorter hospital length of stay, the transition from hospital to home is a vulnerable recovery period that frequently requires astute self-monitoring, attention to modified medication regimens, ability to gauge recovery and recognize delayed complications. The absence of reliable social/family support complicates the scenario. Appropriate patient education pre-discharge is the best tool available to minimize the challenges described above. This case illustrates the importance of health care provider driven education. Using the teach-back method, discharge instructions were effectively communicated. The patient articulated an appropriate understanding of the complications of her diarrheal illness, including GBS.

THE IMPORTANCE OF TIMELY REASSESSMENT TO AVOID PREMATURE CLOSURE IN A CASE OF COEXISTENT DISSEMINATED NOCARDIOSIS AND METASTATIC LUNG ADENOCARCINOMA Kristin D'Silva²; Anil N. Makam¹. ¹UT Southwestern, Dallas, TX; ²University of Texas Southwestern, Dallas, TX. (Tracking ID #2194970)

LEARNING OBJECTIVE #1: Recognize that patients with nocardiosis may have concomitant lung cancer, necessitating timely reassessment in patients with a high pretest probability for lung cancer to avoid premature closure.

LEARNING OBJECTIVE #2: Recognize the limitations of lung biopsy in the diagnosis of infection and malignancy.

CASE: A 71-year-old male with past medical history of chronic obstructive pulmonary disease (COPD) and former heavy smoker presented with increased shortness of breath, cough, sputum production, and weight loss of 20 lb over 3 months. The patient appeared ill, with pursed lip breathing, diffuse rhonchi, and end-expiratory wheezing but no accessory muscle usage. He was initially treated for a COPD exacerbation with prednisone and azithromycin, but his symptoms did not improve. Chest CT revealed 2 spiculated pulmonary nodules in each lung, unseen on prior imaging studies. Brain MRI showed a nonspecific enhancing solitary lesion in the left frontal lobe with associated vasogenic edema. Biopsy of one of the lung nodules was negative for malignancy but culture grew *Nocardia nova*. He was started on intravenous imipenem-cilastatin and trimethoprim-sulfamethoxazole. After 6 weeks, chest CT showed improvement of some pulmonary nodules and worsening of others, and brain MRI showed no improvement in the solitary lesion. Biopsy of the brain lesion revealed metastatic poorly differentiated adenocarcinoma, consistent with a primary lung source.

DISCUSSION: *Nocardia* are branched aerobic weakly acid-fast Gram-positive bacilli that live in the soil and can cause local or disseminated infections in immunocompromised patients from inhalation or minor cutaneous trauma. The most common presentation of disseminated disease is pulmonary nodules with hematogenous spread to the central nervous system. *Nocardia* are rarely found as a contaminant in culture and thus should not be ignored. *Nocardia nova* is a rare species but causes an aggressive pattern of dissemination with mortality risk greater than 85 % if untreated. *Nocardia nova* is usually susceptible to amoxicillin, erythromycin, or trimethoprim-sulfamethoxazole, with treatment duration of at least 6 months for pulmonary lesions and 12 months for CNS lesions. In this case, the patient had not only pulmonary nocardiosis but also metastatic lung adenocarcinoma that was discovered on repeat imaging. Given his high pretest probability for lung cancer (smoking history, weight loss, and spiculated nodules), timely reassessment is important to prevent premature closure that can lead to diagnostic delays, even in a setting where the initial results indicate a potentially unifying diagnosis. Additionally, lung biopsy is an imperfect test for detecting cancer and infection, as demonstrated in this case.

THE KEYS TO UNLOCKING THE CASE OF AN ENTRAPPED HEART David M. Pinn¹; Jaime Deseda¹; Jose A. Cortes². ¹Mount Sinai Beth Israel, New York City, NY; ²Beth Israel Medical Center, New York, NY. (Tracking ID #2192176)

LEARNING OBJECTIVE #1: Recognize the challenges of diagnosing and treating TB pericarditis in AIDS patients.

CASE: Forty-two year old Filipino male with AIDS not on HAART (CD4 count 108) presented with shortness of breath, night sweats, weight loss, fevers, and chills. Of note,

negative PPD 1 year prior. Patient fulfilled SIRS criteria and TTE diagnosed a pericardial effusion without tamponade. He was admitted to the CCU and pericardiocentesis significant for no malignancy, elevated LDH, elevated adenosine deaminase (ADA), and negative AFB; culture initially pending. Quantiferon gold test was positive, however, serial sputum and blood AFB were negative. Pan-CT scan showed diffuse lymphadenopathy. Despite broad spectrum antibiotics, breakthrough fevers persisted. Bone biopsy and axillary FNA were negative for malignancy or infection. Patient was discharged once afebrile but readmitted 2 weeks later when the pericardial fluid culture returned positive for pan-sensitive *Mycobacterium tuberculosis* (TB). Axillary and cervical lymph node biopsies also revealed a positive AFB and necrotizing granuloma. Treatment initiated with rifampin, isoniazid, pyrazinamide and ethambutol (RIPE) as well as Stribild. Two days later, acute renal failure and hepatotoxicity developed, new onset atrial fibrillation noted and high clinical suspicion for Addisonian crisis. Intubation was required and TB and HIV treatments were held. Thoracentesis was negative for AFB or malignant cells. Second line TB regimen of Rifampin, Ethambutol and Moxifloxacin was started, as well as intravenous corticosteroids. Renal and hepatic functions normalized, patient extubated and RIPE regimen restarted with Dolutegravir and Epzicom. Follow up care via the New York City Department of Health.

DISCUSSION: Tuberculosis is the leading cause of HIV-related morbidity and mortality in underdeveloped countries, with an estimated 11 million people co-infected and an incidence of 500,000 cases per year. In patients with AIDS, typical TB symptoms may be absent and sputum and blood AFB are often negative. Therefore, atypical presentations such as pericarditis and pericardial effusions in AIDS patients should raise concern for disseminated TB. Chest x-ray and EKG are frequently non-diagnostic; echocardiogram and pericardiocentesis are recommended for diagnosis. However, in the setting of AIDS, diagnostic modalities such as effusion analysis, AFB stains and cultures may still be negative. Elevated pericardial ADA may suggest TB pericarditis. Aside from diagnosis difficulties, TB pericarditis in AIDS patients present treatment challenges such as drug interactions and toxicities, risk of immune reconstitution inflammatory syndrome (IRIS) and controversy involving corticosteroid use. Our case highlights many of the factors that make diagnosing and treating TB pericarditis in AIDS patients so challenging and serves as a lesson for physicians confronting similar scenarios.

THE LOW OF GETTING HIGH—AN UNUSUAL CAUSE OF RENAL CALCULI Sunina Nathoo; Amir Kazory; Maryam Sattari. University of Florida, Gainesville, FL. (Tracking ID #2196789)

LEARNING OBJECTIVE #1: Recognize guaifenesin as a potential cause of renal calculi in patients with drug abuse

LEARNING OBJECTIVE #2: Identify substance abuse as a non-conventional risk factor for stone formation

CASE: A 27 year old man with history of polysubstance abuse and depression presented with nausea, vomiting, and left flank pain. Physical exam revealed normal vital signs, left-sided abdominal pain without rebound or guarding, and left costovertebral angle tenderness. Urinalysis showed pH of 6.0, 66 red blood cells, and moderate hemoglobin. Serum creatinine was 1.26 mg/dL (normal 0.80–1.20 mg/dL). Abdominal/pelvic CT showed 2 renal calculi in the left kidney and distal ureter measuring 4 and 6 mm, left hydronephrosis, and perinephric stranding. Urine uric acid was 880 mg/24 h (normal 250–750 mg/24 h) and urine citric acid was 81 mg/24 h (normal 320–1240 mg/24 h). The patient denied personal or family history of renal calculi, but endorsed taking 8–10 pills of Mucinex DM every 8 h for 6 days prior to admission to “get high.” Mucinex DM is composed of dextromethorphan and guaifenesin, so the patient had been ingesting approximately 1.4 g of dextromethorphan and 29 g of guaifenesin daily. Treatment with intravenous fluids, analgesics, and tamsulosin was initiated. His creatinine normalized after intravenous fluid administration and symptoms resolved completely after 3 days of conservative therapy.

DISCUSSION: The renal calculi in our patient were thought to be due to drug abuse, given the reported amount of ingested medication and temporal association. While dextromethorphan has been associated with high levels of abuse due to its dissociative hallucinogenic effects, the guaifenesin component is actually thought to be responsible for stone formation. In fact, guaifenesin has been reported to account for 35 % of drug-induced stones. The stones are thought to be composed of guaifenesin and its metabolites, which have very high urinary excretion and very low solubility resulting in crystallization. Patients can present with pain, nausea, vomiting, dysuria, hematuria, acute renal failure, and bilateral renal calculi. Interestingly, guaifenesin stones are radiolucent on plain radiographs, but appear similar to uric acid stones on CT imaging and with polarized light microscopy. Stone analysis using infrared spectroscopy may identify beta-2-methoxy-phenoxylactic acid, a guaifenesin metabolite. Moreover, urine uric acid level is usually elevated due to guaifenesin's uricosuric effect and hypocalcemia has also been reported, although its cause is unknown. Treatment options include hydration, urine alkalization, ureteroscopy, and lithotripsy. Similar to our case, rehydration alone has been reported to be effective for stone dissolution without the use of alkalization or other

methods of stone retrieval. Based on this case and previous reports, we suggest that clinicians be aware of the abuse potential of dextromethorphan-containing medications as well as their possible complications and maintain a high level of suspicion in patients presenting with nephrolithiasis as well as history of previous substance abuse or recent drug ingestion. Counseling and treatment for drug abuse will be important to prevent recurrence of calculi.

THE LOW SALT DIE-T Jianhua A. Tau; Jeffrey T. Bates; Andrew Caruso. Baylor College of Medicine, Houston, TX. (Tracking ID #2200264)

LEARNING OBJECTIVE #1: Recognize that salt substitute is almost entirely composed of potassium salt and clinically significant hyperkalemia can develop in CKD patients with sufficient ingestion.

LEARNING OBJECTIVE #2: Recognize that the population which potassium salt substitutes benefit (hypertensive patients) overlaps significantly with the population whom they are most dangerous (CKD patients).

CASE: A 65-year-old man with hypertension, stage 4 chronic kidney disease (CKD), and ischemic cardiomyopathy presents with weakness, bradycardia and sinus arrest. Six months prior to admission, the patient was instructed to adhere to a low salt diet after an admission for heart failure exacerbation. A lover of savory foods, he stopped taking table salt (sodium chloride) and instead switched to Morton's Salt Substitute, using three tablespoons a day with his food. He was taking a stable doses of lisinopril, spironolactone, furosemide, metoprolol, aspirin, high-intensity statin and clopidogrel. One week prior to admission, he developed ascending motor weakness that began in his legs and progressed to his trunk and arms. On the day of admission, he felt lethargic and too weak to get out of bed; he was dizzy upon standing. He had no recent viral syndrome, diarrhea, dyspnea, orthopnea, paroxysmal nocturnal dyspnea, cough, chest pain, or overt bleeding. En route to the emergency room, he developed bradycardia and then cardiac arrest. Cardiopulmonary resuscitation was initiated and he had return of spontaneous circulation within five minutes. A post-resuscitation electrocardiogram showed sinus rhythm with widened QRS complexes. Laboratory data revealed hyperkalemia (8.7 meq/L) and a creatinine of 3.5 mg/dl, which was unchanged from baseline. His cardiac enzymes were normal. He was given IV calcium gluconate and underwent emergent hemodialysis. His neurological symptoms resolved completely with correction of the hyperkalemia. He made a full recovery.

DISCUSSION: Dietary sodium reduction reduces blood pressure. A decrease in sodium intake of approximately 75 meq/day for 4 weeks results in a fall in BP of 5/3 mmHg among. (1) Potassium chloride (KCl) is the salt substitute sold in all major grocers in the USA. One table spoon of Morton's Salt Substitute contains approximately 100 meq of KCl. While severe hyperkalemia from oral potassium is extremely rare if kidney function is normal, oral potassium doses can be large enough to overcome renal excretion in either patients with CKD or those who take potassium-sparing diuretics, angiotensin receptor blockers, or angiotensin-converting enzyme inhibitors. The cohort of patients with renal impairment overlaps significantly with the hypertensive cohort who may perceive salt-substitutes to be a healthy alternative to sodium. In fact, the prevalence of CKD in persons with hypertension is 30–35 %. (2) Meanwhile, the prevalence of hypertension is practically universal in patients with CKD (3). This remarkable case of cardiopulmonary arrest from routine use of potassium-containing salt substitutes emphasizes the need for monitoring nutritional supplement intake in all patient populations. We believe that patients are unaware of these potentially serious adverse effects of potassium in renal disease, and there are inadequate consumer warnings. In summary, clinicians should be vigilant in monitoring potassium intake from salt-substitutes because the population for whom they target (hypertensive patients) overlaps significantly with the CKD population for whom it may be most deadly.

THE MAN WHO CRIED RATTLESNAKE: A CASE ABOUT CROTALINAE ENVENOMATION Chinelo Udemgba; Joseph Camarato; Courtney Shappley; Terry J. Hundley. University of South Alabama, Mobile, AL. (Tracking ID #2199008)

LEARNING OBJECTIVE #1: Recognize the systemic manifestations of snake envenomation.

LEARNING OBJECTIVE #2: Consider further antivenom therapy for complications related to coagulation in moderate to severe envenomation after initial stabilization.

CASE: A 57-year-old man with history of hypertension and dyslipidemia presented to the emergency department with total body stiffness, diaphoresis, fasciculation, paresthesia, and excruciating pain after a rattlesnake pierced his shoe-covered right foot. On arrival, the patient was hemodynamically stable but was profusely bleeding around his intravenous sites and described experiencing episodes of explosive diarrhea, nausea, and vomiting. He had a single puncture wound on the dorsum of his right foot and considerable pitting edema, erythema, and ecchymoses extending up to his mid tibial region. X-ray confirmed

no foreign body within the effected foot. Initial laboratory data included: platelet count of 35,000/mm³, prothrombin time >300 s, activated partial thromboplastin time >300 s, fibrinogen <60 mg/dL, and an incalculable INR. He received 4 vials of crotalidae polyvalent immune fab ovine but showed minimal improvement in subsequent laboratory values and continued symptomatology. He then received intermittent dosing of antivenom for a total of 12 vials overnight and showed significant improvement and subsequently received a standard maintenance therapy dose of 2 vials of antivenom every six hours for 3 doses the following morning. Starting on day 3, the platelet count, PT, PTT, and INR fluctuated widely with the symptom of lethargy. An initial attempt to correct values with fresh frozen plasma proved unsuccessful. His condition eventually stabilized after three separate administrations of maintenance therapy. Before the final third dose, laboratory values improved then plateaued for approximately 24–48 h before declining. The patient was discharged on hospital day 8 with normalized lab values and in stable condition, which remained consistent during a follow-up visit two days post-discharge.

DISCUSSION: The management of snakebites is a relatively common clinical situation encountered by general internists. The family Viperidae, subfamily Crotalinae, includes rattlesnakes, water moccasins, and copperheads and is native throughout the United States, except Alaska, Hawaii, and Maine. Viperidae, also called pit vipers, are responsible for 98 % of the nearly 5000 annual venomous snakebites that occur mostly in summer months when snakes are most active. Approximately 20 % of cases are non-venomous, while 25 % cause mild envenomation. Envenomations by Viperidae are characteristically vasculotoxic and hemotoxic due to proteins and peptides within the venom causing vessel wall damage, impaired platelet aggregation, thrombocytopenia, consumption coagulopathy, and anticoagulation. Other common features of envenomation include neurotoxicity, rhabdomyolysis, and non-specific symptoms such as nausea, vomiting and diarrhea. Antivenom is the standard treatment for moderate to severe snake envenomation. Recognition of the severity of envenomation is key to treatment. The patient experienced severe symptoms, characterized by significant coagulopathy, on admission from apparent poisoning by an Eastern diamondback rattlesnake (*Crotaleus adamanteus*) and was immediately treated with antivenom after the poison control center was contacted, as recommended by an evidence-based unified treatment algorithm. He then required maintenance dosing with antivenom along with supportive care, radiological studies for a possible embedded fang, tetanus prophylaxis, and monitoring for hypersensitivity reactions. As general internists, it is important to be able to recognize and treat recurring coagulopathy associated with snake envenomation. The patient experienced defibrinating syndrome on arrival, which responded well to treatment with antivenom. However, because of an assumed large amount of envenomation in combination with the short half-life of the antivenom, several maintenance doses of antivenom, not fresh frozen plasma, were necessary to control his coagulopathy. By closely monitoring platelet and coagulation values, late-onset envenomation-associated hemorrhaging in this patient was prevented.

THE MAN WHO SWALLOWED A WHISTLE: LOCALIZING AIRWAY OBSTRUCTION IN ANAPHYLAXIS Amy S. Tang. NYU School of Medicine, New York, NY. (Tracking ID #2199274)

LEARNING OBJECTIVE #1: Recognize an atypical presentation of anaphylaxis

LEARNING OBJECTIVE #2: Localize airway obstruction based on characteristics of breath sounds

CASE: A 69-year old man with coronary artery disease and hypertension presented with subacute chest pain, dyspnea, and weight loss. Laboratory studies revealed negative troponins, acute on chronic anemia, elevated creatinine, hypercalcemia, and elevated total protein. Skeletal survey showed innumerable osseous lytic lesions involving the ribs, skull, spine, pelvis, and long bones. Bone marrow biopsy confirmed multiple myeloma and the patient received bortezomib, cyclophosphamide, and dexamethasone as induction chemotherapy with acyclovir and allopurinol for prophylaxis. The patient's dyspnea improved with blood transfusion however his chest pain persisted, exacerbated by sudden movements and deep palpation. He received pamidronate, tylenol, and oxycodone for presumed bony pain. An exercise radionuclide myocardial perfusion study showed ST depressions without coronary perfusion or focal wall motion abnormalities limited by dyspnea. Transthoracic echocardiogram was unremarkable with normal ejection fraction. Cardiology consult recommended ranolazine for possible angina. Six hours after taking ranolazine, he developed a loud high-pitched polyphonic expiratory wheeze localizing to his neck and not improved with nebulized albuterol. He maintained normal oxygen saturations on room air but reported mild respiratory distress. His expiratory wheeze worsened overnight with new tongue swelling and facial edema. Laryngoscopy showed no oropharyngeal, laryngeal, or tracheal edema. Chest imaging showed no evidence of pulmonary congestion or obstructing mass such as plasmacytoma. He received intravenous benadryl and solumedrol with marked improvement in his angioedema and bronchial wheeze. Ranolazine and allopurinol were identified as possible causal agents and added to his allergy list. He was discharged on a five day course of oral prednisone with follow-up in hematology for chemotherapy.

DISCUSSION: Anaphylaxis is frequently underdiagnosed due to failure to recognize presentations without obvious rash or shock. This patient fulfilled diagnostic criteria for anaphylaxis by his acute onset respiratory compromise and facial and tongue edema. The intensity, timbre, and timing of a patient's wheeze can help to localize the site of obstruction. Stridor, a loud monophonic inspiratory wheeze, reflects narrowing of extra thoracic large airways and risk of impending airway collapse that requires quick action. Expiratory polyphonic wheezes reflect dynamic compression of the large, more central airways such as the mainstem and lobar bronchi, whereas monophonic wheezes reflect disease in small bronchioles and terminal airways such as in asthma. Subtle facial and tongue edema can be difficult to appreciate without multiple reference points. Family members' recognition of the patient's facial edema during a period of transition in care teams helped guide the timely diagnosis and management of the hypersensitivity reaction over other considerations such as upper airway compression from plasmacytoma and cardiac wheeze from heart failure, and led to clinical improvement in the patient's symptoms.

THE PARADOX OF A RISING CD4: HYPERTHYROIDISM IN HIV PATIENTS ON COMBINED ANTIRETROVIRALS Emory Hsu¹; Minh Nguyen². ¹Emory University, Atlanta, GA; ²Emory University SOM, Atlanta, GA. (Tracking ID #2199403)

LEARNING OBJECTIVE #1: Recognize the risk of autoimmune hyperthyroidism in HIV patients treated with combined antiretroviral therapy (cART)

LEARNING OBJECTIVE #2: Recognize that unlike other immune reconstitution inflammatory syndromes (IRIS), Grave's disease due to immune restoration (G-IRD) can occur years after cART initiation and is not associated with increased inflammatory markers

CASE: A 38 year old Black male diagnosed with HIV 7 years prior, presented for care with a nadir CD4 T-cell count of 3 cells/uL. He was started on combination highly active antiretroviral therapy (cART) of efavirenz-etrizabine-tenofovir, with good medication adherence. He presented 23 months later with heat intolerance, palpitations, tremors, mild weight loss, and breast tenderness. Physical exam demonstrated enlarged thyroid, bilateral gynecomastia, a fine resting tremor, and irregularly irregular heart rate. His CD4 count was 486 cells/mL, TSH 0.016 IU/mL, free thyroxine (fT4) of 3.87 (normal 0.6–1.6 ng/dL), and triiodothyronine (T3) of 425 (normal 87–178 ng/dL). Further workup including pituitary hormones was unremarkable. He was treated with methimazole 20 mg daily and metoprolol XL 25 mg daily leading to normalization of fT4 and complete resolution of symptoms after 3 months, with plans to continue monitoring. During the same year in our clinic, a total of 7 HIV infected individuals - 6 female, 6 Black, all without previous history of thyroid disorder - developed Graves' immune restoration disease (G-IRD). At the time of initiation of cART, these patients had a median (range) baseline CD4 count of 12 (3–47) cells/uL, followed by an interval of 48 (23–97) months on cART until diagnosis of hyperthyroidism, with a CD4 count of 492 (170–728) and a TSH of 0.026 (0.014–0.095) IU/mL at the time of G-IRD diagnosis.

DISCUSSION: Graves' disease is a common autoimmune thyroid disorder, primarily in middle-age females, caused by autoantibodies to the thyroid stimulating hormone receptor (TSHR), with common presenting signs and symptoms including anxiety, tremor, weight loss, heat intolerance, diarrhea, palpitations, and proptosis. Diagnosis is confirmed through presence of TSHR and thyroid peroxidase antibodies. The majority of Graves' cases are idiopathic, but immune restoration (also called reconstitution) has been identified as a cause of Graves' disease. Our series of HIV-infected patients who developed Graves' disease raises the need for awareness of autoimmune hyperthyroidism as a potential long-term sequelae of cART. The first reported cases of Graves' disease in patients on cART (Gilquin 1998) occurred 16–22 months after initiation of therapy. Additional cases have been reported since (Rasul 2011; Crum 2006; Chen 2005). Reports suggest that HIV-associated Graves' disease is an immune restoration disease (G-IRD), similar to immune reconstitution inflammatory syndrome (IRIS). IRIS typically occurs within 6 months of memory T-cell recovery after initiation of cART, thought to be an exaggerated response of a recovering immune system to a foreign antigen. However, G-IRD often occurs later, usually 1–3 years after cART. Aberrant B-cell and T-cell recovery allows autoantibodies to TSHR to proliferate. The exact mechanism by which this occurs - in both idiopathic Graves' disease and in G-IRD—is still unclear. However, in G-IRD, there appears to be an absence of the inflammatory cytokines that characterizes IRIS. Rather, it is likely mediated through Th2 immune response through CD4 expansion. Longitudinal work involving 7 patients and matched controls found increased proportions of naïve CD4+ T cells and non-thyroid related autoantibody titers in G-IRD. IRIS, in contrast, involves memory CD4+ T cells. It is postulated that perhaps the migration of naïve CD4 cells from the thymus is responsible for the late presentation of G-IRD. (Sheikh 2014) Given the limited number of patients, it remains unclear whether G-IRD is more common in women as is the conventional (idiopathic) form. Treatment of G-IRD is similar to that of conventional Graves', initially with antithyroid medication such as methimazole, and symptomatic medications as needed such as beta-blockers (Weetman 2009). In general, patients can continue to

receive cART. A consultation with an endocrinologist is warranted to discuss definitive treatment such as radioactive iodide thyroid ablation or thyroidectomy. In the era of antiretrovirals, primary care physicians must be cognizant of autoimmune disorders arising as a consequence of immune system recovery. While these autoimmune disorders most commonly involve gastrointestinal and dermatologic findings, Graves' disease is one such immune-related adverse event, and can occur months to years after cART initiation. Further studies are needed to elucidate predictors of G-IRD development in cART-treated HIV patients.

THE SEIZURES MAY BE PSYCHOGENIC, BUT THE CALCIUM IS REAL Angela Arbach; Nidhi Agrawal; Jennifer Ogilvie; Michael Janjigian; Jennifer Adams. NYU School of Medicine, New York, NY. (Tracking ID #2196530)

LEARNING OBJECTIVE #1: Formulate a differential diagnosis for hyperparathyroidism

CASE: A 45 year-old woman presented after a witnessed seizure. She had a history of non-epileptic seizures, diabetes mellitus, bipolar disorder, and parathyroidectomy 10 years prior for parathyroid adenoma. Three weeks prior to admission, she was seen in clinic for lower extremity edema, which was treated with furosemide. A week later, she went to the emergency room with the chief complaint of fatigue, constipation, and "feeling unwell", with labs significant for hypercalcemia. She was hydrated and discharged for outpatient workup but was readmitted under our care after having a non-epileptic seizure in the endocrine surgery clinic. She had no history of calcium supplementation, renal stones, chronic infections, or malignancies. On physical exam, she was obese, with poor attention. She had a left-sided, well-healed transverse cervical incision with no appreciable thyromegaly or other neck masses. Her calcium level was 13.6 mg/dL, phosphorus 2.2 mg/dL, PTH 395 pg/mL, PTH-rp <0.74 pmol/L, creatinine 0.6 mg/dL, and Vit D 9.6 ng/mL. Thyroid ultrasound revealed small sub-centimeter thyroid nodules with no evidence of parathyroid enlargement. Sestamibi parathyroid scan was without abnormalities. CT scan of the neck revealed sub-centimeter nodular foci in the right pre-tracheal and left para-esophageal regions. Despite treatment with pamidronate, the patient continued to have symptomatic hypercalcemia and underwent exploratory parathyroidectomy with intra-operative PTH monitoring. She was found to have parathyromatosis, with diffuse seeding of parathyroid tissue over the entire left thyroid lobe, which was also encased in scar tissue. After a left thyroid lobectomy, her intraoperative PTH level decreased from 454 to 39 pg/mL, and her post-operative calcium levels have been 9.0–9.9 mg/dL.

DISCUSSION: The etiologies of hypercalcemia are numerous and include primary hyperparathyroidism, malignancy, vitamin D excess, increased bone turnover, and medication side effects. Laboratory studies, such as PTH and calcium levels, can help clarify this differential. Primary hyperparathyroidism and malignancy account for over 90 % of cases of hypercalcemia, and an elevated or high-normal PTH greatly favors the diagnosis of the former. Imaging studies, while not indicated for diagnosis, may assist surgical intervention by localizing disease. Parathyroid adenomas are the cause of most cases of primary hyperparathyroidism, and focused parathyroidectomy by experienced surgeons has a cure rate over 95 %. Persistent or recurrent hypercalcemia following parathyroidectomy is most commonly associated with missed adenoma and surgeon inexperience, multiple gland disease, supernumerary or ectopic parathyroids, parathyroid carcinoma, and parathyromatosis. Parathyromatosis may occur from inadvertent seeding of benign parathyroid tissue during previous parathyroidectomy, which scatters hyperfunctioning parathyroid tissue throughout the neck, making diagnosis and treatment particularly difficult. The time from prior parathyroidectomy to newly diagnosed parathyromatosis can span years. In most cases, surgery cannot cure parathyromatosis, and patients are medically managed with therapies that are not well established, including calcimimetics and bisphosphonates. Our case demonstrates a disease that, although rarely documented, may prove to be an underdiagnosed cause of recurrent hyperparathyroidism.

THE SEVEN-YEAR LIVER MASS: AN UNCOMMON MANIFESTATION OF A COMMON DISEASE Neal Yuan¹; Leslie Sheu²; Rene Salazar². ¹University of California, San Francisco, Walnut Creek, CA; ²University of California, San Francisco, San Francisco, CA. (Tracking ID #2179474)

LEARNING OBJECTIVE #1: Generate a differential diagnosis for hepatic granulomas

LEARNING OBJECTIVE #2: Learn the epidemiology and presentation of hepatic tuberculosis (TB)

CASE: A previously healthy 25 year-old woman with a 7-year history of a known liver mass presented to our hospital with worsening right upper quadrant abdominal cramping. She denied fevers, chills, or other constitutional symptoms. She had no diarrhea, constipation, but endorsed a 20-pound weight loss within the last 6 months. The first episode of her abdominal pain began 7 years ago and self-resolved while she was living in the Philippines. After moving to the United States 2 years later, she re-developed these

symptoms and underwent abdominal imaging. MRI revealed a heterogeneous right liver lobe mass with partially cystic focal lesions, punctate calcifications, and peripheral biliary duct dilatation, suspicious for malignancy. The patient was unfortunately lost to follow-up until presenting to our institution. At our hospital, the patient was afebrile with lab values significant for aspartate transaminase (AST) and alanine transaminase (ALT) levels in the 200 s, alkaline phosphatase (ALP) of 300, but normal total bilirubin levels. Liver synthetic functions were also normal. An MRI revealed a large infiltrating mass that had grown from 5 years prior. Positron Emission Tomography (PET) showed that the liver lesion was PET-avid and also uncovered a PET-avid pulmonary hilar node. A CT demonstrated small pulmonary nodules in the upper lobes bilaterally. The patient had negative serum tests for HIV, coccidioides, cryptococcus, histoplasma, and hepatitis A, B, and C. A QuantiFERON-TB Gold (Cellestis, Carnegie, Australia) assay was positive. Serial sputum smears were negative for acid-fast bacilli. The differential diagnosis at the time included cholangiocarcinoma, hemangioendothelioma, and other hepatic malignancies. TB, fungal, and indolent bacterial infections were also considered. An ultrasound-guided liver biopsy was obtained. Both stains and cultures were negative for bacteria, acid-fast bacilli, and fungi. Pathologic examination of the specimen revealed many granulomas with small focal necrosis and no evidence of malignancy. The patient was empirically started on rifampin, isoniazid, pyrazinamide, and ethambutol. Polymerase chain reaction (PCR) analysis of biopsy samples later returned positive for *Mycobacterium tuberculosis*.

DISCUSSION: Although known best for its pulmonary manifestations, TB infects the liver through hematogenous spread in 1.2 to 15.7 % of TB cases. While this most commonly presents in the setting of disseminated TB, isolated hepatic TB is extremely rare and exists on the case report level. Symptoms of hepatic TB are non-specific and can include hepatomegaly, fever, weight loss, and abdominal pain. Liver function tests often show an infiltrative pattern with high ALP without concomitant elevated bilirubin. AST and ALT may also be mildly increased. Other documented laboratory abnormalities include hyponatremia, hypergammaglobulinemia, and signs of liver synthetic dysfunction. A positive tuberculin skin test or interferon gamma release assay can support a TB diagnosis but is unable to distinguish among current, latent, and previously cleared infections. They are therefore less helpful if the patient is from a TB-endemic region. In addition to producing non-specific signs and symptoms, hepatic TB masses are often difficult to interpret on imaging, exhibiting multiple coexisting pathologic states including necrosis, fibrosis, and calcification. They are frequently suspicious for malignancies. A liver biopsy is necessary for diagnosis and can spare certain patients unnecessary surgery for suspected cancer. While Ziehl-Neelsen staining and AFB culture can have low sensitivities for TB (0–45 and 10–60 % respectively), pathologic analysis of biopsy specimens often reveals granulomas with or without caseation. The differential for granulomas in the liver includes autoimmune diseases (sarcoidosis, primary biliary cirrhosis), infections (TB, cryptococcus, Q fever, brucellosis), malignancies (lymphoma, renal cell carcinoma), and drug reactions. In cases where there is a high suspicion for TB despite negative stains and cultures, empiric treatment and PCR diagnosis should be considered. Treatment for hepatic TB is often with rifampin, isoniazid, pyrazinamide, and ethambutol for at least a year. The liver toxicity of these medications should prompt close monitoring and may even raise consideration of alternative regimens such as those involving fluoroquinolones, which have been used in post liver transplant cases. Patients will often experience significant clinical improvement within weeks to months of therapy. Guidelines on repeat imaging to ensure resolution do not exist and are done on a case-by-case basis. Secondary malignancy in the setting of hepatic TB is extremely rare.

THE SKIN RASH THAT WAS NOT A RASH—EXTENSION OF T-CELL PROLYMPHOCYTIC LEUKEMIA INTO THE SKIN Akshay Amaraneni; Devin B. Malik. Western Michigan University School of Medicine, Kalamazoo, MI. (Tracking ID #2194169)

LEARNING OBJECTIVE #1: Understand that T-cell Prolymphocytic Leukemia is a rare leukemia that can present similar to B-cell Chronic lymphocytic leukemia and is differentiated best by flow cytometry.

LEARNING OBJECTIVE #2: Recognize the indications for treatment in T-Cell PLL, Skin involvement being one of them.

CASE: A 75-year-old man was referred to a hematologist following consecutive, routine complete blood counts showing a lymphocytosis of 19,200 cells/microliter. Given the patient's age and indolent presentation, Chronic Lymphocytic Leukemia was suspected. The patient's medical history was significant for hypertension, diabetes mellitus type 2. His surgical history was unremarkable. He had a long medication list that included lisinopril, hydrochlorothiazide, subcutaneous insulin and donepezil. The patient is a retired aerospace engineer and had a 10-pack year smoking history but last smoked in 1959. His family history was unremarkable. Physical examination revealed pre and post-auricular lymphadenopathy along with right upper cervical, left lower cervical and infraclavicular lymphadenopathy but was otherwise normal. Flow cytometry was performed on peripheral blood and revealed >90 % T cell involvement with CD2, CD3, CD4, CD5 (atypically

bright), CD7, CD19, CD45 and CD52 positive. FISH showed a rearrangement of TCL1A rearrangement on chromosome 14. This profile is diagnostic of T-Cell PLL. Two months later, the patient developed a diffuse, non-blanching, maculopapular skin rash that appeared over his neck, chest and back. It was not known what the rash was as he had not started any new medication and did not appear to be allergic. A skin biopsy was performed that showed lymphocyte infiltration in the dermis that stained positive for CD4. This is consistent with T-Cell PLL infiltration of the skin. The patient was started on mini-R-CHOP (Rituximab, cyclophosphamide, Adriamycin, vincristine and prednisone) therapy. The patient progressed on this regimen with his lymphocyte count eventually reaching 72,000 cells/microliter. He was then started on Alemtuzumab, a biologic agent that is a monoclonal antibody to CD52. Follow up appointments revealed that the patient's lymphadenopathy and rash resolved and his most recent lymphocyte count was 5000 cells/microliter.

DISCUSSION: T-Cell prolymphocytic leukemia (T-Cell PLL) is a rare post-thymic T-cell leukemia. Because the cancer is so infrequently encountered even by hematologists, it is often misdiagnosed and as a result can lead to incorrect treatment and management. We present a case of a 75-year-old man who presented with a peripheral T-cell leukemia and eventually developed a mysterious skin rash. Flow Cytometry findings are important in this case as they help differentiate between a T-cell leukemia and B-cell leukemia when peripheral smear or bone marrow biopsy is not diagnostic. Special stains are also useful in the differentiation of the two, however not enough to establish a true diagnosis. Flow cytometry also gave us another important characteristic in this case, the presence of the CD52 marker on the T-cells. The importance of this marker is for the use of Alemtuzumab, which is a biologic monoclonal antibody against CD52 that is shown to improve survival in T-cell PLL patients. T-Cell PLL accounts for just 2 % of all leukemias. One fifth of patients will go on to develop skin manifestations with fewer having pleural effusion or CNS involvement. The skin manifestation is important because it is a direct extension of the PLL and not a paraneoplastic dermatosis. Indications for treatment include constitutional symptoms, bulky lymphadenopathy, symptomatic anemia, thrombocytopenia, skin or CNS involvement, pleural effusion related to the disease or demonstration of quick progression. Once he developed skin manifestations, the patient was quickly treated. This case also highlights the importance of flow cytometry and FISH in the diagnosis of leukemia and lymphoma.

THE SWEET SIDE OF ISONIAZID: MANAGING A DRUG INTERACTION IN AN INTERPROFESSIONAL TRAINING CLINIC Megan S. Lemay^{1, 2}; Katherine Hofstetter². ¹Yale-New Haven Hospital, New Haven, CT; ²West Haven VA Hospital Center of Excellence in Primary Care Education, West Haven, CT. (Tracking ID #2198845)

LEARNING OBJECTIVE #1: Identify the potential interaction between isoniazid and sulfonylureas that may lead to hyperglycemia in diabetic patients

LEARNING OBJECTIVE #2: Identify potential roles of other disciplines, team work, and interprofessional clinical training for the mutual care of complex patients

CASE: Mr. H is a 67 year old male veteran with a history of type 2 diabetes mellitus, obesity, depression, and recently diagnosed latent tuberculosis infection. Over the past year, his hemoglobin A1C had increased from 7.6 to 9.6 %. His primary care provider (a nurse practitioner fellow) added glipizide to metformin to control his hyperglycemia. The patient recorded fasting blood glucose levels of 100–170 on this regimen. The veteran then had a PPD placed which resulted in 10 mm of induration. He had no symptoms of active TB infection and a normal chest x ray. Isoniazid was initiated for treatment of latent TB infection. Six weeks into his therapy, he presented with hyperglycemia. He noted morning fasting blood glucose levels of 230–350 and was experiencing polyuria and polydipsia. During the clinic encounter, the NP fellow precepted with her NP supervisor and an MD chief resident. Together, they identified a potential drug-drug interaction between isoniazid and sulfonylureas. They consulted with the pharmacist and pharmacy trainee present in the same precepting room who recommended discontinuing glipizide. Within the primary care clinic, they were able to work with a pharmacist, pharmacy trainees, and the patient aligned care team (PACT) nurse to start the veteran on insulin glargine. The veteran was able to continue isoniazid therapy and now has a hemoglobin A1C of 6.1 %.

DISCUSSION: Isoniazid (INH) is known to cause metabolic derangements and hepatotoxicity. It is thought to cause hyperglycemia (even in non-diabetic patients) by stimulating the release of glucagon and inhibiting the release of insulin from pancreatic beta cells. This directly antagonizes the action of sulfonylureas, which exert their primary hypoglycemic action by stimulating pancreatic insulin release. Isoniazid therapy for latent TB infection is recommended for 9 months. Therefore, patients beginning this therapy, especially those with diabetes, should be monitored for hyperglycemia. Often, oral hypoglycemic medications need to be stopped and insulin therapy initiated to maintain glycemic control. This complicated scenario was managed with multiple disciplines within the West Haven VA Primary Care Center of Excellence (CoE) in Primary Care Education. The CoE is a unique training environment for internal medicine residents as they learn alongside trainees from

other disciplines (including nurse practitioner fellows, pharmacy residents, and health psychology fellows). Residents are supervised by and precept with nurse practitioner faculty. Likewise, nurse practitioner trainees work with MD faculty. Within this training environment, pharmacists and pharmacy trainees are available directly in the precepting space to listen to trainee presentations and offer guidance. Patients are able to experience a “warm hand off” wherein the NP or MD trainee seeing the patient in primary care clinic can introduce the patient to another team member (such as a pharmacy or mental health trainee) to assist in management without the patient even needing to leave the room. The CoE also places importance on sustained longitudinal relationships (for patients and between disciplines) to ensure that patients are followed long term by the entire team. Nurses and health technicians are also an equal voice in team structure and changes and actively follow patients on their team. With this model of teamwork and interdisciplinary care, this veteran was able to complete treatment for latent TB infection while attaining superior glycemic control.

THE TELL-TALE HEART: A CASE OF GROUP B STREPTOCOCCUS (GBS) ENDOCARDITIS PRESENTING AS COMPLETE HEART BLOCK Amceera Ahmed; Daniel S. Zhang; I-Hui Chiang. Baylor College of Medicine, Houston, TX. (Tracking ID #2199240)

LEARNING OBJECTIVE #1: Recognize that the rate of invasive Group B Streptococcus (GBS) infections is rising in non-pregnant adults particularly in the elderly

LEARNING OBJECTIVE #2: Identify GBS as a rare pathogen causing destructive native valve infective endocarditis and treat with antibiotics and early cardiac surgery

CASE: A 62 year old Caucasian male with well controlled chronic obstructive pulmonary disease, diabetes and hypertension presented with progressive dyspnea on exertion. He had noted productive cough, fevers, congestion, shortness of breath and wheezing 2 weeks prior to admission. All the symptoms had resolved except the fevers and shortness of breath that had continued to worsen. The patient said that at baseline he was able to walk about a mile but now walking to the bathroom left him winded. He denied recent travel. His roommate had been sick with him. Vitals showed that he was febrile and bradycardic with normal blood pressure. Physical exam revealed lower extremity edema, crackles at lung bases and a new III/VI systolic murmur at the apex. EKG showed complete heart block. Laboratory studies were significant for leukocytosis. Blood cultures grew 4/4 bottles of GBS. Echo showed a 8×4 mm mobile mass on the mitral valve, possible aortic root abscess with preserved ejection fraction. Coronary angiography was notable for chronic total occlusion of the right coronary artery. He was started on ceftriaxone and gentamicin and a temporary trans-venous pacemaker was placed.

DISCUSSION: GBS was long thought of causing infections more commonly in pregnant women and neonates. However now it is increasingly recognized as a cause of bacteremia without a focus, sepsis, soft tissue infections, infectious endocarditis, urinary tract and central nervous system infections in non-pregnant adults. It affects elderly adults more commonly with the case fatality rate for elderly adults being estimated at 15 %. Increased rates of skin, rectum, and pharyngeal carriage are seen in nursing home residents and men who have sex with men. In the pre-antibiotic era, most cases of GBS infective endocarditis were seen in pregnant women usually with prior rheumatic heart disease. At the time mortality rate was almost 100 %. Several recent studies have shown that GBS infective endocarditis now usually occurs in older patients, with a ratio of male to female patients of 1:1. There is an association between GBS infective endocarditis and chronic systemic diseases, such as alcoholism, diabetes mellitus, cirrhosis, cancer and HIV infection. GBS infective endocarditis has been compared to staphylococcus endocarditis given its propensity to infect and rapidly destroy native valves. In one review the incidence of emboli was 50 and 40 % of patients underwent cardiac surgery because of extensive valve destruction. GBS isolates have traditionally been uniformly penicillin-sensitive. However, there is greater penicillin resistance seen with GBS than with group A streptococcus. Some authors recommend the addition of gentamicin to penicillin or a cephalosporin for at least the first 2 weeks of a 4 to 6 week course of antimicrobial therapy. Data suggests that that early cardiac surgery has improved overall survival rates among more recently treated patients as compared with patients treated in the past.

THE UNUSUAL CASE OF SEVERE ABDOMINAL PAIN Andrey A. Samal¹; Armen Simonian². ¹Capital Health Regional Medical Center, Trenton, NJ; ²Capital Health Center, Pennington, NJ. (Tracking ID #2159090)

LEARNING OBJECTIVE #1: Diagnose small bowel ischemia based on HPI and risk factors, recognize that LDH, bicarbonate and initial abdominal CTA may remain normal on presentation.

LEARNING OBJECTIVE #2: Be aware that prompt surgical intervention is proven to be the only life-saving procedure in patients with acute small bowel ischemia.

CASE: This is a 65-year-old overweight Caucasian male with PMH of HTN, erectile dysfunction, two myocardial infarctions status post two stents and a CABG who presented with intense abdominal pain that began abruptly and shortly after eating breakfast. In the ED he was found to have a markedly elevated blood pressure (204/118) and a CTA of the chest and abdomen, EKG, LDH and troponins were ordered but came back nondiagnostic. His hemoglobin was found to be 17.5, WBC of 8.9, BUN was 18, creatinine was 1.1 and bicarbonate was 20. The patient was started on IV fluids and pain medications. A Cardene drip was initiated. The next day the patient's white count increased to 15.8 and was associated with a neutrophilia (91 %) and no bandemia. The patient was started empirically on Zosyn, as initially, his symptoms were attributed to acute cholecystitis since abdominal ultrasound showed multiple gallstones with slightly thickened gallbladder wall measuring 4 mm and positive Murphy's sign. The HIDA scan, however, was non-conclusive for acute cholecystitis, and despite the aggressive pain management, the patient's condition did not improve. He still experienced severe abdominal pain, out of proportion to physical findings. Upon further questioning the patient reported having mild intermittent abdominal discomfort for the last several years within 30 min post-meal that made him decrease the amount of food intake and eat more frequently. The patient admitted weight loss of 55 lb over last 6 months. This new information strongly indicated possible bowel ischemia, although normal LDH and bicarbonate argued against it (597 and 25 respectively). A follow up CTA abdomen and pelvis showed signs of possible small bowel wall pneumatosis. This finding along with severe abdominal pain out of proportion to his physical examination, a silent abdomen, and hemoconcentration combined with a PMH of CAD strongly suggested small bowel ischemia. The patient was emergently taken to OR for an exploratory laparotomy and upon discovery of a necrotic segment of jejunum underwent a small bowel resection. The patient tolerated the procedure well. He was started on heparin drip with transition to Coumadin to prevent possible thrombosis. His overall condition gradually improved. The diet was gradually advanced with no abdominal symptoms. He remained in the hospital until therapeutic INR was achieved. The rest of his hospitalization was unremarkable. The INR on discharge was 2.5.

DISCUSSION: Aggressive intervention, diagnostic and surgical, tends to be the only life-saving approach in the management of acute on chronic ischemic bowel syndrome. In the above intricate case the history of CAD and erectile dysfunction were indicators of systemic atherosclerosis with possible mesenteric arterial involvement, but its presentation, initial CTA and negative LDH combined with a normal bicarbonate level argued against mesenteric ischemia. Fortunately for the patient, the diagnosis of mesenteric ischemia was considered in a timely fashion prompting repeat radiographic imaging. This led to his expedited surgery with confirmation and proper treatment of this potentially life threatening condition.

THE WORMS INSIDE ME: A CASE OF *STRONGYLOIDES* HYPERINFECTION SYNDROME PRESENTING WITH MENINGITIS AND INTESTINAL PERFORATION Yumi Ando; Celia M. Divino; Gopi Patel. Mount Sinai Hospital, New York, NY. (Tracking ID #2167247)

LEARNING OBJECTIVE #1: Identify possible *Strongyloides* hyperinfection syndrome in patients from endemic areas receiving immunosuppressants.

LEARNING OBJECTIVE #2: Recognize the potential role of screening for *Strongyloides* prior to initiating immunosuppressants in patients from endemic areas.

CASE: An 81-year-old Puerto Rican man presented with several days of fever, lethargy, and confusion. His medical history was significant for chronic obstructive pulmonary disease with frequent exacerbations requiring systemic glucocorticoid therapy. He had no sick contacts and had not been out of New York since moving from Puerto Rico 10 years ago. Vital signs were notable for fever, tachycardia, and hypotension. On examination, he was somnolent and only oriented to self. He was also noted to have nuchal rigidity and mild epigastric tenderness. Rectal exam revealed guaiac positive brown stool. Blood tests revealed leukocytosis of $12.6 \times 10^3/\mu\text{L}$ with neutrophilic predominance and no eosinophilia. Cerebral spinal fluid examination was notable for 280/ μL white blood cells with 77 % polymorphonuclear cells, elevated protein, and low glucose consistent with bacterial meningitis. The CSF Gram-stain did not reveal any organisms. Blood and CSF cultures were negative. The patient was started on dexamethasone and broad-spectrum antibiotics for bacterial meningitis. On hospital day two, the patient's mental status improved but he developed an acute abdomen. Emergent exploratory laparotomy revealed an intestinal perforation transecting 75 % of the diameter of the duodenum. Histopathologic examination of the duodenum demonstrated deep fissuring ulcers and larvae consistent with *Strongyloides stercoralis*.

DISCUSSION: Initially, the patient in this case appeared to exhibit two unrelated disease processes -bacterial meningitis and intestinal perforation secondary to a duodenal ulcer. However, both processes are potential manifestations of *Strongyloides* hyperinfection syndrome. Strongyloidiasis is endemic in tropical and subtropical regions including the Southeastern United States. In healthy individuals symptoms are often mild and self-

limited. However, *Strongyloides* has the unique ability to autoinfect their host and latent infection can persist without directed treatment. Thus, even a remote history of living in an endemic area should raise the possibility of subclinical *Strongyloides* infection. In hyperinfection syndrome, the autoinfection process is accelerated. This causes direct organ and blood vessel damage resulting in bronchospasm, hemoptysis, acute respiratory distress syndrome, intestinal ulceration, and diffuse purpuric rash. It also causes secondary bacterial infections from enteric bacteria tracking with the disseminating larvae, which manifests as bacteremia, meningitis, and pneumonia. Eosinophilia, although considered a hallmark of parasitic infections, is rare in the setting of hyperinfection. Because the clinical features are nonspecific, obtaining a thorough epidemiological history of the patient and maintaining a high index of suspicion is needed for early diagnosis. Corticosteroid use is highly associated with the development of the hyperinfection syndrome. A review of the literature suggests that there is wide variability in dose and duration of glucocorticoid therapy prior to development of the hyperinfection syndrome. Thus, it is suggested that physicians maintain a low threshold for screening patients for *Strongyloides* using stool ova and parasite examination and/or serologies prior to starting immunosuppressive therapies.

THINK OUTSIDE THE BOX: A 31 YEAR OLD MALE WITH FEVERS AND MYALGIAS Hachem Nasri; Elyse Love; Leon Bemal-Mizrachi. Emory University, Atlanta, GA. (Tracking ID #2196072)

LEARNING OBJECTIVE #1: Recognize the rare presentation of a common disease, like multiple myeloma (renal failure, hypercalcemia, lytic lesions and anemia), in a younger population.

LEARNING OBJECTIVE #2: Carefully assess the value of ordering a wide array of expensive and extensive tests (like viral panels and vitamin levels) in a subacute illness

CASE: A 31 year-old previously healthy African-American male presented with a vague complaint of "feeling terrible" for 3 days. He complained of diffuse non-radiating abdominal discomfort, ongoing for 3 days prior to his presentation, associated with non-bilious non-bloody vomiting, but no diarrhea. In addition, he reported 1 week history of rhinorrhea, fevers, and severe generalized myalgias. Review of systems was notable for decreased exercise tolerance over the past 3 months as well as a 15 lb unintentional weight loss, but he had no cough, change in urine output, night sweats, or anorexia. He had no travel history, sick contacts or tick exposure, and was only taking a multi-vitamin daily. His family history was negative for any malignancy or autoimmune diseases, and the patient denied any high-risk behaviour. On exam, he was well appearing with a body mass index of 23, a pulse of 114 beats per minutes and a temperature of 38.4 °C. His blood pressure was 125/82 mmHg and he was breathing comfortably on room air. Otherwise he had no oral thrush, no lymphadenopathy, and no cardiac murmurs. His abdomen was mildly tender but without rebound tenderness, and he had moderate tenderness to palpation of the bilateral thighs and arms, but no associated motor weakness or skin rashes. Initial labs showed WBC: 5100 cells/mcL, Hgb: 8.2 g/dL, MCV: 77 fL, BUN: 45 mg/dL, Cr: 7.3 mg/dL, Ca: 11.8 mg/dL, CPK: 3042 u/L, serum Total Protein: 7.5 g/dL, Albumin: 4.2 g/dL, and ESR: 75 mm/hr. Urinalysis came back with 2+ protein (>100 mg/dL), 3+ hemoglobin (>1 mg/dL), and no RBC casts. His liver function tests were normal, and his HIV and ANA tests were both negative. In the setting of fever, non-oliguric acute renal failure, moderate rhabdomyolysis, microcytic anemia, and hypercalcemia the differential in a previously healthy 31 year old was broad. This included viral etiologies (especially with fever and upper respiratory tract infection symptoms), vitamin toxicity (given his daily intake of multi-vitamins) or occult malignancy. On admission, an extensive viral panel and various vitamin levels were sent, all of which eventually came back negative. After an expensive initial workup and aggressive IV hydration, his hypercalcemia was not improving and his renal failure continued to worsen. A renal ultrasound showed only increased renal echogenicity bilaterally, but a serum and urine electrophoresis revealed atypical protein bands in the anodal gamma (serum) and beta (urine) zones, as well as IgG kappa and free kappa light chains. Bone marrow biopsy showed diffuse plasma cell infiltrate (>80 % plasma cells) with mild rouleaux formation on peripheral smear, and skeletal survey showed multiple ill-defined lucencies within the bilateral pubic rami consistent with myelomatous lesions. His serum Free Kappa was significantly elevated at 27,980 mg/L with a Kappa/Lambda ratio >1000 and his Beta-2 Microglobulin was 21.5 mg/L. Patient was diagnosed with Stage 3 Multiple Myeloma, based on International Staging System (ISS). Eventually he was started on Bortezomib and Dexamethasone as an inpatient, his hypercalcemia trended down, his kidney function improved, and he was discharged to follow up in clinic. Twelve months later, he is still receiving chemotherapy and is now status post second autologous bone marrow transplant.

DISCUSSION: There have been very few reports of multiple myeloma in patients younger than 30 years. Ludwig et al., in 2008, reported that 3 % of patients diagnosed with Multiple Myeloma were less than 40 years and only 0.26 % were younger than 30. However, it has been reported that only few young patients present with less favorable prognostic factors (anemia, renal impairment, or higher stage at diagnosis) when compared to older patients. Our patient presented with poor prognostic factors (elevated Beta-2

Microglobulin, serum Free Kappa >20,000, renal failure and ISS stage 3). In addition, his presentation was nonspecific, which made reaching a diagnosis more difficult. When this patient presented to the hospital, an extensive work-up was done searching for viral etiologies and vitamin toxicities as a unifying diagnosis. This led to subsequent anchoring bias and delay in the diagnosis of multiple myeloma in someone presenting with renal failure, hypercalcemia, and anemia, albeit normal serum total protein and albumin. Had this patient been an elderly male, the diagnosis would have seemed more obvious. Although it is important to establish a diagnosis early on, at times we have step back, take a look at the bigger picture and think outside the box.

THROMBOSIS IN A GIANT PULMONARY ARTERY ANEURYSM Cherinne Arundel^{1, 2}; Samah Nasserddine²; Jennifer Kerns^{1, 2}; Lakhmir Chawla^{1, 2}. ¹Washington DC Veterans Affairs Medical Center, Washington, DC; ²George Washington University, Washington, DC. (Tracking ID #2154076)

LEARNING OBJECTIVE #1: Diagnose pulmonary artery aneurysm and potential etiologies

LEARNING OBJECTIVE #2: Recognize the risk of thrombosis associated with pulmonary artery aneurysms

CASE: A 63 year old male patient with chronic obstructive pulmonary disease and chronic asymptomatic PAA presented with gradual worsening of shortness of breath over 2 months. The PAA of 4.4 cm had been incidentally discovered in 2001 on CT angiography (CTA) and subsequent CTAs showed a gradual increase in the size of the aneurysm to 7×6 cm in 2009. A right heart catheterization showed mild pulmonary hypertension with mean PA pressure of 26.6 mm Hg and pulmonary function testing demonstrated severe airflow obstruction with mild hypoxemia. The history, physical exam, and laboratory workup including a PET scan did not reveal any inflammatory, infectious or traumatic causes of the PAA (HLA B-27 was positive but without other features of collagen vascular disease, and RPR and quantiferon gold were negative). On this admission, physical exam revealed hypoxemia with SPO2 of 77 % on room air, rales at the left lung base, and an accentuated second heart sound. Repeat CTA showed an increase in size of the left PAA to 8.4×7.0×5.9 cm with an intraluminal thrombus occupying the PAA with an extensive endovascular filling defect extending into the right pulmonary artery and associated chronic pulmonary emboli. An agitated saline transthoracic echocardiogram revealed normal left ventricular systolic function and elevated right ventricular systolic pressure of 85 mm Hg. He was started on anticoagulation with low molecular weight heparin and bridged to warfarin. As for work up of his pulmonary embolism, the patient did not have signs of deep vein thrombosis; he denied any family or personal history of hypercoagulable state, and age appropriate cancer screening was negative. He was evaluated again by cardiothoracic surgery for possible repair; however, his surgical risk was deemed too high for operative intervention.

DISCUSSION: PAA is a rare condition and characterized as a vascular abnormality with focal dilatation of all three layers of the vessel wall. Most PAAs involve the main trunk of the pulmonary artery (80–85 %) with only 3 % involving the left branch. The causes of PAA are either congenital or acquired. Congenital causes are frequently related to cardiac anomalies (e.g., ductus arteriosus, atrial septal defect, ventral septal defect, or pulmonary valve stenosis) causing pulmonary hypertension. Secondary causes can be infectious in origin or related to structural arterial wall abnormalities from connective tissue diseases or vasculitis. Boyd et al. reviewed 111 autopsy cases of PAA and found that both genders were equally affected and the mean age was 37.7 years for women and 38.7 years for men¹. The clinical manifestations are nonspecific and include dyspnea, palpitations, chest pain, cough, fever, hemoptysis, hoarseness from compression of the laryngeal nerve, or symptoms from local compression^{1–3}. Complications include dissection and rupture which increase with the size of the PAA^{4–7}. Noninvasive imaging such as CT angiography or MRI imaging can help make the diagnosis⁸. Longitudinal data on the natural evolution of the disease are sparse.⁹ This case is unique given the size of the PAA, the longitudinal follow up of the patient, and associated rare complication of thrombosis. Thrombosis of the PAA has been described in Bechet's disease and is likely related to inflammation and endothelial injury, but it is exceedingly rare in other causes of PAA.^{10,11,12,13,14–17}. Serali et al. reported two cases of pulmonary embolism associated with PAA; however, neither patient had intraluminal thrombosis of the PAA¹⁰. Davutoglu et al. described the only case of PAA associated with chronic pulmonary thromboemboli and they postulate that the mechanism of thrombus formation was due to stasis of blood and endothelial dysfunction¹¹. An alternate hypothesis is that cystic medial degeneration even in the absence of connective tissue disease is an important factor in the pathogenesis of PAAs and may lead to increased hemodynamic forces and aneurysm formation^{18,19}. There are no clear management guidelines for PAA. Some have suggested surgery for enlarged aneurysms (>60 mm), those with symptoms of any size and right ventricular dysfunction or elevated pulmonary artery pressures^{20–22}. There is little guidance in the literature on the management of patients with PAA-associated thrombosis but all reported cases were treated with anticoagulation. Questions remain about the optimal follow up/frequency of imaging for

patients who opt for conservative management or who are not surgical candidates. Further data is also needed to determine the risk of thrombosis in patients with idiopathic pulmonary artery aneurysm and the possible benefit of anticoagulation for the primary prevention of thrombosis.

THROMBOTIC THROMBOCYTOPENIC PURPURA PRESENTING AS ACUTE PANCREATITIS Matthew R. Mohorek; Pinky Jha. Medical College of Wisconsin, Wauwatosa, WI. (*Tracking ID #2155887*)

LEARNING OBJECTIVE #1: Review the clinical manifestations of TTP.

LEARNING OBJECTIVE #2: Recognize that TTP can present as acute pancreatitis.

CASE: Fifty-five year-old female presented to OSH with 2-day history of abdominal pain and nausea. No significant PMH or medication use. ROS positive for unusual bruising that started 2 weeks ago. Lipase (208) was mildly elevated and CT abdomen showed extensive peripancreatic and retroperitoneal inflammatory edema concerning for acute pancreatitis, with no clear etiology. Severe thrombocytopenia was also present at admission (platelets = 8 k). Hb and WBC were within normal limits. Hematology was consulted and idiopathic thrombotic thrombocytopenic purpura diagnosed and treated with 60 mg prednisone. Over the next 36 h patient clinically declined: platelets remained critically low, hemoglobin began trending downward, and mental status progressively worsened eventually requiring intubation. CT of head showed no evidence of acute intracranial pathology. After reassessment, diagnosis of TTP was made. ADAMTS13 was obtained and patient transferred from OSH to tertiary medical center where plasmapheresis was available. Upon admission to MICU at tertiary medical center, patient was sedated, febrile, thrombocytopenic (platelets 12 k), and had signs of a microangiopathic hemolytic anemia (hemoglobin 9.9, LDH 1373, total bili 2.9, reticulocytosis and schistocytes). Plasmapheresis was immediately initiated. By day two of plasmapheresis, LDH had decreased to 502 and platelets increased to 31 k. Patient was extubated on day 3 but was aphasic. MRI of head showed a recent small left frontal lobe infarct along the pre-central sulcus. Despite this, by day five, patient had returned to baseline mental status and abdominal pain/nausea had fully resolved (lipase 38). On day six, patient suffered a minor reaction during plasma exchange with nausea, hives, and chills. Symptoms resolved and plasmapheresis was administered for two more days. In total, eight days of plasmapheresis were administered (day six held because of reaction concern). Patient was discharged on day nine in stable condition with discharge labs: platelets 327 k, Hb 7.3, LDH 211, indirect bilirubin .2, and plans for follow up with outpatient hematology two days later. ADAMTS13 activity came back at 6 %.

DISCUSSION: Thrombotic thrombocytopenic purpura (TTP) is a rare hematological disorder of platelet consumption that presents with thrombocytopenia, microangiopathic hemolytic anemia, fever, neurological symptoms and (less commonly) acute renal failure. Because the diagnosis of TTP is clinical, it must be made in a timely manner, as any delay in treatment can be life threatening. Here we report a case of TTP presenting as acute pancreatitis. The presenting clinical symptom of TTP is most commonly neurologic changes (60 %). Other common presenting clinical symptoms include: purpura/hemorrhage, malaise/fatigue/weakness, nausea/vomiting, and fever. TTP presenting with abdominal pain is uncommon (11 %) and abdominal pain secondary to acute pancreatitis, is even less common ~2 %. The cause of TTP is a deficiency in ADAMTS13, a von Willebrand factor-cleaving protease. When vWF multimers are secreted from vascular endothelial cells, ADAMTS13 normally functions as a protease for multimer break down. TTP occurs when there is a deficiency of ADAMTS13 either because of a hereditary deficiency (Upshaw-Schulman syndrome) or autoantibody destruction (acquired TTP). In the absence of ADAMTS13, large vWF multimers have an increased sensitivity to activate in small blood vessels because of shear forces present. Platelet activation in these small vessels leads to microthrombosis and a microangiopathic hemolytic anemia. An interesting debate within the realm of this topic is the cause/effect relationship between acute pancreatitis (AP) and TTP. The traditional understanding is that TTP can trigger AP by mechanical impairment of the pancreatic circulation by thrombotic occlusion of small vessels. There have been a number of recent case studies, however, that report AP as the trigger for TTP. The postulated mechanism in this case being that AP creates a systemic inflammatory response that release cytokines which stimulate endothelial cells to release multimers while simultaneously inhibiting ADAMTS13 multimer cleavage. Regardless of cause, TTP must be treated with plasmapheresis immediately. The treatment is effective in that it both removes patient plasma containing autoantibodies to ADAMTS13 and vWF multimers and infuses donor plasma containing ADAMTS13 protease. Before the use of plasmapheresis, likelihood of immediate survival after TTP diagnosis was 10 %. With plasmapheresis, latest reports suggest mortality to be as low as 9 %. This vast improvement in survival justifies a low threshold for starting plasmapheresis.

THYROID HORMONE RESISTANCE: A CASE REPORT Samaneh Dowlatshahi. Presence St Francis Hospital, Chicago, IL. (*Tracking ID #2193381*)

LEARNING OBJECTIVE #1: Resistance to thyroid hormone is a rare condition caused by tissue refractoriness to the effects of circulating thyroid hormone, and may be

misdiagnosed as hyperthyroidism. This syndrome is characterized by elevated circulating thyroid hormones, and unsuppressed TSH levels.

LEARNING OBJECTIVE #2: Although most patients are euthyroid, rarely they may present with clinical hyperthyroidism, if the pituitary gland is more insensitive than other tissues to thyroid hormones. In this study we present a case of thyroid hormone resistance with clinical evidence of hyperthyroidism.

CASE: A 58 year old male who suffered from thyrotoxicosis and diarrhea for many years and had been under treatment for atrial fibrillation with rate control medications. He had been tested for thyroid function in the past which revealed elevated FT3 and FT4 with slightly elevated TSH concentration. Pituitary adenoma was excluded as magnetic resonance imaging showed normal pituitary gland, alpha subunit was within normal range and TSH concentration increased after TRH administration. Sonography revealed normoechogenic, slightly enlarged thyroid gland. Methimazole had been tried in the past without any significant improvement. The diagnosis of thyroid hormone resistance was made and he was started on bromocriptine at a dose of 10 mg per day. After 2 months of treatment he achieved a state of constant euthyrosis and following next few months thyroid volume diminished.

DISCUSSION: Failure to differentiate thyroid hormone resistance from primary thyrotoxicosis has resulted in the inappropriate treatment of nearly one-third of patients. Also, the diagnosis allows appropriate genetic counselling, and initiation of treatment. In this case report we emphasize the importance of timely diagnosis of thyroid hormone resistance, which prevents many patients from being wrongly diagnosed as Graves disease and therefore various inappropriate treatments. Also, we present a successful treatment of this rare condition with bromocripten.

TIMING IS EVERYTHING Arshia A. Soleimani; Deepa Bhatnagar. Tulane University Health Sciences Center, New Orleans, LA. (*Tracking ID #2198530*)

LEARNING OBJECTIVE #1: Identify the differential diagnosis for precipitous development of thrombocytopenia

LEARNING OBJECTIVE #2: Discuss treatment options for these conditions

CASE: A 55 year old woman was admitted to the intensive care unit after a motor vehicle collision secondary to hemorrhagic cerebrovascular accident. She was noted to have a pulmonary embolism and deep vein thrombosis on day 2 of her hospitalization. Given the extensive thromboembolic disease, she was started on anticoagulation with heparin. Despite treatment with heparin, her lower deep vein thrombosis extended. Three days into the hospitalization, the patient received a blood transfusion due to blood loss during her multiple orthopedic surgeries. Nine days later, the patient developed a fever and elevated white blood cell count of 15,600/UL. She was started on vancomycin and piperacillin-tazobactam for empiric coverage of a possible hospital-acquired infection. The next morning, the platelet count precipitously dropped from 516,000/UL to 10,000/UL. On repeat labs platelet count was 7000/UL and hemoglobin remained stable at 7 GM/DL. No other medications were given in proximity to this event. Peripheral smear showed no schistocytes. Serotonin release assay in addition to IgG PF4 ELISA test were ordered to rule out Heparin induced thrombocytopenia (HIT). Suspicious medications such as heparin and vancomycin were discontinued. By the next day, platelets increased to 21,000 and a few days later the platelet count was within normal limits.

DISCUSSION: Thrombocytopenia is often encountered in hospitalized patients. Many patients are admitted with thrombocytopenia that may be due to a broad differential. However, the acute fall in platelets during hospitalization often have a narrower differential. Heparin induced thrombocytopenia (HIT) can happen precipitously but does usually result in a profound degree of thrombocytopenia. When the fall in platelets is severe and occurs over 1–2 days, the most likely culprits are drug induced immune thrombocytopenia (DITP), and post-transfusion purpura (PTP). In this case, HIT was considered on the differential as the patient's thromboses progressed while on therapeutic anticoagulation. However, the severity of the thrombocytopenia was not consistent with HIT. During HIT, Heparin binds to platelet factor-4 (PF4) and creates a complex where IgG antibodies bind and lead to the activation and consumption of platelets. Typically, the median platelet count nadir is 50,000-60,000/UL or a 30–50 % drop after heparin administration. HIT is frequently detected with the PF4 ELISA, which uncovers the HIT antibodies produced against the heparin PF4 complex. This test has a sensitivity of 98 %, but a lower positive predictive value, so often times HIT is confirmed by a serotonin release assay that reveals if a patient's serum can activate donor platelets in the setting or heparin. Both of these tests came back negative and made the diagnosis of HIT improbable. Next on the differential was PTP, a very rare and fatal thrombocytopenia that occurs 5 to 12 days after a blood transfusion. It usually occurs in multiparous women who are negative for an antigen on their platelets called HPA-1a but alloimmunized by their HPA-1a positive fetus. For reasons unknown, once these patients are transfused with blood products containing HPA-1a antigen, their own platelets precipitously drop, resulting in a count <10,000/UL. First line therapy is IVIG, but plasmapheresis or corticosteroids can also be effective

agents. Genotyping studies revealed that our patient was HPA-1a positive, so PTP was also quickly ruled out. By process of elimination, the main diagnostic consideration in this patient was DITP. This reaction is highlighted by drug dependant antibodies that lead to sudden thrombocytopenia with a platelet nadir <20,000. Numerous reports have established that vancomycin can be associated with rapid thrombocytopenia. Since, thrombocytopenia developed while patient was on vancomycin and improved and did not recur once the offending drug was discontinued, DITP best fit the clinical picture. A re-challenge test of vancomycin possibly could have confirmed the diagnosis. This case illustrates a narrowed approach to precipitous thrombocytopenia. Recognition of the sudden onset and severity of the thrombocytopenia puts the focus on 2 disorders and most importantly hastens appropriate and immediate intervention.

TO B OR NOT TO B ISLET CELLS—THE STORY OF LADA Camille M. Webb; Carla Spagnoletti. University of Pittsburgh, Pittsburgh, PA. (Tracking ID #2198963)

LEARNING OBJECTIVE #1: Recognize clinical characteristics of LADA

LEARNING OBJECTIVE #2: Distinguish LADA from type 1 and type 2 diabetes mellitus

CASE: A 45-year-old man presented to the Emergency Department with nausea and weakness and was found to be in diabetic ketoacidosis. His past medical history was significant for diabetes diagnosed at age 41 with a hemoglobin A1c of 10.9 %. At that time he had been started on insulin and began tight diet control. Subsequently, after significant weight loss, he was transitioned to metformin 1 year prior to presentation to the ED, due to steadily declining insulin requirements and associated low hemoglobin A1c. While on metformin, his hemoglobin A1c ranged from 5.6 to 6.0 %. On presentation to the ED, heart rate was 107 beats per minute and blood pressure was 122/75 mmHg. Physical exam showed a well-nourished male in no apparent distress. Laboratory studies revealed a blood glucose of 601 mg/dL, serum osmolality of 300 mOsm/kg and anion gap of 16 mEq/L. Potassium was 5.9 mEq/L, sodium was 123 mEq/L and CO2 was 14 mEq/L. Urinalysis revealed ketones. Beta-hydroxybutyrate level was elevated at 1.84 mmol/L. He was admitted to medicine and started on an insulin drip, with rapid normalization of anion gap to 9 mEq/L, and of blood glucose to 130 mg/dL. Further laboratory studies revealed a hemoglobin A1c of 13.7 %, increased from 5.8 % over a period of 3 months. A C-peptide level was on lower end of normal at 1.15 ng/mL. Islet cell antibodies (ICA) were positive. He was diagnosed with latent autoimmune diabetes of adults (LADA). He was discharged on an insulin regimen with glargine 10 units daily and low dose insulin of 3 units before meals.

DISCUSSION: Latent autoimmune diabetes of adults (LADA) represents 2 to 12 % of patients with diabetes mellitus, and shares characteristics with both type 1 and type 2 diabetes mellitus. Patients with LADA have circulating antibodies towards beta cell antigens (islet cell antibodies or GAD65 antibodies) similar to type 1 diabetes, however present later in life, typically between ages of 30 and 50. At time of diagnosis, patients often have a brief period of insulin independence, which distinguishes LADA from type 1 diabetes. They are often misclassified as having type 2 diabetes, due to age of presentation and clinical characteristics. They then progress rapidly to insulin dependence and often ketoacidosis, as in the case of our patient. While patients with type 2 diabetes develop beta cell destruction over the course of several years, patients with LADA can develop beta cell destruction as early as the first 6 months after diagnosis due to the presence of antibodies. There is ongoing debate whether LADA represents a different entity from type 1 diabetes, and there is significant genetic overlap with both type 1 and type 2 diabetes. Currently, requirements for diagnosis are 1) presentation over the age of 30, 2) circulating antibodies and 3) initial insulin independence. Suspicion for atypical forms of diabetes should be raised in patients who have lower body mass indexes, other autoimmune diseases, no associated hypertension or hyperlipidemia, and a strong family history of diabetes. C-peptide levels can be useful in determining remaining beta cell function. The presence of circulating antibodies can identify patients who are likely to respond poorly to metformin and be at increased risk of ketoacidosis. There is questionable benefit to testing for autoimmune antibodies in patients with suspected type 2 diabetes, and research suggests that close glucose monitoring is equally as effective in determining when patients become insulin dependent. Although definitive treatment is insulin, glitazones may be useful in early stages of LADA. In contrast, metformin is thought to contribute to metabolic abnormalities in patients with autoimmune beta cell dysfunction.

TO BLEED OR TO CLOT? Lorelei Vandiver; Arti Thangudu; Chad S. Miller. Tulane University Health Sciences Center, New Orleans, LA. (Tracking ID #2198508)

LEARNING OBJECTIVE #1: Learn how to manage procedures in patients who are Hemophilia B carriers.

LEARNING OBJECTIVE #2: Consider implications of a patient who is a carrier of Hemophilia B and a Factor V Leiden mutation.

CASE: A 46 year-old Caucasian woman with coronary artery disease who had a bare metal stent placement in 2008 to the left anterior descending artery (LAD) presented with pressure-like left-sided chest pain for four days. She was sent from an outside hospital given her history of hemophilia B and the likely need of cardiac catheterization. Past medical history was notable for being a hemophilia B carrier, having spontaneous hemarthrosis, and factor V Leiden mutation. Family history was significant for a father and son with hemophilia B and a daughter who was a carrier for hemophilia B. Her physical examination was noncontributory. A Lexiscan revealed a small area of myocardium in jeopardy in the right coronary artery territory and intermediate risk for obstructive coronary artery disease and major cardiac events. Factor IX activity was 46.0 %. Thirty minutes prior to the cardiac catheterization, the patient was given recombinant factor IX 25 u/kg. Right radial artery access was obtained for ease of compression. Coronary angiography revealed 50–60 % mid stenosis of the LAD; no stent was placed. The patient tolerated the procedure well and had no bleeding at the access site. Aspirin was held at discharge given her bleeding history.

DISCUSSION: This patient presented a unique dilemma given her need for cardiac catheterization and her genetic predisposition for both bleeding and clotting. Bleeding in hemophilia carriers has gained recognition in recent literature, especially during and after surgical procedures. One study emphasizing this increased risk demonstrated that 28 % of study participants with the carrier status had prolonged bleeding (>3 h) after an operation as compared to noncarriers (11 %). Conversely, heterozygous carriers of Factor V Leiden have been shown to have a 5 % risk of developing an unprovoked venous thromboembolus (VTE) by the age of 65. Our patient had no history of pulmonary embolus or deep vein thrombosis and she had no other risk factors that would increase her likelihood of developing a VTE, such as use of hormonal contraceptives, hormone replacement therapy or current pregnancy. Given the epidemiology of these disorders and their complications, as well as our patient's history of spontaneous hemarthrosis, we believed the patient was more likely to have a bleeding rather than clotting complication following catheterization. There are recommendations regarding percutaneous cardiac intervention (PCI) in patients with hemophilia. Correction of factor IX before and after the procedure is recommended and heparin may be used in hemophilia patients for anticoagulation. Although this patient was fortunate to not require a coronary artery stent, it is possible to administer dual antiplatelet therapy as long there is close supervision of factor levels. Hemophilia B and Factor V Leiden mutations can exist together and may bestow an evolutionary advantage over either one of these disorders when they are singularly present. The bleeding tendency in hemophilia may be modulated by the prothrombotic tendency in patients with Factor V Leiden. In the rare subset of patients with both hemophilia and factor V Leiden, care must be taken to balance the risk of bleeding with the risk of clotting, especially in cases where anticoagulation may be warranted.

TO CLOT OR NOT TO CLOT: LUPUS ANTICOAGULANT-HYPOPROTHROMBINEMIA SYNDROME TREATED WITH RITUXIMAB Sara Jane Cromer; Natalie Uy; Courtney N. Miller-Chism. Baylor College of Medicine, Houston, TX. (Tracking ID #2198330)

LEARNING OBJECTIVE #1: Recognize the classic presentation of lupus anticoagulant-hypoprothrombinemia syndrome (LAHS)

LEARNING OBJECTIVE #2: Treat LAHS with immunosuppressants such as rituximab in cases uncontrolled by factor replacement

CASE: A 57 year-old Hispanic male with history of alcohol abuse presented with gross hematuria preceded by flank pain and non-traumatic epistaxis for 3 days. He denied prior bleeding episodes, family history of hematologic or auto-immune disorders, and usage of antiplatelet or anticoagulant medications. On presentation, vital signs and physical exam were within normal limits, with the exception of mucosal bleeding and petechiae on the soft palate. Labs were remarkable for slight leukocytosis (12,100/ μ L), significant elevations in prothrombin time (PT, 33.6 s) and partial thromboplastin time (PTT, 130.6 s) with an INR of 3.6, and gross hematuria. Liver profile, D-dimer, and fibrinogen were normal. A mixing study showed normalization of PT but incomplete correction of PTT. After a precipitous drop in hemoglobin to 5.5 mg/dL (from 15.4 mg/dL on admission), up-trending INR to 4.5, and development of mild headaches, abdominal and head CT scans on hospital days (HD) 2 and 3 showed spontaneous and progressing retroperitoneal hemorrhage and interval development of two small subdural hematomas. He was admitted to the intensive care unit on HD 3 and started on 100 mg prednisone daily and vitamin K. Prothrombin complex concentrate, complex factor IX, and 36u of fresh frozen plasma (FFP) were administered over three days with limited and fleeting clinical and laboratory improvement. On HD 4, he was found to have Factor II activity at 17 % (normal 75–130 %), and a positive lupus anticoagulant (LA). Bleeding continued until HD 6, and the decision was made to start weekly rituximab at 375 mg/m². His hemoglobin and INR stabilized that day, and he received only two units of FFP during the remainder of his hospitalization. Repeat factor II activity on HD 8 improved to 60 %. He was discharged in

stable condition on HD 13 with plan for a prednisone taper and a total of 4 cycles of rituximab which were completed without complication as an outpatient. Coagulation studies remained stable 2 months after discharge.

DISCUSSION: While lupus anticoagulant (LA) is classically associated with venous and arterial thromboses, lupus anticoagulant-hypoprothrombinemia syndrome (LAHS) should be suspected when patients with positive LA present with a bleeding diathesis. In this syndrome, non-neutralizing anti-prothrombin antibodies lead to increased clearance of prothrombin and diagnostic studies suggesting both an inhibitor and a factor deficiency. LAHS can be associated with viral infections, autoimmune diseases (most commonly systemic lupus erythematosus), and hematologic malignancies. It is most commonly treated with factor replacement (FFP), vitamin K supplementation, and corticosteroids; however, there are no standardized recommendations for the treatment of this condition. Corticosteroids raise prothrombin levels by decreasing clearance of prothrombin-antibody complexes but do not prevent new antibody production. Other immunosuppressive treatments reported in the literature include azathioprine and cyclophosphamide in non-emergent cases, and IVIG or plasmapheresis in cases of acute hemorrhage. Recently, however, several case reports have suggested that rituximab may be a powerful tool in the suppression of acquired anti-prothrombin antibodies. In our case, rituximab infusion normalized the patient's INR and prevented the progression of developing retroperitoneal and subdural hemorrhages, supporting its clinical utility in the treatment of LAHS.

TO CONSIDER MAY- THURNER SYNDROME IN LEFT LOWER EXTREMITY DVT TO PREVENT FATAL THROMBOSIS shriyanka Jain; Apama Basu; Aasim Mohammed; David gevorgyan; krishna Devakiamma. Mercy Catholic Medical center, Philadelphia, PA. (Tracking ID #2198594)

LEARNING OBJECTIVE #1: Recognize May-Thurner as an important differential diagnosis in left lower extremity edema.

LEARNING OBJECTIVE #2: Recognize duration of anti-coagulation therapy in patient with may-thurner syndrome(MTS) and anti-phospholipid antibody.

CASE: Here we present a case of 37 y o Asian female who came with left lower extremity swelling and pain for past 3 days. Her past medical history is significant for lupus anti coagulant, 3 miscarriages and recent OCP use(2 weeks back). She denies any prior history of DVT. She works as an airline agent and has to stand for long periods of time. She denies Smoking or alcohol use. She has a brother who has history of DVT. On examination, the patient's vital signs were within normal limits. Her left lower extremity was warm, swollen, and erythematous from mid-calf to mid-thigh. Dorsalis pedis and posterior tibial pulses were normal, and reflexes, strength, and sensation were all normal. A complete blood count and basic metabolic profile were within normal limits. Her prothrombin time was 12.8 s, activated prothromboplastin time was 46.2 s, and international normalized ratio was 1.0. The patient had an elevated D-dimer at 5.34 ug/mL. Left lower extremity ultrasound showed Occlusive thrombus throughout the left lower extremity deep veins from common femoral to popliteal. CT abdomen and pelvis was done, with high suspicion for may-Thurner syndrome which showed DVT of left thigh extending to left external, internal and common iliac veins as well as 7.8 cm into infrarenal IVC. The Right common iliac artery was compressing on left common iliac vein. Patient immediately got placement of inferior vena cava filter to prevent Pulmonary embolism. A catheter was placed and thrombolysis was initiated with tissue plasminogen activator (tPA) at rate of 0.5 mg/hr. Heparin protocol for DVT was also started. Next day, she developed right neck hematoma, which was expanding, so the tPA and heparin were stopped. She was taken for Iliac vein stenting. Following placement of the left common and external iliac stent, venogram demonstrated no residual thrombus. She was restarted on heparin drip and bridged with Coumadin, without complications. She was discharged with 6 months of anticoagulation and outpatient heme/onc follow up to decide further treatment therapy.

DISCUSSION: May-Thurner syndrome is described as anatomical defect where right iliac artery compresses on left iliac vein. This anatomical defect increases the likelihood of clot formation in left lower extremity, as per Virchow's triad. May-Thurner syndrome causes 2-5 % of all symptomatic DVT's. Despite its prevalence, it is sometimes overlooked. One of the postulated reasons is that once we have other reasons to explain DVT, we pay less importance to anatomical variance. May-Thurner causes extensive thrombosis and if missed can lead to fatal pulmonary embolism and post-phlebitis syndrome. Therefore, May-Thurner should be included in differential diagnosis in patients with LEFT lower extremity swelling and edema. The diagnosis of May-Thurner syndrome is best made radiographically. The study of choice for May-Thurner syndrome is contrast venography, which shows compression of the iliac vein with spur or web formation. The treatment for MTS is not only limited to anti-coagulation, but also includes catheter-directed thrombolysis and stent placement. Our case is unique, as this patient has three predisposing factors for developing DVT including Anti-phospholipid antibody, recent OCP use and anatomic defect (may-Thurner syndrome). Therefore this case highlights that even patient has other predisposing factors, May Thurner should be ruled out as its treatment is entirely different and complications are fatal. The treatment as per ACCP

guidelines for duration of anticoagulation is not affected by the fact that the patient has may-Thurner, as she got stent placement that will prevent or eliminate the risk of stasis. The criteria to decide duration of treatment is dependent on the presence of antiphospholipid antibody and OCP use (provoked DVT) in this case. However, there are some case-reports suggesting the risk of developing in-stent thrombosis. Hence, regular follow-up is required to identify high-risk patients and further evaluate the treatment therapy that might include- re-stenting, repeat thrombolysis or life long anticoagulation.

TOO FEW MICE Robert Mocharla³; Synphen Wu³; Joshua Denson³; Douglas Bails¹; Richard E. Greene². ¹Bellevue Hospital Center, New York, NY; ²NYU School of Medicine, New York, NY; ³NYU School of Medicine, New York City, NY. (Tracking ID #2196451)

LEARNING OBJECTIVE #1: Re-assess a working diagnosis when there is deviation from the predicted clinical course.

LEARNING OBJECTIVE #2: Recognize and take into account geographic and epidemiologic factors when generating a differential diagnosis.

CASE: A 49-year-old man with no medical history presented with 4 days of fevers and headaches. Two days before presentation, he noticed a painless white papule on his left wrist that grew in size. He denied any recent skin breaks or trauma to the wrist. He also denied gardening, travel, or sick contacts. He lived in an apartment in a major urban city. On admission, he was febrile to 101.9 F with a heart rate of 109 beats per minute. He had a 3x3cm clear vesicle with a white center on his left wrist. Laboratory data revealed a white blood cell count of 5.1, C-Reactive Protein of 37, and a normal Erythrocyte Sedimentation Rate. Radiographic examination revealed mild soft tissue swelling over the ulnar styloid. On initial impression, diagnosis of a superficial infection was made (folliculitis). He was started on oral cephalexin. The following day, he became febrile to 102.6 F with a severe headache. Vancomycin was started out of concern for Methicillin-resistant *Staphylococcus aureus*. His fevers and headaches continued despite treatment. On hospital day four, his wrist lesion darkened into an eschar, and non-grouped papules developed on his arms and back. At this point, the team questioned the patient's working diagnosis and returned to the patient for further questioning. This revealed the patient had frequently spotted mice in his apartment for several months. With this information, the team suspected Rickettsialpox based on the constellation of symptoms, rodent contact, and exam findings. He was started on doxycycline and his symptoms resolved within 3 days. Initial serologic testing for Spotted Fever Group of Rickettsial agents (SFG) returned negative, but converted to positive on a sample taken 2 days after discharge.

DISCUSSION: Rickettsialpox is a rare zoonotic disease caused by the intracellular bacteria *Rickettsia akari*. The common house mouse (*Mus musculus*) serves as its natural reservoir, and it is transmitted to humans via a bite from an infected mite (*Liponyssoides sanguineus*). Infected mites don't routinely feed on humans, but may do so when unable to find mice. The disease is primarily found in urban settings, and the first case was described in New York City in 1946.¹ There have been roughly 800 documented cases since the first description, though this is believed to be a gross underestimate of worldwide cases. The disease has been associated with homelessness and intravenous drug abuse.² Outbreaks have occurred following rodent extermination campaigns, presumably as infected mites turn to humans after losing their natural hosts. After inoculation, the incubation period can range from 10 to 14 days. The first clinical manifestation is the formation of a painless vesicle at the site of inoculation. Over the next several days, the vesicle evolves into the classic, painless eschar. At this time, patients experience systemic symptoms such as fever, malaise, sweats, and headaches. This is followed by eruption of papulovesicular lesions involving the extremities and trunk, but rarely the palms and soles. Common laboratory tests can reveal a leukopenia with lymphocyte predominance, and more recent reports have shown mild hepatitis.³ The natural course of the disease is self-limited within 2-3 weeks, hospitalization is rare, and there are no reported fatalities. Doxycycline is the standard treatment, and should be continued until patients are asymptomatic for 48-72 h. Definitive diagnosis is made by serologic antibody testing (SFG testing includes *R. akari*), though patients may not seroconvert for 1-2 weeks. Diagnosis is also made by PCR testing of a biopsied lesion, however this test is not widely available.^{4,5} Although rickettsial diseases are generally associated with rural areas and outdoor travel, rickettsialpox is primarily found in major cities. Patients presenting in urban areas with the classic eschar should be questioned on possible rodent exposure, and particularly if there has been any recent rodent extermination. Treatment should be started if there is strong clinical suspicion. Most importantly, a working diagnosis should be promptly re-examined whenever there is deviation from the normal clinical course. 1. TOUGH TO SWALLOW: A RARE CASE OF DYSPHAGIA DUE TO THORACIC AORTIC ANEURYSM Ani A. Kardashian², Yile Ding¹. ¹UCSF, San Francisco, CA; ²University of California, San Francisco, San Francisco, CA. (Tracking ID #2193846)

LEARNING OBJECTIVE #1: Differentiate pseudoachalasia from true achalasia

LEARNING OBJECTIVE #2: Recognize aortic aneurysm as a rare but potentially fatal cause of dysphagia

CASE: An 81 year-old woman with a 3-year history of progressive dysphagia to both solids and liquids presented with sudden worsening of dysphagia and odynophagia during a meal. The patient reported “pressure” in her throat that extended down her esophagus, emesis, and regurgitation of food and saliva. Review of systems revealed a 5-pound weight loss over 1 month and occasional acid taste in her mouth. Past medical history included hypertension, hyperlipidemia, ischemic stroke with residual left leg weakness, and bilateral kidney transplant 5 years prior due to microscopic polyangiitis. Medications included prednisone, tacrolimus, amlodipine, metoprolol, pravastatin, aspirin, famotidine, calcium, and vitamin D. The patient had normal vital signs, normal cardiopulmonary exam, and a soft, nontender abdomen without palpable masses. Distal pulses were intact. Neurologic exam revealed left leg weakness consistent with her prior stroke. X-ray esophogram showed a dilated, tortuous, aynamic esophagus with residual food material and contrast. There was no evidence of mass, focal stricture, or narrowing of the gastroesophageal junction. Modified barium swallow study showed oropharyngeal dysphagia with reflux into the trachea. Upper endoscopy revealed a normal esophagus, gastroesophageal junction, and stomach without anatomic explanation for her dysphagia. She was given the presumptive diagnosis of atypical achalasia and empirically treated with botulinum injections at the site of the lower esophageal sphincter with improvement in her dysphagia. She was discharged with a nasogastric feeding tube, and plan for outpatient esophageal manometry with possible percutaneous endoscopic gastrostomy tube placement. The patient returned 12 days later with left-sided chest pain. An electrocardiogram demonstrated normal sinus rhythm without ischemic changes. Chest radiograph revealed tortuosity and ectasia of the thoracic aorta and left basilar atelectasis. Computed tomography of the chest revealed a dilated aorta measuring 8.0 by 6.6 cm with irregular contour at the diaphragmatic hiatus compressing the distal esophagus and causing leftward deviation of the stomach. The diagnosis of dysphagia aortica was made. The patient declined surgical correction of the aneurysm. Percutaneous endoscopic gastrostomy tube was not pursued due to concern for precipitating aneurysmal rupture and she was discharged home with a nasogastric feeding tube.

DISCUSSION: This case demonstrates the difficulty and importance of differentiating pseudoachalasia from true achalasia. While the classic description of “gradual progressive dysphagia of both solids and liquids” triggers the thought of achalasia, clinicians must remain vigilant in searching for conditions that cause pseudoachalasia in older patients, namely a gastroesophageal junction tumor and, more rarely, dysphagia aortica. True achalasia is a benign esophageal motility disorder characterized by failure of lower esophageal relaxation with swallowing and “bird’s beak” appearance on esophagram. This patient has a classic case of dysphagia aortica, a rare condition of low sternal dysphagia from external esophageal compression by an ectatic, tortuous, or aneurysmal aorta. Dysphagia aortica is classically seen in elderly women with a history of hypertension, atherosclerotic aortic changes, and kyphosis. The diagnosis is often difficult to make due to coexisting conditions such as gastroesophageal reflux disease or motility disorders. Barium esophagram, esophageal manometry, and endoscopy may show extrinsic compression of the esophagus. However, findings are subjective and inconsistent, and radiographic and/or endoscopic findings can be minimal or absent. In an elderly patient, findings suggestive of significant atherosclerotic disease and features inconsistent with classic achalasia should push clinicians to search for dysphagia aortica with computed tomographic angiography or aortography. Timely diagnosis of dysphagia aortica has therapeutic implications. The aneurysm should be surgically corrected and the aorta should be separated from the esophagus, as mortality rates from aneurysmal rupture are high. In summary, dysphagia aortica is a rare type of pseudoachalasia seen in the elderly that should not be overlooked, as it is a fatal yet treatable condition.

TOXIC SHOCK SYNDROME FOLLOWING INFLUENZA B INFECTION Suzuki Hirofumi; Ayako Kumabe; Yuka Sagara; Yoshiaki Nishimura; Tsuneaki Kenzaka; Masami Matsumura. Jichi Medical University Hospital, Tochigi, Japan. (Tracking ID #2195548)

LEARNING OBJECTIVE #1: Recognize toxic shock syndrome as complication of influenza.

LEARNING OBJECTIVE #2: Diagnose fever, hypotension, skin rash, and multi-organ involvements post influenza.

CASE: A 59-year-old Japanese man presented with a 10-day history of fever and a 3-day history of hypotension. Ten days prior to admission to our hospital, he visited a nearby hospital with fever of 39 °C. He was diagnosed as influenza B by rapid influenza diagnostic test and was given oseltamivir, but fever of over 38 °C persisted. Four days before admission to our hospital, he was admitted to nearby hospital and was given intravenous ceftriaxone. However, fever continued and his blood pressure decreased to 80 mmHg. He was transferred to our hospital for close examination and treatment. He had had a 1-year history of hypertension and a 5-year history of sinusitis. He was receiving 5 mg per day of amlodipine and 200 mg per day of clarithromycin. On examination, his temperature was 37.7 °C, blood pressure was 132/80 mmHg, and pulse rate was 96/min. Conjunctivae were hyperemic and icteric. Erythematous macular rash was noted over the chest and back. Laboratory findings included a leukocyte count 6600/μL, hemoglobin 10.6 g/dL, platelet count 40,000/μL, total bilirubin 4.9 mg/dL, direct bilirubin 4.0 mg/dL, aspartate aminotransferase 27 IU/L, alanine aminotransferase 23 IU/L, creatinine kinase 17 IU/L, urea nitrogen 28 mg/dL, and creatinine 1.3 mg/dL. The blood cultures were sterile. Abdominal computed tomography disclosed no abnormalities in liver, gallbladder, and bile duct. Although no tick bite mark or eschar was noted, we firstly suspected rickettsial infection based on hyperemia, skin rash, and liver dysfunction. He was started on 200 mg per day of intravenous minocycline for 3 days without improvement. Secondly, we suspected drug fever and all medication was ceased, however, symptoms did not improve again. On hospital day 5, total-bilirubin increased to 14.1 mg/dL and platelet count decreased to 35,000/μL. Post influenza toxic shock syndrome (TSS) due to *Staphylococcus aureus* was considered from the history, especially episode of hypotension in nearby hospital, physical examination, and data. He started on 12 g per day ampicillin-sulbactam. On hospital day 6, culture of sputum yielded methicillin-resistant *Staphylococcus aureus* that was thought of as colonized organism in respiratory tract. This strain was producing enterotoxin D. We added 2 g per day of vancomycin. On hospital day 13, fever and erythematous macular rash ameliorated. Platelet count increased to 370,000/μL and total-bilirubin decreased to 3.9 mg/dL. On hospital day 19, desquamation of both fingers were observed. TSS complicating influenza B was diagnosed. He made a full recovery.

DISCUSSION: TSS can occur as complication of influenza infection in rare cases. Non-pulmonary complications of influenza include myositis, myocarditis, pericarditis, central nervous system complications, Reye’s syndrome, and TSS. In these complications, cutaneous symptom can only be noted in TSS. Changing colonization and replication characteristics of the toxin-producing staphylococcus in respiratory tract by influenza infection is thought as the cause of TSS. Physicians should consider TSS as complication of influenza when persisted fever, hypotension, skin rash followed by desquamation, and multi-organ involvements observed in patients with post influenza infection.

TREATMENT OF BING-NEEL SYNDROME Ronen Harel; Diana Lee; Dana Shani. Lenox Hill Hospital, New York, NY. (Tracking ID #2192430)

LEARNING OBJECTIVE #1: To recognize subtle signs and symptoms of Bing-Neel Syndrome

LEARNING OBJECTIVE #2: Diagnose and treat Bing-Neel Syndrome

CASE: A 65 year old Caucasian female with a past medical history of hypertension, Non Hodgkins Lymphoma treated with R-CHOP 10 years prior and a recent diagnosis of Waldenstrom’s Macroglobulinemia presented with 6 h history of expressive aphasia. The symptoms started suddenly and were not associated with any other focal neurological deficits. In the weeks prior to presentation she had increased lethargy, headaches, malaise and worsening exercise tolerance. Upon arrival to the emergency department the patient had CT & MRI of her head/neck, both of which showed no evidence of CVA, however demonstrated on the Flair/T2 weighted images scattered punctuate foci of increased signal within the periventricular and subcortical white matter. Serum viscosity level was checked which was in the normal range. Further workup was conducted including a lumbar puncture. CSF examination illustrated IgM level >6 mg/dl (normal <.1), cytology and flow cytometry showed a monoclonal kappa, CD10 positive B-Cell population was present consistent with CNS involvement. The patient was started on systemic chemotherapy with Rituximab 375 mg/m² and Bendamustine 90 mg/m² every 4 weeks as well as intrathecal Methotrexate 15 mg twice weekly for 3 months. At that time patient had a repeat MRI of the brain showing marked diminution in pathologic enhancement and signal abnormalities, repeat cytology and flow cytometry no longer identified a monoclonal B-Cell population of cells and CSF IgM levels have decreased to 2.94 mg/dl. Clinically, the patient had improved markedly and no longer had any focal neurological deficits.

DISCUSSION: Waldenstrom’s Macroglobulinemia is a lymphoplasmacytic lymphoma characterized by a clonal production of dysfunctional plasma cell that produces an excess amount of IgM immunoglobulins. When this disease involves the central nervous system,

it is referred to as Bing-Neel syndrome. The incidence of this disease is very rare and because of this, there are no guidelines or standard of treatment. This case demonstrates a case of Bing-Neel treated with Bendamustine, Rituximab and intrathecal Methotrexate with a positive initial response to treatment.

TWISTED CYSTER Julie Steinbrink; David Macari; Gail Larsen; Paul J. Grant. University of Michigan, Ann Arbor, MI. (Tracking ID #2180170)

LEARNING OBJECTIVE #1: Recognize the clinical manifestations of neurocysticercosis in a patient with the appropriate exposure history.

LEARNING OBJECTIVE #2: Learn how to diagnose and treat a patient with neurocysticercosis.

CASE: A 21 year old Spanish-speaking male immigrant from Guatemala with no significant past medical history presented to the emergency department with nausea, vomiting, neck pain, and vertigo. He was noted to have bilateral horizontal nystagmus on exam. A CT scan of the head was normal, and lumbar puncture with cerebrospinal fluid (CSF) analysis demonstrated lymphocytic predominance, elevated protein, and low glucose. He was admitted to the hospital and started empirically on broad-spectrum antibiotics, dexamethasone, and antiviral coverage for meningitis. CSF cultures showed no growth, and the patient clinically improved. He was diagnosed with aseptic meningitis and discharged home without antibiotics. However, he later presented four more times to the emergency department with recurrent symptoms of nausea, dizziness, and back pain. When his presentation included new-onset ataxia, he was again admitted to the hospital. A repeat lumbar puncture demonstrated an increased opening pressure. MRI showed an enhancing fourth ventricle mass and mild obstructive hydrocephalus, along with a mass at the L2/L3 spine. He underwent ventriculostomy placement, but was found to have normal intracranial pressures. The spinal lesion was biopsied, and demonstrated reactive macrophages. CSF analysis returned positive for cysticercosis antibody by ELISA, and was confirmed by serum cysticercosis IgG/Western Blot. The patient remained stable and due to financial difficulties with albendazole treatment, it was decided to monitor the patient with outpatient follow-up.

DISCUSSION: Cysticercosis is a parasitic infection transmitted by ingestion of *Taenia solium* (pork tapeworm) eggs. It is prevalent in Central and South America, and in endemic regions is one of the most common helminthic infections of the central nervous system. It can be challenging to diagnose, as clinical symptoms are nonspecific and can vary significantly between individuals. Parenchymal involvement of neurocysticercosis commonly presents with seizures. In extraparenchymal disease, hydrocephalus can develop if the cysts are trapped in the interventricular foramina. Diagnostic criteria for neurocysticercosis includes neuroimaging, serology, CSF analysis, and biopsy in the appropriate population. After diagnosis, the patient should be started on antiparasitic therapy, most commonly a combination of albendazole and corticosteroids. Patients that present with seizures may also require antiepileptic therapy. The prevalence of cysticercosis is increasing in the US with the rising number of immigrants from endemic areas. Neural involvement can be the presenting manifestation with a wide range of signs and symptoms, including seizures, nausea, vomiting, ataxia, and hydrocephalus. It is important to consider this diagnosis in patients with nonspecific neurologic complaints and the appropriate exposure history.

TWO CASES OF HERPES ZOSTER NEUROLOGICAL COMPLICATIONS

Daiki Morikawa; Eiji Hiraoka. Tokyo bay Urayasu Ichikawa Medical Center, Urayasu, Japan. (Tracking ID #2194408)

LEARNING OBJECTIVE #1: Recognize the features of herpes zoster neurological complications

LEARNING OBJECTIVE #2: Recognize the importance of early treatment of herpes zoster neurological complications

CASE: **Case1:** A 84 year-old Japanese male with significant past medical history of hypertension and benign prostatic hyperplasia presented with 5-day history of back pain and 2-day history of rash on left buttock which spread to his left thigh. His vital signs were stable except for temperature of 37.5 °C. He had red papular rash with vesicle and crust from left buttock to left anterior thigh. Due to the distribution of L1 and L2 dermatome, disseminated herpes zoster was diagnosed and acyclovir was started. Three days after admission, he developed muscle weakness of left lower extremities. Left knee reflex was hyperactive. Babinski signs were positive bilaterally. The sensation to touch and pin prick was disturbed mildly in the left L1 and L2 dermatome. Atonic bladder was found as well. MRI of the head was within normal limit. Herpes zoster myelitis was diagnosed clinically. Three days later, methylprednisolone 60 mg/day was started with continuation of acyclovir. His neurological symptoms gradually subsided and became able to walk in 19 days. He was transferred to another hospital for further rehabilitation. **Case2:** A 73 year-old Japanese male with end stage renal disease on maintenance hemodialysis secondary to

diabetes mellitus type II was admitted for the treatment of cellulitis associated with the infection of arteriovenous synthetic graft in the left arm. His vital signs showed temperature of 38.5 °C, blood pressure of 147/68 mmHg, heart rate of 92 beats/min, respiratory rate of 31 breaths/min, and oxygen saturation of 94 % on 2 l of oxygen. He was treated with antibiotics and removal of the graft. Two days after admission, he became afebrile. The blood culture grew up *Staphylococcus aureus*. Five day after admission, he developed painful red papular rash with vesicles and blisters on left upper extremity. He was diagnosed with herpes zoster clinically. Valaciclovir had been prescribed. 12 days after onset of rash, he had significant muscle weakness at left arm. The sensation was disturbed mildly in left C5 to Th1 area. Deep Tendon Reflex was hypoactive at left upper extremity. There was no neurological abnormality on both lower extremities. Negative Babinski sign was noted. He did not have bladder or rectal problems. The head MRI was within normal limit. Peripheral neuropathy was diagnosed. Five days after onset of the neuropathy, methylprednisolone 60 mg/day was initiated with re-prescription of valaciclovir. On the following days paralysis was a little resolved. He was discharged with paralysis remained. Finally, 5 months later, paralysis subsided.

DISCUSSION: We experienced two cases of herpes zoster neurological complications, helps zoster myelitis and peripheral neuropathy. The neurological complications of herpes zoster include meningitis, encephalitis, myelitis, peripheral neuropathy, postherpetic neuralgia, and vasculopathy. Myelitis is rare complications. The frequency of myelitis during or after herpes zoster is 0.3 %. Muscle weakness caused by herpes zoster peripheral neuropathy was also uncommon. Chih-Hsien Hung et al. reported 17 patients (54.8 %) of herpes zoster myelitis were immunocompromised. In our cases, their immunocompromised state as hemodialysis, diabetes mellitus, old age and severe infection, was considered to be related with their rare neurological complications. It has been suggested that not only direct viral invasion but also host immune response contribute to the pathology of neurological complication. Therefore, it is important to treat with acyclovir to prevent multiplication and spread of the virus in the nervous system as well as with prednisolone to prevent the damage of neuron by overwhelming immune reaction. Furthermore, the early initiation of the treatment is a key to the better neurological outcome. Cheng-Chia Lee et al. reported that in immunocompetent patients, the longer the interval between onset of myelopathy and administration of acyclovir/corticosteroids, the slower the observed improvement, and the longer the recovery time. In our first case, the steroid was initiated 3 days after the onset of muscle weakness. In second case, the steroid was started 5 days after the onset of neurological abnormality. First case patient recovered 19 days after the treatment and second case patient had recovered gradually for 5 months. We believe that early medical intervention is necessary to improve functional outcome. Conclusion: We reported two cases of herpes zoster complicated with myelitis and peripheral neuropathy. Early treatment with acyclovir and prednisolone is important for the neurological outcome. For the early diagnosis, physicians should be careful of neurological symptoms and signs especially among herpes zoster patients with old age, DM, and end stage renal disease as our cases.

UNDERCOVER PSORIATIC ARTHRITIS Steven Beckoff; Alexander Diaz de Villalvilla. Montefiore Medical Center, New York, NY. (Tracking ID #2200164)

LEARNING OBJECTIVE #1: Recognize diagnostic criteria for psoriatic arthritis in absence of psoriasis.

LEARNING OBJECTIVE #2: Understand the extra-articular manifestations of psoriatic arthritis

CASE: Forty-seven year-old woman from Congo with hypothyroidism presented to clinic with generalized fatigue. She noted that since moving to the US 10 years ago, her hands were slowly changing. Her fingernails had become abnormal and she was covering up these with synthetic press-on nails. She also noticed the distal hand joints were becoming more lax and had difficulty grasping objects with them. She had no loss of sensation and also no consistent pattern of pain, warmth, or redness in these joints. No family history of arthropathy or autoimmune conditions. Her vital signs were normal, and exam was significant for swelling of the distal phalanges, with increased distal interphalangeal joint laxity and telescoping of these joints. Of the non-artificial nails, there was pronounced onycholysis with nail plate dystrophy. Full range of motion and without synovitis in all other joints. No abnormalities of the feet. Normal intact skin. Laboratory data revealed a CRP 0.5 mg/dL, ESR 34 mm/h, ANA negative, RF negative, Anti-CCP negative. Bilateral hand radiographs showed prominent erosive changes at scattered distal phalanges of both hands, worse on the right than the left, compatible with acroosteolysis. Smaller erosive changes are noted at the base of the left first proximal phalanx, left fifth metacarpal head, base of the right fifth metacarpal and bases of the right second and fifth proximal phalanges. Joint space narrowing at the left fifth distal interphalangeal joint with periarticular osteophytes. With these skeletal, nail, and serologic markers, patient was diagnosed with psoriatic arthritis.

DISCUSSION: The diagnosis of psoriatic arthritis in a patient without overt psoriasis can be challenging. A recent study revealed that the CASPAR (CIASSification criteria for

Psoriatic Arthritis) is both sensitive and specific for diagnosis. A patient needs 3 points from the following: Current psoriasis (2 points); history of psoriasis (1); family history of psoriasis (1); dactylitis (1); juxtaarticular new bone formation (1); Rheumatoid factor negativity (1); Nail dystrophy (1). If meeting these >3 points, these criteria were 98.7 % specific and 91.4 % sensitive for psoriatic arthritis. By While it is often the internist who raises clinical suspicion for the diagnosis of psoriatic arthritis, this disease necessitates collaboration with specialists for its long-term manifestations. For example, ocular involvement occurs in 30 % of patients, most commonly conjunctivitis and acute anterior uveitis; thus ophthalmologic referral is recommended. Patients with psoriatic arthritis are at higher risk of developing other autoimmune conditions, including inflammatory bowel disease and Multiple Sclerosis. Also, not uncommonly, the appearance of psoriatic plaques appears years after the initial joint manifestations, for which dermatology consultation is recommended. The patient was referred to dermatology, rheumatology, and ophthalmology. Because of her relative lack of symptoms, she is on a current regimen of ibuprofen as needed, which is about once weekly.

UNILATERAL PTOSIS AND EYE SWELLING AS INITIAL MANIFESTATIONS OF ACUTE MYELOID LEUKEMIA Anjani Pillarisetty¹; Puja Choksi¹; Allan Cruz²; Joseph Catlett². ¹Medstar Washington Hospital Center, Silver Spring, MD; ²Medstar Washington Hospital Center, Washington, DC. (Tracking ID #2199305)

LEARNING OBJECTIVE #1: Recognize atypical presentations of acute myeloid leukemia

LEARNING OBJECTIVE #2: Diagnosing acute myeloid leukemia in a patient with new eye swelling

CASE: A 27 year old female from El-Salvador with no significant past medical history initially presented with complaints of swelling and pain in her right eye associated with ptosis, blurring of vision and a diffuse headache. An MRI of the brain and orbits revealed an extensive tumor involving the right orbit, cavernous sinus, maxillary sinus, ethmoid sinus, pterygopalatine fissure, infratemporal fossa and nasopharynx. Systemic examination was otherwise unremarkable. The mass was biopsied by Ophthalmology and she was found to have extramedullary acute myeloid leukemia, also known as orbital myeloid sarcoma. The tumor was positive for myeloperoxidase, CD34, CD43, CD99, BCL-2 and TdT, and negative for CD3, CD4, CD5, CD8, CD10, CD20, CD79a, PAX5, CD23, CD138, CD30 and S100. A complete blood count was obtained and normal. Bone marrow biopsy and lumbar puncture were negative for leukemic cells. She was started on induction chemotherapy with cytarabine and idarubicin with a repeat CT scan on day 14 showing significant regression of the leukemic infiltrate.

DISCUSSION: Acute myeloid leukemia can present in various extramedullary tissues as a solid tumor composed of immature myeloid cells. It was first described by Burns in 1811 and was later named "chloroma" by King in view of its green tint due to the presence of myeloperoxidase. It may also be referred to as granulocytic sarcoma or myeloid sarcoma. Myeloid sarcoma is reported in 2.5 to 9.1 % of patients with acute myeloid leukemia, and most commonly involves bone, soft tissues, lymph nodes, skin and kidneys. Although orbital myeloid sarcoma typically affects children and young adults, it can present at any age between infancy to 61 years, as is the case with our patient. These tumors may occur concomitantly, as a relapse or precede systemic leukemia. A large study by Zimmerman and Font demonstrated 88 % of orbital myeloid sarcomas to precede onset of systemic leukemia, and in the absence of treatment, the median time to development of systemic acute myeloid leukemia is generally 5 to 12 months. Orbital myeloid sarcomas can exhibit various clinical features such as orbital swelling, ptosis and periorbital cellulitis in the setting of an otherwise normal systemic examination and normal blood counts; however, proptosis has been described to be the most common presenting sign. These tumors are most often mistaken for non-Hodgkin lymphoma, but other differential diagnoses include rhabdomyosarcoma, neuroblastoma and melanoma. A CT scan and MRI are often not sufficient to differentiate myeloid sarcomas from these other tumors. A tissue biopsy is required to confirm diagnosis, along with immunohistochemistry, flow cytometry, fluorescence in situ hybridization, and molecular analysis. Once diagnosis is established, a bone marrow biopsy and lumbar puncture should also be performed in order to determine the presence of any systemic involvement. This clinical case emphasizes just how vital it is for a clinician to recognize the possibility of myeloid sarcoma in a patient presenting with orbital swelling, ptosis or proptosis, so that he or she is able to treat the patient adequately and perhaps prevent development of systemic acute myeloid leukemia.

UNIVERSAL VITILIGO, HEMOLYTIC-UREMIC SYNDROME, AND A GASTRIC MASS: AN UNUSUAL PRESENTATION OF HIV-2 Francis E. Dailey²; Bianca Chang²; Helen Huang²; Teo Soleymani¹; Ali Rezaie¹; Kapil Gupta¹; Robert I. Goodman². ¹Cedars Sinai Medical Center, Glendale, CA; ²Cedars-Sinai Medical Center, Los Angeles, CA. (Tracking ID #2198355)

LEARNING OBJECTIVE #1: Recognize HIV-2 in those from West Africa.

LEARNING OBJECTIVE #2: Diagnose patients with signs of HIV/AIDS despite a negative rapid HIV test.

CASE: HIV has been associated with renal disorders including hemolytic-uremic syndrome (HUS), dermatologic conditions such as vitiligo, and malignancies like Kaposi's sarcoma (KS). These conditions typically manifest late in the course of the disease and are infrequently the initial manifestation of infection. Here we describe a heterosexual Nigerian gentleman, diagnosed with both HUS and vitiligo in the past year, who presented for work-up of a gastric mass. Approximately 5 months prior, at an outside institution, he had received two separate esophagogastroduodenoscopies (EGDs) with over twenty biopsies of a gastric mass, presumed to be adenocarcinoma. All biopsies were inconclusive; thus, he never received treatment. On presentation to our medical center, he complained of severe abdominal pain, nausea, and vomiting. EGD revealed a large, ulcerating gastric mass, with biopsies demonstrating KS. Rapid HIV test performed at his follow-up appointment was negative. One week later, he returned to the hospital, this time with hematemesis. Upon admission, patient was started on a pantoprazole infusion and gastroenterology was consulted. HIV antibody testing was rapidly reactive and negative for HIV-1, but positive for HIV-2. The next morning, he had two more episodes of hematemesis, then melena and hematochezia associated with orthostatic hypotension. He was transferred to the intensive care unit (ICU) for closer monitoring and received, over 24 h, 6 units packed red blood cells, 1 unit plasma, and 1 unit platelets. He was also started on octreotide infusion as an adjunctive therapy for gastrointestinal bleeding (GIB). Bedside EGD revealed bright red blood and a large clot in the stomach that could not be suctioned nor bypassed with the endoscope. The procedure was subsequently aborted and interventional radiology consulted for embolization of the feeding vessel. After embolization of the left gastric artery, patient underwent radiation to his stomach and started doxorubicin chemotherapy with plans to initiate highly active antiretroviral therapy (HAART) upon completion. Day 8 post-GIB, he is medically stable and tolerating chemotherapy and HAART well.

DISCUSSION: This case illustrates the importance of a higher index of suspicion for HIV-2 in patients who have immigrated from or spent significant time in West Africa, as well as those with signs of HIV/AIDS despite a negative rapid HIV test. Although rare in the U.S., with only 166 cases reported to the CDC between 1987 and 2000, HIV-2 is endemic to West Africa. It is suspected that reported cases in the U.S. are an underestimate, given the large number of immigrants from HIV-2 endemic areas, and that most patients are asymptomatic. The ultimate treatment of HIV-2 remains the same as HIV-1- initiation of HAART for reconstitution of CD4+ T cells. Moreover, this case underlines the importance of a collaborative multidisciplinary approach among internists, gastroenterologists, interventional radiologists and oncologists in the management of GIB secondary to KS.

UNUSUAL CAUSE OF GASTRIC OUTLET OBSTRUCTION Meredith M. Barr; Tulane University Health Sciences Center, New Orleans, LA. (Tracking ID #2198478)

LEARNING OBJECTIVE #1: Recognize typical and atypical causes of gastric outlet obstruction

LEARNING OBJECTIVE #2: Discuss a rare form of lymphoma with variable presentation and approach to diagnosis

CASE: A 59-year old African American man with no significant medical history presented with a 1-month history of nausea, vomiting, and poor oral intake. He also complained of increasing abdominal girth. He reported non-bloody emesis after every meal consisting of undigested food. On physical exam he had a palpable mass in the right upper quadrant. Initial laboratory diagnoses showed severe electrolyte derangements including a sodium of 124, potassium of 2.7, chloride of 76, and creatinine of 1.8. His laboratory evaluation also showed an acute transaminase elevation with total bilirubin 4.0, AST 174, ALT 251, Alkaline Phosphatase of 341 and lipase elevation to 2670 (laboratory reference range 1-400). Computed tomography revealed a soft tissue conglomerate in the gastric outlet concerning for neoplasm. Subsequent esophagogastroduodenoscopy revealed a large friable circumferential lesion in the duodenum. Multiple biopsies were consistent with intravascular large B cell lymphoma. Oncology was consulted and recommended evaluation for staging of lymphoma. He received one round of methotrexate, rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisone with plans for 8 more rounds of chemotherapy. Elevation of transaminases and lipase were due to obstruction of the common bile duct by duodenal mass; therefore, an external biliary drain was placed. After multiple complications during his stay, he was discharged with plans for continued R-CHOP Therapy as an outpatient.

DISCUSSION: This patient presented with signs and symptoms of gastric outlet obstruction. Gastric outlet obstruction is due to a pyloric stricture and can be related to numerous medical conditions. Prior to 1970, the most common etiology of gastric outlet obstruction was related to peptic ulcer disease. However, these cases have declined with development of proton pump inhibitors and recognition and treatment of *Helicobacter pylori*. Malignancies now cause a large portion of these lesions with peri-pancreatic malignancies

reported in 10–20 % of cases. Other malignant causes may include gastric cancer, cholangiocarcinoma, and primary duodenal cancer. Other benign causes included in a differential for gastric outlet obstruction include corrosive ingestion, gallstone obstruction, chronic pancreatitis, sarcoidosis, and infective causes including tuberculosis and syphilis continue to be possible. Early signs include early satiety, gastric fullness, indigestion, anorexia and emesis containing undigested food within hours after meals. Laboratory findings may be non-specific reflecting hyperemesis with hypokalemia, hypochloremia, and signs of dehydration. While diagnosis is often made through imaging, Endoscopy is preferred for evaluation of gastric outlet obstruction. Biopsies taken on endoscopy may prove to be diagnostic, as in the case of the patient above. Intravascular large B cell lymphoma is a rare non-Hodgkins type lymphoma estimated to occur in less than one in one million cases. It is defined as an extra-nodal lymphoma in the endothelium with a preference for capillaries, sparing larger vessels. The most common presentation is central nervous system involvement, occurring in two thirds of cases; however case reports have suggested that presentations with skin involvement and individual organ involvement are also possible. Intravascular B cell lymphoma rarely presents with peripheral blood involvement in only 5–9 % of all diagnosed patients. The diagnosis of intravascular B cell lymphoma is made by histopathology of primary lesion. Patients often have a poor prognosis related to delay of diagnosis given highly variable presentation and rapid progression.

VENOUS THROMBOSIS ON RIVAROXABAN? Manisha Bhide. University of Colorado Denver, Aurora, CO. (Tracking ID #2195907)

LEARNING OBJECTIVE #1: Review newer oral anticoagulants in management of DVT and compare and contrast with older anticoagulants.

CASE: Fifty-five year male presented to his primary care physician for acute left leg swelling, calf pain and prominent painful veins with increasing redness. He had past medical history of 2 episodes of recurrent deep vein thrombosis (DVT) and Heterozygous Factor V Leiden mutation. He had been on chronic anticoagulation for past 10 years. He has family history of DVT and Factor V Leiden mutation in his father. He also had superficial saphenous vein thrombosis and mild lower extremity edema which is well controlled with compression stockings. He has been compliant with INR monitoring for many years. He heard about the newer anticoagulants in media and was keen to take them. He had a detail discussion regarding anticoagulants and decided to take rivaroxaban for chronic anticoagulation for DVT prophylaxis. He took rivaroxaban for 14 months and was doing well, until 2 days ago when he noticed increasing left leg pain and swelling. On exam, his vitals were normal. He had bilateral superficial prominent lower extremity veins and 1+ edema in left leg. Urgent ultrasound of left leg was done. The posterior tibial vein failed to compress, demonstrating filling defect. Greater saphenous vein failed to compress and demonstrated filling defect to the level of the ankle. The lesser saphenous vein contains a septation and partial filling on color Doppler. Thus a ultrasound diagnosis of new acute superficial venous thrombus in the greater and lesser saphenous veins in setting of chronic DVT was reached. Pt denied travel or prolonged immobilization. This thrombosis was concerning since he developed it while on rivaroxaban. Rivaroxaban was stopped and dalteparin 200 units/kg was started and he was transitioned back to warfarin.

DISCUSSION: There are many newer oral anticoagulant agents like dabigatran, rivaroxaban, apixaban, edoxaban that are FDA-approved for DVT and Pulmonary Embolism prophylaxis and treatment. They have been found to be as safe and as efficacious as warfarin by EINSTEIN study(2). Insurers are covering them since they may be cheaper than warfarin management. Since they act by directly binding activated clotting factors, there are no concerns about vitamin K or dietary impact on drug effect. They can be reliably given in a fixed dose for most people. Monitoring is not needed. A therapeutic range has not been defined, and dosage adjustment based on results has not been established. If a dose is missed, there is rapid loss of anticoagulation, in contrast to warfarin where there is lingering effect for an extended period of time. Once the drug is resumed, however, there is an immediate full anticoagulant effect within 2–4 h, again in contrast to warfarin which may take days to re-achieve a therapeutic effect. The reliability of these drugs, given without monitoring or dose adjustment, is based on a GFR of at least 60 ml/min and the absence of potentially interacting medications. Since there are no standardized tests for checking levels, use in people with lower renal function or with potentially interacting medications may result in a different safety profile than reported for most subjects in the clinical studies. Medications to reverse actions of these new oral agents are not commercially available yet. Unlike warfarin, they do not act on vitamin K-dependent mechanisms. Since they directly bind to activated factors, administration of FFP is unlikely to provide benefit. Rivaroxaban has a much shorter half-life than warfarin and after missing just one dose, patients essentially are unprotected. In contrast, missing a single dose of warfarin may drop the INR but still leave some protection from new thrombotic events. A 3 year medication persistence study showed rivaroxaban had better medication persistence as compared to warfarin(1) but more studies are needed. We are likely to see more and more use of the newer anticoagulants. Internists are going to be in

charge of prescribing and managing them. Thus it is important for all primary care providers to be familiar with risks and benefits of the newer anticoagulants and use them for appropriately selected patients.

VESICULAR RASH AND RESPIRATORY FAILURE IN A 28 YEAR-OLD: A CASE REPORT Elaine Cristan; Phoebe King; Adriel Malave; Heather Briggs. The University of Texas Health Science Center at San Antonio, San Antonio, TX. (Tracking ID #2194356)

LEARNING OBJECTIVE #1: Recognize cutaneous and pulmonary manifestations of varicella zoster virus (VZV) in the adult population

LEARNING OBJECTIVE #2: Recommend workup for underlying immunocompromised state in adults who present with disseminated VZV

CASE: A 28 year-old Mexican immigrant presented to the emergency department with 4 days of worsening pruritic skin lesions. He had no prior medical history and was evaluated a few days earlier and prescribed an antihistamine without any relief. Soon after presentation, he acutely developed respiratory distress and was intubated for respiratory failure. On exam, he was febrile to 103 °F, hypotensive with blood pressure of 89/46mmHG, heart rate of 79 beats per minute, and oxygen saturation of 97 % on 100 % fraction of inspired oxygen. He had coarse breath sounds bilaterally and vesicular lesions in different stages were noted on his face, lips and throughout his trunk and extremities. Computed tomography of chest showed diffuse groundglass opacities and nodularity of bilateral lungs. Bronchoscopy further revealed vesicular lesions within his airways. Diagnosis was confirmed with positive direct fluorescent antibody of skin lesions for varicella zoster and positive varicella zoster virus (VZV) polymerase chain reaction from bronchial washing. Further testing revealed a positive human immunodeficiency virus (HIV) with a viral load of 424,000copies/mL. Remainder of infectious workup including tuberculosis, fungal serologies and *Pneumocystis jirovecii* was negative. Patient initially received broad antimicrobial therapy on admission, including intravenous acyclovir, which was narrowed to acyclovir alone on day 2. Within the first 24–48 h, patient rapidly improved and was extubated on day 4 to room air. As the patient showed rapid improvement, he was discharged on day 5 with oral acyclovir to complete a total of 7 days of treatment with plans to start antiretroviral therapy after discharge.

DISCUSSION: Varicella is a disease caused by VZV and is one of the most common and highly contagious infections in childhood. When it does present in the adult population it is associated with increased morbidity and mortality. Treatment of choice is Acyclovir at 10 mg/kg every 8 h for a total of 7 days. If therapy is not initiated promptly, patients may require mechanical ventilation and are at increased risk of mortality. Workup for risk factors is also recommended, which in this case, HIV was diagnosed in the subsequent workup. Per guidelines, in the HIV patient population, long-term prophylaxis of varicella with antiviral drugs is not recommended. Also, initiation of antiretroviral therapy can be considered, in addition to intravenous acyclovir for severe varicella. With the development of the VZV vaccine, the incidence has decreased dramatically in all populations; therefore it is also less commonly seen in the inpatient population. There are currently no studies of the vaccine in HIV-seropositive adults but could be considered in VZV-seronegative patients with CD4 counts greater than 200 as a preventive strategy as per the Centers for Disease Control and Prevention. Although the vaccination is extensively used in the United States and Canada, in other countries, such as Mexico, the VZV vaccine is not commonly implemented leading to continued prevalence of varicella infections. Therefore, in a hospital where migrant workers or immigrants make up a portion of the patient population, it is vital as a hospitalist to recognize the cutaneous and pulmonary complications of VZV.

WALK IT OFF: AN INTERESTING CASE OF FOOT PAIN Karthik J. Kota; Amar Kohli. UPMC, Pittsburgh, PA. (Tracking ID #2197249)

LEARNING OBJECTIVE #1: Describe the differential diagnosis of uncomplicated limb pain in adult patients

LEARNING OBJECTIVE #2: Recognize the sequelae of arterial hypercoagulability and describe management after an arterial clot has been found

CASE: JJH is a 42 year old man with history of HTN and CKD stage I who presented with right calf pain of five days duration. The patient noticed right calf pain while walking around the hospital to get a CT scan for evaluation of a renal cyst 5 days prior. At the time, he thought it was a muscle strain. He described it as a dull, crampy pain, present at rest and worsened with walking. Associated symptoms included numbness and tingling in his right 1st and 2nd toes, subjective intermittent coolness, and pallor. He denied trauma or edema to the area. Three days prior to admission, JJH noticed acute left sided chest pain and shortness of breath at rest. After an hour, the pain resolved and did not recur. JJH worked as a repairman, denied smoking, played soccer weekly, binge drank (>6) a few times a month, and had a distant history of cocaine use. Family history was notable for a half-sister

with polyarteritis nodosa (deceased age ~8). Physical exam on presentation was significant for a BP of 158/80, palpable right DP pulse, pale and cool 1st-5th right toes with some decreased sensation to light touch, and a tender calf that was soft and without edema or erythema. Lab data showed a normal PT/PTT/INR, a troponin-I of 0.33, a CK-MB of 2.7, and a D-dimer of 776. CT chest with contrast was negative for PE. EKG was notable for Q waves in I, aVL, and V1-V3, alongside flattened T waves in I, TWI in aVL (no priors). Upon admission, he was started on a heparin drip. Cardiac catheterization showed a non-occlusive thrombus in the LAD and diagonal arteries that were reperfused with contrast injection only. Arteriogram of the right common femoral artery showed a filling defect of the right profunda and distal right SFA. Echo revealed antero-apical wall hypokinesis and an LV thrombus; bubble study was negative. JJH had a cut down and embolectomy of the right femoral, tibial, and peroneal arteries. Hypercoagulability workup was negative for FVL, factor 2, LAC, and ANA; JJH was discharged on baby aspirin and warfarin. As of 12/11/14, due to the negative results thus far, autoimmune phenomena such as polyarteritis nodosa are being considered; Heme/Onc plans to see the patient in early February 2015 for continued work-up.

DISCUSSION: This case demonstrates an uncommon manifestation of arterial clotting in a patient presenting with right calf pain. The differential for non-traumatic limb pain can be divided into infectious, neurologic, musculoskeletal, and vascular etiologies. Given JJH's lack of systemic or localized symptoms, infectious etiologies were ruled out. Neurologic causes (e.g., radiculopathy, neuropathy, plexopathy) were unlikely due to the lack of inciting events (e.g., recent heavy exercise, diabetes, birth trauma/defect) and the nature of the pain (neuropathic pain usually being less "crampy," more "burning"). In a self-described "fit" 42 year old, musculoskeletal etiologies (e.g., muscle cramps, shin splints, inflamed/torn muscles) might be the obvious diagnostic route. However, a careful history would have elicited both his half-sister having PAN and his past cocaine abuse, while a focused neurologic exam of the leg would have revealed decreased sensation in his toes. Acute vascular etiologies can be subdivided into venous (cramping pain, erythema, warmth) and arterial (pale/cold limb, cramping/burning pain, pulselessness, paresthesias) insufficiency. JJH did not present with these classic symptoms initially, likely due to his good physiologic reserve and presence of collaterals; however, there were clues pointing towards a vascular etiology even during his CT. Work-up for an arterial clot centers around determining thrombus versus embolus and determining a hypercoagulable etiology. A TTE/TEE helps with the former by ruling out endocarditis, paradoxical emboli, and atrial/ventricular wall thrombi; in JJH's case, it was thought that the LV clot formed initially due to hypercoagulability, and the patient's subsequent MI and acute limb ischemia were due to emboli from this. Work up then focuses on various genetic (e.g., FVL deficiency, antiphospholipid syndrome) and autoimmune diseases (e.g., SLE, PAN). Initial work-up has been negative for JJH. In terms of management, after the patient was immediately placed on heparin, the next decision was for thrombolytics versus surgical revascularization. Determination in a young, healthy patient with embolus is location of the clot: distal is better treated with thrombolytics, while proximal is more a candidate for surgery. Finally, after dealing with the clot, if no provoked etiologies are found, patients must be kept on lifelong anticoagulation (with the added bonus of effectively treating JJH's LV clot).

WELLENS' SYNDROME IN A YOUNG JAMAICAN INDIAN MALE
Aditya S. Pawar^{1, 3}; Priyanka T. Bhattacharya^{2, 3}; Rajiv Bhattarai^{1, 3}. ¹Mercy Catholic Medical Center, Darby, PA, U.S.A., Philadelphia, PA; ²Mercy Hospital of Philadelphia, Philadelphia, PA; ³Drexel University College of Medicine, Philadelphia, PA. (*Tracking ID #2199358*)

LEARNING OBJECTIVE #1: Recognize Electrocardiographic(EKG) changes of Wellens' syndrome to prevent Acute Myocardial Infarction.

LEARNING OBJECTIVE #2: Recognize increased susceptibility of young, healthy Indo-Jamaicans to Coronary Artery disease especially Wellens' syndrome due to genetic predisposition compared to whites.

CASE: A 33 year old Indo-Jamaican male, smoker with past medical history of gastritis on Prilosec, presented to Emergency Department with sub sternal chest pain that was intermittent, 10/10, non-radiating and associated with nausea and diaphoresis, relieved by nothing. Patient denied having similar episodes of chest pain in the past or any positive family history. Vitals on presentation were BP of 113/53, Pulse 52, Respiratory rate 18, Temperature 97.5, oxygen saturation of 99 % on room air. Physical examination was unremarkable. Initial EKG revealed biphasic T waves in leads V1, V2 and V3 and T wave inversions in leads II, III and aVF. The initial troponin I concentration was 0.11 with total cholesterol of 246 and LDL of 175. The patient was immediately taken for percutaneous coronary intervention. Coronary angiography revealed stenosis of 80 % of the mid- left anterior descending artery which was successfully treated with a drug eluting stent. His troponin I after revascularization was 0.09 ng/ml and EKG revealed new T wave inversions evident in V1, V2 and V3. He had an unremarkable hospital course after revascularization. 2D echocardiogram showed a left ventricular ejection fraction of 60-65 %, bicuspid aortic valve and no wall motion abnormalities. The patient was started on Brilinta, Aspirin, Statin and Carvedilol. Patient was discharged after receiving smoking cessation counseling and Cardiac Rehabilitation referral.

bicuspid aortic valve and no wall motion abnormalities. The patient was started on Brilinta, Aspirin, Statin and Carvedilol. Patient was discharged after receiving smoking cessation counseling and Cardiac Rehabilitation referral.

DISCUSSION: Wellens' syndrome was first described as a potentially unrecognized EKG manifestation of critical proximal Left Anterior Descending Artery (LAD) stenosis in patients with unstable angina pectoris in a chest pain-free period. This syndrome is a preinfarction condition of coronary artery disease with a high predictive value for the development of acute myocardial infarction. Diagnostic criteria includes: Biphasic or deeply inverted T waves in leads V2 and V3; occasionally in leads V1, V4, V5 and V6; No or minimal ST elevation (<1 mm); No or minimal elevation of cardiac enzymes; No loss of precordial R-wave progression; No pathological precordial Q wave and history of angina. There are two types, Type 1, encompasses 76 % of patients who have deep symmetrical inverted T waves in V2 and V3, often in V4, V5 and sometimes in V6. The type 2 have biphasic T waves in lead V2 and V3 and this exists in about 24 % of the patients and is accompanied by a greater level of lethality. These patients are at risk of myocardial infarction and sudden death, and early revascularization is recommended. The patient reported here had all the criteria of Wellens' syndrome but also had some uncommon features. First, on admission the typical EKG pattern of Wellens' Syndrome was accompanied with sinus bradycardia and T wave inversions in inferior leads. Second, the critical stenosis was found in the middle rather than the proximal part of LAD. Third, our patient had no past medical history of cardiac disease. In addition, our patient had EKG changes from Wellens' type 2 to type 1 post revascularization. The importance of biphasic T waves may sometimes be overlooked in emergency department settings, with these kind of findings frequently being reported as nonspecific ST-T wave changes. It is also imperative to do serial EKGs or EKG monitoring in patients with unstable angina in a chest pain-free period. An ergometer stress test is contraindicated in these patient because it can lead to anterior myocardial wall infarction. The presented patient had no prior medical history of chest pains, and being low risk, the EKG findings could be presumed unimportant, but coronary angiography showed severe mid LAD stenosis. The patient was immediately stented and lethal outcome was prevented. Although our patient showed EKG changes typical of Wellens' Syndrome, the critical lesion was found to be in the middle part of LAD. Patients such as this may be a subgroup of Wellens' Syndrome, but this would need to be clarified in a larger case series. It has been shown in studies that young healthy patients of Indian origin are at increased risk of CAD compared to whites due to a genetic susceptibility, mediated through elevated levels of lipoprotein(a) which magnifies the adverse effects of lifestyle factors. It is not known if the same set of patients are prone to develop Wellens' changes specifically. A more aggressive approach to prevention and treatment is warranted in these patients to prevent fatal outcomes. Presented case underlines the importance of mentioned EKG changes to indicate the site of the critical stenosis and genetic susceptibility being an important factor in risk stratification of a patient.

WHAT HAPPENS TO VAGUS DOESN'T NECESSARILY STAY IN VAGUS...

Bradley Anderson; Andrew Greenlund. Mayo Clinic, Rochester, MN. (*Tracking ID #2158477*)

LEARNING OBJECTIVE #1: Recognize altered gallbladder kinetics, manifested by chronic postprandial abdominal pain, as a complication of left-sided surgical vagotomy.

CASE: A 35-year-old woman presented for the outpatient evaluation of a 3-month history of postprandial abdominal discomfort and vomiting. One month prior to the onset of her symptoms, the patient had been diagnosed with a left jugular foramen schwannoma on a MRI of the head and neck performed as part of the evaluation for a several-year history of dysphagia. Subsequently, a left level II and III dissection with transmastoid exposure of the jugular foramen was successfully performed to facilitate tumor removal. Intraoperatively, EMG monitoring of cranial nerves VII, X, XI, and XII was performed; as the left vagus and spinal accessory nerves (cranial nerves X and XI) were found to be involved in tumor, the patient sustained unilateral transection of both nerves in the process of tumor resection. One month after surgery, the patient experienced the onset of nausea and large-volume emesis consisting of undigested food with the onset of symptoms beginning approximately 4-6 h after meals, preceded by epigastric discomfort. She quantified her symptoms as occurring on average 6 times per month with noted worsening after consumption of fatty foods, bread, acidic foods, chocolate, or pre-prepared food. Physical examination yielded a soft, non-distended abdomen with gastric sounds present; no guarding, rebound, or bruits were noted. As the patient had described emesis with undigested food, both a gastric emptying scan and small bowel nuclear medicine transit study were performed and were normal. With symptomatic persistence, an EGD was performed and was additionally unremarkable for esophagitis or obstruction; a pH probe placed on endoscopy also yielded normal results following a 48-h monitoring period. Subsequent abdominal ultrasound demonstrated a partially contracted gallbladder and a follow-up abdominal CT re-demonstrated gallbladder contraction without additional intra-abdominal pathology. Following outpatient surgical evaluation, the patient proceeded to

cholecystectomy for diagnostic and therapeutic intent. Post-operative surgical pathology confirmed chronic cholecystitis as typically is seen in the setting of chronically altered gallbladder kinetics. On several follow-up visits after surgical recovery, the patient has reported complete symptomatic resolution.

DISCUSSION: Sustained postprandial gallbladder contraction is a rare and frequently unrecognized complication of left-sided surgical vagotomy. As the left vagus nerve principally governs gallbladder parasympathetic motor function, compromise of its innervation predisposes to cholecystokinin sensitivity resulting in sustained contraction. Though vagotomy has historically been associated with these alterations in gallbladder kinetics, it serves as a historic clue that can be overlooked in patients presenting with chronic abdominal discomfort. This case illustrates the importance of thorough history gathering and contextualization of historical comorbid conditions, surgical history, and seemingly unrelated symptoms. As the change in gallbladder kinetics following left-sided vagotomy can predispose to chronic cholecystitis, earlier recognition of this association may have facilitated expedited symptomatic relief and minimized unnecessary diagnostic evaluation.

WHEN 'BETA' DOESN'T MAKE YOU BETTER: A CASE OF INHALED ALBUTEROL-INDUCED STRESS CARDIOMYOPATHY Opeyemi Fadahunsi; Oluwaseun Shogbesan; Anene Ukaigwe; Adetokunbo Oluwasanjo. Reading Health System, Reading, PA. (Tracking ID #2193983)

LEARNING OBJECTIVE #1: Recognize excessive inhaled albuterol use as a cause of stress cardiomyopathy

CASE: Fifty-three year old male with moderate persistent asthma was admitted for acute asthma exacerbation and atypical substernal chest pain. A week prior to presentation, he had been requiring albuterol inhaler more than six times daily. He was not compliant with his controller fluticasone/salmeterol due to cost issues. Risk factors for coronary artery disease (CAD) were male sex and older age. TIMI risk score was 1. He had no history of pheochromocytoma or myocarditis. He denied cigarette smoking, alcohol or recreational drug use. On examination, respiratory and heart rates were 24 and 112 per minute respectively. Blood pressure and oxygen saturation were within normal limits. Cardiopulmonary examination revealed diffuse expiratory wheezes. The rest of the physical examination was normal. Chest X-ray was unremarkable. He was placed on bronchodilator nebulizer treatment as well as systemic steroids. Troponin I was 0.97 but subsequently peaked at 2.85 (normal ≤ 0.06 ng/ml) 4 h later. Electrocardiogram (EKG) showed sinus tachycardia with no other abnormalities. Serial EKGs remain unchanged. Transthoracic echocardiogram (TTE) revealed left ventricular (LV) systolic dysfunction, LVEF of 36 % with mid to distal hypokinetic segments but preserved basal segment. Left heart catheterization done to evaluate new hypokinetic segments revealed normal coronaries. He was discharged after resolution of his asthma exacerbation on controller medications to prevent further recurrence and carvedilol and lisinopril for LV systolic dysfunction. He will follow up in 3 months with a repeat TTE to assess LV function.

DISCUSSION: Stress cardiomyopathy (SCM) is a known clinical syndrome resulting from psychosocial or physical stress. The underlying pathophysiology is linked to elevated plasma catecholamine levels. The mechanism of injury is incompletely understood and proposed mechanisms include myocardial stunning, microvascular dysfunction and direct cardiac myocyte toxicity. SCM is usually reversible after resolution of stress event. In the case described above, a repeat TTE was scheduled in the outpatient setting. Beta-agonists are associated with increased cardiac events including cardiomyopathy and ischemic heart disease. Although, albuterol selectively stimulates beta-2 adrenergic receptors, this selectivity is lost at higher doses accounting for cardiac effects. There are increasing reports linking inhaled beta-2 agonists to SCM. This highlights the importance of appropriate controller medications in patients with increasing frequency of asthma symptoms. Our patient exhausted a 3 month supply of inhaled albuterol within a week for moderate persistent asthma. It is also important to note that SCM can reoccur and can be potentially fatal. Therefore, alternative medications should be recommended for control of asthma attacks. In conclusion, in the setting of low pretest probability for CAD and excessive inhaled albuterol use, findings of elevated troponin and depressed LV function should raise the possibility of albuterol-induced stress cardiomyopathy.

WHEN A MURMUR IS NOT JUST A SOUND: DIAGNOSING CARCINOID SYNDROME Min Ji Kim; Maulin Shah; Muneza Muhammad. Baylor College of Medicine, Houston, TX. (Tracking ID #2198943)

LEARNING OBJECTIVE #1: Recognize heart failure as an initial presentation of carcinoid syndrome.

LEARNING OBJECTIVE #2: Diagnose carcinoid syndrome through definitive modalities following a new physical exam finding of tricuspid and/or pulmonic valve murmur(s).

CASE: The patient is a 33-year-old Caucasian male who was referred to a cardiologist when a new heart murmur was identified by his primary care physician. He was in his usual state of health until 4 years prior to presentation when he developed gradual but slowly progressive dyspnea on exertion. He also began to have random episodes of flushing without identifiable social triggers or stressors. For the past year he has had a chronic non-productive cough with intermittent wheezing. In more recent months, he developed abdominal discomfort, watery diarrhea occurring throughout the day and during sleep, and bilateral lower extremity edema. He had lost 23 kg weight loss in the past year. He denied any illicit drug use. Physical exam was notable for a holosystolic murmur along the left sternal border that increased in intensity with inspiration and a parasternal heave along the left lower sternal border. Jugular venous pressure was elevated. Soft wheezes were heard in bilateral upper lung lobes. A pulsatile liver was noted. He also had pitting peripheral edema of the lower extremities. Echocardiogram revealed an enlarged right ventricle and atrium, severe tricuspid regurgitation with a thickened valve and restricted motion of the leaflets, moderate pulmonary hypertension, mild pulmonary valve stenosis, and paradoxical septal motion. While imaging the inferior vena-cava, incidental hepatic masses were seen. CT and MRI delineated multiple large hepatic masses. High levels of 5-HIAA were detected in urine. An octreotide scan showed focal uptake a small lesion in the duodenum. Ultrasound-guided biopsy results of a liver lesion confirmed carcinoid tumor. Treatment with intramuscular octreotide was initiated and evaluation for valvular surgery was scheduled.

DISCUSSION: Heart failure is an uncommon presentation of carcinoid syndrome and requires a high index of suspicion for evaluation. Only 5–10 % of patients with carcinoid tumors develop symptoms of carcinoid syndrome, and about 50 % of those with carcinoid syndrome develop carcinoid heart disease involving the tricuspid and pulmonic valves. Therefore, in a patient with a new-onset heart murmur and signs of right-sided heart failure, obtaining an echocardiogram and involving a cardiologist early are important first steps for diagnosis and treatment. Unfortunately, due to initially subtle symptoms, many cases of carcinoid are diagnosed incidentally. In the case of carcinoid syndrome causing heart disease, a poor prognosis is associated with valvular involvement, with valvular surgery offering limited mortality benefit. While the symptoms of carcinoid syndrome can be treated with octreotide or other various agents, the decision regarding the appropriate time point at which valvular surgery should be pursued must be made on a case-by-case basis. Early coordination among oncology, cardiology, and cardiothoracic surgery specialties are imperative for expedient treatment of carcinoid heart disease.

WHEN A PHYSICAL EXAM POINTS TO THE WRONG DIAGNOSIS: GOUT MASQUERADING AS RHEUMATOID ARTHRITIS Devin B. Malik; Sukhpreet Singh; Akshay Amaraneni. Western Michigan University School of Medicine, Kalamazoo, MI. (Tracking ID #2198575)

LEARNING OBJECTIVE #1: To recognize that the typical findings in rheumatoid arthritis can be found in other rheumatologic conditions

CASE: Seventy-four years old African American lady presented with urinary tract infection complicated by sepsis and acute kidney injury. After patient returned to baseline with appropriate management, rheumatology was consulted for bilateral hand and foot pain with deformities. Patient admitted to approximately 15 years history of morning stiffness lasting 30–60 min, along with recent onset joint swelling and pain in all metacarpophalangeal joints as well as bilateral first metatarsophalangeal joints. On exam patient had ulnar deviation, swan neck deformities on second through fifth digits as well as cock up and hammer toes all consistent with RA. However, serology was negative for rheumatoid factor and cyclic citrullinated peptide. X-ray showed "rat bite lesions" and joint aspiration revealed monosodium urate crystals confirming the diagnosis of gout.

DISCUSSION: Polyarticular gout is an inflammatory arthritis that is often misdiagnosed as another form of destructive arthritis such as Rheumatoid Arthritis (RA). Diagnosing gout often requires quick recognition by clinicians in order for a correct diagnosis. Physical exam findings are paramount in aiding clinicians evaluate patients for suspected diagnoses. The textbook finding of swan neck deformity is almost always indicative of RA. However, any destruction of the flexor and extensor tendon of the finger can cause the deformity, including gout as in our patient.

WHEN ANTICOAGULATION ISN'T ENOUGH: EFFORT RELATED VENOUS THROMBOSIS Tala Achkar¹; Gregory M. Bump². ¹UPMC, Pittsburgh, PA; ²University of Pittsburgh School of Medicine, Pittsburgh, PA. (Tracking ID #2188648)

LEARNING OBJECTIVE #1: 1) Recognize causes of upper extremity DVT that require therapy beyond simple anticoagulation

LEARNING OBJECTIVE #2: 2) Diagnosis and management of Paget-Schroetter syndrome

CASE: The patient is a 48-year-old man with a history of hypothyroidism and a remote history of testicular cancer, who presented with left upper extremity (LUE) swelling and tingling. The patient reported exercising at a gym 2 days prior to presentation and completing a chest work out including 75 pushups. Afterwards, he noticed swelling of his LUE that worsened over the next day, associated with cyanosis of the limb. The day of presentation, he noticed paresthesias in the 3rd to 5th digits of his left hand. He denied any previous history of DVT, any history of manipulation of the vessels of the LUE including port placement, IVs, etc. During routine follow up for testicular cancer, he was considered cured. He denied a personal or family history of hypercoagulable state or thrombosis. Physical exam was notable for LUE edema from the upper arm to the wrist with associated overlying erythema. He had no palpable cord, and 2+ radial pulses. The limb was warm, well perfused, and without cyanosis. There was no facial edema or venous distention of the neck or chest veins. The patient was thought to have Paget-Schroetter syndrome (PSS), previously known as effort thrombosis, based on history, and clinical appearance. The patient was started on a heparin drip followed by an upper extremity venous doppler that did not reveal thrombosis, however, the proximal subclavian could not be visualized by doppler. Vascular surgery performed a venogram which showed severe subclavian vein stenosis near the costoclavicular junction with thrombosis. Balloon angioplasty and tPA thrombolysis were performed, followed by Angiojet thrombectomy of the subclavian vein. Enoxaparin was initiated with complete resolution of the thrombus. On follow up with the vascular surgeon it was noted that his first ribs bilaterally were quite prominent, and that although the subclavian vein was patent, there was extrinsic compression at the thoracic outlet. The patient underwent left first rib resection, with anterior scalenectomy and thoracic outlet decompression.

DISCUSSION: PSS is an uncommon cause of thrombosis in the subclavian vein, but when it occurs, it is seen in the dominant arm of patients who are physically active particularly in the setting of excessive overhead activity. The pathophysiology is similar to compression syndromes, where the subclavian vein is compressed in the costoclavicular space which leads to stagnation of blood flow. Then, with activity there is repetitive microtrauma to the venous endothelium, which leads to initiation of the coagulation cascade and venous thrombosis as well as thickening and fibrosis of the vessel [1, 2]. Early on, the patient can describe a "bursting feeling" in the affected limb, and this is secondary to venous hypertension [2]. As the thrombosis occurs in the proximal subclavian vein, which is obscured by the clavicle, upper extremity doppler has a sensitivity of 78–100 % and a specificity of 88–100 % when done correctly [1]. The initial treatment is catheter-directed pharmacologic or mechanical thrombolysis, with repeat venograms to check for resolution of the thrombus [1, 3]. If thrombolysis is successful, the patient should be therapeutically anticoagulated on heparin until rib resection, followed by therapeutic LMWH at the discretion of the surgeon [2]. There are no clear guidelines on anticoagulation following rib resection with different regimens including aspirin alone or warfarin alone [2]. Since the management differs significantly from a typical upper extremity thrombosis, it is important these patients be recognized and referred to vascular surgery as early as possible. The optimal treatment window for these patients is 2 weeks, after which the patient may suffer significant disability with a high risk of post-thrombotic syndrome (up to 46 %) [4].

WHEN CD4 LYMPHOCYTES DISAPPEAR Ashlee Metcalf¹; Lawrence Dubuske².

¹George Washington University, Alexandria, VA; ²George Washington University, Washington, DC. (Tracking ID #2200607)

LEARNING OBJECTIVE #1: 1. Describe an association between an autoimmune process, angioedema and CD4 lymphocytopenia

CASE: A 42 year old Caucasian female with past medical history of seasonal allergies presented to allergy clinic with recurrent episodes of angioedema. She initially presented complaining of angioedema of the lower lip and inner cheek after eating chicken and a baked potato. One year later she presented after two more episodes of angioedema; once after eating spinach and artichoke soup and once after eating crab dip and grilled shrimp with lower lip swelling. She denied hives, pruritus, throat closing sensation, shortness of breath, wheezing, cough, chest tightness, nausea, vomiting, diarrhea, abdominal pain, and lightheadedness. The swelling gradually resolved within 24 h, using diphenhydramine 25 mg orally immediately after onset of symptoms. On exam, lungs were clear and no evidence of a rash on skin exam but had dermatographic skin responses to stroking her skin. Skin prick tests was positive for tree pollen, dust mite, weed pollen, and cat; and negative to orange, cashews, chicken, shellfish, scaled fish, potato, peanut, egg, soy, garlic, onion, spinach, lemon, orange, and potato. She had slightly elevated allergen specific IgE to spinach (0.35 kU/L) and artichoke (0.14 kU/L) with Total IgE of 26 kU/L. C4 levels were repeatedly normal (16/17 mg/dl) as were C1 esterase inhibitor levels (26/31/35 mg/dl) and C1 esterase functional levels (83 %/97 % normal) excluding C1 esterase inhibitor deficiency. Anti-thyroid antibodies revealed Hashimoto's Thyroiditis (anti-TPO 150 IU/ml and anti-Thyroglobulin 17.6 IU/ml) but normal T3 (95 to 114 ng/dl) and normal T4 (6.5 mcg/dl) with elevated TSH (6.83/8.2 uIU/ml) consistent with thyroid hormone

insufficiency. Repeatedly low absolute CD4 counts (72/76/67/85) were noted, with negative studies for HIV-1, negative HTLV 1/2 and negative Hepatitis B/C panel. The consistently low CD4 levels meet the criteria for the diagnosis of idiopathic CD4 lymphocytopenia.

DISCUSSION: Idiopathic CD4 lymphocytopenia (ICL) is a rare disorder defined by the Centers for Disease Control as a documented absolute CD4 T lymphocyte count of less than 300 cells per cubic millimeter or less than 20 % of total T cells on more than one occasion. The patient must also have no evidence of HIV or any defined immunodeficiency or therapy associated with depressed levels of CD4 T cells. ICL is associated with opportunistic infections and autoimmune disease. This patient presented with recurrent facial angioedema, and was found to have labs consistent with ICL occurring along with Hashimoto's thyroiditis. Hashimoto's thyroiditis can be associated with increased T cell turnover and urticarial angioedema. This case shows a rare presentation of ICL, with a patient presenting with angioedema initially thought to be secondary to food allergy later found to have Hashimoto's thyroiditis and CD4 lymphocytopenia. Based on elevation in TSH, she was treated with low dose levothyroxine with complete resolution of her angioedema, reduction in her dermatographic skin responses and interestingly, some improvement in her absolute CD4 cell levels now ranging from 119 to 123. She no longer uses any antihistamines and has not developed any opportunistic infections.

WHEN THE PICTURE IS NOT WORTH A THOUSAND WORDS Hao Chi Zhang; Matthew Novakovic; Ihab Hamzeh. Baylor College of Medicine, Houston, TX. (Tracking ID #2198996)

LEARNING OBJECTIVE #1: Assess a patient presenting with typical angina

LEARNING OBJECTIVE #2: Recognize the limitations of cardiac stress testing

CASE: A 57-year-old Hispanic woman underwent pre-operative cardiac evaluation for bilateral blepharoptosis. She had a history of well-controlled diabetes mellitus type 2, diastolic heart failure with preserved left ventricular ejection fraction, hypertension, 44-pack-year smoking, hypothyroidism, chronic back pain, and obesity. She reported having had new chest pain for over 2 weeks. The chest pain was substernal and pressure-like, radiating to the left shoulder. The pain was associated with dyspnea, nausea, palpitations, and exhaustion. The pain had been worsening in frequency and intensity; it had occurred at rest 2 days prior to evaluation. She did not take daily aspirin and was not prescribed nitroglycerin. The patient did not drink alcohol or use cocaine. She had no family history of premature coronary artery disease (CAD). On physical examination, the patient was afebrile with a blood pressure of 131/72 mm Hg, a pulse of 56/min, normal respirations and oxygen saturation, and a body mass index of 45 kg per square meter. Except for mild bradycardia, the cardiac exam was otherwise normal; there were no gallops or pericardial rubs. There was no elevation in the jugular venous pressure. The pulmonary exam was also normal without evidence of rales. The patient's electrocardiogram (ECG) demonstrated sinus bradycardia without T-wave inversions or ST-segment changes. Results of the metabolic panel was within normal limits. The levels of cardiac enzymes were normal. Her probability of CAD was intermediate. In light of her chronic back pain, pharmacologic ECG stress testing with regadenoson and myocardial perfusion imaging (MPI) were pursued. The stress test did not elicit chest pain, and there were 0.5-mm ST-depressions in inferolateral leads. The MPI was interpreted as normal with homogeneous tracer distribution throughout the myocardium. Nonetheless, the history was consistent with unstable angina. The patient underwent coronary angiography, which demonstrated 80 % proximal left anterior descending artery stenosis, 80 % proximal left circumflex stenosis, 80 % mid-left circumflex stenosis, 70 % second obtuse marginal stenosis, and non-obstructive atherosclerotic disease of the proximal right coronary artery (right-dominant). The patient underwent two-vessel coronary artery bypass grafting (CABG) and was discharged 2 weeks post-operatively in stable condition.

DISCUSSION: This patient had presenting symptoms that were highly suggestive of unstable angina. The cardinal features of typical angina should be explored in all patients presenting with chest pain. The TIMI risk score can help risk-stratify, but the score should not be interpreted in isolation. Perfusion defects can be evaluated using gated single-photon emission computed tomography myocardial perfusion imaging (SPECT MPI). Pharmacologic SPECT MPI has a reported sensitivity of 83 to 97 %. In this case, the critical step was acknowledging unstable angina despite the MPI being interpreted as normal. The sensitivity of the test can also be affected in cases of diffuse balanced ischemia, a relatively rare phenomenon seen in triple-vessel CAD where all the nuclear counts appear equally low. Evaluating left ventricular dilatation by assessing the transient ischemic dilatation index on post-stress images may be able to unmask diffuse ischemia. Soft tissue attenuation by the diaphragm, breast tissue, or adipose tissue may also decrease the accuracy of MPI. Furthermore, perfusion defects may be masked by adjacent intense tracer uptake in the bowel resulting in reconstruction artifacts. In conclusion, this patient's case illustrates an important situation in which the patient's history taking priority over results of unrevealing initial cardiac tests allowed for a diagnosis of significant CAD requiring CABG.

WHEN THE TREATMENT BECOMES THE PROBLEM Simeng Sun; Patricia Dharapak. Mount Sinai Beth Israel, New York, NY. (Tracking ID #2193925)

LEARNING OBJECTIVE #1: Recognize drug-induced immune thrombocytopenia in acute thrombocytopenia

LEARNING OBJECTIVE #2: Assess aztreonam as a potential cause of drug-induced immune thrombocytopenia

CASE: A 61-year-old male with traumatic brain injury, paraplegia, HCV cirrhosis and a cephalosporin allergy presented with hematemesis secondary to esophageal varices. His hospital course was complicated by aspiration pneumonia and empiric treatment with Vancomycin, Aztreonam and Metronidazole was initiated. On the 6th day of antibiotic therapy, the patient's platelet count acutely dropped from a baseline of 130 K/UL to 3 K/UL. There was new hematuria but no signs of clinically significant bleeding. All antibiotics were stopped and 2 units of platelets were transfused without response. Workup for hemolysis, DIC, HIT and TTP was negative. Peripheral smear was unremarkable. HIV was nonreactive. Within 2 days of antibiotic cessation, the platelet count rose to 35 K/UL and recovered to 172 K/UL at the time of discharge one week later without additional therapy. Given the time course and improvement after drug cessation, Vancomycin-induced immune thrombocytopenia was considered. Four months later, the patient presented with sepsis secondary to pneumonia. Empiric treatment with Linezolid, Aztreonam and Metronidazole was initiated. Within 3 days of antibiotic exposure, the patient's platelet count dropped from 160 K/UL to 2 K/UL. Linezolid was discontinued and 3 units of platelets were transfused without response. On the following day, Aztreonam was substituted with Imipenem to complete the antibiotic course. As a result of new petechiae and oral mucosal bleeding, 2 doses of IVIG were given with good effect. The platelet count recovered to 34 K/UL immediately following treatment and improved to 123 K/UL by the time of discharge 3 weeks later. Evaluation for hemolysis, DIC, HIT and TTP was again negative. Given the time course, an immune mediated process from re-exposure to myelosuppressive drugs in the setting of sepsis was presumed as the cause of the acute thrombocytopenia. Aztreonam was favored as the culprit since Linezolid-induced thrombocytopenia usually occurs after more prolonged treatment (>2 weeks)

DISCUSSION: In acutely ill patients, drug-induced thrombocytopenia (DITP) can often be overlooked because thrombocytopenia is generally attributed to sepsis or another underlying condition (e.g., chronic HCV or cirrhosis). Like other idiosyncratic drug-sensitivity reactions, only a small fraction of exposed patients will develop DITP and no predisposing factors have been identified. The mechanism of platelet destruction is usually by drug-induced antibodies but testing is often not readily available. A careful history and a high index of suspicion are crucial for timely diagnosis. At least one week of exposure to the sensitizing drug is needed before thrombocytopenia is clinically evident (i.e., petechial hemorrhages and ecchymoses). Catastrophic bleeding is unusual but fatal intracranial and intrapulmonary hemorrhage, DIC, renal failure, HUS and TTP have been reported. After the culprit drug is discontinued, bleeding symptoms usually subside within 1–2 days and platelet counts normalize in 4–8 days but rarely, thrombocytopenia may persist for several weeks to even years. Corticosteroids, IVIG and plasma exchange have been used with uncertain benefit. Fortunately, drug-induced antibodies tend to be specific to the sensitizing drug and patients usually tolerate structurally different pharmacologic equivalents. As the drug sensitivity probably persists indefinitely, patients should be advised to permanently avoid the medication and the medical record should be updated to reflect this reaction. In review of our patient's clinical course, Aztreonam was the likely culprit in both cases of DITP. While previously described as causing myelosuppression, to our knowledge we are the first to describe isolated thrombocytopenia in association with Aztreonam use. While uncommon, DITP can be devastating but preventable by simply discontinuing the causative drug. This phenomenon should be considered in any patient with acute thrombocytopenia of uncertain etiology

WHERE THE FANCONI DID THE PHOSPHATE GO? Talia R. Kahn¹; Ryan Laponis². ¹UCSF, San Francisco, CA; ²University of California San Francisco, San Francisco, CA. (Tracking ID #2190378)

LEARNING OBJECTIVE #1: Utilize a systematic approach to evaluating hypophosphatemia

LEARNING OBJECTIVE #2: Recognize antivirals as a cause of Fanconi's syndrome and hypophosphatemic osteomalacia

CASE: A 66 year-old man with a history of chronic hepatitis B (HBV) and hepatocellular carcinoma (HCC) presented with hypophosphatemia. Nine years prior to presentation, he was diagnosed with HBV associated cirrhosis and HCC and started on lamivudine with subsequent addition of adefovir. Two years later, he underwent liver transplantation and was noted to be hypophosphatemic. Over the ensuing 7 years, he continued to be hypophosphatemic and fractured his ribs walking into a banister, developed kyphoscoliosis and debilitating pain in his back and hips, and was diagnosed with

metastatic HCC. On exam, he was 5'4" although at one time was 5'9". He was kyphotic with a bell-shaped chest. Liver was non-palpable. Labs showed 7 years of hypophosphatemia. He had an elevated fractional excretion of phosphate with a normal serum parathyroid hormone, calcium, and calcitriol. His bone specific alkaline phosphatase was elevated, and he had a high urinary glucose, normal plasma glucose, an inappropriately normal urinary uric acid in the setting of a low serum uric acid, and elevated urinary amino acids. Based on these results, he was diagnosed with Fanconi's syndrome and osteomalacia secondary to his adefovir therapy.

DISCUSSION: The causes of hypophosphatemia can be divided into three categories: (1) increased intracellular uptake, (2) decreased intestinal absorption, and (3) renal phosphate wasting. Calculating the urinary fractional excretion of phosphate can help differentiate these causes; when the fractional excretion of phosphate is >5 % it is likely secondary to renal phosphate wasting and when <5 % is likely due to either increased intracellular uptake or decreased intestinal absorption. In this case, the patient was found to have an elevated fractional excretion of phosphate, placing him in the category of renal phosphate wasting. The main causes of renal phosphate wasting include: (1) primary hyperparathyroidism, (2) secondary hyperparathyroidism due to vitamin D deficiency, and (3) primary renal phosphate wasting. The serum calcium can help differentiate between these etiologies: a high serum calcium indicates primary hyperparathyroidism, a low serum calcium indicates secondary hyperparathyroidism, and a normal serum calcium indicates primary renal phosphate wasting. This patient's normal calcium suggested primary renal phosphate wasting. Primary renal phosphate wasting is generally caused by one of the following: (1) primary renal phosphate wasting syndromes, (2) Fanconi's syndrome, (3) drugs, and (4) malignancy. Distinguishing these etiologies involves determining if the patient has had low phosphate since birth, reviewing the medications, assessing the urinary glucose, uric acid, amino acid and bicarbonate levels, and measuring the calcitriol level, which if inappropriately low in the setting of hypophosphatemia, may suggest tumor-induced osteomalacia. Consistent with Fanconi's syndrome, this patient had an elevated urinary glucose despite his normal plasma glucose, an inappropriately normal urinary uric acid in the setting of a low serum uric acid, and elevated urinary amino acids. Adefovir, tenofovir and cidofovir have been associated with Fanconi's syndrome. Because prolonged severe hypophosphatemia causes inadequate mineralization of the bone matrix, he developed osteomalacia and severe bony pain. The main treatment for Fanconi's syndrome is removal of the offending drug (if there is one) and phosphate repletion. With this, the improper bone mineralization stops and the bone pain improves. Some patients are also eventually able to discontinue phosphate repletion if the damage to the proximal renal tubules is reversible. However, in this case, after 9 years of adefovir treatment, this drug may have irreversibly damaged his proximal tubules.

WHO IS THE CULPRIT?—A CASE OF HYPERCALCEMIA WITH CONCOMITANT SARCIDOSIS AND PRIMARY HYPERPARATHYROIDISM (PHPT) Ricardo Cabello²; Naoka Murakami¹; Alfred Burger². ¹Beth Israel Medical Center, New York, NY; ²Mount Sinai Beth Israel, New York, NY. (Tracking ID #2199105)

LEARNING OBJECTIVE #1: Recognize when to evaluate for primary hyperparathyroidism (PHPT) in the setting of a more obvious cause of hypercalcemia

LEARNING OBJECTIVE #2: Discuss the rationale for the hypercalcemia work-up. Review mechanisms of hypercalcemia

CASE: Case: A 47 year-old female with a history of sarcoidosis, vitamin D deficiency, prior episode of symptomatic kidney stone and bilateral nephrolithiasis, presented with left-sided flank pain radiating to her left leg for 1 day. The patient reported passing a kidney stone a few hours prior. Past medical history revealed that the patient was diagnosed with sarcoidosis with neurologic and pulmonary involvement (bilateral hilar lymphadenopathy and left-sided facial and vocal cord palsy), confirmed with lung biopsy 10 years prior. She had been intermittently treated with prednisone and hydroxychloroquine in the past but was in remission for more than 2 years without medication. Vital signs on presentation were all within normal limits. Physical exam on admission was significant for suprapubic and left-sided flank tenderness to deep palpation. Labs were significant for Ca 11.1 mg/dL (2 years prior Ca levels were normal at 10.4 and minimally elevated at 10.8 mg/dL (normal 8.6–10.4)), Phos 3.7 mg/dL, normal BUN and creatinine. CT scan revealed non-obstructing nephrolithiasis at right ureterovesical junction with mild left hydronephrosis. Patient's pain was controlled, Ca was normalized IV hydration and she was discharged with referral to endocrinology for further work-up. The outpatient work-up for hypercalcemia revealed Ca 11.1 mg/dL, Phos 3.6 mg/dL, Albumin 4.4 g/dL, Alk phos 109 (normal 38–126) U/L, 25-(OH) vitamin D3 total 16 (normal 30–100) pg/mL, 1,25-(OH) vitamin D3 71 (normal 18–72) pg/mL, intact PTH 179 pg/mL. Angiotensin converting enzyme (ACE) 66 (normal 9–67) U/L. The normal range of ACE and clinical picture both supported non-active state of sarcoidosis. The patient was not on supplemental vitamin D on admission, and also exogenous hypervitaminosis D was ruled out by low vitamin D2 levels. The elevated PTH was consistent with primary hyperparathyroidism, and excluded malignancy as a cause in this 47 year old woman. Sestamibi

scintigraphy showed two left parathyroid adenoma and ultrasound confirmed 12-mm and 7-mm hypoechoic hypervascular nodules. Twenty-four hour urinary Ca was 224 mg. Given her age, recurrent nephrolithiasis and osteopenia in DEXA scan (T-score -0.9), patient underwent double parathyroidectomy with normalization of serum Ca.

DISCUSSION: Hypercalcemia in setting of sarcoidosis may have several causes: renal insufficiency, sarcoid-related hypercalcemia (with incidence of 4–11 %), vitamin D supplement for prevention of osteoporosis under steroid treatment, malignancy or concomitant PHPT. Previously, the mild hypercalcemia in our patient was attributed to sarcoidosis. Given that sarcoidosis and primary hyperparathyroidism (PHPT) are both relatively common diseases and may separately contribute to hypercalcemia, it is important to consider when to pursue further evaluation. In our case, given recurrent symptomatic kidney stones, progressive hypercalcemia and inactivity of sarcoidosis, it was decided to evaluate for hyperparathyroidism, and exclude malignancy—both of which were accomplished with a single PTH level. 25-OH vitamin D levels are obtained to establish the context of parathyroid bone disease and to replenish levels pre- and post-operative if vitamin D deficiency is identified. There are multiple mechanisms of hypercalcemia. In sarcoidosis, increased extrarenal production of 1,25-(OH) vitamin D by granulomatous tissue results in increased intestinal calcium absorption as well as bone resorption. However, a cohort study of sarcoidosis showed concomitant PHPT accounts for 8.5 % of hypercalcemia and only 36.1 % had an elevated 1,25-(OH) vitamin D3, which make it difficult to differentiate sarcoid-related hypercalcemia from other causes. If PHPT is present, surgical removal of adenoma is the treatment of choice with 86 % treatment response. It is a challenge for clinicians to identify the major cause or causes of hypercalcemia especially when one has a probable explanation like sarcoidosis. However, as our case illustrates, it is always important to distinguish the cause of hypercalcemia based on clinical and laboratory findings. Given the surprisingly higher than expected incidence in sarcoidosis, physicians may wish to use a lower threshold for the measurement of a single PTH level to exclude hyperparathyroidism in this population.

YOU OUGHTA KNOW THAT BRUGADA Angela Christensen; Julie M. Collins; Pavan Thangudu. Tulane University Health Sciences Center, New Orleans, LA. (Tracking ID #2198340)

LEARNING OBJECTIVE #1: Recognize the diagnostic EKG criteria and clinical criteria for Brugada Syndrome

LEARNING OBJECTIVE #2: Distinguish other causes of ST-segment elevation on EKG

CASE: A 64-year-old man presented after syncope while at rest. The event was witnessed and he was unconscious for less than 3 min. He did not remember the event and was unsure if he had any precipitating factors, prodrome, or associated symptoms. Witnesses denied bowel or bladder incontinence or shaking. He denied any current chest pain or palpitations. He had no previous history of syncopal episode. His past medical history included hypertension and diabetes. He was recently started on hydrochlorothiazide. There was no history of cardiac death in his family. Orthostatic vital signs were negative. He was alert and oriented to person, place, and time. He had a regular rate and rhythm. No cardiac murmur was heard. There was no jugular venous distention. There were no focal findings or evidence of tongue biting. He had grossly decreased sensation to his bilateral upper extremities in a stocking and glove distribution. He also had twitching of his left pectoralis major muscle. His potassium was slightly low at 3.4 mmol/L. His calcium was low at 7.9 mg/dL with a normal albumin. His ethyl alcohol level was 305 mg/dL. His trended cardiac enzymes were negative. His chest x-ray and cat scan of his head showed no abnormalities. His EKG revealed coved ST-segment elevation displaying J-point amplitude followed by a negative T wave in the right precordial leads (V1 and V2). As his ethyl alcohol level decreased, the ST-segment elevation resolved.

DISCUSSION: Brugada Syndrome is a rare autosomal dominant disease that can lead to sudden cardiac death. It is important for the general clinician to recognize the Brugada Syndrome EKG pattern, which has two main variants. In both Type I and Type II Brugada, there is a pseudo-right bundle branch block with 2 mm or more ST segment elevation (J-wave) in the right precordial leads (V1 to V3). Unlike true right bundle branch block, the widened S wave is absent in the lateral leads in Brugada Syndrome. In Type I and Type II Brugada are distinguished by the ST-T wave configuration - “coved” type vs. “saddle back” type. The ST segment elevation in Brugada Syndrome must be distinguished from other causes of ST elevation, which can be benign or serious. The differential includes normal variant repolarization (concave upwards in V2-V6), ST-elevation myocardial infarction, pericarditis (diffuse concave elevations), Prinzmetal’s angina, and hypothermia. After identifying type 1 Brugada pattern and ruling out other causes of ST-elevation, it is important to determine whether the patient has Brugada syndrome. To make this diagnosis a patient must have the type 1 EKG pattern and meet at least one clinical criterion. The three clinical criteria are: sudden cardiac death in a family member younger

than 45 years or EKG type 1 in a family member; arrhythmia related symptoms, which include syncope; or documented ventricular arrhythmias). If the clinical criterion is not fulfilled in the presence of type 1 EKG, this is referred to as idiopathic Brugada EKG pattern. After diagnosing Brugada Syndrome, patients must be risk stratified and treated. The only proven effective strategy to prevent sudden cardiac death is an implantable cardioverter-defibrillator (ICD). In this case, the patient presented with syncope, alcohol intoxication, and an EKG showing type 1 Brugada pattern. It has been discovered that alcohol can unmask the Brugada pattern as in this case. As his blood alcohol level decreased, the pattern began to resolve and then return to normal once his alcohol level was zero. Due to his presentation of syncope of cardiac origin and spontaneous type 1 EKG an ICD was placed. He was also counseled on alcohol cessation. It was recommended that his daughter and siblings have a baseline EKG done and possible EKG with antiarrhythmic drugs.

YOUNG AND WOBBLY Raghd Zeitouni; Thomas Montgomery; James Horton. Carolinas Medical Center, Charlotte, NC. (Tracking ID #2195167)

LEARNING OBJECTIVE #1: Recognize possible causes of acute cerebellar ataxia.

LEARNING OBJECTIVE #2: Manage post-infectious cerebellar ataxia.

CASE: An 18 years old man presented with ataxia and dysarthria. He had suffered a recent injury while playing basketball 3 weeks ago resulting in a grade II splenic rupture, which was managed conservatively. Five days ago, he developed ataxia and dysarthria with development of nausea and vomiting two days later. A computed tomography (CT) of the head without contrast at that time was normal. He returned with persistent symptoms. He reported feeling “off balance” with no headaches, neck pain, focal neurological symptoms, or fevers. He denied a recent viral illness, sick contacts, or recent vaccinations. He had no other past medical history and was on no medicines. He denied any recent alcohol or drug use and was not sexually active. He was afebrile and hemodynamically stable. He was in no acute distress and was alert and oriented x4 but his speech was slightly dysarthric. His neck was supple and had a very subtle torsional nystagmus. He had a wide based gait and fell backwards with Romberg testing. He also had mild dysmetria with finger-to-nose testing on the left and the heel-to-shin test was difficult for him to perform. The rest of his exam was benign including normal sensation and strength, and intact reflexes. His laboratory studies on the day of admission, including white blood count (WBC), electrolytes, liver function tests (LFTs), Thyroid-stimulating Hormone, Vitamin B12, Rapid Plasma Reagen, serum ethanol level and urine toxicology test, were within normal limits. A review of his labs from 3 days ago, however, revealed slight LFT elevations with Alanine Transaminase at 76 IU/L and Aspartate Aminotransferase at 80 IU/L. The patient underwent a repeat CT head which was negative followed by a negative Magnetic Resonance Imaging (MRI) of the brain. Neurology was consulted and a lumbar puncture was performed. The cerebrospinal fluid (CSF) was colorless with only 1 WBC, a glucose of 68 mg/dL, and a protein of 22 mg/dL. The CSF gram stain and cultures were negative and no Varicella Zoster Virus or Herpes Simplex Virus was detected. With a recent splenic rupture and mild hepatitis, a recent Epstein Barr Virus (EBV) infection was suspected. An EBV serology was ordered which revealed a positive EBV viral capsid antigen (VCA) IgM and IgG with a negative nucleic acid IgG indicating an acute EBV infection. The patient was managed conservatively. He showed gradual improvement during his stay and was able to ambulate with assistance prior to being discharged home within a week of admission. He followed up with an outpatient medicine clinic within 10 days of discharge and reported significant improvement in his symptoms. At the time he followed up with a neurologist 3 weeks later, he was back to his normal self and was starting to play basketball again.

DISCUSSION: The patient was presumed to have post-infectious acute cerebellar ataxia secondary to a recent EBV infection. Although he reported no recent symptoms commonly seen with EBV, most patients can be asymptomatic during an acute EBV infection. Acute ataxia can result from structural lesions, vascular disorders, infections, trauma, demyelinating lesions, paraneoplastic processes, toxins, or medications. With normal imaging and CSF, one should also consider post-infectious processes especially in the young. In children, this is mostly related to a Varicella infection. However, in older individuals, EBV is more commonly the preceding infection. Post-infectious EBV associated ataxia usually occurs 1 to 3 weeks post prodrome. Most patients present with predominant cerebellar motor symptoms but could also have cognitive dysfunction. An MRI and CSF analysis are usually normal. Symptoms are usually self-limiting with most patients having complete recovery. Some, however, could take months to improve and others can have permanent symptoms, especially patients older than 60 years of age and with underlying cerebellar atrophy. Considering the self-limiting course, patients are usually managed conservatively although it has been recommended that a more aggressive approach be taken in patients with no improvement within 1 week. Steroids can be effective in some but plasmapheresis or intravenous immunoglobulins are the initial treatment of choice as steroids can sometimes delay a more effective treatment.

YOUNG PATIENT WITH CHEST PAIN, ST ELEVATION, ELEVATED TROPONIN BUT WITH NORMAL CORONARY ARTERIES Tarun Jain¹; Meghan G. Liroff¹; Tariq Turfe¹; Robert Han¹; Kyle Martin¹; Aisha Aslam²; Janak Kansagra¹; Chike Obi¹; Bobak Rabbani¹. ¹Henry Ford Hospital, Detroit, MI; ²Botsford Hospital, Detroit, MI. (Tracking ID #2193273)

LEARNING OBJECTIVE #1: Importance of understanding the pathological process of ECG changes and troponin elevation and possible clinical challenges that arise, when faced with combination of these abnormalities

LEARNING OBJECTIVE #2: Importance of various kinds of imaging modalities in recognizing cardiac pathology

CASE: Twenty year-old male with no previous medical problems presented with 2 days of "pressure-like", intermittent, sub-sternal chest pain radiating to lower jaw. Patient had viral upper respiratory tract symptoms 2 weeks prior to presentation. Patient was afebrile on presentation, with heart rate at 80/min and blood pressure of 146/96 mmHg. There was normal S1 and S2, with no rubs, murmurs or gallops on cardiac exam. Rest of the physical exam was unremarkable. Initial EKG revealed 1–2 mm ST-elevation in the inferior leads. His chest pain improved with aspirin and sub-lingual nitroglycerine. All electrolytes and white count were within normal limit. His urine toxicology was negative and initial troponin was 6.59 ng/ml. Anticoagulation was initiated, and emergent cardiac catheterization revealed normal coronary arteries. Follow-up echocardiogram revealed normal cardiac function with no wall motion abnormalities. Troponin peaked at 51.57 ng/ml before trending down. Serology for adenovirus, coxsackie, cytomegalovirus and influenza were negative. Autoimmune work-up was negative as well. Cardiac MRI was performed and demonstrated Increased abnormal T2 weighted signal with delayed gadolinium epicardial and mid-myocardial enhancement in the basal to mid-lateral and infero-lateral walls, consistent with acute myocarditis. Patient remained hemodynamically stable throughout the course and was discharged home on Lisinopril and metoprolol.

DISCUSSION: Myocarditis is myocardial inflammation with necrosis of the myocytes in the absence of ischemia or infarction. Most commonly results as a sequelae of infectious etiology, especially viruses. Non-infectious causes include autoimmune diseases, hypersensitivity and toxic reaction to medications, radiation, trauma etc. It can present as chest pain and can progress to result in malignant arrhythmias, acute congestive heart failure and cardiogenic shock. Serum concentrations of troponin I and T are elevated more frequently than creatine kinase myocardial band fraction, and higher levels of troponin T has prognostic value, less in focal compared to diffuse involvement. ECG findings may vary from non-specific ST-segment and T-wave changes to ST-segment elevation mimicking acute myocardial infarction. Cardiac magnetic resonance imaging besides being non-invasive has evolved as a valuable tool for diagnosis of myocarditis. The management includes close hemodynamic and ECG monitoring and initiation of prophylactic low dose of beta blockers. Malignant arrhythmias and cardiogenic shock may necessitate anti-arrhythmic therapy and/or circulatory hemodynamic support therapies.

*INNOVATIONS IN MEDICAL EDUCATION (IME)

"AIDET SMILE": A DIDACTIC AND EXPERIENTIAL CURRICULUM ALIGNING MEDICAL STUDENTS' PATIENT-CENTERED COMMUNICATION TRAINING WITH A MEDICAL CENTER-WIDE INITIATIVE Talia R. Kahn; Diane Sliwka; Cindy Lai. UCSF, San Francisco, CA. (Tracking ID #2190375)

NEEDS AND OBJECTIVES: Patient-centered communication positively impacts patient outcomes. To improve provider communication skills with patients, our medical center adopted the "AIDET SMiLe" (Acknowledge, Introduce, Duration, Explanation, Thank You, Sit Down, Manage Up, Listen) framework for provider-patient communication. Video training for "AIDET SMiLe" is required for attendings, residents, and staff. However, there is no formal communication training for third-year medical students despite their daily care of patients as part of a medical team. To align students' communication training with this medical center-wide initiative, we developed a clerkship curriculum to teach medical students to employ the same communication skills.

SETTING AND PARTICIPANTS: Third-year medical students on their medicine clerkship at a large, urban, academic medical center participated in this curricular pilot.

DESCRIPTION: We developed a didactic and experiential curriculum for third-year students on their medicine clerkship. This pilot was designed with the "flipped classroom" model in mind (pre-recorded lectures are viewed at home followed by in-class discussion) and consisted of three components: (1) Training Video, developed to introduce the components of "AIDET SMiLe," which students completed prior to the workshop; (2) Workshop, an interactive discussion of examples of good and bad communication that students had witnessed on wards and review of "AIDET SMiLe" and data supporting this framework; (3) Peer-to-peer observation and feedback, with pairs of students observing

each other in patient encounters at the bedside and providing oral and written feedback using a structured template.

EVALUATION: Three blocks ($n=35$ students) have completed the pilot. Using a 1 (poor) to 5 (excellent) point Likert scale evaluating the components of the curriculum, the majority ($>75\%$) of students thought the overall educational value of the program was "very good" or "excellent" (average 3.94). Based on open-ended comments, the aspect of the curriculum that students found most helpful was evenly split between the training video, the workshop, and the peer-to-peer observation. Additionally, students commented that they appreciated having their patient-centered communication curriculum aligned with the medical center's initiative.

DISCUSSION / REFLECTION / LESSONS LEARNED: Prior to this pilot, there was no formal communication training for third-year medical students despite their daily care of patients. We developed a three-pronged communication curriculum for third-year medical students on their medicine clerkship that was aligned with a medical center-wide initiative. Students' responses were evenly split when asked to identify the curricular component they found most useful, suggesting that the curriculum was able to meet the needs of a wide variety of learners. Additionally, students appreciated that their patient-centered communication curriculum taught them to approach bedside patient encounters using the same model as their supervising physicians and staff.

A BLAST FROM THE PAST: RESIDENT AND FACULTY ATTITUDES WITH RE-INSTITUTION OF 24+4-HOUR CALL AT ONE MEDICAL CENTER Joel C. Boggan^{1,2}; Vaishali A. Patel¹; Aimee K. Zaas¹. ¹Duke University Health System, Durham, NC; ²Durham Veterans Affairs Medical Center, Durham, NC. (Tracking ID #2192157)

NEEDS AND OBJECTIVES: To comply with duty hour regulations, many programs have switched from overnight (ON) call inpatient coverage systems to night float (NF) team structures. This study investigates attitudes after reinstitution of ON systems at a single academic medical center.

SETTING AND PARTICIPANTS: Residents and attendings on inpatient general medicine services at Durham Veterans Affairs Medical Center, beginning April 2014.

DESCRIPTION: Rotations were changed from a NF (daily admissions, including 'rollovers', and occasional 'long' shifts of 16 h with night float coverage) to an ON (24+4-h call every fourth night for upper-level residents) system. Interns continued to do 12-h day shifts, with one week of night shifts per rotation (Table 1). Because of intern staffing, the ON system resulted in resident-only teams during the day when the paired intern was on the week of night shifts.

EVALUATION: We tracked team census, admission flow, and inpatient length of stay for 8 weeks pre-intervention and 18 weeks post-intervention. We anonymously surveyed interns, residents, and attendings using Likert scales regarding schedule changes, patient knowledge, daily census, education, and workload. Duty hour violations were tracked, in aggregate, from our reporting system. Student t-testing for team censuses and admissions, χ^2 and nonparametric testing of trends for survey responses, and Kruskal-Wallis testing for length of stay differences were performed.

DISCUSSION / REFLECTION / LESSONS LEARNED: The resident general medicine capacity increased by 14 patients, while the total daily resident admission capacity decreased from 24 patients to 18 patients (Table 1). Mean team census decreased from 9.3 \pm 1.7 patients pre-intervention to 6.6 \pm 2.2 post-intervention ($p<0.01$). While patients were perceived by trainees to be discharged more quickly post-intervention, there was no statistically significant reduction in length of stay (4.9 days pre-intervention vs. 4.4 days post-intervention, difference in means 0.5 days, $p=0.16$). Mean reported weekly hours and monthly violations were similar (71.2 h and 34.6 violations pre-intervention vs. 73.9 h and 29.2 violations post-intervention). Fifty-four trainees (84 %) and 11 attendings (61 %) responded to surveys. Trainees were in favor of keeping the ON system (48.1 % in favor vs. 24.1 % opposed), although they were significantly more likely than faculty to oppose this change (0.0 % of faculty opposed, $p=0.03$). The majority of interns (72.7 %) who worked in both systems reported a more favorable experience with ON, while residents were divided (44.8 % more favorable, 34.5 % less). Most trainees (74.5 %) endorsed better patient knowledge post-intervention. Self-reported quality of learning either improved (50.0 %) or did not change (33.3 %). Upper-level residents (62.0 %) and faculty (0.0 %) differed significantly about whether resident-only weeks were 'unmanageable' ($p<0.01$). Structure changes to ON call at a single center allowed for improved resident-patient continuity, patient knowledge, and reduced average team census without worsening reported duty hours or increasing duty hour violations. Changes based on resident feedback have included lower resident-only team and admission caps. Longitudinal study of ON systems will provide better information about educational quality and patient-centered outcomes.

A HIGH YIELD, MULTI-DISCIPLINARY PRIMARY CARE ELECTIVE FOR RESIDENTS Nancy A. LaVine⁵; Lauren Block²; Jennifer Verbsky¹; Frank Cacace¹; Saima Chaudhry⁶; Joseph Conigliaro³. ¹Hofstra North Shore LIJ, Great Neck, NY; ²Johns Hopkins University School of Medicine, Baltimore, MD; ³North Shore LIJ Health System, New Hyde Park, NY; ⁴North Shore LIJ Health System, Great Neck, NY; ⁵North Shore/LIJ, New Hyde Park, NY; ⁶nslij, Manhasset, NY. (Tracking ID #2189797)

NEEDS AND OBJECTIVES: Residents in categorical internal medicine are choosing careers in primary care at ever decreasing rates. Standard residency continuity clinic experiences can give residents a limited view of the scope of primary care practice and can have a negative influence on resident attitudes toward primary care. Primary care residency tracks are one way to provide residents with a more comprehensive experience in primary care. However, even residents in these dedicated tracks are reported to choose a primary care career less than half of the time. At our institution, the primary care track was dissolved for funding reasons several years ago. Our goal was to create a high yield primary care experience for interested residents. We developed an enhanced two week elective for second and third year residents that incorporated an additional exposure to primary care practice during residency training, increased direct mentorship by GIM faculty, expanded exposure to the multi-disciplinary nature of primary care practice in providing patient centered care, and offered instruction on high yield ambulatory practice skills.

SETTING AND PARTICIPANTS: Second and third year residents interested in primary care at the North Shore/LIJ Internal Medicine Residency program. The elective was directed by General Internal Medicine faculty with significant input from a multi-disciplinary team members (PharmD, nutritionists, certified diabetes educators, health coaches, nursing staff and reimbursement/billing staff) already working in ambulatory GIM practices across the institution.

DESCRIPTION: A pilot version of this elective was offered during the 2013–2014 academic year, and based on feedback from participating faculty and residents the curriculum was expanded for the current academic year. The two week elective encompasses experiences from a number of areas of general internal medicine. Residents performed acute care visits in a private practice setting. They gained experience teaching interns together with preceptors and educating medical students on physical diagnosis and communication skills. Residents had sessions on quality improvement in the ambulatory setting and incorporating evidence based medicine at the point of care. They participated in managing transitions of care in high risk patients in the patient centered medical home. Primary care skill building was also emphasized in the areas of anticoagulation management, nutritional counseling, medication management, immunization administration, alcohol and drug screening and diabetes education. Residents were also given time in high yield subspecialties: preventative cardiology and dermatology. Time was dedicated to curriculum vitae development and discussion of career planning.

EVALUATION: For the 2014–2015 academic year, nine residents will participate in primary care elective, including 8 third year residents, 5 women, 5 from our hospital based resident clinic, and 4 from our combined resident/faculty clinic. To date, 7 of the 9 have completed their rotation, and all five are actively seeking primary care positions. Participating residents are being surveyed on satisfaction with overall training, the learning environment, and preceptors/faculty, with particular attention to preparation for clinical practice and impact on their GIM career plans. Resident survey data on the primary care elective will be shared.

DISCUSSION / REFLECTION / LESSONS LEARNED: Standard resident ambulatory experiences can have a negative impact on resident's attitudes towards primary care careers, and we seek to change this trajectory. We initiated an enhanced primary care experience for our residents, incorporating additional primary care experiences, multi-disciplinary team exposure, mentorship and primary care skill building. By utilizing the skills and resources of current GIM faculty and multi-disciplinary team members, we created a high yield two week elective without the need for additional funding or staff. Through this elective, we hope to sustain and solidify our residents' interest in primary care and provide them with the skills necessary for excellence in clinical practice.

ENHANCING LEARNING AND TEACHING OF RESIDENTS ON NIGHT-FLOAT ROTATIONS: CREATING A STANDARDIZED FEEDBACK TOOL Tyler Anstett²; Matthew Hoegh²; Read Pierce³; Darlene Tad-y¹. ¹University of Colorado Denver School of Medicine, Aurora, CO; ²University of Colorado SOM, Denver, CO; ³University of Colorado, Denver, Aurora, CO. (Tracking ID #2196333)

NEEDS AND OBJECTIVES: In response to the 2011 ACGME duty-hour restrictions, an increased amount of work has shifted to night float systems. This has led to an increase in patient care transitions in which admitting residents do not discuss the case with attending physicians. At the University of Colorado Hospital (UCH), patients admitted between the hours of 4:00 pm and 7:00 am are admitted by residents who don't interact

with the attending physician for the primary daytime team. As a result, night-float residents often work in isolation without receiving feedback on clinical decisions. Feedback, both instructive and formative, is a central tenant of post-graduate medical education. The goal of this program was to design a system for daytime attending physicians to provide feedback to night residents without direct contact. Objectives included creating a feedback tool that was formative, informational, and efficient. Ultimately, we hoped to improve the educational value of night float rotations and provide an avenue for attending hospitalists on teaching services to reach a broader scope of learners.

SETTING AND PARTICIPANTS: Internal Medicine residents who completed night-time inpatient admissions to the Internal Medicine service at the University of Colorado Hospital.

DESCRIPTION: Internal Medicine residents who completed nighttime admissions at UCH were surveyed on the amount of feedback received and the over-all educational value of night-float rotations. Simultaneously, a tool was designed to provide feedback in the areas of clinical decision-making, documentation and billing, triage, and the appropriateness of diagnostic studies. The tool was provided to attending physicians caring for patients admitted by residents the previous night, completed, then returned to residents for review. Residents then provided input on the effectiveness of the feedback received. The tool was piloted on a single service and subsequently deployed to six teaching services that routinely receive admissions performed by night residents. Through consultation with attendings and residents, the tool has been improved and the distribution process modified.

EVALUATION: Prior to implementation of the feedback form, only 42 % of residents received any feedback during night-float rotations and none of the feedback was from daytime providers. To date, both attendings and residents have felt the tool is a valuable way to communicate and is minimally time-consuming - averaging just over 5 min to complete. Residents have felt that the feedback has generally been helpful, particularly when written comments are provided. Thus far, we have achieved a daytime provider feedback rate of 50 % for patients admitted to participating services.

DISCUSSION / REFLECTION / LESSONS LEARNED: A standardized tool can provide nighttime residents with much needed feedback on their performance during unsupervised periods and help to mitigate the divide created by night float rotations and cold-handoffs. Continued evaluation and adaptation will be needed to engrain the program into routine and provide formative and tangible feedback to more residents. With work-hour restrictions creating more situations for shift-based care, innovations such as a structured feedback tool are needed in order to continue to provide high-value education to residents.

PEER REVIEW IN GRADUATE MEDICAL EDUCATION: A NOVEL MEANS OF RESIDENT ENGAGEMENT IN SYSTEM IMPROVEMENT Laura P. Perry²; Rachel E. Chan Seay¹; Juliet Lee³. ¹The George Washington University, Washington, DC; ²Washington DC Veterans Affairs Medical Center, Washington, DC; ³George Washington University School of Medicine and Health Sciences, Washington, DC. (Tracking ID #2200330)

NEEDS AND OBJECTIVES: Resident physicians are in an optimal position to identify operational problems within academic teaching hospitals. Yet many academic hospitals have reported struggles to develop and maintain housestaff engagement in quality improvement efforts. We propose an alternate model for resident involvement in operational change on an institutional level: a resident peer review committee. The process of peer review engages residents in critical appraisal of their co-residents' activities, and allows for thoughtful reflection on each participant's own practices. Additionally, review of cases with poor outcomes allows residents to identify system-level problems. Peer review thus helps residents experience the benefits of root cause analysis-style quality improvement while also helping to develop a deeper sense of professionalism.

SETTING AND PARTICIPANTS: The Resident Peer Review Committee is a resident physician advocacy group that was created at The School of Medicine and Health Sciences at The George Washington University (GWU SMHS).

DESCRIPTION: The Committee is composed of residents from all specialties that train at GWU SMHS. Its purpose is to review cases involving resident physicians relating to professionalism, communication, safety and supervision. In its early stages, the Committee received few case referrals. The members nevertheless found the meetings to be an opportunity to discuss common problems encountered in the hospital setting. Residents began to share and analyze their experiences of hospital administration and logistics, and ultimately decided to formally address some of the common problems by producing Committee Opinions. These reports were disseminated to the hospital leadership and residency program directors, and resulted in a variety of initiatives to improve patient care. As the Committee grew more visible, residents and faculty began to refer cases more frequently. The Committee generally found that cases with poor outcomes usually resulted from a combination of individual error and systems-level problems. The identification of

these large-scale problems during reviews naturally led to the production of more Opinions.

EVALUATION: The Committee has engaged in constant reflection and self-reinvention throughout its lifespan, taking shape to accommodate the needs of the housestaff in general and its members. Challenges during the early phases included member recruitment and resistance by hospital stakeholders. Early experiences led to a practice of constant communication with a wide range of stakeholders, including resident-to-resident outreach for recruitment, and back-and-forth with hospital and faculty stakeholders in the dissemination of Opinions. In its second year, the Committee struggled to maintain member participation and engagement, ultimately voting to approve a set of member expectations that would more evenly distribute work. As additional residents were recruited, the workload could be distributed among a larger number of committee members. The general housestaff body also remained skeptical of the Committee's effectiveness at its inception, with misperceptions including that the Committee was a disciplinary board. As a remedy, a Resident Town Hall was held to update the entire housestaff body on the Committee's activities, and to encourage correspondence with the Committee when residents had concerns. The feedback received from this Town Hall was overwhelmingly positive, and the volume of referrals continued steadily to increase. In its fourth year of existence, the Committee has become the predominant voice for resident representation at GWU SMHS, establishing credibility and building relationships.

DISCUSSION / REFLECTION / LESSONS LEARNED: If teaching institutions are dedicated to educating mature, responsible and professional physicians, they must accept a full range of methods for dealing with issues of professionalism and self-assessment, including peer review. Additionally, teaching institutions that seriously address the problem of resident burnout will find that residents want to feel that their voice is valued, that they are protected from retribution, and that they can impact change. We present our experience with resident peer review as a novel model that other programs may consider in the effort to increase resident engagement.

STUDENT AS TEACHER: A STUDENT INITIATED, LEARNER CENTERED, FOURTH YEAR MEDICAL SCHOOL EDUCATION ELECTIVE Martin C. Fried²; Dr. Sarah Milburn³; Sheira Schlair¹. ¹Albert Einstein College of Medicine/Montefiore Medical Center, Bronx, NY; ²NYU, Astoria, NY; ³Mount Sinai, New York, NY. (Tracking ID #2190322)

NEEDS AND OBJECTIVES: Medical school graduates are expected to teach immediately as interns. Few US medical schools offer structured teaching for senior students motivated to develop teaching skills. Two fourth year medical students (MF, SM) created a learner centered, 4-week MS-4 elective entitled "Student-as-Teacher" (SAT). This elective aimed to develop teaching skills by increasing knowledge about teaching and applying that knowledge in various educational settings for MS-1 students. Ultimately we hoped this project would garner interest in establishing a permanent teaching elective at our medical school.

SETTING AND PARTICIPANTS: This pilot elective was designed by two fourth year medical students at Albert Einstein College of Medicine (AECOM) who had K-12 teaching experience prior to medical school. They also participated in the elective, enlisting first-year medical students as student-learners whenever possible. Course directors included a basic science course director who directs an elective for PhD students about course design and an internal medicine core clinical faculty member who leads the resident-as-teacher program at our hospital (SS). They supervised elective development and delivered didactic sessions.

DESCRIPTION: The SAT elective curriculum was designed to approximate 3 ascending levels of Bloom's taxonomy from building mastery of basic knowledge of teaching skills and advancing to application and evaluation. In component 1, student-teachers (STs) engaged in a learner-centered didactic curriculum with interactive sessions covering topics like adult learning theory principles and Socratic method in clinical teaching and precepting. In component 2, STs applied acquired knowledge by leading two sessions for MS-1 students: a small-group case conference on lipid transport and large-group lecture on EKG fundamentals with formal learner feedback. In component 3, STs were tasked to synthesize their teaching experience by working with a faculty preceptor to evaluate and enhance an element of the undergraduate medical school curriculum. For this project the STs chose to revamp a case conference in the disease mechanisms course by realigning conference objectives with course learning objectives and changing the format to increase student engagement.

EVALUATION: STs were evaluated by student-learners in the application component activities via post-session online and in-person surveys. Overall comments were quite positive: 96 % of MS-1 students felt more comfortable interpreting EKGs after the EKG lecture and 78.2 % felt that the lecture encouraged self-directed learning. Qualitative feedback from case conference included, "... loved the interactive element" and "Very engaging and helpful in eliciting our responses". After participating in the elective STs

created 'teaching philosophy' reflections. STs felt better prepared to execute learning activities in varied settings. Unanticipated benefits included the opportunity to improve academic writing and engage with faculty and administration in novel ways like collaborating on curricular innovations. Opportunities for formal teaching observation of STs by faculty observers were sparse in the pilot elective. Later iterations will therefore aim to include more robust observation and feedback opportunities by experienced medical school teachers. Implementation of a formal medical education elective at AECOM was ultimately approved by the Clinical Directors Subcommittee. Long-term goals include the creation of a Medical Education scholarship track for students.

DISCUSSION / REFLECTION / LESSONS LEARNED: In designing the elective we discovered that much of the framework for a formal SAT elective at AECOM and affiliate teaching hospitals exists within courses currently offered to students, faculty and residents. As such, few novel educational activities were required to achieve our goals. Other institutions seeking to incorporate similar "student-as-teacher" programs may also be pleasantly surprised to find great resources available for student-teacher training. The importance of working within the established curriculum while creating new academic content was a paramount lesson that STs learned. Innovation in medical education curriculum, especially student-driven innovation, should augment and not necessarily replace existing resources. ST choice and flexibility was an important theme in our elective design. We believe that STs should have the ability to craft learning experiences that would complement their own skills and career ambitions. We found that SAT electives have the potential to not only provide basic teaching skills to medical students interested in teaching. By offering the opportunity for fourth-year medical students to act as teachers to their peers in structured environments such courses can augment the desire to pursue careers in medical education and have lasting effects that extend into residency and beyond.

A NOVEL, WEB-BASED, ASYNCHRONOUS AND INCREASINGLY INTERACTIVE COURSE TO MEET THE NEEDS OF FOURTH YEAR MEDICAL STUDENTS Thomas D. Shiffler; David Feldstein; Yuyen Chang. University of Wisconsin School of Medicine and Public Health, Madison, WI. (Tracking ID #2193981)

NEEDS AND OBJECTIVES: Students in their fourth year of medical school face increasing off-campus demands including residency interviews and away rotations. Courses that allow students to meet these demands would be useful. Clinical Therapeutics, a fourth year elective, prepares students to treat common conditions and diseases that they will encounter during residency. We adapted this elective to: 1) provide an asynchronous and completely online course that allows maximum flexibility to meet students' geographic and schedule needs; and 2) integrate new methods of interactive online learning.

SETTING AND PARTICIPANTS: The course was first modified to be entirely online in 2012. All fourth year medical students at the University of Wisconsin School of Medicine and Public Health (UWSPH) are eligible to take the elective and can sign up for 2-4 credits.

DESCRIPTION: Clinical Therapeutics is entirely online and focuses on diseases, conditions or content that will be important to students during their residency and beyond. More than 70 topics are included, covering a wide range of issues such as depression, hyperlipidemia, cost of care, and team-based care. Various methods are used to deliver the content. Most topics are recorded lectures that can be viewed online when convenient. After viewing the lecture, the student demonstrates learning by developing a boards-type question and answer based on one of the lecture's main points. The second content delivery method uses Case Scenario Builder (CSB), a novel, interactive tool developed at the University of Wisconsin-Madison. CSB allows faculty to create interactive questions and case scenarios that require students to be more active learners. They must answer questions correctly before continuing and eventually completing each scenario. While CSB is more interactive than recorded lectures, it also takes substantially more faculty time to develop. The final method of content delivery involves web-conferencing. Each web-conference is based on a recorded lecture, which students view in advance. A faculty member then leads students through multiple cases during the web-conference. Students can be virtually placed in breakout groups to collaborate on questions with colleagues.

EVALUATION: In 2011, the last year the course was offered in a classroom setting, 10 students enrolled (7 % of the graduating class). In 2012 the course was converted to be entirely online and 52 fourth year students enrolled (35 % of the graduating class). Enrollment increased to 107 students (64 % of the graduating class) in 2014. End-of-course evaluations from 2014 showed that: 93 % (96/103) of students agreed or strongly agreed that the course was excellent; 90 % (95/106) agreed that the web conferences were valuable for learning the content; and 96 % (101/105) felt the CSB sessions were a valuable learning experience. One student noted, "Case scenarios were great—allowed me to answer questions during the lecture which allowed me to digest the material." We found that 69 % (65/94) of students preferred the interactive case scenarios to recorded lectures. Another student commented, "Make more of them (case scenarios). Walking us through how to approach a case in an interactive format is probably the best way for us to learn. Lectures don't stick for very long."

DISCUSSION / REFLECTION / LESSONS LEARNED: A web-based, predominantly asynchronous course was very well received by students and led to a dramatic increase in student enrollment. The course clearly fit a need for fourth year students by providing increased schedule and geographic flexibility. Further online and asynchronous elective options for students should be explored. While students prefer the interactive nature of the CSB, additional faculty time is required to develop the sessions. Evaluating whether CSB sessions actually improve student learning compared to recorded lectures is critical to determine whether this additional faculty time is worthwhile. We have continued to expand the number of CSB sessions and plan to perform a randomized controlled trial to look at the benefits of CSB versus recorded lectures. We will also continue to explore other methods of content delivery to provide students with the best learning experience.

A RANDOMIZED TRIAL OF AN INTERVENTION TO IMPROVE RESIDENT-FELLOW TEACHING INTERACTIONS ON THE WARDS Shruti Gupta²; Kevin Heaton²; Jehan Alladina²; Alberto Puig¹; Eli Miloslavsky². ¹MGH/Harvard Med School, Boston, MA; ²Massachusetts General Hospital, Department of Internal Medicine, Boston, MA. (Tracking ID #2196445)

NEEDS AND OBJECTIVES: Clinical fellows can serve as a tremendous educational resource to residents. However, multiple barriers to an effective resident-fellow teaching interaction in the setting of inpatient consultation exist. We designed a resident-directed intervention to address some of the known barriers and conducted a randomized study of the intervention with the goal of improving the initial consult request and subsequent teaching interactions between Internal Medicine (IM) residents and fellows.

SETTING AND PARTICIPANTS: Five medical teams consisting of 5 interns and 1 or 2 supervising residents were randomized to receive the intervention (2 intervention, 3 control) over a period of 3 months.

DESCRIPTION: The intervention consisted of four tasks that interns were asked to complete for every new consult to an IM subspecialty service: • Intern and supervising resident determine a specific consult question • Intern asks to have an in-person interaction with the fellow after the fellow has seen the patient • Intern encouraged to initiate the teaching interaction and elicit at least one teaching point • Intern shares the teaching point on rounds with the team. The intervention was evaluated with pre and post-intervention surveys measuring communication and teaching between interns and subspecialty IM fellows on all teams.

EVALUATION: Results: A total of 112 interns participated in the study. Sixty nine interns completed the pre-intervention survey and 64 (57 %) completed the post-intervention survey. The pre-intervention survey demonstrated that among new patient consults, 82 % of interns had in-person interactions with fellows less 50 % of the time, 81 % stated they received teaching in less than 50 % of consult interactions and 58 % of interns felt that they received "pushback" from fellows during 15–50 % of their consult requests. Forty nine percent of interns felt that they initiated the teaching interaction more than 50 % of the time. No baseline differences were noted between the intervention and control groups. Following the intervention, interns in the intervention group more frequently reported receiving teaching in 50 % or more of their interactions compared to those in the control group (40 vs. 16 %, $p=0.047$). In addition, interns on the intervention team reported a trend toward more frequent in-person interactions with fellows (28 % vs. 9 % having in-person interactions more than 50 % of the time, $p=0.087$). There were no differences in the overall level of communication between the primary team and fellows, overall teaching or the amount of perceived "pushback" from fellows as a result of the intervention. Seventy two percent of interns reported that they were able to implement the intervention "some" or "most of the time."

DISCUSSION / REFLECTION / LESSONS LEARNED: Conclusions: IM interns at our institution perceive that teaching interactions with fellows occur in less than half of consult interactions and "pushback" occurs in a considerable share of consult requests. A time-efficient, resident-directed intervention demonstrated some improvement in resident-fellow teaching interactions, though was limited by incomplete adherence. Further efforts to improve the resident-fellow teaching interaction, including further studies of this (or similar) intervention, are warranted.

A REAL-WORLD STRATEGIC NEEDS ASSESSMENT THAT ENGAGES HOUSE STAFF OUTSIDE THE CLINIC TOWARD COMMUNITY HEALTH David M. Levine; Colleen Vessell; Matthew R. Augustine; Kathleen Hanley. New York University School of Medicine, New York, NY. (Tracking ID #2196293)

NEEDS AND OBJECTIVES: While house staff work daily in the clinic and hospital to achieve health for their individual patients, they often feel uninformed and unable to effect change in their patients' surrounding community. Through action outside of the clinic, they may be able to impact their community's health. Yet few strategies exist for house staff to practice community health. Strategically assessing the needs of a community is

often considered difficult and time-consuming but is paramount to correctly identifying impactful interventions. While zip code-level data often suggests significant health needs within the larger community, these data are often not sufficiently granular to identify the needs of a clinic's specific population. Our objectives: 1) provide residents the opportunity to perform a feasible needs assessment of their clinic population; 2) describe the social and medical needs of our community clinic's patients; and 3) distill the community needs assessment data into actionable projects feasible for our entire medical team and its community. Here we present an ongoing resident-engaged, clinic-involved, patient-centered needs assessment that requires a relatively small resource base yet yields a substantial data set for planning real-world community-based interventions that engages house staff toward action outside the traditional clinic.

SETTING AND PARTICIPANTS: We practice in a densely populated urban area with large unmet medical and social needs. Our clinic is community-based, publicly supported, and provides primary care services on a sliding scale fee schedule to almost exclusively Medicaid and uninsured patients. Internal medicine—primary care house staff, medical assistants, and pre-medical undergraduate students devised and delivered a survey, along with input from patients. Patients could be surveyed if they were orally proficient in English, Mandarin, or Spanish and presented to our clinic for an appointment. They were excluded if they had a condition that precluded oral conversation (e.g. severe dementia, psychosis, deafness).

DESCRIPTION: House staff developed a brief survey utilizing validated questions from national surveys as well as home-grown questions relating specifically to our practice environment and changes that could be made in our community and clinic. The survey was refined with feedback from our medical assistants (most of whom live in our patients' neighborhood), clinic administration, and small sample of patients. Volunteer undergraduates fluent in Chinese and Spanish administered the survey to a convenience sample of patients while they awaited their appointment.

EVALUATION: We analyzed survey data via descriptive statistics and cross-tabulation. English- and Spanish-speaker data analysis ($n=168$) is complete, while Mandarin-speaker data collection is ongoing. Already clear trends in our community are present: poor health literacy, food insecurity, and few exercise opportunities. Clear areas for action are also evident: over 50 % would be interested in volunteering as a health coach, a specific demographic segment is in need of health insurance counseling, and about a third of patients would participate in exercise classes if offered at our clinic. Additionally, the majority of our patients have internet access and use email, often via mobile devices. Project planning is ongoing.

DISCUSSION / REFLECTION / LESSONS LEARNED: A brief evidence- and community-based survey can identify key flex points where community- and clinic-centered interventions will address the community's expressed needs. Involving our entire medical team (patients, medical assistants, house staff, and administration) enormously benefited and focused our survey. Support from volunteer undergraduates was at times difficult to solicit, but their inclusion was certainly a strength. For the design and execution of our community-based intervention, we anticipate a similarly inclusive process. Thus far our needs assessment has uncovered important areas where house staff can be engaged in further health-related work outside the walls of the clinic and hospital with members of their medical team.

A RESIDENT WORKSHOP ON GIVING PERFORMANCE FEEDBACK TO PROBLEMATIC MEDICAL STUDENTS Gita Mehta¹; Neil J. Farber³; Simerjot K. Jassal²; Peggy Wallace¹; Robert MacAulay¹. ¹UCSD, La Jolla, CA; ²UCSD/VASDHHS, San Diego, CO; ³University of California, San Diego, La Jolla, CA. (Tracking ID #2199630)

NEEDS AND OBJECTIVES: Learning to give performance feedback is critical to Competency training for residents. Residency in Medicine usually does not provide adequate training for providing meaningful feedback to difficult learners, which is essential for ensuring clinical competence in medical students. We developed a workshop for evaluating and training resident' in handling difficult clinician -student interactions, and then assessed their confidence in giving meaningful feedback.

SETTING AND PARTICIPANTS: We trained fourth year medical students to represent difficult learners (Standardized learners), and medical residents were required to provide feedback to the students. Twenty four medical residents participated in a structured feedback sessions that involved communication with 4 medical students. Residents were asked to give performance feedback to students representing the disorganized, disinterested, know-it-all and the knowledge deficit student. Residents moved in pairs from one student to the next, assigned as participant or observer, while faculty were assigned to a specific student. Faculty members were able to view each interaction remotely in a monitoring room, before joining the student and residents to debrief on each encounter and provide feedback.

DESCRIPTION: Twenty-four R1-R3 residents participated in 2 separate sessions. Prior to the session faculty and residents were provided pertinent reading materials and a tutorial

on giving feedback. Residents were given 15 min to communicate with each student. Following each encounter, 15 min were spent in giving feedback to each resident by the colleague, medical student and observing faculty member.

EVALUATION: Residents indicated infrequent experience in dealing with problematic medical students; few residents felt they had significant teaching experience with a know-it-all learner (1/24), disorganized (6/24), disinterested (2/24), and the knowledge deficit student (3/24). Before this workshop, only 15/24 residents reported ever being directly observed and given feedback in delivering performance feedback to learners.

DISCUSSION / REFLECTION / LESSONS LEARNED: All residents felt the workshop allowed them to reflect on their ability to provide quality performance feedback in "difficult learner" situations and gained ideas to implement in the future. 23/24 residents felt the workshop helped remove the fear and uncertainty of the performance feedback process. All residents felt it enabled them to practice performance feedback skills in a supportive and instructional setting. Our workshop supports the use of a structured feedback session to train medical residents to provide feedback to medical students. This setting permits immediate feedback to the resident from the medical student, peers and faculty members. Despite the inherent constraints of simulated encounters, this workshop provides a safe environment for residents to learn key skills relevant to competency training.

A SAFE AND EFFECTIVE DISCHARGE CURRICULUM IMPLEMENTED IN ELEVEN INTERNAL MEDICINE PROGRAMS OF THE EDUCATIONAL RESEARCH OUTCOMES COLLABORATIVE Lauren B. Meade¹; Kathleen A. Heist³; Ron Jones⁴; Cheryl O'Malley²; Kenji Yamazaki⁶; Aimee K. Zaas². ¹Baystate Medical Center, Springfield, MA; ²Duke University, Durham, NC; ³University of Colorado at Denver, Aurora, CO; ⁴Summa Health Systems, Akron, OH; ⁵Banner Good Samaritan, Phoenix, AZ; ⁶ACGME, Chicago, IL. (*Tracking ID #2197746*)

NEEDS AND OBJECTIVES: The transition from hospital to home is a vulnerable time for patients and families and is ripe for physician training. We implemented a discharge curriculum focusing on the competence of a 'Safe and Effective Discharge (SAFE-D) From the Hospital'. The primary objective for the SAFE-D innovation was to assess the usefulness of determining competence using direct observation and feedback. Our secondary objectives include: 1. To increase attending and resident awareness of 6 physician behaviors for a SAFE-D 2. To increase the quality of feedback from attendings when they observe residents in the SAFE-D behaviors 3. To assess the usefulness of multi-source feedback on the determination of resident competence and 4. To assess the feasibility of using behavior-based direct observation in assessment for SAFE-D. We will also assess the effect of a Collaborative process in implementation across programs.

SETTING AND PARTICIPANTS: Eleven Internal Medicine (IM) programs of the Educational Research Outcomes Collaborative (Collaborative) participated in the SAFE-D innovation including 251 attendings and 299 Post Graduate Year 1 residents. The discharge innovation was required for all attendings and residents on the wards as part of the educational requirements of the wards rotation. Faculty and residents were oriented to the discharge curriculum in a 1 h interactive session by the site principle investigator (PI). Site PIs from all the programs collaborated on monthly conference calls to implement the discharge curriculum by sharing barriers and successes throughout the year.

DESCRIPTION: From September 2013 to June 2014, 11 IM programs implemented a workplace direct observation discharge curriculum. The discharge curriculum consists of serial direct observations in the following domains: Medication Reconciliation, Discharge Summary, Patient Communication, Anticipates Post Hospital Needs, Actively Collaborates, and Team Communication. Attendings observed these domains during their usual work on the wards with the resident. Attendings rated the resident on a competence 5 point scale from 'resident cannot perform even with assistance' to 'resident can act as an instructor on this skill'. Attendings gave corrective feedback until the resident had reached a level of competence defined by being 'ready for indirect supervision'. At the completion of one year discharge curriculum, attendings and residents completed a voluntary survey to assess the objectives of the discharge curriculum.

EVALUATION: One hundred and nineteen attendings and 181 residents completed a post innovation survey. Sixty percent of attendings and 51 % of residents agreed that the curriculum made them more aware of discharge behaviors. Fifty-three percent attendings agreed that they increased their direct observation using the curriculum. Sixty-seven percent attendings and 57 % of residents agreed that the curriculum provided a structure for giving feedback. Fifty-one percent of attendings and 76 % of residents agreed that they are more confident in assessing how well the resident engages with other health professionals. Forty-six percent of attendings and 57 % of residents agreed the curriculum was easy to use on the wards. Seventy-nine percent of attendings agreed that this curriculum was more effective than their prior practice of teaching the discharge. Sixty-five percent of attendings agreed that they were more confident in assessing resident competence using

the discharge curriculum. Sixty-four percent of residents agreed that the curriculum helped them understand the requirements to progress toward increased independence.

DISCUSSION / REFLECTION / LESSONS LEARNED: The SAFE-D curriculum improved attending and resident awareness of discharge behaviors, increased attending direct observation and increased feedback. Applying the educational method of direct observation and feedback for the purpose of advancing the resident by competence was shown to be both useful to the attending and the resident. In addition, this educational innovation is unique in that multiple programs developed and implemented a standardized curriculum across programs using a collaborative model. The Collaborative was established in 2008 by members of Alliance for Academic Internal Medicine to share educational innovations and study their outcomes. Lessons learned from the Collaborative approach to medical education innovations include: 1. The Collaborative enhanced idea generation as we had a diverse group of programs by size, region and university affiliation. 2. The work of the Collaborative energized the faculty to try new approaches to the SAFE-D curriculum and health education overall and 3. There was more buy-in from both leadership and program faculty for the educational initiatives as a member of a national Collaborative in medical education.

A SYSTEMATIC FACULTY DEVELOPMENT APPROACH FOR A NEWLY FORMED PROGRAM IN HOSPITAL MEDICINE Somnath Mookherjee; Christy McKinney; Thomas Gallagher. University of Washington, Seattle, WA. (*Tracking ID #2199353*)

NEEDS AND OBJECTIVES: Scholarly productivity and effective teaching can be challenging for academic hospitalists. Few have had training in research, project development, or teaching skills. In 2012 our institution created a Program in Hospital Medicine with the goal of supporting hospitalist academic work and raising the scholarly profile of this group of faculty. We developed a Faculty Development Program (FDP) with the broad aims of providing faculty with the skills and knowledge needed for academic success and career satisfaction. Specific goals were to create a curriculum based on systematic needs assessment (phase 1), to deliver content that was well received and attended (phase 2), and to periodically adjust the program to better meet the needs of faculty based on regular needs assessment (phase 3).

SETTING AND PARTICIPANTS: The Program in Hospital Medicine is part of the Division of General Internal Medicine and is composed of hospitalist and medicine consult faculty at two hospital sites at our University (expanded to all three hospital sites for the 2014–2015 academic year).

DESCRIPTION: Phase 1: We conducted a baseline needs assessment survey of hospitalist faculty between October 2012 and March 2013. Using a five point Likert scale where 1=low confidence, 3=neutral, 5=high confidence, faculty were queried on their confidence in skills in clinical, educational, research, and professional development domains. Phase 2: Curriculum development and deployment. We identified areas of high need using the survey results, and wrote specific learning objectives to address the needs across all four domains. We invited speakers to lead seminars to achieve the learning objectives and evaluated each seminar by surveying attendees. Phase 3: Program assessment and adjustment. In May 2014 we asked all hospitalist faculty to repeat the needs assessment survey to assess for changes in confidence.

EVALUATION: Phase 1: 27 of 40 eligible faculty (68 %) responded to the needs assessment survey. Representative areas of low confidence included "Ability to apply for grants to help fund a scholarly project" (mean±SD, 1.8±1.1), "Confidence in designing a scholarly project" (3.0±1.1), "I have a mentor that can support me in my scholarly projects" (2.9±1.3), "Confidence in publishing a manuscript reporting a scholarly project" (3.0±1.2), and "I know what I need to do to be promoted" (3.3±1.2). Phase 2: Curriculum development and deployment. Invited speakers gave 30 seminars during the 2012–2013 and 2013–2014 academic years. On average, 7.6±3.7 faculty attended each seminar. Seminars were rated highly for quality of instruction (4.8±0.5; 1=lowest possible, 3=neutral, 5=highest possible), relevance to faculty development needs (4.7±0.6), organization and format (4.7±0.5), and overall quality (4.8±0.4). Phase 3: Re-assessment and adjustment. Thirty-eight of 55 eligible faculty responded to the re-assessment survey (69 %). Although the faculty at our third hospital site were included in the survey and FDP activities, their responses were not included for comparison purposes since that group was not surveyed in 2012. Average confidence ratings for skills in clinical, educational, research, and professional development domains were compared with the baseline results: there were no significant changes. Therefore, in order to have a greater impact, the FDP was re-designed for 2014–2015. We focused on the main theme of "Excellence in teaching," with the majority of seminars centered on teaching skills. We created a structured peer observation program of bedside teaching to encourage the dissemination of faculty development out of the classroom and into the workplace. We also created a website to publicize upcoming events and archive seminar materials. In the 17 seminars to date, attendance has remained steady and ratings remain high. We will survey faculty at the end of the academic year to re-assess the program.

DISCUSSION / REFLECTION / LESSONS LEARNED: Consistent attendance and strong evaluations over 3 years support the sustainability of the program. Improved confidence in specific skills has yet to be demonstrated. We are developing more objective measures of success, such as dissemination of scholarly work and ratings of teaching efficacy.

A TRANSITIONS-OF-CARE CLINICAL ROTATION FOR INTERNAL MEDICINE RESIDENTS: CURRICULUM AND EFFECTS ON READMISSIONS OF A MILESTONES-BASED Asaad Nakhle; Rimma Polevoy; George Samuel; John Veljanovski; Vinay Shah; David E. Willens. Henry Ford Hospital, Detroit, MI. (Tracking ID #2199224)

NEEDS AND OBJECTIVES: The American College of Graduate Medical Education (ACGME) has mandated new resident evaluations based on developmental milestones. The ACGME's Clinical Learning Environment Review (CLER) has increased attention on education on transitions in care. We developed the Transition Of Care (TOC) clinic, a 1-month ambulatory resident rotation with objectives of (1) Improving resident medical knowledge and clinical care of complex patients; (2) Improving resident skills in transition of care medicine; and (3) Providing earlier hospital follow up and higher intensity ambulatory care for patients at high risk of readmission. The evaluation of residents utilizes the milestones relating to team-based care, cost-consciousness, transition from inpatient to outpatient care, and communication to ensure care continuity. In this abstract, we describe the curriculum and the results of a retrospective cohort analysis examining the effects of the TOC clinic on hospital readmission and ED utilization.

SETTING AND PARTICIPANTS: This study's setting was an urban academic internal medicine (IM) teaching clinic in Detroit, Michigan. Providers include 90 residents, 18 faculty physicians, a psychologist, a pharmacist, and two midlevel providers.

DESCRIPTION: Patients were referred by inpatient general or specialty medicine teams when providers felt the patient was at high risk of readmission due to social or medical complexity. We compared patients seen in the TOC clinic to those seen in usual care for hospital follow up. Office visits in the TOC clinic were 60 min long with a senior resident and preceptor with special interest in complex, transitional care medicine. Clinical pharmacists were available, patients were contacted with test results on the same day, and psychosocial issues were addressed with the help of behavioral health psychologists. More intense interventions, such as intravenous fluids or diuresis, nebulizer treatments, and reduction of polypharmacy were also regularly done in the TOC clinic. These resources were also available in usual care, but more time was available for their use in the TOC clinic. Usual care consisted of a standard 30 min office visit and could be with a faculty physician alone or with a supervised resident physician in the same clinic. Other teaching strategies included didactic and discussion sessions led by the faculty preceptor, and online modules on readmissions, cost-conscious care, community resources, insurance, and billing. To increase collaboration skills, residents communicated directly with patients' primary care providers, and they often cared for patients with the pharmacist and/or health psychologist. Readmission within 30 days of discharge to Henry Ford Health System was the primary clinical outcome. Multivariate analysis adjusted for confounders, including Charlson comorbidity index, patient sex, age, and time from discharge to follow up. Patients were seen between December 2013 and May 2014. Data was extracted from the electronic medical record.

EVALUATION: Each resident was evaluated by the preceptor using milestone-based online assessment, which was developed by the preceptor with assistance from a faculty physician trained in milestone-based evaluation. Resident outcome analysis is in progress. 456 patients and 1632 patients were seen in the TOC clinic and usual care clinics for hospital follow up, respectively. TOC clinic patients were significantly more likely to be readmitted within 30 days when compared to the non-TOC patients (15.1 % versus 11.3 %, $P=0.028$) and had a significantly lower mean number of days from discharge to visit (7.8 versus 10.1, $P<0.001$). However, after accounting for the other study covariates, TOC patients were not significantly more likely to be readmitted within 30 days ($P=0.205$).

DISCUSSION / REFLECTION / LESSONS LEARNED: After adjusting for comorbidities and demographics, the TOC clinic did not have a significant effect on the rates of patient readmission. Unadjusted analysis showed increased readmissions in TOC patients. These findings support prior evidence, which showed that no single intervention implemented alone was regularly associated with reduced risk for readmission. Results may underestimate readmissions, since data was limited to our single healthcare system. Qualitative feedback from the TOC preceptor and residents on the milestone-based evaluation was overall positive. The preceptor felt it was easy to map existing rotation activities to ACGME milestones for internal medicine. Residents felt the evaluation clarified the important transition of care skills. Future research on resident knowledge, skills, and attitude outcomes is in process.

ACADEMIC HOSPITALIST ATTITUDES TOWARD TEACHING HUMANISM: A WORKSHOP EVALUATION AND NEEDS ASSESSMENT Mina R. Kang¹; LuAnn Wilkerson²; Michael Soh³. ¹David Geffen School of Medicine at University of California, Los Angeles, Santa Monica, CA; ²David Geffen School of Medicine at University of California, Los Angeles, Los Angeles, CA; ³Graduate School of Education & Information Studies at University of California, Los Angeles, Los Angeles, CA. (Tracking ID #2197009)

NEEDS AND OBJECTIVES: Humanism is fundamental to excellence in patient care and is continuously emphasized by patients, professional accrediting agencies and educational councils for undergraduate and graduate medical education. However, little is known about attitudes surrounding the teaching of humanism in medicine and if, and how, it differs between faculty members that have engaged in humanism specific faculty development vs. those that have not. We attempted to shed light in this domain by assessing faculty attitudes around the practice and teaching of humanism as a means for performing a workshop evaluation as well as a faculty development needs assessment.

SETTING AND PARTICIPANTS: Seven hospitalists received a health-system-wide teaching humanism award since its conception in 2010. Awardees were nominated by colleagues and selected through a faculty peer-review process. All awardees participated in a series of workshops that focused on developing strategies for explicit teaching of humanism at the bedside. Four awardees had completed the workshop series and 2 awardees were currently enrolled in the workshop series.

DESCRIPTION: In this cross-sectional, qualitative study, we conducted semi-structured interviews of 6 hospitalist awardees (4 senior and 2 junior faculty physicians) and 11 matched controls (5 senior and 6 junior faculty hospitalists) and compared their attitudes toward the teaching of humanism. A thematic analysis was performed with second-person, outside-group validation.

EVALUATION: Three major themes were identified: teaching scope, teachability, and overcoming barriers. Significantly more awardees had a broad teaching scope (100 vs. 64 %), perceived humanism as teachable (83 vs. 45 %), and were optimistic about overcoming barriers (100 vs. 55 %) than their matched control counterparts. Subgroup analysis of the control group showed bimodal distribution with senior controls more than junior controls perceiving humanism as teachable (60 vs. 33 %) and demonstrating greater optimism about overcoming barriers (80 vs. 33 %). However, there was no difference in regards to teaching scope between senior and junior control faculty indicating that this aspect of teaching humanism was most affected by the workshop experience. Between the senior and junior awardee subgroups, teaching scope and attitudes toward barriers remained the same with the only difference being the perception of teachability (100 vs. 60 %).

DISCUSSION / REFLECTION / LESSONS LEARNED: Learning to practice and teach medicine with humanism was observed to be a developmental process. Senior control faculty developed favorable attitudes toward teaching humanism solely based on experience over time. However, this growth and maturation was not to the extent of those physicians that participated in the faculty development workshops. Awardees had a greater ability to more broadly identify teachable moments, which was not a skill gained by seniority alone. Additionally, the differences observed among the subgroups further demonstrate the spectrum that our faculty represents along a continuum of development. For example, 2 out of the 6 awardees were junior faculty that had not yet completed the humanism workshop, and the difference in attitudes between these subgroups could demonstrate a growth phase in faculty development. The "stages of change" model can be used to demonstrate the developmental process of learning to practice and teach humanism. The Teaching Humanism at the Bedside Workshop facilitates this progression more efficiently than how faculty would progress on their own with only personal experience over time. As a program evaluation, this study shows there is clear efficacy of the Teaching Humanism at the Bedside Award and Workshop to identify faculty learners open to moving up the stages of change ladder and then helping them to achieve the final stages. As a needs assessment, we learned that it would be important to identify the stage of the faculty learner in order to target learning objectives. This would entail convincing some faculty why this is worth their time—"re-branding" humanism in medicine, raising awareness and creating more opportunities for conversations about humanism, and evaluating the teaching of humanism more consistently.

ACCEPTANCE AND EFFECTIVENESS OF A TELEPHONIC NURSE-LED BASAL INSULIN TITRATION PROGRAM IN AN INTERNAL MEDICINE ACADEMIC PATIENT-CENTERED MEDICAL HOME Benjamin Swanson; Mira Samet; Daryl Sudasena; Andrew Bissonette; David E. Willens; Mona Hassan; Anupama Nair; Sean Drake. Henry Ford Hospital, Detroit, MI. (Tracking ID #2199318)

NEEDS AND OBJECTIVES: Interdisciplinary team based care is an important aspect of healthcare, but in many settings this is a shift from doctor-centered culture. As the healthcare system continues to grow in complexity and national attention focuses more

and more on healthcare costs it is increasingly important for healthcare providers to seek the most effective and efficient methods of delivering care. This requires that physicians in training have a significant exposures to avenues where interdisciplinary teams provide creative solutions to common problems. Uncertainty exists about the acceptability To improve effectiveness of diabetes care in January, 2014 a telephonic nurse-run basal insulin titration protocol was developed and implemented at our urban, academic internal medicine (IM) clinic. Our objectives were to determine the intervention acceptance by providers and patients and to assess the effectiveness on diabetes outcomes.

SETTING AND PARTICIPANTS: This study's setting was an urban academic internal medicine (IM) teaching clinic in Detroit, Michigan. Patients are cared for by 90 residents, 18 faculty physicians, a pharmacist, a health psychologist, advance practice nurse with specialization in diabetes care, and a physician assistant. A registered nurse trained in motivational interviewing and diabetes care carried out the intervention.

DESCRIPTION: Patients were referred to the telephonic nurse diabetes protocol by IM residents or faculty if they were recently diagnosed with diabetes, newly started on insulin, or had poorly controlled blood glucose by hemoglobin A1c (HbA1c) or home glucose monitoring. The registered nurse contacted patients by phone approximately weekly to address diabetes education, barriers to change, and fasting blood glucose (FBG) levels. All patients were on basal insulin (glargine or detemir), which was titrated per protocol until age-specific targeted FBG (<70 years: 80–120 mg/dl; ≥70 years: 100–120 mg/dl) was obtained over several days by patient self-monitoring. Once FBG goal was met, patients were graduated from program and instructed to follow with their primary care team. The resident curriculum consists of four weekly 1-hour small-group sessions led by faculty, the diabetes nurse, and clinic nurse practitioner to improve diabetes medical knowledge and teamwork system based practice. These include patient cases illustrating team processes and feedback on clinic diabetes quality metrics. Online diabetes care knowledge modules are completed by faculty and residents also.

EVALUATION: Four hundred seventy-six patients had A1c values greater than 9.0 %; 155/476 (32.6 %) were referred to the program, and 149 were successfully contacted. 67/149 (44.9 %) patients successfully contacted met goal FBG at a median time from first contact of 48 (IQR 43) days. 24 (16.1 %) patients were still undergoing insulin titration at publication; 38 (15.5 %) were lost to follow up; and 20 (13.4 %) were referred to specialists or followed up outside our healthcare system. A per-protocol evaluation was conducted using pre- and post-intervention HbA1c values assessed near enrollment and approximately 3 months later. These were available at publication for 42 of 67 patients who reached goal, demonstrating a mean reduction in HbA1c of 3.31 % (SD 3.06) ($P<0.001$). Complete data will be available by April, 2015.

DISCUSSION / REFLECTION / LESSONS LEARNED: A teaching clinic-based nurse-led telephone basal insulin titration protocol for type 2 diabetes patients demonstrated good referral rates and rapid time to control of fasting blood glucose. Thirty-three percent of patients with uncontrolled diabetes were referred, representing good acceptance by faculty and residents. Though there is little prior research on time to FBG control by nurse phone intervention, 48 days from contact may be faster than could be achieved in usual care physician office visits. Patients also found the intervention acceptable. Ninety-six percent of those referred engaged with the nurse, possibly because referral was done by the primary care faculty or resident. The per-protocol change in A1c appears to be substantial in patients who achieve FBG goal. A complete population analysis for program efficacy is underway. This study is limited by small sample size, and available post-intervention A1c values may be from a subset of more motivated patients. Future work is underway to compare patient outcomes in this program to those receiving usual office-based care and to determine predictors of acceptability to providers and patients.

AN EDUCATIONAL IBOOK ON HANDHELD CARDIAC ULTRASOUND CASES Charles Nadeau-Routhier; Atul Jaidka; Matthew Church; Amer M. Johri. Queen's University, Kingston, ON, Canada. (Tracking ID #2196868)

NEEDS AND OBJECTIVES: Handheld cardiac ultrasound (HHCU), also known as focused cardiac ultrasound, is emerging as a valuable tool that can easily be integrated into the physical exam at the patient's bedside. In the hands of an experienced user, this compact portable imaging device has been shown to augment the diagnostic accuracy of the conventional cardiac physical exam. The curriculum of most medical schools and residency programs does not typically include dedicated teaching for learners to develop skills in HHCU. We created an interactive learning tool targeted at medical trainees that proposes an approach on how to interpret HHCU views in relation to clinical vignettes. This free resource takes the form of an iBook (a digital book format available on iPad and Mac computers). **Learning objectives:**—Understand and recognize standard handheld cardiac ultrasound (HHCU) views: apical four chamber view, parasternal long axis view, parasternal short axis view, and subcostal view.—Identify the anatomical landmarks of each standard HHCU view.—Provide a qualitative interpretation for each HHCU view in relation to a clinical vignette.—Summarize HHCU findings in a structured manner.—Develop a differential diagnosis using HHCU-derived information.

SETTING AND PARTICIPANTS: Target audience: Medical trainees (senior medical students and non-cardiology residents) with beginning/intermediate knowledge about cardiac ultrasound.

DESCRIPTION: The iBook begins with a tutorial chapter describing standard handheld cardiac ultrasound (HHCU) views and highlighting main anatomical landmarks. The introductory chapter is followed by a series of clinical cases, each of which incorporates the HHCU as part of the physical exam. The reader is then asked questions about the HHCU views such as: labelling cardiac structures, naming the major finding(s), commenting on the severity of the lesion(s), narrowing down the differential diagnosis and prioritizing the immediate next steps in the overall management. These self-assessment questions are followed by a brief discussion about the patient's particular clinical condition. Finally, each case is wrapped up with a suggested HHCU interpretation, a summary of the case, an acknowledgement of the limitations of the HHCU views, and immediate next steps in management.

EVALUATION: With our handheld cardiac ultrasound iBook now published and available for free online (as of December 2014), our objectives in evaluation of this resource are twofold: 1) Assessment of the usefulness of the resource: We have an upcoming session scheduled for senior medical students who have no prior experience with handheld cardiac ultrasound (HHCU). Participants will undergo a pre-test on their knowledge of HHCU, then will read through the tutorial and cases and be able to practice with HHCU devices. A post-test will be administered to assess knowledge development in this training session using our iBook resource. The pre-test and post-test will be in multiple-choice format and will consist of questions related to the learning objectives (see previous section) of our resource. 2) Assessment of the overall reach of the resource: The number of downloads is our measure of this objective. Daily data is available through the iBook online publishing platform.

DISCUSSION / REFLECTION / LESSONS LEARNED: The usefulness of this iBook consists of three key components: 1) Case-based, interactive, user-friendly learning tool: The iBook is designed such that the reader navigates throughout a stimulating, structured and self-directed learning environment. The real-world clinical cases used in the iBook facilitate integration of new knowledge by the learner. 2) Competency-based self-assessments for each clinical case: Within the iBook, self-assessments are used for evaluating the reader's newly acquired knowledge on handheld cardiac ultrasound (HHCU) interpretation. Questions are written in a similar pattern, quizzing first about anatomical landmarks, and then challenging the reader with questions of increasing difficulty. 3) Acknowledgement of the limitations of HHCU: There are two main obstacles facing effective implementation of HHCU in the cardiovascular assessment of a patient: lack of adequate training and lack of experience. This iBook focuses on the former obstacle. The case-based approach to interpreting HHCU views is meant to guide the trainee in appreciating the strengths and limitations of HHCU-derived information. Each clinical case reinforces the global thinking behind the decision-making process in the medical management of the patient. The essential message is that HHCU will augment but not replace a conventional cardiac physical exam.

ONLINE RESOURCE URL (OPTIONAL): Link: <https://itunes.apple.com/ca/book/handheld-cardiac-ultrasound/id950815260?mt=13> iBook: "Handheld Cardiac Ultrasound: Case Series" Published: Dec 11, 2014 (Available on iPad and Mac computers)

BRIDGING THE GAP: A POST HOSPITAL DISCHARGE VISIT CURRICULUM Brielle Spataro^{1,3}; Asher Tulskey²; Diane Comer²; Doris Rubio²; Carla Spagnoletti². ¹UPMC Presbyterian Hospital, Pittsburgh, PA; ²University of Pittsburgh, Pittsburgh, PA; ³VA Pittsburgh Healthcare System, Pittsburgh, PA. (Tracking ID #2193329)

NEEDS AND OBJECTIVES: The Accreditation Council for Graduate Medical Education and the American Board of Internal Medicine identify that internal medicine residents should be able to transition patients efficiently within and across health care delivery system. Medicare created "transitional care management" (TCM) criteria for post-hospital discharge services in the outpatient setting and reimburses at higher levels for these services. The transition of care from the inpatient to outpatient setting is a vulnerable time for patients. Following hospital discharge, patients may experience medical errors, adverse events and are readmitted to the hospital at unacceptable rates. The literature is primarily based on interventions to decrease errors and readmissions from the inpatient side of care. The objectives of this project were to 1) increase resident confidence with and attitudes about effective post-hospital discharge outpatient care and 2) standardize the post hospital discharge follow up visit and documentation in our internal medicine resident clinic.

SETTING AND PARTICIPANTS: A total of 48 PGY1, 2, and 3 internal medicine residents who see outpatients at a large academic center.

DESCRIPTION: We developed a curriculum consisting of a didactic and interactive case-based discussion regarding post discharge outpatient follow-up visits, a handout that highlighted key points, and a visit note template for the electronic medical record. The curriculum was implemented during a pre-clinic conference for all residents at our university-based resident clinic in January 2014. The curriculum was modeled after a

checklist for post-hospital discharge visits published by the California HealthCare Foundation and consistent with the Medicare requirements for a TCM visit. Key principles included review of the hospital course (including tests and studies), medication reconciliation, home care services, follow-up with consultants, goals of care and patient education. Clinic preceptors were debriefed on the curriculum, emailed a copy of the didactic presentation, and encouraged to attend the pre-clinic conference.

EVALUATION: A survey was given to participants immediately before the pre-clinic conference and 3 months later. The survey assessed resident attitudes and confidence level with providing transitional management care. Attitudes and confidence were assessed using a 5 point Likert-type scale. Attitude items addressed perceived importance and effectiveness of the curriculum. The survey also addressed demographic characteristics of the residents. The three month survey also assessed how often the residents used the template and how frequently they saw patients for the post-hospital discharge visit. Each participant was assigned a unique identifier and survey responses remained confidential. We found statistically significant increases in mean scores in resident attitudes and confidence at 3 months. Average attitude scores increased for importance of the discharge follow up visit from 4.3 to 4.6 ($p < 0.005$) and for seeing a patient within 14 days of hospitalization from 4.2 to 4.6 ($p < 0.05$). All aspects of confidence increased including ability to conduct the visit from 3.8 to 4.4 ($p < 0.0001$), provide adequate documentation from 3.5 to 4.4 ($p < 0.0001$), perform accurate medication reconciliations from 4.3 to 4.7 ($p < 0.005$), reduce hospital readmissions from 3.1 to 3.7 ($p < 0.005$), and reduce medical errors from 3.4 to 4.1 ($p < 0.0001$) in their clinic patients. On the 3 month follow up survey residents indicated they liked the template and 71 % of them had used it at some point since its introduction with 63 % using it at least half of the time. To evaluate whether residents used information taught in actual practice, a checklist, adapted from the California Healthcare Foundation criteria, will be used to grade outpatient documentation for post-hospital discharge visits for 6 months prior and 6 months after curricular implementation. Chart review for this portion of the project is currently underway.

DISCUSSION / REFLECTION / LESSONS LEARNED: We developed a curriculum to teach residents how to conduct a thorough post-hospital discharge visit with their outpatients, and provided them with a template to ensure adequate documentation of topics covered. Residents' confidence and attitudes towards providing TCM services improved. Project evaluation is ongoing to determine whether documentation improved in response to the curriculum. Other programs may benefit from a similar curricular effort in order to increase awareness of the unique aspects of the post-hospital discharge visit and ensure adequate documentation for these visits in order to meet TCM criteria for Medicare reimbursement. More research is needed to see if this training translates to clinical end points including decreased rates of medical errors and re-hospitalization.

BST MODE (BITE-SIZED TEACHING MODE): AN INNOVATIVE APPROACH TO MAXIMIZING RESIDENTS' EDUCATIONAL EFFICIENCY THROUGH A FACULTY-COACHED PEER TEACHING EXERCISE Jennifer O. Spicer²; Golub Lucas²; Kimberly D. Manning¹. ¹Emory University, Atlanta, GA; ²Emory University School of Medicine, Decatur, GA. (Tracking ID #2197614)

NEEDS AND OBJECTIVES: Attendance at internal medicine residency conferences has been shown to correlate with standardized examination scores, but duty hour restrictions continue to challenge residents balancing educational needs with patient care responsibilities. Shorter lecture length has been associated with improved learner satisfaction and knowledge retention, yet the standard hour-long lecture format prevails as the primary mode of didactics. We developed a new educational conference format of resident-taught "bite-sized" lectures with three principle aims: increase learners' satisfaction with and attendance at educational conferences; improve content delivery to encourage learners to pay attention to the entire lecture; and provide residents with the opportunity to develop their teaching skills.

SETTING AND PARTICIPANTS: At our institution, most formal didactic sessions for internal medicine residents consist of a 1-hour lecture at lunchtime each day. The attendance of medical students, interns, and residents is encouraged but not required. This bite sized teaching (B.S.T.) conference was a new educational initiative that replaced one lunchtime lecture each month. Emails were sent out to all internal medicine medical students, interns, residents, and faculty members rotating at the hospital informing them of the new conference. Recruitment emails were also sent to all interns and residents in the internal medicine program looking for volunteers interested in teaching the sessions.

DESCRIPTION: Five residents were selected for each conference, and each resident was instructed to prepare an engaging and high-yield 8-minute lecture focused on the subspecialty theme chosen for that date. A faculty mentor was assigned to each resident to aid with content selection, innovative use of audiovisual materials, and lecture delivery with observation and feedback. Following each conference, an electronic survey was sent to all attendees to assess: 1) satisfaction with the conference format, 2) effectiveness of the conference format, and 3) interest in attending similar conferences. A survey was also sent to the resident teachers to determine if preparing for this conference: 1) increased the

residents' ability to prepare an engaging lecture, 2) developed the residents' public speaking skills, and 3) improved the residents' confidence in teaching.

EVALUATION: Evaluation is ongoing, but audience survey responses have been collected following two of these conferences. Sixty-two individuals responded to the survey: 13 faculty members, 12 PGY-3 s, 9 PGY-2 s, 25 PGY-1 s, and 2 medical students. Respondents were satisfied with the teaching format of multiple short lectures (average rating 4.6 on a 5-point Likert scale) and preferred this format to the standard 1-hour lecture (average rating 4.3). Attendees felt that the shorter length of the lectures helped individuals pay attention (92 % agreed, 6 % neutral, 2 % disagreed), and almost everyone enjoyed having residents give the lectures (97 % agreed, 3 % neutral). One hundred percent of respondents said that they would be interested in attending this type of conference again. Comments included "best didactics of the year", "I usually struggle to stay awake...not for this", "shorter format was captivating and I learned a ton", and "I love this conference...so far I've driven from other hospitals twice to attend!". Seven of the nine residents who participated as teachers responded to the survey sent to them. All respondents strongly agreed that this experience: 1) increased their ability to great an engaging lecture (average rating 4.7 on a 5-point Likert scale), 2) developed their public speaking skills (average rating 4.6), and 3) improved their confidence in their teaching ability (average rating 5.0).

DISCUSSION / REFLECTION / LESSONS LEARNED: Innovative teaching formats are critical in graduate medical education given the increasing restraints on residents' educational time. Although online curricula have grown, these educational formats lack the personal engagement of lectures. Our bite-sized, high-yield lectures preserve the interaction of in-person education while forcing teachers to present topics in an efficient and memorable manner. Based on the feedback that we have obtained, learners appreciate the brevity and creativity of these lectures and their shorter format. By using residents as teachers, this conference format has the added benefit of providing residents with the opportunity to grow as educators and develop their public speaking skills. Pairing a faculty mentor with each resident ensures that the residents deliver high-quality lectures. Through this bite-sized teaching conference, we have introduced a novel conference format that provides engaging lectures in a time-efficient manner allowing five topics to be presented within 40 min.

CLINICAL REASONING CURRICULUM: TEACHING CLINICAL REASONING PRINCIPLES AS PART OF RESIDENCY EDUCATION Erin J. Goss¹; Shwetha Iyer¹; James Grigg²; Darlene LeFrancois¹; Gerald Paccione¹. ¹Montefiore Medical Center, Bronx, NY; ²University of Florida, Gainesville, FL. (Tracking ID #2199234)

NEEDS AND OBJECTIVES: Diagnostic errors are common, accounting for 40–80,000 deaths per year and an even higher morbidity in medical practice. Medical errors encountered in the primary care setting include errors in data gathering, interpretation of clinical, laboratory, and radiologic data, as well as the inappropriate use of heuristics (mental shortcuts). Medical students and residents are increasingly taught to reflect on their own clinical reasoning to potentially reduce sources of error. Over the past 2 years, we attempted to fill this gap in our own residency program by creating and implementing a clinical reasoning curriculum at our institution. We evaluated this course by assessing residents' knowledge and attitudes towards their competence of recognizing and applying clinical reasoning skills.

SETTING AND PARTICIPANTS: Our target audience was PGY2 residents in the Internal Medicine Residency Program at Montefiore Medical Center, Bronx, New York. Out of 75 residents, 25 opted to take the curriculum from December 2013 through December 2014.

DESCRIPTION: The Clinical Reasoning Curriculum is an elective 8-part seminar series offered to second year residents during an ambulatory rotation. The curriculum was initially created with input of five key faculty members following a thorough review of existing medical literature. It was devised to focus on key themes related to clinical reasoning and cognitive errors. Key themes include: Introduction to clinical reasoning theory, Use and interpretation of diagnostic tests, Causal reasoning, Bayesian analysis, Diagnostic verification, Cognitive errors, and Therapeutic decision-making. Each seminar focuses on 1–2 key themes and incorporates several educational strategies including 1) team based learning, 2) clinical vignettes highlighting key themes, 3) discussion of diagnostic dilemmas identified from participants' ambulatory clinic, and 4) journal clubs focused on medical education literature and clinical prediction rules. Seminars are facilitated by two core faculty members. Residents completed a 15-item questionnaire to self-assess their competence in certain clinical reasoning domains. Questions were scored on a 4 point Likert scale from 1=Not at all capable to 4=very capable. Survey scores before and after participation in the curriculum were compared using chi square analysis. In 2014, residents also completed a 9-item multiple-choice questionnaire to assess their knowledge on clinical reasoning topics. Scores on the knowledge assessment were compared using the Wilcoxon test.

EVALUATION: The curriculum has been offered 3 times in the past 2 years to approximately 25 residents. Seventeen residents completed the pre and post-test surveys (68 %).

Resident self-reported competency following completion of the elective increased significantly in 12 of 15 domains ($p < 0.05$ for each). Specific domains with the greatest increase in self-reported competency include Applying sensitivity and specificity to history and physical exam findings, Applying Bayesian analysis to clinical scenarios, and Identifying errors in diagnostic verification. Less than 40 % of residents reported being “somewhat” or “very capable” in these 3 domains before the course, compared to greater than 80 % afterward. Resident scores on the knowledge assessment improved from 77.8 % \pm 7 to 96.2 % \pm 5.6 following the elective ($p = 0.002$).

DISCUSSION / REFLECTION / LESSONS LEARNED: Participation in this clinical reasoning curriculum improved resident confidence in recognizing and performing several clinical reasoning skills. Our evaluation supports the literature that residents can be taught to recognize clinical reasoning processes. Residents reported the greatest increase in their ability to applying quantitative reasoning strategies (like Bayesian analysis) to clinical scenarios. This may be due to less familiarity at baseline with this type of reasoning strategy. Months later, several residents commented that they felt more able to reflect on their own reasoning process and recognize potential errors. Further evaluation is needed to investigate whether course participation is associated with longer-term changes in attitudes as well as application of clinical reasoning skills during precepting and patient care.

COMPLEX CASE CONFERENCE: MULTI-DISCIPLINARY ROUNDS IN AN OUTPATIENT RESIDENCY CLINIC Brinton Clark¹; Mari Kai². ¹Providence Portland Medical Center, Portland, OR; ²providence portland medical center, Portland, OR. (Tracking ID #2199505)

NEEDS AND OBJECTIVES: There is increasing emphasis placed on multi-disciplinary care teams within the patient-centered medical home model (PCMH). Teaching resident physicians to be successful leaders in PCMH settings is an important dimension of their training. In addition, residents must learn to successfully manage their most complex patients by optimally using multi-disciplinary team members in care. Many residents have complex patients in their residency continuity clinic. Many of these patients have both complicated medical histories as well as complex psychosocial factors. Our experience is that residents often feel overwhelmed in caring for this population and do not always fully utilize the multi-disciplinary resources available in our clinic setting. Our objective was to develop a complex care conference, where residents can present their most complicated patients to a multi-disciplinary team. The goal was for the resident to hear multiple perspectives and advice from different team members. The team would help the resident develop a comprehensive plan to tackle complex problems. The ultimate goal is to deliver the highest quality, patient-centered care for complex patients and for residents to learn how care can be optimized by working with a multi-disciplinary team. By giving the residents time to review patients in depth, we also hoped they would have a better grasp of their complicated patients.

SETTING AND PARTICIPANTS: Providence Portland Medical Center is a community-based residency program with 30 internal medicine residents and 10 general medicine faculty. We have a resident-faculty internal medicine clinic practice officially designated as a PCMH. Our multi-disciplinary team includes a social worker/case manager, clinical pharmacist, behaviorist/psychologist, psychiatrist, community outreach worker, nurse, and medical assistants.

DESCRIPTION: The Complex Case Conference (CCC) was implemented in our program 18 months ago. Each week, the PGY1 or PGY2 resident on ambulatory block rotation reviews one of their most complex patients to present for CCC. The resident presents the case in structured format to the multi-disciplinary team including the team general medicine faculty. The resident raises specific questions and issues that they would like input on to optimize care for their patient. The resident leads the multi-disciplinary team in a 1 h discussion of the patient and together they come up with strategies for engaging the patient in care and improving their health outcomes. Discussions focus both on complex medical problems and psychosocial issues affecting care. Resident physician documents the care plan in the patient's chart in a structured format. After the CCC, team faculty and resident meet to review successes and areas for growth in leading the conference. The faculty member completes a direct observation evaluation of the resident which incorporates ACGME milestones (PC2, SBP1, PBLI3, PROF1, PROF3, ICS2).

EVALUATION: Since its inception, approximately 60 Complex Case Conferences have taken place with nearly 250 milestones captured. Feedback on CCC is sought during the end-of-rotation debriefing by the clinic medical director. CCC has been a highly rated and valued experience. Residents state the conference has been a great opportunity to improve care for challenging patients, and increases their ability to engage the multi-disciplinary team not only for the patients presented at CCC but also for other patients. We will present qualitative feedback from residents.

DISCUSSION / REFLECTION / LESSONS LEARNED: Although internal medicine residents often participate in multi-disciplinary rounds in the hospital setting, we feel our Complex Case Conference represents a unique model for resident engagement in multi-

disciplinary team rounds in the ambulatory setting. Our CCC helps to improve multi-disciplinary communication within a PCMH, teaches residents leadership skills, and enhances team-based care for patients with complex medical and psychosocial needs. Evaluation of resident's ability to lead CCC allows faculty to capture resident skills in communicating effectively with a multi-disciplinary. As our CCC has been highly successful and achieved the goals we set out to accomplish, we plan to continue our innovation.

DELIVERING PRIMARY CARE BEHIND BARS: DEVELOPING A STUDENT-FACULTY COLLABORATIVE CLINIC IN A BOSTON JAIL Kimberly Sue⁴; Samuel L. Dickman⁴; Manjinder Kandola⁴; Stephanie Choi⁴; Nora Abo-Sido⁴; Meissa M. Jones³; Jacquelyn Moss¹; Marya J. Cohen². ¹Harvard Medical School/MGH-Chelsea, Boston, MA; ²MGH, Boston, MA; ³Massachusetts General Hospital, Boston, MA; ⁴Harvard Medical School, Boston, MA. (Tracking ID #2191972)

NEEDS AND OBJECTIVES: Incarcerated patients or patients with a history of incarceration face numerous structural and health disparities that predispose them to increased morbidity and mortality. Our model allows medical students to simultaneously address these neglected health issues with a structural intervention while also learning about important social determinants of health and the practice of social medicine in a real world setting. Objectives: 1) To provide health care and education specifically addressing the needs of incarcerated patients, and to improve the continuity of care post-release. 2) To establish a student-faculty clinic to better present health disparities and social medicine to medical and nurse practitioner students in a real-world setting.

SETTING AND PARTICIPANTS: The Nashua Street Jail is a men's facility where inmates stay for a period ranging from several days to 2 years. The majority of inmates are pre-trial detainees or those currently engaged in court processes. The clinic is staffed by approximately 30 students and takes place at the jail two evenings a month. The students see patients in teams of two while precepted by an attending physician from a local community health clinic, Massachusetts General Hospital-Chelsea, or by a resident preceptor. Furthermore, students not providing direct patient care engage in inmate health education on the housing units as well as conduct research. The night generally concludes with a brief educational session led by the resident preceptor relating to a health condition observed during the clinic.

DESCRIPTION: This clinic focuses on providing compassionate, evidence-based healthcare to inmates with a specific focus on the transition back to the community. It is a unique, collaborative clinic between Harvard Medical School students, MGH-Institute for Health Professionals students, the Nashua Street Jail and the Stoeckle Center for Primary Care Innovation. The clinic complements a non-academic private clinical service that provides the majority of care for inmates. In the pilot semester this student-faculty clinic involved approximately 30 students. Many of these students saw patients alongside the residents and the attending physician. Students on the inmate education team delivered workshops to inmates in a larger-group setting on topics such as nutrition and Hepatitis C virus. In addition, students on the research team formulated a project centered on diabetes management in the jail which will commence in the spring semester.

EVALUATION: Students are participating in qualitative assessments of their experience in this clinical environment, including measurements on interest/motivation to practice primary care, interest in health disparities/social medicine, as well as their subjective experiences of clinical skills and history-taking. There are further plans for qualitative assessments of the clinic by patient-inmates and resident preceptors in the upcoming semester.

DISCUSSION / REFLECTION / LESSONS LEARNED: 1) There are currently few existing partnerships between prisons or jails and primary care training programs (including medical schools). However, such programs undoubtedly present valuable opportunities. This clinic demonstrates the potential for increased transparency of prison-based healthcare through providing greater continuity of care pre and post-release of inmates. 2) With careful planning and appropriate learning methods, such a program can be an effective teaching tool for medical and nursing students to learn about the chronic and mental illnesses that are common in the prison population. Consequently, this program allows students to gain exposure to the structures and systems that directly contribute to health disparities affecting millions of Americans.

DEVELOPING A LEARNER CENTERED MULTIMODAL AMBULATORY TEACHING PROGRAM FOR SENIOR HOUSESTAFF: THREE-YEAR FOLLOW-UP Sudha Dubey²; Darlene LeFrancois³; Sheira Schlair¹. ¹Albert Einstein College of Medicine/Montefiore Medical Center, Bronx, NY; ²Mount Sinai Beth Israel, New York, NY; ³Montefiore Medical Center, Bronx, NY. (Tracking ID #2199560)

NEEDS AND OBJECTIVES: While there are ample observed teaching opportunities for residents on inpatient rotations, academic training programs rarely create formal

teaching opportunities for residents in the ambulatory setting. Our objective was to create a curriculum and formalized ambulatory teaching program to coach senior residents.

SETTING AND PARTICIPANTS: Senior internal medicine residents, interns and fourth year ambulatory rotation medical students, and attending supervisors at three ambulatory internal medicine clinic sites at Montefiore Medical Center (Bronx, NY) from 2012 to 2014.

DESCRIPTION: In 2012 when senior residents identified an interest in obtaining ambulatory teaching skill experience, a “resident as preceptor” elective was created. In this pilot, one faculty member led a 2-hour learner-centered curriculum focused on effective ambulatory teaching strategies, adult learning theory, the 1-minute preceptor model and RIME scheme. Sentinel readings were provided. Residents who opted in were then assigned to precept medical students for 1–2 sessions each supervised by an attending physician instructed to silently observe the session and interject only if they disagreed with management. Formal feedback was obtained by surveys of program participants. Starting in 2013, this training model was integrated into a new residency-wide “Resident as Teacher” PGY-3 elective, which focuses on teaching skills in multiple venues but continues to incorporate resident ambulatory teaching as a core component. The elective now includes three separate ambulatory clinic sites and a larger group of resident preceptors and attending observers, with interns as learners.

EVALUATION: Resident preceptors, learners, and supervising attendings were surveyed anonymously and voluntarily at the conclusion of each observed precepting session in order to promote systematic real-time feedback. Survey items targeted precepting goals and learner satisfaction. All questions were scored on a 1–4 Likert scale (1: strongly agree, 2: agree, 3: disagree, 4: strongly disagree) or open-ended qualitative format. Precepting goals mirrored the curricular intervention content about the one minute preceptor model, namely to what degree the resident preceptor: 1. Elicited clinical reasoning and independent assessment and plan; 2. Taught general principles; 3. Delivered behaviorally specific positive feedback; 4. Corrected errors with specific feedback; and 5. Completed the encounter efficiently. To date, 46 attending surveys, 40 learner surveys, and 45 resident preceptor surveys have been collected. Qualitative and quantitative data reveal an overwhelmingly positive assessment of achieving precepting and programmatic goals. Ninety-seven percent of attendings, 97 % of learners, and 93 % of resident preceptors agreed or strongly agreed that the learner’s clinical reasoning was effectively elicited. Ninety-five percent of attendings, 97 % of learners, and 93 % of resident preceptors agreed or strongly agreed that residents taught general principles. Ninety-one percent of attendings, 92 % of learners, and 77 % of resident preceptors agreed or strongly agreed that the encounter was completed in a timely way. Over 70 % of residents each year indicated that they felt comfortable in their role as preceptor and over 80 % indicated that the experience added value to their residency training. Qualitative survey comments from learners suggested increased focus on teaching of physical exam skills by resident preceptors. Further analysis will be performed with final data collection in spring 2015 using paired t-tests in order to examine for associations between resident, attending and learner assessments.

DISCUSSION / REFLECTION / LESSONS LEARNED: Three-year pooled data analysis suggests that a self-selected group of senior residents were quite effective at applying lessons learned about adult learning theory and learner assessment in observed precepting encounters. On preliminary analysis, it appeared that time management was one of the greatest challenges, which may suggest that residents require more experience to promote efficiency. Residents were their own harshest critics, followed by attendings and lastly by learners who give the most positive feedback. This is akin to previous literature suggesting that physicians may be poor self-assessors. Learners indicate an overall very positive experience, which may be partially due to comfort and decreased stress in working with senior residents who they consider peers rather than with supervising attendings. Overall learners and residents consistently rank this elective as an educationally valuable experience and it has demonstrated value in expanding educational and assessment opportunities to the ambulatory setting. Future work is warranted to develop more robust program and learner assessment methods and to integrate peer assessment methods and observation training into the curriculum.

DEVELOPING AND EVALUATING THE ROUNDS TABLE PODCAST FOR CONTINUING MEDICAL EDUCATION IN GENERAL ADULT MEDICINE Amol Verma¹; Hareem Naveed²; Fahad Razak^{1, 3}. ¹University of Toronto, Oakville, ON, Canada; ²University of Toronto, Toronto, ON, Canada; ³St. Michael’s Hospital, Toronto, ON, Canada. (Tracking ID #2199508)

NEEDS AND OBJECTIVES: The *Rounds Table* (TRT) is a new free weekly podcast devoted to general adult medicine that is approved for Category 1 Continuing Medical Education (CME) credits in the United States and Canada. The needs assessment included an environmental scan, literature review, and consultation with practicing clinicians, which revealed: 1) It is difficult for clinicians to stay current with academic literature. 2) Web-based educational materials such as podcasts can facilitate CME. 3) Podcasts are typically produced by academic journals or specialty groups, thus relatively few are

devoted to general adult medicine. 4) Many existing medical podcasts are difficult to listen to because they present dry academic content without analysis or humor. 5) Evaluations of podcasts have occurred chiefly in traditional undergraduate medical education settings. Podcasts in CME have received relatively little study. The objectives of TRT are to: 1) Develop a podcast that can be sustainably produced by busy clinicians. 2) Offer rigorous analysis about new research in adult medicine. 3) Target a diverse audience of generalist clinicians. 4) Provide content that is entertaining and easy to listen to.

SETTING AND PARTICIPANTS: TRT is hosted by a team of early-career academic clinicians. The following strategies allow regular high-quality content production despite busy schedules: Interns manage the sound editing, uploading and social media. Every episode is hosted by two clinicians from a rotating team who each present one study. Thus, each host must learn only one study in detail every few weeks. TRT is aimed at a general audience of clinicians and trainees who are interested in adult medicine. Episodes are hosted by the non-profit health affairs website, *Healthy Debate*. Listeners can access the podcast online or through iTunes.

DESCRIPTION: TRT episodes are 20 to 30 min long and present new medical studies that are selected using the following criteria: 1) Likely to have significant clinical impact. 2) Relevant to generalist clinicians in adult medicine. 3) Collectively represent diverse topics. TRT has been developed in accordance with pedagogical principles. It uses a conversational style, provides *priming* and *pre-training* to allow listeners to process information, highlights essential material, and eliminates extraneous information.

EVALUATION: A mixed-methods evaluation of TRT is underway. Patterns of use are being studied using *Blubrry* podcast analytics. Listener perspectives are being assessed using CME evaluation forms and a listener survey. Since its launch in March 2014, 32 new episodes of TRT have been published online. Web analytic data has been collected since October 2014. The podcast is downloaded approximately 4000 times per month. Canadian and American listeners account for 55 and 38 % of downloads, respectively, and there are listeners in 37 countries around the world. Older episodes continue to be downloaded long after their release. For example, episodes posted in March were downloaded nearly 500 times between October and December. The majority of episodes (69 %) were downloaded directly to mobile devices. In total, 38 CME feedback forms were submitted. Of these, 35 (92 %) indicated that the podcast met the stated learning objectives. All 38 responses (100 %) stated that they learned something new and felt the material was of clinical importance, 23 (61 %) noted that their practice would be improved, and 28 (74 %) were motivated to learn more. A web-based survey to solicit listener perceptions on style, content, and impact was launched on November 26, 2014. Complete results will be available for presentation by April 2015. A preliminary thematic analysis of 14 responses suggests that listeners value the podcast’s conversational tone, short episode length, and portability.

DISCUSSION / REFLECTION / LESSONS LEARNED: TRT uses an innovative platform to help clinicians stay abreast of research in adult medicine. The podcast is novel because it provides analysis and context about new research, draws from a variety of scientific journals, and specifically targets a general audience. The format permits busy academic clinicians to produce a regular high-quality podcast and could be replicated. The TRT evaluation is ongoing. An online survey will provide further information about listener perceptions and may help answer questions about why relatively few have redeemed CME credits. TRT listeners predominantly uses mobile devices, which differs from podcasts in traditional medical education where students prefer to listen on a desktop computer without distractions. Episodes continue to be downloaded long after they are published, suggesting that people listen to the podcast asynchronously, not according to its weekly schedule. These findings suggest that TRT listeners value portability and flexibility. Tens of thousands of downloads and a global audience in the first year of production suggests that TRT is widely appealing and highlights the potential of podcasts in CME.

ONLINE RESOURCE URL (OPTIONAL): <http://healthydebate.ca/about-us/the-rounds-table>

DEVELOPING FACULTY SKILLS IN VETERAN-CENTERED CARE: UNDERSTANDING WHERE SOLDIERS REALLY COME FROM Monica L. Lypson¹; Paula Ross¹; Divy Ravindranath MD, MS². ¹University of Michigan, Ann Arbor, MI; ²VA Palo Alto Healthcare System, Palo Alto, CA. (Tracking ID #2189755)

NEEDS AND OBJECTIVES: Faculty development is one strategy for answering the call to improve the care of our nations’ military personnel. Within the medical education context, faculty development is critical for ensuring trainees receive proper education, effective feedback, and witness appropriately role-modeled behavior. Trainees commonly learn to care for military patients through rotations at affiliated Veterans Affairs (VA) hospitals, where their cultural competence develops via modeled physician behavior, teaching and direct patient care. In 2013, over 20,000 medical students and 40,000 residents received their medical training at a VA Health Center. As such, it is essential that faculty are prepared to educate their trainees to care for veteran patients, regardless of

location (e.g., civilian or VA). We developed a multi-stage faculty development workshop for practicing clinicians using an award-winning documentary *Where Soldiers Come From*® as well as other active learning techniques focusing on the invisible wounds of war, primarily Traumatic Brain Injury (TBI) and Post-Traumatic Stress Disorder (PTSD).

SETTING AND PARTICIPANTS: The 90-min faculty development workshop has been conducted at three separate locations (two VA centers and one national conference) with 46 health care professionals. The 34 participants who completed the anonymous workshop evaluations included 27 physicians, 3 nurses, and 1 psychologist (6 participants did not list their role), 31 indicated they practiced in a VA Health Center.

DESCRIPTION: This active-learning workshop guided faculty through a series of activities to develop their skills in the delivery of veteran-centered care. Upon viewing scenes from the award-winning documentary *Where Soldiers Come From*® participants engaged in semi-structured discussions as well as small group active-learning exercises, such as paired and group discussions, and reflective writing. Scenes from the documentary were used as the basis for faculty to explore their own personal and professional experiences and identities. Faculty members were also guided in activities to help them develop their teaching skills and identify strategies train learners at their home institution on veteran-centered care.

EVALUATION: In this workshop, participants: Acknowledged their personal assumptions of veterans Identified subtle symptoms for patients with PTSD and TBI Recognized potential barriers patients face to receiving medical care Recommended strategies patients can use to circumvent barriers to care Discussed changes they would make in their approach to caring for patients with PTSD and TBI The evaluation results indicated that 78 % of participants indicated that the activity changed their knowledge/attitudes/skills, 59 % stated they had a better understanding of how to develop a care plan for veterans, 65 % of participants stated they gained a better understanding of how to prepare for issues around the returning veterans. Even with the majority of participants hailing from a VA Center, 97 % indicated that the scenes from the documentary helped them to reflect on their own attitudes toward veterans.

DISCUSSION / REFLECTION / LESSONS LEARNED: The delivery of veteran-centered care has remained elusive at all levels of medical training, thus training faculty in this area is an important step in developing skills and knowledge related to military and veteran culture and facilitating better care to the surge of over 2.6 million returning military personnel.

ONLINE RESOURCE URL (OPTIONAL): The materials for this workshop are available on MedEdPORTAL Publications: <https://www.mededportal.org/publication/9818>

DEVELOPING QUALITY IMPROVEMENT LEADERS: A PILOT CURRICULUM FOR INTERNAL MEDICINE RESIDENTS Rachel Hathaway; Maren Batalden; Priyank Jain. Cambridge Health Alliance, Cambridge, MA. (Tracking ID #2192650)

NEEDS AND OBJECTIVES: The ACGME has identified competency in leadership and quality improvement as a requirement for Internal Medicine residents. In order to address this need, we have expanded our curriculum from a didactic series to now include substantive engagement in quality improvement (QI) initiatives. This initiative embeds QI work within the existing structure of resident ambulatory continuity clinic sites. We have developed a pilot longitudinal QI curriculum for our Internal Medicine training program with the following learning objectives. 1) Residents will have increased awareness of quality and safety issues during clinical experiences, 2) residents will learn how to identify opportunities for improvement of care, 3) residents will learn principles and methods of quality improvement, and 4) residents will execute a longitudinal quality improvement project in the ambulatory setting.

SETTING AND PARTICIPANTS: The Internal Medicine residency program at Cambridge Health Alliance (CHA) is an academic, community based primary care training program, with a total of 24 trainees. Resident schedules are organized in a "2+4" immersion schedule, where they participate in 2 weeks of ambulatory rotations alternating with 4 weeks of other experiences (inpatient wards, ICU, etc.). Eight residents across three training years rotate with each other on ambulatory rotations, and come together every 6 weeks throughout the academic year, facilitating a planned longitudinal curriculum. Residents are supported and mentored by the course director, ambulatory quality directors, and clinic level leadership.

DESCRIPTION: The curriculum is comprised of three longitudinal components. First, residents will complete the Institute for Healthcare Improvement (IHI) Open School Quality Improvement Practicum which serves as a scaffolding for the course using the principles of the flipped classroom. Residents completed the IHI prerequisite courses early in the curriculum in order gain foundational knowledge, thus allowing them to engage in more interactive learning. Second, residents also participate in CHA QI and patient safety didactics. These didactics are six 90 min sessions spaced throughout the year lead by a

faculty expert in QI. The sessions address current quality and patient safety work that is occurring at CHA, as well as broader learning objectives related to quality improvement. Third, the curriculum incorporates experiential learning, as the residents design and execute an ambulatory quality improvement project. They are collaborating with clinic leadership from their primary care clinic to design a project, apply QI tools (i.e. cause and effect diagrams) and then run several PDSA cycles. The data from this project will be collected and reported within our institution, as well as more broadly.

EVALUATION: Residents' knowledge and attitudes will be evaluated via a post-course survey. Project mentors will evaluate resident participation and leadership in QI ambulatory cohort. Residents' RISK report filing will be used to assess identification of patient safety concerns and engaging institutional processes. RISK reports are the institutional system for employees to report patient safety concerns. Data collection is underway and will be available at the time of the National SGIM meeting.

DISCUSSION / REFLECTION / LESSONS LEARNED: We have already learned several lessons from this pilot curriculum. When designing a QI project for residents, the scope and size of the project is critical. By implementing the same initiative in three clinics, it allows for micro level experimentation as well as larger institution-wide effort. Sufficient dedicated curricular time is important for advancing the project. Further, we have found that it is helpful to integrate the project with existing improvement infrastructures. Residents were encouraged to explore ongoing institutional quality work and to develop a project within that in order to engage existing supports and to learn about real-life institutional change that is occurring. This ensured that the residents' project was meaningful while not being too time intensive, as there are many competing educational priorities.

DEVELOPMENT, IMPLEMENTATION, AND ASSESSMENT OF A CURRICULUM FOR INTERNAL MEDICINE RESIDENTS ON ELECTRONIC COMMUNICATION WITH PATIENTS Katherine C. Wrenn; Christy K. Boscardin; Alexandra Ristow; Karen E. Hauer. University of California, San Francisco, San Francisco, CA. (Tracking ID #2194186)

NEEDS AND OBJECTIVES: Physicians are increasingly communicating with patients via email and secure messaging. To ensure safe and effective patient care, there is a need to train residents in how to communicate with patients electronically. However, few residency programs have curricula dedicated to this topic, and tools to assess electronic communication skills are lacking. Thus, our objectives are to: 1) develop and implement a curriculum for internal medicine (IM) residents on electronic communication with patients; 2) develop an assessment tool to evaluate residents' electronic communication skills; and 3) use the tool to assess the effectiveness of the curriculum.

SETTING AND PARTICIPANTS: We developed a curriculum for IM residents at UCSF who have a continuity clinic at the Mt. Zion campus. The clinic uses an electronic health record (Epic Systems, Inc.), with a secure, web-based portal that allows patients to send secure messages to their physicians. We are developing an assessment tool to evaluate residents' electronic communication skills and assess the effectiveness of the curriculum. Our study population for this phase of the project includes 20 PGY-1 residents during the 2014–2015 academic year who participated in the curriculum, and 20 residents who were PGY-1 residents the prior year and did not participate in the curriculum (historical controls).

DESCRIPTION: We created and distributed a targeted needs assessment survey to IM faculty and residents at the clinic during monthly meetings. A literature search and the needs assessment guided curriculum development using the 6-step curriculum development model (Kem). The 1-h curriculum includes a didactic component and case-based learning, with the goals: 1) review guidelines, policies, and expectations related to electronic messaging; 2) prepare residents to communicate electronically with patients in a professional manner; and 3) teach residents to triage messages appropriately and work within an inter-professional team. We piloted the curriculum in spring 2014, and conducted pre- and post- satisfaction surveys. We implemented the curriculum for all PGY-1 residents in fall 2014. Based on guidelines for tool development (Artino 2014), we are developing a tool to evaluate residents' electronic communication skills. Information from a literature review and interviews with expert faculty will define effective electronic communication skills and inform items for a checklist that represent these skills. As part of gathering evidence for content validity, we will consult with expert faculty about tool content and the items' representativeness, clarity, and relevance. We will then revise and pilot test the tool. We will conduct a prospective cohort study investigating if curriculum participants demonstrate better electronic communication skills than non-participants. We will analyze de-identified messages sent during a 1-month period, 2 months after the curriculum, to evaluate sustained effects (intervention residents), and messages from the prior resident class in the same 1-month period 1 year prior (historical controls). Using our tool, raters blinded to study group will score the messages. We will calculate mean scores, mean differences, and 95 % CIs. Our preliminary plan is to conduct unpaired *t*-test

analyses to examine differences between intervention and historical control residents' average scores.

EVALUATION: Of 37 faculty members, 26 received needs assessment surveys during monthly clinic meetings, and of 65 residents, 34 received surveys. The faculty response rate was 85 % (60 % total faculty); the resident response rate was 97 % (51 % total residents). Most (85 %) residents did not have prior training about electronic communication, and 68 % desired training. Among faculty, 100 % agreed such training is important. 26 PGY-1 residents participated in the curriculum in fall 2014; 22 completed pre- and post-surveys. Eighty-six percent agreed/strongly agreed that the curriculum covered topics relevant to their clinical practice. Sixty-four percent agreed/strongly agreed with a statement that they would change the way they respond to patient messages. The percentage of residents who agreed/strongly agreed that they felt comfortable responding to electronic messages increased from 59 to 77 %. We will use the assessment tool we develop to evaluate if participation in the curriculum leads to better electronic communication skills.

DISCUSSION / REFLECTION / LESSONS LEARNED: Most participants felt that the curriculum covered topics relevant to their clinical practice, and that, based on the curriculum, they would change the way they respond to patient messages. Participation increased comfort in responding to messages. We will study if the curriculum improves electronic communication skills. Tools to assess residents' electronic communication skills are lacking, and thus we are creating an assessment tool to serve this need. The instrument may be used not only as a curricular evaluation tool, but also as a tool for assessing competency in communication skills for residents at other institutions.

DOES FLIPPING THE CLASSROOM IMPROVE CLINICAL SKILLS?

Barbara Porter²; mridula naidu³; Sondra Zabar³; Lisa Altshuler³; Margaret Horlick¹.
¹NY Harbor VA Healthcare Center, Brooklyn, NY; ²NYU SOM, New York, NY; ³NYU School of Medicine, New York, NY. (Tracking ID #2200563)

NEEDS AND OBJECTIVES: In a needs assessment of our curriculum we noted knowledge gaps in the musculoskeletal exam and in women's health. In years past, we sought to bridge this gap with OSCE cases on knee pain and prescribing OCPs. Despite this intervention, residents continued to report feeling unprepared in these areas. We therefore sought to bolster the retention of material taught in the OSCE by "flipping the classroom", i.e. providing multimedia educational material to our residents prior to their OSCE session. The objectives of our curricular innovation were that learners would be able to: perform a knee exam, identify pathology, and counsel a patient on next steps; counsel a patient on risks and benefits of oral contraceptive therapy; retain curricular material delivered via different modalities, and use this knowledge to diagnose, counsel, and activate patients.

SETTING AND PARTICIPANTS: Forty-three PGY2 Internal Medicine residents participating in an OSCE.

DESCRIPTION: In prior years, residents were not given any information about cases prior to the OSCE. In 2014, 3–5 days before the OSCE, residents received an email alerting them that their OSCE would include a case of knee pain or contraception counseling, and that they might find it helpful to review either an instructional video or attached reading prior to participating in the case. Before the OSCE, 31 residents were given material on the knee exam, 12 residents were given material on prescribing OCPs. Each OSCE actor was trained in standardized patient portrayal and evaluation. A checklist assessing general communication and case specific skills was completed immediately following each resident's participation. The evaluation tool had response options of not done, partly done and well done, each offering descriptive behavioral anchors to enhance rating reliability.

EVALUATION: In the domains of communication, patient activation, and patient satisfaction, residents who received a video of the knee exam ($n=31$) prior to the OSCE scored no differently than residents who did not ($n=12$) (Communication (0.48 vs 0.51 (t score = -0.43; $p=0.67$), patient activation (0.26 vs 0.33 (t score = -0.66; $p=0.51$)), patient satisfaction (0.37 vs 0.40 (t score = -0.22; $p=0.83$))). Residents who received educational material about oral contraception ($n=12$) scored no differently than residents who did not ($n=23$) in the domains of communication and patient satisfaction, but did score significantly better in patient activation (communication (0.56 vs 0.51 (t score = 0.55; $p=0.58$)), patient activation (0.75 vs 0.48 (t score = 2.06; $p=0.047$)), patient satisfaction (0.54 vs 0.53 (t score = 0.077; $p=0.93$))).

DISCUSSION / REFLECTION / LESSONS LEARNED: We believed that flipping the classroom, i.e. providing education material to a resident before a clinical encounter, would improve our residents' clinical skills and lead to higher patient satisfaction. Our limited study does not support this hypothesis. We postulate that there are advanced clinical skills, such as musculoskeletal exam skills, that improve only with supervision and repeated clinical practice and supervision. In the past, we have seen correlations between clinical skills and patient satisfaction and activation, but this study suggests that asynchronous, independent training may not be the way to boost these clinical and

communication skills. The significant difference in the patient activation score in the oral contraception case weakly suggests that a provider's knowledge about contraception may lead to a more activated patient. It is difficult to draw a conclusion based on the small number of residents who received material prior to the oral contraception case. Flipping the classroom, or asynchronous education, has been studied in other educational venues, including undergraduate medical education, but there is very limited evidence in the literature of its value in graduate medical education. We intend to continue this study to learn what curricular material is best suited for this venue in order to have measurable impact on clinical skills.

DYAD TEAMS: INTERPROFESSIONAL COLLABORATION AND LEARNING IN THE AMBULATORY SETTING

Laura Clementz²; Mary Dolansky⁴; Renee H. Lawrence¹; Anne Rusterholtz⁵; Simran Singh⁵; Alli Heilman⁵; Mamta K. Singh^{2, 5}.
¹Cleveland VAMC, Cleveland, OH; ²Case Western Reserve University, Cleveland, OH; ³Cleveland VA Medical Center, Cleveland, OH; ⁴Louis Stokes VA, Cleveland, OH; ⁵Louis Stokes VA Medical Center, Cleveland, OH. (Tracking ID #2198273)

NEEDS AND OBJECTIVES: Interprofessional collaboration is not just about "learning to work together, it is about working to learn together" (Howkins, 2012). Current healthcare professional education models do not have many venues where interprofessional learning takes place side by side thus physician trainees and nurse practitioner (NP) students are ill-prepared to practice together after graduation. Additionally, teaching in ambulatory settings is still faculty driven and "resident teaching residents" still thought to be an inpatient activity. Current health care educational models need to be redesigned so more venues allow for "working to learn together."

SETTING AND PARTICIPANTS: In our VA Center of Excellence in Primary Care Education – Transforming Outpatient Care (TOPC CoE), we combine MD Residency and NP Student training and address interprofessional collaboration through clinical care workplace learning to teach communication, negotiation, delegation and collaboration. The redesign strategy we implemented is a dyad work place learning experience in which MD Residents and NP students work together one half day a week in our primary care clinics.

DESCRIPTION: The goal of the weekly 4 h dyad clinic is to provide care for 4 primary care patients while incorporating ambulatory teaching skills learned during microteaching sessions. These sessions are 5–10 min faculty lead discussion at the outset of the dyad clinic that expand on interprofessional team skills and principles of the RIME (Reporter-Interpreter-Manager-Educator) model (Pangaro, 1999). The educational model promotes reflection and continual learning that is an essential feature for quality outpatient primary care.

EVALUATION: From July 2013 to December 2014, 22 dyad pairs completed a 12 week rotation working together in the primary care clinic. A two part survey evaluation was administered four times a rotation to monitor progress and improve the dyad experience. Of the 22 dyad pairs, 16 completed the evaluations at the beginning and end of a rotation. MD Residents perceived the act of allowing the NP students to develop a diagnostic commitment and treatment plan (average increase of 1.2 on 1–7 scale) with provision of supporting evidence (average increase of 0.96 on 1–7 scale) as the areas of greatest improvement, illustrating increased confidence in communication, negotiating and delegation. The NP Students also showed an increase in these categories but it was lower (average increase of 0.30 and 0.34 respectively). NP students perceived provision of specific performance feedback from MD Residents as the greatest area of improvement (average increase of 0.69 on 1–7 scale), which corresponded with MD Resident self-report of feedback provision to NP students (average increase of 0.91). These results are evidence of increased communication and collaboration among the learners. MD and NP perceptions diverged most in the area of opportunity identification for clinical improvement. NP students reported a lack of improvement on the part of the MD Resident in encouragement and identification of opportunities for clinical improvement (average decrease of 0.2 on a 1–7 scale), whereas MD Residents consistently self-reported improvement in this skill (average increase of 0.92).

DISCUSSION / REFLECTION / LESSONS LEARNED: The dyad work place learning experience has enhanced communication, negotiation, delegation and collaboration among MD Residents and NP Students in the VA TOPC CoE. This was illustrated in increased scores in these areas as well as in ensuring students provided supporting evidence for this decision. Additionally, it was found that the dyad model was an effective method of addressing preceptor shortage within the primary care clinic and should be investigated for translatability to other ambulatory settings. Lessons learned were numerous; however two stand out. First was the aspect of feedback where learners reported low scores, indicating a deficiency in feedback exchange. In the spirit of process improvement, dyad faculty developed a micro teaching session dedicated to providing and receiving feedback among learners. Additionally, faculty remained available to learners for support and guidance in situations where feedback was imperative. Secondly, the divergent perceptions among learners regarding opportunities for clinical improvement and

encouragement are worth noting. NP students and MD residents reported different outcomes and moving forward faculty plan to identify specific experiences and opportunities for learner development which will serve to better understand this gap. Implementing, maintaining and improving the dyad work place learning experience has been a labor intensive process that demands time, effort and dedication of the clinicians and staff involved. However, this approach ensures a high quality educational experience. Moreover, this educational model helps address the preceptor shortage pervasive in many ambulatory clinics.

EMPOWERING ACTION: A RESIDENT-LED CURRICULUM IN PHYSICIAN ADVOCACY Zoe Tseng^{1, 2}; Megha Garg²; Pamela Egan²; Grayson Baird³; Kelly McGarry². ¹Brigham and Women's Hospital, Boston, MA; ²Brown Alpert Medical School, Providence, RI; ³Lifespan, Providence, RI. (Tracking ID #2199178)

NEEDS AND OBJECTIVES: Physician advocacy is becoming increasingly recognized as an important component of medical education. However, few residency programs offer advocacy training, and much of the teaching is about health policy and health systems, with no training for specific skills for physician advocacy such as communicating with media and elected representatives. At Alpert Medical School of Brown University in Providence, Rhode Island, there was no formal physician advocacy training in the Internal Medicine residency program. We designed and implemented a resident-run physician advocacy curriculum for the General Internal Medicine (GIM) residency program.

SETTING AND PARTICIPANTS: Three GIM residents with varied experiences and interest in advocacy initiated the curriculum with support of the GIM residency program director. Starting in 2013, the curriculum was implemented during the ambulatory block month at Rhode Island Hospital for the 10 s year GIM residents. Four cycles of the curriculum have taken place in July and November of the past two years, with approximately five residents participating at a time.

DESCRIPTION: The curriculum is organized into four 90-min sessions facilitated by the curriculum organizers, all of whom are residents. The first session is a discussion surrounding the role of the physician as an advocate. Questions posed during the session include: What is physician advocacy? Do physicians have a duty to advocate and to what extent? How comfortable do you feel with physician advocacy? How can physician advocacy help you take care of your patients? The second and third sessions are dedicated to learning how to write an op-ed or letter-to-the-editor. During the second session, the residents read recent opinion pieces in various news publications and medical journals regarding health care. Then in small groups they systematically critique the articles and discuss why a piece of writing was effective and chosen for publication. At the third session the residents share their own letters and op-eds for critique and feedback. Residents are encouraged to submit these pieces of writing to various news publications. The fourth session focuses on legislative advocacy, specifically how to call an elected representative's office and set up an appointment, how to select and prepare issues to be discussed, and the logistics of follow-up after the visit. We teach residents that their medical expertise, their passion for a specific cause or issue, and their personal stories from clinical encounters are what make their voice distinct and memorable to an elected representative.

EVALUATION: An evaluative component was added in the second year of this curriculum in July 2014 with IRB approval. Our survey uses a 5-point Likert (Strongly Agree/Disagree) scale to measure pre- and post- curriculum changes in attitude regarding physician advocacy and comfort level with advocacy skills. The survey was completed by the July 2014 participants; November 2014 participant results are pending. There were positive changes in the residents' perceived comfort level with working to get policy passed about a healthcare issue ($p=0.005$) and with speaking to the media ($p=0.003$). Residents also responded in a positive direction regarding how likely they were to get involved in advocacy through communicating with elected representatives ($p=0.004$) and writing an op-ed or letter to the editor ($p=0.001$). There was also a positive but not statistically significant change in residents' understanding of opportunities available for physicians to advocate ($p=0.08$).

DISCUSSION / REFLECTION / LESSONS LEARNED: Since July 2013, a total of 21 GIM residents have completed the curriculum. Several of them have published opinion pieces in the local newspaper, and have had multiple meetings to discuss GME and resident workforce issues with Rhode Island Congressman David Cicilline and Senator Jack Reed's staff members. The goal of our curriculum is to teach residents a set of skills so that they feel empowered to engage in health care advocacy through concrete, practical ways that can be integrated into their future careers. We deliberately chose not to incorporate didactics regarding health policy or systems into our curriculum. They leave the sessions with tangible skills and knowledge to write an op-ed and letter to the editor as well as to communicate with elected representatives. Our survey showed statistically significant positive change in residents' comfort in these skills after completing the curriculum. We hope to standardize our curriculum in such a way that it can be taught by residents with limited experience in physician advocacy. Our curriculum lends itself to

replication because it requires few resources, limited training of resident-leaders, and few, if any, funding requirements. The Brown physician advocacy curriculum is simple, resident-initiated, requires few resources and minimal time commitment, and is easily adoptable.

EMPOWERING INTERNAL MEDICINE RESIDENTS TO DISCUSS ADVANCE CARE PLANNING IN PRIMARY CARE CLINIC Jessica Bender¹; Jennifer Russo¹; Irina Vovnoboy¹; Sandhya Rao²; Ryan Chippendale². ¹Boston Medical Center, Boston, MA; ²boston university, Boston, MA. (Tracking ID #2198986)

NEEDS AND OBJECTIVES: Advance care planning in primary care is increasingly important as the population ages, yet internal medicine trainees report lack of confidence and skills in leading these discussions. We conducted a needs assessment and educational intervention to improve the confidence and skills of internal medicine interns in discussing advance care planning in the primary care setting.

SETTING AND PARTICIPANTS: The study was conducted in an urban academic medical center in Boston. Participants included categorical and primary care interns in an internal medicine residency program.

DESCRIPTION: A voluntary needs assessment survey was conducted to assess interns' attitudes about and confidence in leading advance care planning discussions in the primary care setting. Based on this needs assessment, several educational interventions were developed. First, a practice improvement module was created; each intern was asked to perform a chart audit to determine their baseline practice of advance care planning in primary care clinic. Second, based on the results of the needs assessment survey, a one hour, small-group educational session was developed to address areas of lower confidence. After the educational sessions, participants will conduct a second chart audit to determine if their practice has changed. In addition, a post-intervention survey will be conducted to determine if interns' confidence and attitudes have changed.

EVALUATION: The needs assessment survey response rate was 86 % ($n=38$). More than half of the respondents (68 %) had not had formal training in advance care planning during medical school. The majority of respondents (74 %) indicated that advance care planning in primary care is important or very important. However, 45 % reported that they had not facilitated any advance care planning discussions with their primary care patients. Despite this low frequency of advance care planning discussions, interns reported a high level of confidence in discussing advance directives, naming healthcare proxies, and facilitating advance care planning in the ambulatory setting. Interns reported lower confidence (able to perform with distant or close supervision) in estimating prognosis and discussing changes in care needs. The most frequently reported barriers to facilitating ACP discussions were time (87 %), patients with multiple comorbidities (76 %), and provider confidence (42 %). The most frequently reported factors that led to high prioritization of advance care planning were patient age (32 %), functional decline (26 %) and the existence of multiple comorbidities (24 %).

DISCUSSION / REFLECTION / LESSONS LEARNED: This needs assessment survey indicates that participants had high levels of confidence in discussing advance care planning, yet they reported holding very few discussions in the primary care setting. It is possible that interns' high level of self-reported skill is due to experiences they have had in the inpatient setting, where they frequently are responsible for assisting patients in naming healthcare proxies, discussing goals of care, and leading family meetings. The interns' lower confidence in estimating prognosis in the outpatient setting likely results in an underestimation of the number of primary care patients who would benefit from advance care planning. Thus, the goal of the educational session was to increase interns' ability to identify patients who would benefit from advance care planning discussions. To facilitate this, the sessions focused on improving skills in prognosticating and on sharing strategies to overcome other barriers such as time and multiple comorbidities. The aggregate results of the initial and follow-up chart audits are still pending at this time but will be used to determine if this educational intervention results in a change in practice facilitating advance care planning with primary care patients.

ENGAGING HOUSESTAFF IN TEAM-BASED CARE: THE USE OF INTERDISCIPLINARY TEAM MEETINGS IN THE INTERNAL MEDICINE RESIDENCY AMBULATORY EXPERIENCE Jonathan Arend¹; Eva Waite¹; Aparna Sarin¹; Lauren Peccoraro¹; Rachel Solomon¹; Athanasia Vasiliadis¹; Linda Pagan²; Theresa Soriano¹. ¹Icahn School of Medicine at Mount Sinai, New York, NY; ²Mount Sinai Hospital, New York, NY. (Tracking ID #2199550)

NEEDS AND OBJECTIVES: Amid increasing enthusiasm for team-based models of patient care, incorporation of team-based care into residency curricula is starting to emerge. As academic primary care practices embrace the Patient-Centered Medical Home (PCMH) model and residency programs seek ways to satisfy Next Accreditation System (NAS) milestones related to team-based care, educators must develop methods for

teaching the skills needed to operate effectively in interdisciplinary care teams. As part of a comprehensive PCMH curriculum, we instituted an outpatient interdisciplinary team meeting structure to support team-based care and quality improvement. We sought to determine the feasibility of team meetings, assess their impact on resident satisfaction with interdisciplinary care, and measure the effect of team-based quality initiatives.

SETTING AND PARTICIPANTS: In our academic primary care practice at the Icahn School of Medicine at Mount Sinai in New York, NY, internal medicine residents are assigned to 1 of 3 firms, in which they provide patient care and work with firm-based attending physicians, medical assistants, registered nurses, nurse practitioners, social workers, care coordinators, patient navigators, and front desk registration staff. In July 2013, we implemented weekly team meetings in each firm, attended by members of each of the above disciplines. All residents attended their respective team meeting during ambulatory blocks.

DESCRIPTION: We developed the format of the team meetings based on literature review, collaboration with other academic medical centers, and local priorities. Prior to initiating the meetings, we trained the residents, general internal medicine faculty, and clinic staff in principles of teamwork, effective meeting skills, and quality improvement methodology. We redesigned the resident schedule and clinic staffing to provide 1 h per week of protected time for the meetings. The meetings were co-led by a registered nurse and an attending physician and focused on team communication, clinical workflows, and quality improvement.

EVALUATION: We conducted baseline and 10-month follow-up surveys to assess resident satisfaction with interdisciplinary care at the practice. Sixty-six surveys were returned (51.5 % response rate) for both assessment periods. After implementation of the meetings, resident satisfaction with the practice's team-based functioning increased substantially. The percentage of residents who were very satisfied with the practice's overall team-based functioning increased from 8 to 22. Levels of satisfaction (very satisfied) for components of team-based care, including co-management of patients' medical conditions, communication about patient care, shared responsibility of patient care, and personal support from team members, ranged from 7 to 13 % at baseline and from 17 to 24 % at follow-up. Quality improvement projects developed in the team meetings resulted in sustained improvements in influenza vaccination, clinical depression screening, fall risk screening, blood pressure control, and primary care provider continuity. The regular meeting schedule was maintained without disruption of clinical care, losses in productivity, or significant use of additional funding sources.

DISCUSSION / REFLECTION / LESSONS LEARNED: Weekly interdisciplinary team meetings are a feasible method of introducing internal medicine residents to team-based care and quality improvement in an ambulatory setting. Team meetings have the potential to increase resident satisfaction with team-based care and lead to improved performance on various quality indicators. The role of team meetings in influencing ACGME core competencies or other performance metrics requires further study.

EVALUATING A HIGH VALUE CARE CURRICULUM IN THE AMBULATORY SETTING Brent W. Thiel²; Doris Rubio¹; Peggy Hasley¹. ¹University of Pittsburgh, Pittsburgh, PA; ²University of Pittsburgh Medical Center, Pittsburgh, PA. (Tracking ID #2199102)

NEEDS AND OBJECTIVES: The American College of Physicians (ACP) and the Alliance for Academic Internal Medicine (AAIM) have developed a curriculum to promote high value cost conscious care (HVC). However, few studies have evaluated the effectiveness of this curriculum on medical trainees. Our educational objectives are for residents to: (1) align case based knowledge with best practices, (2) identify web resources that report on clinical costs, and (3) reduce self-defined wasteful behaviors.

SETTING AND PARTICIPANTS: Participants are categorical and preliminary internal medicine interns and postgraduate year two residents at an academic, tertiary care medical center. Seventy-seven percent ($n=31$) of categorical interns participated in the intervention. Eighty-three percent ($n=33$) PGY2 for comparison at 6 month follow-up and 38 % ($n=12$) preliminary internal medicine interns for comparison at the pretest, participated as comparison groups.

DESCRIPTION: Our intervention consists of a small group session in which interns are provided brief didactics on health care costs and then work through two cases, on headache and low back pain, to explore the topic of healthcare waste. We adapted materials from ACP/AAIM 2012–2013 HVC Curriculum (modules 2 and 9). The course focuses on the overuse of imaging tests and explores barriers to waste reduction. Small group, interactive discussions focus on guidelines for use of imaging studies, and actual local and national charges for these tests. Interns brainstorm personal, patient, institutional, and system-wide barriers to reducing waste and develop strategies to overcome these barriers. Finally, interns develop individual goals to reduced waste and overcome barriers in their own clinical practice.

EVALUATION: A 29 item, confidential survey was developed to assess knowledge, attitudes, and behaviors relating to healthcare waste. Survey administration occurred pre,

immediately post, and 6 months post the curriculum to categorical interns taking the course, as well as to controls. T-tests for summary scores from each of the three domains were used to compare the effect of the intervention across time, and the difference between the experimental and two control groups at baseline.

DISCUSSION / REFLECTION / LESSONS LEARNED: We found no significant difference in baseline knowledge between controls and pre intervention interns ($p=0.14$). There was also no difference in summary score between controls and pre intervention interns with regard to attitudes ($p=0.18$) and behaviors ($p=0.76$). We found a statistically significant increase in knowledge from the pre-test to the immediate post-test ($p<0.001$) among interns who participated in the curriculum. However, this change was not sustained at the 6 month follow-up ($p=0.29$). Similarly, there was a significant change in attitudes summary score from the pre-test to the immediate post-test ($p=0.003$), but this was not sustained at 6 months ($p=0.65$). Behaviors were only assessed at the pre-test and 6 month follow-up with no significant change noted ($p=0.71$). Our study validates the utility of the ACP/AAIM 2012–2013 HVC Curriculum and brief curricular interventions to increase knowledge and attitudes related to HVC practices immediately following the curriculum, however these changes were not sustained over time. Limitations include: single seminar format, lack of randomization, survey response bias, and incomplete follow up. Although our brief curricular intervention alone did not create a durable change in HVC knowledge, attitudes, and behaviors, this is not surprising given that current models of learning theory underscore the importance of repetition in creating lasting knowledge or behavioral change. Furthermore, this intervention was not designed as a stand alone curriculum, but rather a piece of a larger HVC curricular sea change. Used in tandem with other multi-setting interventions, durability of knowledge and ultimately behavioral change can be achieved. More studies will be necessary to validate other interventions and determine the effect of such curricula on outcomes that directly measure behavioral change.

EVALUATION OF A BRIEF HANDOFF SKILLS WORKSHOP TARGETED AT INCOMING INTERNS Christopher J. Smith²; Michael C. Wadman²; Jeffrey Harrison²; Gary L. Beck¹. ¹University of Nebraska College of Medicine, Omaha, NE; ²University of Nebraska Medical Center, Omaha, NE. (Tracking ID #2181183)

NEEDS AND OBJECTIVES: Poor handoff communication has been linked to adverse patient outcomes and inefficient care delivery. In 2014 the Association of American Medical Colleges identified patient care handoffs as one of their core entrustable professional activities for entering residency. Despite this, few medical schools have handoff curricula and student involvement in handoffs is inconsistent. A recent study showed that a day-long handoff workshop aimed at incoming interns could improve self-reported perceptions, however this intervention did not report on learner skills and time constraints may limit its applicability at other institutions. The objective of our intervention was to improve handoff-related perceptions and skills in a diverse group of incoming interns via a brief, interactive educational intervention.

SETTING AND PARTICIPANTS: We conducted a 1-h handoff training session as part of GME orientation for incoming interns at a large, state-funded academic medical center.

DESCRIPTION: We developed the training session based on published handoff research and pedagogy. The workshop addressed 3 aspects of handoff practice: information transfer, responsibility and accountability, and systems-level elements to facilitate handoffs. The training was comprised of didactic lectures, group discussion, and role-play activities. We conducted two sessions, each with approximately 50 interns and 5 faculty facilitators per session. Throughout the training, we stressed the importance of providing unambiguous follow-up tasks and contingency planning, prioritization of patients, and closed-loop communication. Resident dyads practiced written and verbal handoff skills via vignette-based role-play scenarios with direct faculty oversight. Participants practiced written handoff skills by completing EHR-style templates and verbal handoff skills using a modified SBAR mnemonic.

EVALUATION: We conducted paired pre/post-intervention surveys to evaluate Kirkpatrick Level 2a (attitudes and confidence) and 2b (knowledge and skills) outcomes. Participants rated attitude-based questions using a 5-point Likert scale. To evaluate skill acquisition, learners provided examples of both a follow-up task and contingency plan that might occur during a high-quality handoff. These were scored independently by 2 faculty members based upon a previously established scoring system (0–4 points). We analyzed pre/post-surveys using Wilcoxon Signed-Rank test, with p -value <0.05 considered significant. We also looked for associations between survey results and demographic information, including past handoff experiences. Ninety-nine of 108 interns (91.7 %) completed both pre- and post-surveys. Over 50 % of participants were entering primary care residency programs. Participants reported a wide range of prior handoff training and real-world experiences. There was significant improvement in all 10 attitude-based questions. There was also improvement in the skills application portion of the survey (1.07 to 2.16, $p<.001$). Survey findings were consistent regardless of prior handoff training, number of handoffs observed, or number of handoffs performed.

DISCUSSION / REFLECTION / LESSONS LEARNED: Entering interns must be competent to perform unsupervised patient care handoffs. We show that a brief, evidenced-based educational intervention is effective in improving interns' self-reported knowledge and confidence in performing handoffs, as well as their ability to perform core handoff activities (follow-up tasks and contingency planning). Further work is needed to determine if these improvements translate to clinical practice

FINDING JEMS: DESIGNING LONGITUDINAL LEARNING RELATIONSHIPS INTO RESIDENCY TRAINING Daniel R. Wolpaw; Jennifer Kraschewski; Paul Haidet; Jed Gonzalo. Penn State College of Medicine, Hershey, PA. (Tracking ID #2196300)

NEEDS AND OBJECTIVES: Longitudinal learning relationships are the subject of considerable interest and focus in undergraduate medical education, but it has been challenging to achieve consistent faculty-leader relationships in residency programs. At the same time, the Next Accreditation System has focused on the need for trainees to engage in meaningful reflection as part of a competency-based curriculum. Reflection is a critical component of professional development and lifelong learning, but difficult to achieve in the absence of longitudinal mentoring relationships. In response to this challenge, our Department of Medicine has created the Jeffries Educational Mentors and Scholars (JEMS) program with the following objective: to create a structured program of longitudinal mentoring to advance the personal and professional development of residents through: 1) timely formative feedback, and 2) coaching through cycles of meaningful, individualized professional learning plans (PLPs) based on critical self-reflection and linked to Entrustable Professional Activities (EPAs).

SETTING AND PARTICIPANTS: All Categorical Internal Medicine Residents and Med-Peds Residents ($n=68$) are assigned to a JEMS faculty member ($n=22$) for the duration of their postgraduate training. Faculty are selected based on a competitive application process and provided with 5 % departmental support for participation.

DESCRIPTION: Each JEMS faculty member is linked to 3–4 residents at the same stage of training. Residents are instructed to contact their faculty to arrange a meeting during each of their 2-week ambulatory block segments that occur every 6 weeks. Residents are asked to prepare for meetings by identifying a learning need or “disorienting dilemma,” which is then reflected upon and collaboratively crafted into a PLP at the meeting. Additional discussion may address career planning, feedback (adverse or positive), or exam preparation. Following each meeting, residents send a summary of the meeting and PLP to their JEMS faculty, who respond with additional comments on the conversation and plan. All of these reflections are shared with the medicine residency program administrator.

EVALUATION: Resident-faculty reflections were analyzed using a qualitative content analysis to: 1) identify the content of PLPs being discussed, 2) map these plans to the Internal Medicine EPAs, and, 3) identify additional themes in these conversations. Twenty-eight reflections were evaluated from the first 5 months of the academic year. Common themes for PLPs included: practice-based improvements, high value care, scholarship, personal and career growth, medical knowledge and skills, and quality improvement. The 28 discussions mapped to 13 of 16 EPAs, with the majority mapping to >1 EPA. Most common EPA topics included lifelong learning, quality at the individual and systems level, and transitions of care. Additional themes addressed career options and recommendations and work-life balance.

DISCUSSION / REFLECTION / LESSONS LEARNED: The mid-year program launch in 2013 that was hampered by resident uncertainty of program expectations and the lack of a consistent calendar space for meetings (i.e. prior to the ambulatory block scheduling). However, since July of 2014 the JEMS program has shown evidence of significant acceptance and impact. Measures of success include documentation by residents of faculty-resident meetings and PLP development. We have been particularly impressed by the usefulness of the “disorienting dilemma” trigger and the manner in which PLP efforts map to EPAs. We believe these triggers and plans in the context of a consistent mentoring relationship with dedicated faculty will allow us to promote and assess critical reflection in our residents. We have also noted an increasingly positive response of residents to a longitudinal mentoring relationship based on advocacy for professional growth and formative feedback. Several adjustments have been made to the JEMS program since its inception, most notably: 1) focusing on PLPs rather than specific milestones, 2) locating resident-faculty meetings in the ambulatory blocks and transferring the responsibility for arranging these 1:1 discussions from faculty to residents, and 3) working to create a positive environment of personalized advocacy for professional growth that works synergistically with program leadership. Program evaluation has evolved from general satisfaction and feasibility to focus on the analysis of PLPs. Next steps will include more formal study of perceived impact through focus groups with JEMS faculty and residents and a complete evaluation and mapping of resident-faculty discussions and EPAs. The JEMS program is built on the core educational principles of

continuity in learning relationships and professional learning plan cycles. We believe this approach has great potential for advancing the goals of the Next Accreditation System and the professional development of our residents.

FITTING THE BILL: A QUALITATIVE ANALYSIS OF GROUP REFLECTIONS ON PATIENTS' HOSPITAL CHARGES Tanya Nikiforova¹; Maggie K. Benson¹; Megan Hamm³; Kelly Williams³; Susan L. Zickmund²; Anna K. Donovan¹. ¹University of Pittsburgh Medical Center, Pittsburgh, PA; ²University of Pittsburgh/VA Pittsburgh Healthcare System, Pittsburgh, PA; ³University of Pittsburgh, Pittsburgh, PA. (Tracking ID #2198694)

NEEDS AND OBJECTIVES: Physicians play a crucial role in curtailing health care spending in the US, and yet traditionally residents have received little formal teaching about balancing optimal health outcomes with contained healthcare costs. To address this need, our institution recently implemented an inpatient curriculum involving group reflections on a patient's hospital bill. Previously published similar curricula have mixed results, often showing improvement in resident knowledge of medical costs, but little or no change in ordering practices or patient outcomes. Through open-ended interviews with residents, we sought to examine whether this curriculum elicits discussion of High Value [cost conscious] Care (HVC) principles, leads to improvement in perceived knowledge about costs, and influences residents' reported clinical practice. To our knowledge, this is the first study using qualitative methods to evaluate a bill reflection curriculum.

SETTING AND PARTICIPANTS: This curriculum was implemented for residents rotating through General Internal Medicine (GIM) inpatient services at an academic, tertiary care medical center. Each inpatient GIM team included one attending physician, one second or third year resident, two interns, and several medical students. The reflections occurred within these teams once per month in place of traditional attending didactic sessions.

DESCRIPTION: Attending physicians were oriented to this curriculum during weekly meetings and were asked to submit the name of a patient cared for by their GIM team. They were provided with a bill, which included all itemized charges from their patient's hospital stay. The attendings were also given a reflection guide with discussion questions and resources for how to interpret the bill. There were three main components to the reflection. First, residents were asked to discuss the interpretation of the charges and to consider whether anything in the bill was surprising. Second, residents were asked to consider whether any wasteful or harmful care was provided. Suggested discussion questions included: “Can we find anything on this bill that we feel was wasteful? Or harmful? Did we need all of the tests ordered? Are there less expensive medications that we could have used?” Finally, the team was prompted to formulate an action plan for subsequent patients.

EVALUATION: We conducted semi-structured 10–15 min telephone interviews with residents shortly after the completion of their GIM rotation. Interviews were conducted by two trained qualitative interviewers using an interview guide developed with a qualitative expert. Interviewed residents were asked about: the concepts discussed during the group reflection; how the discussion was useful or not useful; whether their self-perceived knowledge of charges for commonly ordered labs, imaging studies, procedures or medications changed; and whether their self-reported clinical practice changed after the reflection. The interviews were audio recorded and transcribed verbatim. The analytic approach used the Editing method developed by Crabtree and Miller and involved the iterative development of a codebook. Formal thematic analysis is currently underway with preliminary observations presented below.

DISCUSSION / REFLECTION / LESSONS LEARNED: The participation rate was 95 %, with 20 of 21 residents from 7 house staff teams completing interviews. There were 12 PGY1, 5 PGY2, and 3 PGY3 participants. The time spent on the bill reflection varied between teams with an average of 30 min. Residents reported that the curriculum improved their knowledge about medical costs and cited several positive ways in which the bill reflection could change their clinical practice. Residents indicated that this exercise stimulated them to consider whether a test will change their management before ordering it, and most frequently this was applied to ordering daily lab work. For example, one resident stated, “Definitely in terms of daily labs...that's something I've been trying to work on since then, like thinking about ‘are we just ordering this because they're in the hospital or is this actually something that we're going to use?’” Residents also cited limitations of the bill reflection as a tool to change their clinical practice. Most commonly mentioned was the lack of cost information at the time of clinical decision making. Other limitations included difficulty interpreting the actual cost to the patient based on the hospital bill charges, as well as their ordering preferences being limited by expectations of consultant and generalist attendings. The inpatient bill reflection curriculum was a logistically feasible, inexpensive, and brief intervention that led to increased awareness of costs among residents and fostered discussion of HVC principles. Given the residents' favorable response to this exercise, we plan to incorporate elements of the bill reflection into future inpatient and outpatient HVC curricula.

HEALTHCARE BY THE NUMBERS: A PROGRAM TO TEACH DATA SCIENCE TO MEDICAL STUDENTS Lindsay E. Jubelt¹; Ruth Crowe²; Martin Pusic¹; Mark D. Schwartz¹; Marc Triola¹. ¹NYU School of Medicine, New York, NY; ²NYU School of Medicine, New York, NY. (Tracking ID #2198919)

NEEDS AND OBJECTIVES: Healthcare is shifting from one-on-one patient care to population health, in which teams of providers care for a panel of patients. This shift requires a new skill set for doctors, centered on data analysis and technology, to enable provider teams to monitor their entire patient panel, not just those actively seeking care. These skills are not taught in today's medical school curriculum. In response, with funding from the AMA's Accelerating Change in Medical Education Program, NYU introduced a program for its medical students called Healthcare by the Numbers. It has the following objectives: 1. Develop skills to examine data across panels of patients, 2. Teach the strengths and pitfalls of big clinical databases, and 3. Provide insight into how administrative data can be used to measure quality and value in health care.

SETTING AND PARTICIPANTS: The Healthcare by the Numbers exercise occurred within the Practice of Medicine (POM) course at NYU School of Medicine. POM is a pre-clerkship core clinical skills teaching module that encompasses medical interviewing and examination along with cultural competence, medical ethics, health policy, and clinical epidemiology. NYU School of Medicine is located in New York City. It has 1360 Full-Time faculty, 975 residents and fellows, and 4788 Post-Graduate Registrants. The Healthcare by the Numbers participants were 150 first-year medical students, the entire first year medical student body.

DESCRIPTION: Faculty delivered a lecture to the medical students providing an overview of large datasets, population health, and panel management as well as an introduction to the New York Statewide Planning and Research Cooperative System (SPARCS) dataset. Students were assigned to work in pairs to identify and investigate a clinical question or hypothesis, using a SPARCS dataset created specially for the students, and to present their findings to a faculty preceptor. Encouraged elements were: a literature search with references, a data description, cross-tabulations, and graphical visualizations. Students were required to meet with a medical librarian to review their research question and to submit the question for faculty review. Faculty held voluntary office hours and a biostatistician was available to meet with students.

EVALUATION: The evaluation included faculty and student evaluations of the exercise (qualitative and quantitative data), librarian evaluations of student research questions (qualitative data), and faculty evaluations of student presentations (qualitative and quantitative data). We also collected student research questions and are conducting analysis of these questions to identify common themes. All 75 student pairs presented final projects. Example questions include: "Differences in Length of Stay for Hip Surgery based on Payer Type at New York Hospitals" and "Association between Race and Length of Stay for Patients Hospitalized with Schizophrenia."

DISCUSSION / REFLECTION / LESSONS LEARNED: We were able to scale the Healthcare by the Numbers program to an entire medical student class, demonstrating the utility of the program and its tools for a large audience. Students enrolled in the program were able to generate and investigate their own questions using a large dataset. For the future iterations, we plan to develop a faculty-training course to teach faculty preceptors basic concepts of data management and analytics.

ONLINE RESOURCE URL (OPTIONAL): <http://education.med.nyu.edu/ace/>

HONING IN ON INPATIENT ROUNDS LEADERSHIP: CREATION & IMPLEMENTATION OF A NOVEL TOOL TO EVALUATE ROUNDS LEADERSHIP & EDUCATION Lekshmi Santhosh; Sarah Schaeffer; Bradley A. Sharpe. UCSF, San Francisco, CA. (Tracking ID #2199482)

NEEDS AND OBJECTIVES: In internal medicine residencies, the leap from intern year to second year represents a dramatic shift of responsibilities from data-gatherer to team leader and educator. Most residencies have little formal training on this transition and even less direct observation of team leadership skills by new senior residents. The objective of this project was to use a structured tool to enable chief residents to directly observe and evaluate new senior residents on their rounds leadership and education skills: the Rounds Leadership Entrustable Professional Activity (EPA).

SETTING AND PARTICIPANTS: The intervention took place at 3 hospitals across our internal medicine residency program. Participants were new second-year internal medicine residents. Six chief residents shadowed 50 new second-year internal medicine residents on rounds on an inpatient wards day.

DESCRIPTION: We developed a 10-item structured observational assessment to evaluate senior resident leadership behaviors during inpatient morning rounds. Morning rounds involved one senior resident, two interns, one attending physician, and third and fourth year medical students rounding on their list of patients. Items in the observation

were chosen based on behaviors that mapped to an entrustment score for an ACGME milestone and/or represented an institution-specific goal for senior wards residents. Each item was quantitatively scored on a Likert-type scale with qualitative examples and feedback also noted for each. Items evaluated were: 1. Showed enthusiasm for the topic and/or the learner, 2. Showed interest through body language, 3. Created a conducive physical environment for learners, 4. Used learners' names, 5. Set an agenda and managed rounds efficiently, 6. Gave positive and corrective feedback to team members, 7. Made clear and salient teaching points during rounds, 8. Demonstrated empathy and compassion with patients and families, 9. Ensured effective communication with team members regarding patient action plans for the day, and 10. Works effectively with the attending physician (e.g. manages "up" when needed). Chief residents shadowed medical teams, completing the assessment over a 1–2 h period with the team. Each senior resident then received reinforcing and corrective feedback in a 1-h one-on-one debriefing with their chief resident observer.

EVALUATION: Throughout the year, we continually reassessed the evaluation metrics and sought feedback on which metrics best captured rounds leadership and education skills. Resident satisfaction with the Rounds Leadership EPA was unanimous with 100 % of residents finding the structured observation and feedback/debriefing sessions useful.

DISCUSSION / REFLECTION / LESSONS LEARNED: This novel tool enabled near-peer chief residents to provide direct observation, feedback, and debriefing with new internal medicine senior residents on aspects of rounds leadership and teaching. The structured tool not only allowed objective benchmarking data of specific behaviors that promote leadership & education, but also allowed opportunity for free-form reinforcing and corrective feedback on these behaviors. Moreover, the feedback and debriefing sessions also offered additional opportunities to check in and discuss intangible factors such as resident-attending dynamics, team well-being, and specific teaching strategies. Implementation of the Rounds Leadership EPA also provided a novel method of assessment that directly maps to the ACGME milestones.

HOSPITALIST PEER OBSERVATION OF TEACHING LEADS TO CHANGES AND ADOPTION OF NEW TEACHING BEHAVIORS Patrick Rendon¹; Deepti Rao¹; John R. Pierce². ¹UNM Health Science Center, Albuquerque, NM; ²Univ New Mexico, Albuquerque, NM. (Tracking ID #2196732)

NEEDS AND OBJECTIVES: Objective: To enhance the effectiveness of teaching by hospitalist faculty using direct peer-to-peer observation and feedback.

SETTING AND PARTICIPANTS: The Division of Hospital Medicine at the University of New Mexico strives to enhance the quality of teaching by hospitalists. Previous strategies to improve teaching effectiveness utilized by the Division have included disseminating results of resident surveys about effective teaching behaviors by attendings, standardizing rounding times, developing written expectations for teaching attendings, and instituting seminars on effective inpatient teaching. Heretofore, the Division has not utilized direct observation. In an attempt to improve teaching effectiveness, we developed a direct observation exercise for academic hospitalists in order to improve teaching effectiveness.

DESCRIPTION: As opposed to previously published strategies that identify effective teachers or effective behaviors and then use an observation to reinforce desirable teaching behaviors, we chose to adopt a peer-to-peer model with the following assumptions: peer observation followed by non-evaluative exchange would result in adoption of more effective teaching techniques; best practices would emerge and be adopted more frequently, and the quality of teaching by all hospitalists (novice and experienced) would improve. We developed a tool for peer observation of teaching behaviors in 5 domains: learner presentations, team leadership, bedside teaching, professionalism, and other. The tool focused on noting differences and similarities in teaching behaviors. All hospitalists participated, and we asked that each hospitalist complete at least one observation of any colleague during inpatient teaching rounds.

EVALUATION: Over 9 months, 18 observations were completed. Observation periods averaged 91 min (range 60–180). Number of learners present, patients discussed, and patients seen at bedside averaged 2.88, 5.29 and 4.12 respectively. An average of 10.33 behaviors/observation were recorded. Similar behaviors averaged 6.5 and different behaviors averaged 3.83. After the encounter, the observing faculty provided feedback to the observed faculty. Both faculty members noted behaviors that they were planning to adopt or change. Planned changes averaged 1.11 by the observed peer and 1.17 by the observing peer. Suggested subjects for changes included resident involvement, teaching on oral presentations, feedback, use of technology and humor, and how to model behaviors. The most commonly planned change in behavior dealt with organizational or leadership issues (12/41). On an anonymous voluntary survey, hospitalists participating perceived the exercise to be useful in improving their professional development (rated 3.85 on a 5 point Likert scale) and 8/13 (62.5 %) hospitalists who filled out the survey made a change to their teaching style on rounds based on the exercise.

DISCUSSION / REFLECTION / LESSONS LEARNED: Peer-to-peer observations of teaching in the hospital can lead to a collegial exchange of ideas about effective teaching behaviors and may result in more effective bedside teaching. Future directions include assessment of learners' perceptions on improvement of teaching during inpatient rounds, and assessment of the impact of changing teaching behaviors on learners' knowledge, attitudes, or skills during their inpatient rotation.

HOW "INFORMED" ARE GRADUATING STUDENTS IN OBTAINING CONSENT? Audrey L. Tanksley⁴; Jeanne M. Farnan³; Nancy Stewart¹; Sean Gaffney⁵; Vineet M. Arora². ¹The University of Chicago, Chicago, IL; ²University of Chicago, Chicago IL, IL; ³University of Chicago, Chicago, IL; ⁴University of Chicago Hospitals, South Holland, IL; ⁵University of Chicago Pritzker SOM, Chicago, IL. (Tracking ID #2198883)

NEEDS AND OBJECTIVES: AAMC released the Core Entrustable Professional Activities for Entering Residency (CEPAER) as a reference for graduating medical students, and includes obtaining informed consent for tests or procedures as vital skill. There are virtually no assessment methods to define whether graduating students are competent. Our objective was to evaluate graduating medical student ability to obtain informed consent.

SETTING AND PARTICIPANTS: Online module, GME orientation Incoming Interns from Internal Medicine, Surgery, Pediatrics, OB/Gyn

DESCRIPTION: Prior to GME orientation, four specialties participated in an e-module which consisted of pre-survey, webcast with introduction of novel strategy for obtaining informed consent (I.N.F.O.R.M.E.D.), posttest, and post-survey. During GME orientation, participants completed an Observed Standardized Clinical Encounter (OSCE) on obtaining informed consent and were evaluated and given feedback by a faculty observer.

EVALUATION: Objective performance ratings and pre- and post-survey data were used to assess the effectiveness of the curriculum.

DISCUSSION / REFLECTION / LESSONS LEARNED: Eighty-seven (100 %) incoming interns participated (52 % internal medicine, 8 % OB/Gyne, 28 % Pediatrics, and 13 % Surgery). While 83 % of students report having had prior training in obtaining informed consent, less than half (45 %) were satisfied with training, and roughly 1 in 5 reported never obtaining informed consent prior to internship. Overall the experience was well received with 92 % reporting the e-module an effective review of informed consent, 92 % being satisfied with their performance and 95 % reporting this exercise useful to their career. Ninety-seven percent reported that the OSCE was realistic, and 99 % felt the e-module prepared them for the experience. Differences were noted among programs in student ability introduce themselves, create rapport with the patient and show empathy. The strengths of this innovation include being a multispecialty pilot, which included high fidelity simulation and direct faculty observation providing an ability to give immediate objective documentation for Program Directors. Also involved multiple teaching modalities to effectively engage learners. Areas for improvement include validating tools to evaluate actual performance.

HOW ARE YOU PUTTING THIS TOGETHER?: ASSESSING THE DIAGNOSTIC EXPERTISE OF CWRU MEDICAL STUDENTS Jennifer Rabjohns¹; Megan McNamara². ¹Case Western Reserve University, Cleveland, OH; ²Louis Stokes Cleveland VAMC, Cleveland, OH. (Tracking ID #2199010)

NEEDS AND OBJECTIVES: Past studies to analyze the diagnostic reasoning of novices, intermediates, and medical experts have focused primarily on patient charting or presentations after a complete patient encounter. This cross-sectional study aimed to evaluate the diagnostic reasoning of preclinical and clinical CWRU SoM students in "real-time" as they worked through an unfolding, challenging patient case.

SETTING AND PARTICIPANTS: All second through fourth-year University Track CWRU medical students were invited to participate, with a research sample limit of 20 students per class.

DESCRIPTION: Through a literature review and discussion with medical education experts, we developed clinical reasoning milestones spanning from the first year of medical school to intern/resident, focusing on the diagnostic reasoning skills of data collection, hypothesis generation, hypothesis refinement, and hypothesis testing. Using this framework we constructed an electronic questionnaire based on an unfolding clinical scenario, in which we asked students to describe their reasoning after each "reveal" in the patient case. Prompting questions were developed from the framework. Data on demographics and satisfaction were also gathered. We analyzed the qualitative data responses using a framework analysis approach. In an iterative process, both investigators used NVivo qualitative analysis software to independently code, compare, and recode data in order to elucidate themes across and within individual survey responses. The clinical reasoning milestones were used to guide analysis. Definitions of cognitive biases from the Society for the Improvement of Diagnosis in Medicine were used to identify respondents'

potential biases. Chi-2 statistics explored an association between gender and types of diagnostic approaches as well as gender and types of bias.

EVALUATION: Respondents used the diagnostic reasoning approaches of guessing, hypotheticals, and comparing problem representations against illness scripts. There were varying levels of problem representation, as measured by semantic qualifiers; problem representation itself was recognized as an important area for improvement in the CWRU SoM curriculum. Respondents showed potential cognitive biases of overconfidence and anchoring/premature closure as well as several strategies to prevent bias (self-reflection, seeking additional resources, seeking confirmation/validation, continuing to consider alternative diagnoses). Most respondents showed enthusiasm for the survey format, with several offering unsolicited suggestions on how to incorporate it into the curriculum.

DISCUSSION / REFLECTION / LESSONS LEARNED: This clinical decision-making survey was successful in assessing CWRU SoM students' "real-time" diagnostic thinking when presented with a clinical scenario, particularly in the areas of hypothesis generation, refinement, and testing. Students had more difficulty than expected in making problem representations, but articulated a variety of strategies to limit cognitive biases. Student responses also provided valuable insight in clinical reasoning milestones which had been omitted from our original framework, particularly in data filtering/selection and data interpretation, both of which are crucial for accurate problem representation. Overall, this clinical reasoning survey provided a dynamic assessment of students' diagnostic reasoning skills, and it did so in a novel format which students found highly engaging. Refining the clinical reasoning milestones and repeating the survey may provide even more valuable information regarding students' "real-time" diagnostic reasoning skills.

IMPACT OF AN ONLINE SPACED REPETITION-LEARNING MODULE ON RESIDENTS' MEDICAL KNOWLEDGE COMPETENCY Andrei Brateanu¹; Ari Garber⁴; Abby Spencer³; Bruce Spevak¹; Neil Mehta². ¹CCF, Cleveland, OH; ²Cleveland Clinic, Cleveland, OH; ³Cleveland Clinic, Chagrin Falls, OH; ⁴Cleveland Clinic, University Heights, OH. (Tracking ID #2199443)

NEEDS AND OBJECTIVES: 1) To test if an online spaced based learning module can decrease the knowledge gap present at the beginning of the residency training. 2) To compare the online spaced based learning module with the traditional method of electronically delivering the pre-rotation curriculum. Hypothesis: spaced repetition learning will reduce the gap between the residents' medical knowledge and the medical knowledge it is expected they have at the beginning of the outpatient rotation

SETTING AND PARTICIPANTS: *Study Participants* Internal medicine residents at Cleveland Clinic that started the training in July 2014 were offered to voluntarily participate in the study. There were no exclusion criteria. The following information was collected from the resident files: -Age -Gender -Type of medical school (conferring medical doctor (MD) or doctor of osteopathy (DO) degrees), -Place of graduation (United States or international medical graduates) -United States Medical Licensing Examination (USMLE) step 1, 2, Clinical Knowledge (CK) scores -Years since graduation from medical school *Pre-rotation curriculum* The medical topics interns are expected to know at the beginning of the outpatient clinical rotation (1/2 day weekly for 1 year) include: -The diagnosis and management of chronic medical conditions such as hypertension, diabetes mellitus, hypercholesterolemia. -CDC recommendations for immunization. -USPTF screening guidelines.

DESCRIPTION: *Study design* Prospective, randomized controlled study of medical knowledge acquisition in post graduate year one (PGY-1) residents. All residents received access to the Cleveland Clinic Lerner College of Medicine (CCLCM) Learning Center Internet site. Using unique, private logins and passwords, residents are able to open PDF files that include the outpatient rotation curriculum and the reference materials associated with it. Residents were randomized into two groups: -The first group did not receive any further information. -The second group received access to an interactive education delivery system within MOODLE, organized in questions and answers and located on the same CCLCM learning center Internet site. After opening each question residents are asked to self-reflect and decide if they know the correct answer. Upon downloading the correct answer, residents are asked to state if they got the question "right" or "wrong". Subsequently, residents receive automatic e-mails reminding them to review the questions unanswered or answered incorrectly. Any question a resident reported to be incorrect is automatically repeated at shorter time intervals (2 days), when compared with a question where the resident reported a correct answer (4 days). Questions answered correctly 3 times in a row are retired and no longer repeated. Thus, the time required to complete the spaced education program vary depending on each resident's individual performance.

EVALUATION: At baseline, all residents had the medical knowledge tested with questions covering the diagnosis and management of chronic medical conditions, the CDC recommendations for immunizations, and the USPTF guidelines for screening of the general population. We used an electronic audience response system to record the questions and answers. At 3, 6, and 9 months from the beginning of the study, residents

from both groups will have their medical knowledge tested again, with questions similar but not identical with the ones used during the spaced education program, but covering the same topics. We will use an electronic audience response system to record the answers and the results will be compared between the two groups of residents. The background independent variables as well as the examination scores obtained by the internal medicine residents are stored in the department of internal medicine residency program office in a password protected electronic file. Each resident was assigned a unique ID in the database. For the purpose of analysis, the data will be de-identified.

DISCUSSION / REFLECTION / LESSONS LEARNED: Fifty-four PGY-1 residents agreed to participate and were enrolled in the study. Descriptive statistics is used to depict the variables of interest and express them as mean and standard deviation or median and interquartile range as appropriate. Multivariable logistic regression models will be created to compare the intervention group with the control group. Regression models will be adjusted for relevant confounding variables, including demographics (age, sex), medical school (MD vs DO), year of graduation, place of graduation, USMLE scores, years since graduation from medical school. The online spaced based learning modules will be used to increase the residents' medical knowledge prior to starting rotations in other medical areas and subspecialties.

IMPLEMENTING A PROCEDURE BOOTCAMP TRAINING PROGRAM ADDS VALUE BY INCREASING CENTRAL LINE PLACEMENT KNOWLEDGE AND SKILLS Alejandro Diaz; Indhu Subramanian; Linda Okamoto; Mohammed Qazi; Simrat Hansra. Alameda Health System - Highland Hospital, Oakland, CA. (Tracking ID #2197908)

NEEDS AND OBJECTIVES: Central line placement is a fundamental skill acquired during internal medicine postgraduate education. We identified a need for better central line training in our residency program, with a majority of outgoing third year residents citing procedure training as an area requiring improvement. We implemented a structured and interactive central line teaching workshop for our incoming intern class. Our aim was to improve knowledge and confidence in placement of central lines and to maximize patient safety by teaching standardized technique.

SETTING AND PARTICIPANTS: We developed this curriculum for our mid-sized internal medicine residency program (64 total residents per year) based at an urban county hospital. Participants included all incoming internal medicine interns matriculating in the 2014 academic year. The teaching sessions were coordinated and staffed by a combination of senior house staff, chief residents and faculty.

DESCRIPTION: We conducted central line training sessions one half day each week during the first month of the academic year for all incoming interns (primary care, categorical, and preliminary interns were included $n=30$). Training sessions were 3 h in length. Each session was divided into four 20–30 min sections covering the following topics: 1. Orientation to a standardized checklist outlining indications, contraindications, materials needed, and procedure complications. Participants received a card version of the checklist with instructions to place in their badge holders as a portable reference. 2. Interns received sterile technique instruction with a primer on proper sterile procedure followed by supervised gown and glove donning with real time feedback. 3. Ultrasound training with orientation to the use of the machine. Interns then used a practice mannequin to correctly identify structures in the neck. 4. To close out the session, each intern was asked to place a central line on the simulation mannequin while being supervised by a senior resident or faculty member with critique and feedback.

EVALUATION: The pilot workshop required all participants to perform a pre-and post intervention test evaluating general knowledge about central line procedures, indications, contraindications, elements of the central line bundle, basic ultrasound technology, and complications. The workshop was concluded by a brief oral examination. After passing the oral examination each intern received a certification card allowing them to perform a supervised bedside procedure. Data revealed that attendees improved their knowledge of correctly obtaining informed consent (33 vs. 93 % correct pre/post-session) and correct use of the ultrasound probe in inserting central lines (70 vs. 96 % pre/post). Pre-test data showed that interns on average could not name any components of the central line bundle and after the session could name 2 items from the bundle. There was no significant difference before and after the session in terms of knowledge about indications for central lines or labs/ studies to be ordered before and after central line placement. Prior to beginning the workshop, we surveyed all PGY-2 and PGY-3 to assess confidence of residents for performing central lines and knowledge of complications and indications. This historical control data will be compared to the intervention group PGY-1's at the half-way point of the academic year to demonstrate sustained efficacy and improved confidence.

DISCUSSION / REFLECTION / LESSONS LEARNED: The central line training workshop piloted in this study was effective in teaching interns the basic knowledge and skills necessary to perform the internal jugular central line procedure. Further long term data can confirm whether these positive results are sustained. Notably, this pilot

intervention was feasible, addressed an important need and was relatively inexpensive and not resource intensive. Our sessions were well received by the intern class and feedback from senior residents indicated that they desired to go through the workshop as well. Faculty have indicated that the intern class who participated in this pilot workshop was better prepared, identified and collected procedure materials correctly, obtained effective informed consents, and ultimately were more equipped to perform an actual patient procedure under supervision safely. Further analysis could evaluate the long term efficacy of a structured central line training workshop with respect to resident competence as well as clinical outcomes such as resource utilization, central line infection rates, number of central lines placed, adherence to the central line bundle components, and complication rates.

IMPLEMENTING AND EVALUATING A FOUR-YEAR INTEGRATED END-OF-LIFE CARE CURRICULUM FOR MEDICAL STUDENTS

Matthew S. Ellman¹; Auguste H. Fortin²; Andrew T. Putnam¹; Margaret Bia¹. ¹Yale School of Medicine, New Haven, CT; ²Yale University School of Medicine, New Haven, CT. (Tracking ID #2157672)

NEEDS AND OBJECTIVES: Meeting the needs of patients with life-limiting and terminal illness requires effectively trained physicians in general medicine and other specialties who are competent to provide skillful and compassionate care. Despite mandates for end-of-life (EoL) care education, graduating medical students do not consistently feel prepared to provide this care. Diverse factors may contribute to this deficiency, including ineffective teaching strategies, curricula with inadequate content or time, and the effects of the hidden curriculum. Recognizing these challenges, we sought to create a longitudinal, integrated 4-year curriculum to teach EoL care skills at our medical school.

SETTING AND PARTICIPANTS: The curriculum was implemented and evaluated in the 4-year program of studies at Yale School of Medicine. All curricular components were mandatory for each class of ~100 students.

DESCRIPTION: We developed a longitudinal, integrated 4-year curriculum to teach basic competencies in EoL care. Developmental learning objectives informed the selections of a variety of teaching strategies which included: interactive lectures and panel discussions; observations of patient interviews; role plays exercises; online interactive learning modules; problem based interactive and simulation workshops; standardized patient experiences; patient care experiences with written reports and case conferences. The curriculum emphasized experiential, skill building activities with special attention to student self-reflection. In addition, we have incorporated interprofessional learning and education concerning on the spiritual and cultural aspects of care. A dedicated webpage fosters continuity of the curriculum and blended learning features combining interactive online modules with live workshops promote flexibility and interprofessional opportunities.

EVALUATION: A mixed method evaluation of the overall curriculum and selected components included: analyses of student written reflections and questionnaires; our own and the AAMC graduating student surveys; and demonstration of students' competency in palliative care with a newly developed observed structured clinical examination (OSCE). Student written reflections demonstrate a high level of meaningful learning engagement. For example, a content analysis of 121 third year student reports from the third year component, *Evaluating and communicating with a patient facing EoL*, demonstrated important themes characterizing the learning impact, including: (1) recognition of the complexity of patients' reactions to dying; (2) appreciation of the value of the clinicians' presence. An analysis of interprofessional student reflections from another component, *Spiritual and Cultural Aspects of Palliative Care and the Interprofessional Team*, indicated that students recognized important issues beyond their own disciplines, the roles of other professionals, and the value of team collaboration. Our graduating student surveys demonstrated that students graduating in 2011 who participated in the full curriculum felt more prepared in many domains of EoL care than those graduating in 2004–2007 who did not. Results from the AAMC questionnaire of 2013 graduates demonstrates favorable student perceptions of the EoL and Palliative Care curricula at our school compared with the composite of other schools, e.g., 92 % of Yale and 79 % of other medical school graduates felt that their instruction was adequate in palliative care and pain management, while 4 % of Yale and 19 % other graduates felt it was inadequate. The 95 third year students who completed the palliative care OSCE in 2014 had a mean score of 75 % on the 16 palliative care history items indicating overall competency in history and communication for the class.

DISCUSSION / REFLECTION / LESSONS LEARNED: A number of features characterize this EoL care skills curriculum. The developmental stage of the students informs the learning objectives and teaching strategies in each year of the curriculum. To mitigate the effect of the hidden curriculum, EoL sessions are integrated into the clinical clerkships. We placed special emphasis on student reflection; the self-awareness it can foster is important in helping students overcome discomfort and fears about EoL care. We incorporated attention to the often neglected cultural, spiritual and interprofessional

aspects of palliative and EoL care. A dedicated website housing learning resources, online modules, and faculty contact information promotes continuity over the four years. A 4-year longitudinal integrated curriculum enhances students' skills and preparedness in EoL care. As faculty resources, clinical sites and curricular structure vary by institution, proven and adaptable educational strategies will be useful to address the mandate to improve EoL care education. Teaching strategies and components of this curriculum can be adapted to other programs.

ONLINE RESOURCE URL (OPTIONAL): <http://palliativecare.yale.edu/>

INNOVATIVE CURRICULUM FOR SECOND YEAR HARVARD-MIT HEALTH SCIENCES TECHNOLOGY STUDENTS: IMPROVING CLINICAL SKILLS WITH VOLUNTEER PATIENTS GIVING IMMEDIATE FEEDBACK Nadaa Ali¹; Christine Chung¹; Hamed Nayeab-Hashemi³; Derek Monette¹; Stephen Pelletier²; Helen M. Shields¹. ¹Brigham and Women's Hospital, Boston, MA; ²Harvard Medical School, Boston, MA; ³David Geffen School of Medicine at UCLA, Los Angeles, CA. (Tracking ID #2191717)

NEEDS AND OBJECTIVES: The Association of American Medical Colleges (AAMC) report on Learning Objectives for Medical Student Education in 1998 emphasized skillful communication with patients and their families as an important learning objective in medical school. The objective of this education initiative was to improve communication skills by using volunteer patients to give immediate feedback.

SETTING AND PARTICIPANTS: For the 2014 Introduction to Clinical Medicine (ICM) course, we created an innovative curriculum to prepare Harvard-MIT Health Sciences Technology (HST) students in the MD program using "real" patients from the new Brigham and Women's Hospital Volunteer Patient Teaching Corps. These patients "role-played" their real life experiences and gave immediate feedback on students' communication skills. Patient volunteers were identified, and clinical scenarios customized to reflect their health care experiences.

DESCRIPTION: Scenarios ranged from delivering a cancer diagnosis to discussing medical mistakes, voluntary organ donation, and coronary artery disease with myocardial infarction in a young man, along with discussion of nursing home placement with the family of a patient with worsening Alzheimer's disease or with an incapacitating stroke. Resident and faculty teachers were recruited to facilitate the interaction between patient volunteers and students and to give additional feedback. A total of 32 students were randomly divided into two groups. Group A participated in the workshop in week 11 of ICM; Group B participated in week 12. Each group was further divided into teams of 4 students. Each Teaching Team, composed of a resident or faculty teacher and patient, reviewed the case, objectives/goals, and teaching points prior to the workshop. Each of the 4 clinical scenarios lasted 18 min. The clinical scenario was taped to the door for students to read prior to entering the room. For week 11, we assigned each student a role. After anonymous student feedback, we modified the exercise to give each student an active role in the exercise and removed the passive roles of timekeeper and scribe. After each student role-played the part of the doctor, patients gave direct feedback on communication skills, supplemented by observations and recommendations from the resident or faculty teacher. Overall, each student had an opportunity to actively communicate in 50 % of the clinical scenarios.

EVALUATION: All of the students ($n=32$) completed an anonymous written survey with a 100 % completion rate. Overall, the two exercises combined were rated as excellent (on a Likert scale of 1 to 5 with 1 being excellent and 5 being poor) with a mean score of 1.468 (S.D. 0.621). The utility of real patients as teachers of communication skills received an overall excellent mean score of 1.218 (S.D. 0.608). Verbatim qualitative comments included: "Great cases, real patients, felt real," "Amazing! Please keep and expand," "I love the feedback at the end." At the end of the HST course, 21 of 27 students gave the workshop a perfect score of 1 on the Likert scale.

DISCUSSION / REFLECTION / LESSONS LEARNED: An innovative second year student HST communications exercise received an overall excellent rating from the students. Immediate feedback from volunteer patients was the most highly praised and rated aspect of the exercise. We look forward to expanding the use of the Volunteer Patient Teaching Corps at HST and Harvard Medical School as a unique and powerful educational resource.

INSPIRING MEDICAL STUDENT CAREER INTEREST IN PRIMARY CARE FOR VULNERABLE POPULATIONS THROUGH THE DEVELOPMENT OF AN UNDERSERVED MEDICINE CURRICULUM IN THE DENVER HEALTH LONGITUDINAL INTEGRATED CLERKSHIP (LIC) Mim Ari²; Jennifer Adams¹. ¹Denver Health, Denver, CO; ²Denver Health and Hospital Authority, Denver, CO. (Tracking ID #2188715)

NEEDS AND OBJECTIVES: Inspiring and maintaining interest in primary care amongst trainees, specifically for underserved populations, is a significant challenge.

Students participating in LICs are more likely to understand challenges and rewards of working in a safety-net system, are more likely to view caring for the underserved positively, and thus are more likely to ultimately practice in urban underserved settings.^{1,2} Students develop authentic roles in clinical settings and are given ample opportunity to care for patients with undifferentiated symptoms through transitions in care. This supports the development of a broad view of disease, a strong sense of patient-centeredness, and a nuanced understanding of health care systems^{3, 4}; skills and knowledge that are paramount to primary care. Through the creation of an LIC at Denver Health, an academic urban safety net hospital system, we aim to demonstrate that students develop not only specialized skills in caring for an urban underserved population, but sustain/increase career interest in primary care for vulnerable populations. To support this goal, we have developed a longitudinal Underserved Medicine curriculum that consists of small group didactics and workshops woven into the core clinical curriculum.

SETTING AND PARTICIPANTS: The Denver Health LIC's inaugural class includes eight University of Colorado third year medical students. Students spend the majority of their third year working with ambulatory preceptors in eight core specialties on a weekly basis and meet clinical competencies across multiple disciplines simultaneously. Students participate in weekly didactics, which include the sessions dedicated to the Underserved Medicine curriculum.

DESCRIPTION: The Underserved Medicine curriculum focuses on interactive, patient-related learning opportunities. Sessions include: A community survey in which students explore the neighborhoods surrounding the community health centers where they work with preceptors. Students present a photo essay that documents access to health care, food, parks and recreation, transportation, and safety issues. A workshop describing quality and safety initiatives within the health care system with particular focus on improving these measures for vulnerable populations. Quarterly reflective writing assignments in which students reflect on access to care, poverty, social determinants of health, and appropriate professional boundaries, and then meet as a group to share experiences and insight with faculty facilitators. An experiential clinical nutrition assignment in which students identify a patient with nutritional needs (obesity, diabetes, etc.) and attend a nutrition-centered activity with the patient. Examples include grocery shopping with a dietician and group weight loss visits. A case-based workshop on providing high value care and balancing cost and quality in a safety net setting, highlighting issues such as use of generic medications, utilizing the Choosing Wisely lists, and discussing the minimization of low value care with patients. A workshop on supporting transitions in care from the inpatient to primary care setting for patients with limited resources (working phone, transportation, co-pays, etc.). A workshop on health literacy demonstrating how physicians can assess literacy level and improve outcomes and communication for patients with low health literacy.

EVALUATION: Medical students participating in the Denver Health LIC provide written evaluations for all didactic sessions, give feedback through mid-course and end-of-year evaluations, and participate in semi-structured focus groups. The entire third year class, including the LIC cohort, will participate in a career interest survey at three points during the year with questions about interest in primary care and working with the underserved.

DISCUSSION / REFLECTION / LESSONS LEARNED: The Denver Health LIC is uniquely based in an urban safety net hospital system, and presents an opportunity to highlight challenges and rewards in providing primary care to underserved populations. Students have been engaged and thoughtful about the curriculum based on early evaluations of the didactics and reflection sessions. Incorporating data based on year-end evaluations of this curriculum and the career interest survey, we hope to show that the underserved medicine curriculum has sparked student interest in primary care careers working with underserved populations. Aspects of this curriculum could be easily exported, as either single activities or as part of a more comprehensive LIC or traditional internal medicine curriculum, to inspire or strengthen career interest in primary care for vulnerable populations among medical students.

INSTITUTING A FLEXIBLE CAP AND FRONT-FILL SYSTEM FOR GENERAL MEDICINE INPATIENT TEACHING SERVICES AT A TERTIARY ACADEMIC MEDICAL CENTER Youngjee Choi; Daniel Kim; Hyemi Chong; Christopher Mallow; Jason Bill; Melvin Blanchard. Washington University School of Medicine, Saint Louis, MO. (Tracking ID #2179188)

NEEDS AND OBJECTIVES: Academic inpatient medicine has multiple competing objectives, including patient care and resident education. With duty hour restrictions limiting resident work hours, a good work flow with a steady stream of admissions on call days is necessary to balance both these objectives. At many large academic internal medicine programs, a main barrier to achieving efficient work flow is the bolus of admissions at the end of a call day. This work compression affects patient care and resident education as residents try to leave call in a timely manner.

SETTING AND PARTICIPANTS: In a tertiary academic medical center with a large internal medicine training program, a flexible cap system along with a "front-fill" mechanism was implemented in the second quarter of the academic year for general ward

teaching services. The physicians on a general ward team include one attending, one upper level resident, and two interns. The call structure is a traditional call cycle with long call every 4 days. On a call day, two teams admit new patients from 7 am to 7 pm. The maximum number of new admissions on a call day are five patients per intern.

DESCRIPTION: The flexible cap system involved allowing interns 90 min to work up each patient from 3 pm to 7 pm on call days. This time period was selected based on resident feedback about work compression and a large number of admissions late in the call day. An upper level resident triaged all of the potential new admissions for the two call teams to ensure 90 min was allotted per patient for each intern. If no intern was available for an additional admission (i.e., within the 90-min window), the admission was reassigned to the non-teaching hospitalist service. Each call team also received two patients admitted by night float at the beginning of call (front-fill) to help ensure a full cap of patients on call. If teams did not achieve the cap of ten new admissions during the call day, they could receive up to three additional patients from night float on the post-call morning.

EVALUATION: Before beginning an inpatient ward rotation with the flexible cap and front-fill system, residents were surveyed regarding their view of the inpatient ward service from prior experience. The same residents were resurveyed after their inpatient experience with the flexible cap and front-fill system. Forty-two eligible residents were surveyed before and after implementation of the new system. Responses from the 33 residents (78.6 %) who completed both the initial and final survey were analyzed. After implementation of the flexible cap and front-fill system, the percentage reporting their workload was not manageable on the inpatient ward fell from 33.3 to 3.0 % of residents ($p<0.0001$). Similarly, while 36.4 % of residents felt that they could not see their patients in a timely manner when assigned an admission in the old system, only 6.1 % of residents expressed this concern with the new call changes ($p<0.0001$). The percentage of residents who felt they had adequate time to spend with their patients rose from 39.4 to 97.0 % ($p<0.0001$), and those that reported they had time to learn from their patients also increased from 48.5 to 87.9 % ($p<0.0001$). In addition, residents who reported they were able to leave on time from call days rose from 31.3 to 81.8 % ($p<0.0001$). Overall satisfaction with the inpatient ward experience rose from 69.7 to 87.9 % ($p=0.0060$).

DISCUSSION / REFLECTION / LESSONS LEARNED: Instituting a flexible cap and front-fill system to allow for a better flow of new admissions can have many positive effects on an internal medicine residency program. With this novel modification to the call structure, internal medicine residents at a large, tertiary academic medical center reported improvement in their education, workload, and time spent providing patient care, with an overall higher rate of satisfaction with their inpatient ward experience.

INTERNISTS, PHARMACISTS AND PSYCHOLOGISTS ON TEAMS, OH MY! AN INTERPROFESSIONAL EDUCATIONAL EXPERIENCE IN GRADUATE MEDICAL EDUCATION Steven Bishop; Allison E. Phillips; Bennett Lee; Sarah Hobgood; Brigitte L. Sicut; Emily Peron; Andrea Garoway; Bruce Rybarczyk. Virginia Commonwealth University, Richmond, VA. (Tracking ID #2196116)

NEEDS AND OBJECTIVES: Interprofessional education and collaboration is critical to medical education and practice and is being increasingly integrated into undergraduate medical education. While graduate medical education (GME) trainees do interact with pharmacists and psychologists to complete parallel patient care activities, they rarely collaborate to learn from one another. Growing out of an interprofessional outpatient residency clinic where pharmacists, psychologists and physicians manage shared patients, our institution developed a series of team-based learning (TBL) activities with learning teams composed of medical residents, pharmacy residents, and clinical psychology graduate students. We describe the development and evaluation of an interprofessional education (IPE) TBL module on depression, delirium and dementia in the geriatric patient. At the end of this TBL, we expected learners to be able to do the following with respect to geriatrics patients with delirium, dementia and depression: 1. Assume responsibility as a provider for developing a non-biased attitude towards patients. 2. Embrace and recognize the necessity of a team-oriented approach toward patients. 3. Recognize risk factors for delirium, dementia, and depression in geriatric patients. 4. Differentiate between delirium, dementia, and depression in geriatric patients. 5. Recognize the utility of common practice tools for assessing patients with these syndromes (e.g., CAM, Mini-Cog, GDS, and PHQ-9). 6. Assess a dementia and delirium management plan for effectiveness, tolerability, and safety.

SETTING AND PARTICIPANTS: Participants included 44 medical residents, 9 pharmacy residents and 10 psychology graduate students in a single TBL session.

DESCRIPTION: The TBL module was developed collaboratively by faculty from all three disciplines. To prepare for the module, facilitators sent participants pre-reading assignments in advance (preparatory work). Readings consisted of guidelines or review articles. Facilitators ensured all teams included at least one pharmacy and one psychology trainee. During the session, teams completed a quiz on the reading, first individually and

then as a team, (readiness assurance test), followed by facilitated discussion of interactive cases requiring complex patient care decisions (group application exercises). Each case was constructed to require input from all professions in order to develop an appropriate answer.

EVALUATION: At the conclusion of the session, learners assessed, on a 4-point scale, with 1=never, 2=sometimes, 3=often and 4=always, their likelihood of developing team-oriented attitudes, performing team-based tasks related caring for patients with common geriatric syndromes, and applying new medical knowledge. The first two response levels 'never' and 'sometimes' were combined due to small numbers reporting 'never' to any of the survey items. The survey asked learners to assess their abilities both before and after training (retrospective pre-post design). Responses expressed with decimal points were rounded up to the nearest whole number. Wilcoxon signed-rank tests were used to determine if mean differences between pre- and post-test scores were significantly different from zero. Generalized estimating equations were used to determine how profession and gender affected participant responses. All survey questions had a statistically significant increase in mean score between the pre- and post- assessment ($p<0.0001$). The largest increases were seen in the knowledge application questions related to the likelihood of: recognizing the utility of practice tools (0.88), assessing a dementia and delirium management plan (0.77), and recognizing risk factors for the co-development of depression and dementia (0.77). Reported scores differed by gender with women reporting higher scores for all tasks in the pre- and post- survey compared to men. Profession also influenced scoring, with psychology learners more likely to report higher scores than medical residents in both the likelihood to embrace a team oriented approach toward patient care and recognizing the utility of practice tools. Lastly, pharmacy residents were more likely to report higher scores in their likelihood to assess a dementia and delirium plan as compared to medical residents. All of these results were significant at the $\alpha=0.05$ level.

DISCUSSION / REFLECTION / LESSONS LEARNED: This IPE TBL experience in GME appears to have had a positive effect on all learners, with increases not only in perceived knowledge of common geriatric syndromes but also in attitudes toward team-based care. The data appear to show disproportionate benefits for non-physician participants as far as changes in team-based attitudes. TBL is a potentially powerful way to leverage interprofessional learning experiences; however, the module did take significant time to plan and implement (approx. 10–15 h of planning). Further study is needed to determine if changes in attitudes seen here are sustained and if they lead to actual changes in team-oriented behavior.

MEDICAL STUDENT LEADERSHIP TRAINING IN HEALTH DISPARITIES THROUGH COLLABORATION WITH NON-ACADEMIC ORGANIZATIONS: WHAT DO COMMUNITY-BASED ORGANIZATIONS VALUE? Brent C. Williams¹; Patricia Mullan¹; Joy Williams²; Andy Haig¹; Senait Fisseha¹. ¹University of Michigan, Ann Arbor, MI; ²Medical University of South Carolina, Charleston, SC. (Tracking ID #2195511)

NEEDS AND OBJECTIVES: Addressing health disparities requires collaboration among different types of organizations such as academic institutions, non-profit social service organizations, and community groups. Adult learning theory suggests that skills in collaborative program development are best learned through practical experience with reflection. However, developing meaningful field experiences for medical students is challenging. To plan the future of a partnership program between community-based organizations (CBOs) and medical students, we sought to determine what aspects of short-term collaboration with medical students were most valued by CBOs.

SETTING AND PARTICIPANTS: In 2013–14, the 34 second-year medical students participating in the co-curricular Global Health and Disparities Path of Excellence at the University of Michigan partnered in teams of 2–4 students with 9 CBOs. A total of 9 CBOs focusing on underserved populations had been recruited during the previous year. Students self-selected into teams for 7 of the 9 pre-identified CBOs; 2 additional projects run by students were accepted as CBO-equivalents. CBOs included 5 community clinics, a social service agency for urban girls in poverty, a school-based clinic network, a public school, and pediatricians' offices instituting enhanced mental health services with UM faculty.

DESCRIPTION: Students and CBOs created and implemented a small project over a 7 month period. The only requirements were that the projects: a) include meaningful participation by students in design and execution, b) be of value to the CBO or its constituents, and c) require a maximum of about 4 student-hours per month over 7 months. At the end of the academic year students presented their work to the CBOs and to each other. At the completion of the projects CBOs completed 5 Likert-type and 3 free text questions regarding the students' behavior and level of engagement, the value of the program to the CBO ('what worked well?'), and suggestions for change.

EVALUATION: Seven of the 9 projects were viewed as complete by the students and CBOs. Two were not completed due to communication or expectation gaps between

students and their CBO liaisons. One project required substantial unexpected work in obtaining security clearances for the students. Eight of the 9 CBOs 'Agreed' or 'Strongly Agreed' that the medical students were communicative and respectful, and had identified a project helpful to the organization. 7 CBOs reported that the students communicated the results of the project to their constituents, and included a plan for continuation of the project. In addressing 'what worked well', CBOs described students' enthusiasm, efficiency, and interest in the CBO; and having a concrete project (rather than observation). The only suggestion for improvement, voiced by 4 CBOs, was that more time be available for the projects.

DISCUSSION / REFLECTION / LESSONS LEARNED: Student-community partnerships can provide crucial opportunities for students' to learn and apply skills in organizational leadership to ameliorate health disparities. From CBOs' perspective, our results are encouraging - organizations responded positively to short-term collaboration with pre-clinical students. In particular, CBOs were uniformly supportive of having students participate in creating new projects rather than merely implementing ongoing projects, a key factor in students' enthusiasm and leadership skills development. Success factors likely included: a) establishing relationships and expectations with each CBO prior to the program, b) setting boundaries with students and CBOs on expected time commitments by students, and c) requiring projects to be of demonstrable and immediate value to the CBOs. Challenges relate primarily to sustainability, and include the substantial time and effort required by the medical school to create and maintain relationships with a large number of CBOs, and (we speculate) enthusiasm of the CBOs in volunteering their time year after year to short-term projects with successive cohorts of students. Strategies for long-term success likely include: a) securing adequate faculty time for CBO liaison work, b) involving individual CBOs less than yearly, and c) protecting curricular time for students' longitudinal engagement in the community.

MUSKULOSKELETAL ULTRASOUND: AN INNOVATIVE APPROACH IN ENHANCING INTERNAL MEDICINE RESIDENT EDUCATION
Padmanabhan Premkumar; Jason Jacob; Cunegundo Vergara; Robert Gionfriddo. Hartford Hospital, Vernon, CT. (Tracking ID #2200275)

NEEDS AND OBJECTIVES: Needs: – Handheld ultrasounds and their clinical utility are well-documented in critical care and emergency medicine. No formal RRC (residency review committee) mandate for ultrasound curriculum in internal medicine residency programs exists, and most internal medicine residency programs have no formal process that integrates office-based ultrasound into ambulatory rotations or continuity clinics. Kessler et al¹ clearly demonstrated the lack of ultrasound training or availability amongst internal medicine residents and medical students. Moreover, our survey with Gronski et al² of 100 residents showed lack of confidence with basic ultrasound techniques, but expressed the need and importance of ultrasound training during residency. -In our hospital-based internal medicine residency clinics the breadth of common musculoskeletal (MSK) complaints has created a need for an alternative diagnostic/therapeutic approach. We clearly see a need to augment the clinical evaluation with ultrasound imaging techniques to enhance resident education, skill sets, and patient care. **Objectives:** – Implementation of a formal ultrasound curriculum aimed at teaching basic diagnostic and therapeutic skills for common ambulatory musculoskeletal conditions - Incorporate office-based ultrasound into the ambulatory block rotation and continuity clinics for real-world application to common MSK conditions as an alternative modality to the traditional diagnostic and therapeutic approach—Create a novel evaluation process for ultrasound proficiency through live peer-to-peer demonstrations in the classroom using pre and post tests -Discuss challenges in the implementation of office-based ultrasound

SETTING AND PARTICIPANTS:—Our primary participants will include 3-year categorical internal medicine residents (Allopathic/Osteopathic) from University of Connecticut Health Center during their Ambulatory Core Rotations. Overall, the residency program has approximately 14 weeks of dedicated Ambulatory experience over the course of 3 years - Residents are instructed through classroom didactic sessions and hands-on training at Hartford Hospital, one of the three major clinical sites for the residency program of University of Connecticut - Residents will perform ultrasound principles at their continuity clinics and/or during their ambulatory block rotations, under the supervision of formally trained MSK ultrasound faculty

DESCRIPTION: Internal medicine faculty, trained in use of office-based ultrasound, provide hands-on training and didactic education over two 3-h sessions during each ambulatory block rotation. Classroom didactics include principles of ultrasound, joint anatomy, and injection techniques using power point/video session. Residents apply and practice the aforementioned principles on each other during the hands-on and interactive portion of the session. Joint protocols devised from AIUM (American Institute of Ultrasound Medicine) will be used as standard of care for joint specific exams. During the ambulatory block rotation, residents work with MSK-trained faculty in providing diagnostic and therapeutic ultrasound-related interventions for common ambulatory MSK conditions.

EVALUATION: To evaluate the basic understanding of ultrasound centered diagnostic and therapeutic skills we will have the residents complete pre and post- tests with each session. We will have our residents participate in virtual diagnosis sessions using common ultrasound images of basic pathology. In addition they will be required to perform various ultrasound guided joint protocols as a tool to evaluate their overall progress in conjunction with MSK trained faculty.

DISCUSSION / REFLECTION / LESSONS LEARNED: We see ultrasound as a novel clinical tool to help improve management of musculoskeletal pain. Ultrasound serves as an alternative to conventional examination and blind injection technique for common musculoskeletal problems. As a diagnostic modality, ultrasound provides a safer therapeutic intervention and serves to enhance resident education by offering a diverse primary care experience. Long wait times and limited access to pain management centers for management of common MSK conditions has increased the demand for primary care physicians with unique skills sets. We have found that MSK ultrasound intervention will be of benefit for patients who are poor surgical candidates due to multiple co-morbidities and/ or deconditioning. In addition, our residency program survey revealed 96.9 % residents favored ultrasound training as part of their IM curriculum. Residents have expressed through feedback marked increase in confidence with regards to use of ultrasound and dealing with primary MSK complaints post initiation of our curriculum. Major challenges to creation of ultrasound based curriculum include faculty training, procurement of resources (ultrasound technology) and incorporation of ultrasound in resident run clinics.

NEW APPROACHES TO COLLABORATIVE LEARNING AND PRACTICE FOR MEDICAL AND NURSING STUDENTS DEVELOPING PAIN MANAGEMENT SKILLS Jeanne Erickson²; Valentina Brashers³; Jennifer R. Marks¹; John Owen³. ¹USC, Glendale, CA; ²UWM, Milwaukee, WI; ³UVA, Charlottesville, VA. (Tracking ID #2199421)

NEEDS AND OBJECTIVES: Ineffective pain management remains a serious public health problem for millions of people. The knowledge and skills of health care providers related to pain assessment and management strategies are often lacking, due in part to insufficient content devoted to the topic of pain in health professions schools. To address these gaps in knowledge and skills in health care professionals, the 2011 Institute of Medicine Report recommended that curricula of medical and nursing schools offer standardized content related to pain management and that students have opportunities to learn about pain management in interprofessional (IP) settings. As IP approaches are fully integrated into health professions schools, a vital component linked to the success of any IPE activity is the initial preparation and continuing support of faculty. Most faculty members are familiar with traditional "uni-professional" education and have relevant knowledge and skills which are more aligned with a didactic teacher role. However, different knowledge and skills are required to be an effective IPE facilitator. Little empirical evidence for the impact of IPE faculty development on student learning outcomes exists to date. **Objectives:** 1. Describe an interprofessional approach to teaching pain management content to medical and nursing students. 2. Examine reasons why interprofessional learning outcomes related to pain management may be different across professions. 3. Develop methods of training faculty to facilitate interprofessional teaching.

SETTING AND PARTICIPANTS: A total of 307 medical and 169 nursing students attended a case-based pain management workshop in 2013 and 2014. The students worked in small groups (either uniprofessional or interprofessional) with and without a mentor (traditionally trained or IP trained) to solve two unfolding case studies - a cancer-related pain case and a post-operative pain case.

DESCRIPTION: Case development. We developed two unfolding case studies that included components of the IASP Interprofessional Pain Curriculum Outline for the workshops. For each case, we identified learning objectives and performance behaviors that covered the domains of the IASP guidelines, and we developed a series of questions in each case for students to respond and apply their knowledge about pain assessment and management. Faculty development. We recruited faculty from the Schools of Medicine and Nursing to be mentors for the student learning groups. The IP faculty development sessions, which included an overview of IPE core competencies as well as a video demonstrating IP facilitation followed by discussion, were led by two faculty with extensive IP faculty development experience. Pain Management Workshops. Two 3-h workshops were held. We randomly assigned students to be in a uniprofessional or IP group of 6-8 students. The groups completed the first pain management case without mentoring and recorded their answers electronically. Faculty mentors then joined the student groups as previously assigned to facilitate completion of the second case.

EVALUATION: Development of scoring checklists. In order to assess and compare learning outcomes between student groups, the collaborative care best practice plan formed the basis of a scoring checklist for interprofessional pain management skills for each case. Scoring checklists were developed to assess and compare learning outcomes between groups.

DISCUSSION / REFLECTION / LESSONS LEARNED: 1. Interprofessional (IP) care is critical for effective pain management, but evidence is lacking about the best way to teach pain management skills to medical and nursing students using IP strategies. 2. The checklist scores for both cases suggest that these students were most competent to perform assessments of the patient's pain. 3. Unprofessional groups of medical students without facilitation had the lowest rubric scores of all student groups for both cases, reflecting their basic understanding of pain management principles at this point in their curriculum where they have not yet had many opportunities for clinical learning to apply their knowledge. 4. For medical students, having IP mentorship of their group and being in an IP group with nursing students significantly improved their scores. These findings suggest medical student competency does improve with IP training. While findings show that IP mentorship and working in IP student groups both improved medical students' abilities to create a comprehensive pain management plan, this improvement was not seen in nursing student performance. Differences in learning across professions are common, and refinements need to be considered in order to achieve optimal learning outcomes for all students. 5. The results of this study showed that mentors with IP training did not significantly improve the pain management competency scores of IP groups. This facet of the study underscores the need for further exploration of optimal ways to train faculty to teach IP learners.

OUTPATIENT ROOT CAUSE ANALYSES—AN INTERPROFESSIONAL CURRICULUM TO TEACH PATIENT SAFETY David Margolius^{2, 1}; Krista Gager¹; Bridget C. O'Brien³; JoAnne Saxe³; Maya H. Dulay^{1, 2}. ¹San Francisco VA, San Francisco, CA; ²University of California San Francisco, San Francisco, CA; ³University of California, San Francisco, San Francisco, CA. (Tracking ID #2195315)

NEEDS AND OBJECTIVES: Educating healthcare trainees in patient safety is imperative for promoting the Culture of Safety and expanding a workforce primed and able to redesign the healthcare system to reduce medical errors. Root cause analysis (RCA) is a patient safety tool used to elucidate the individual and system factors that contributed to an error or near miss. Our goal is to teach patient safety skills in an interprofessional outpatient setting through a curriculum that facilitates each trainee participating in an RCA exercise. Our learning objectives include ability to: identify safety problems in ambulatory settings, distinguish between individual and systems factors, and focus error prevention towards improving processes and systems.

SETTING AND PARTICIPANTS: The San Francisco VA Medical Center (SFVA) is one of five VA Centers of Excellence in Primary Care Education (COEPCE), an interprofessional, team-based training program of which patient safety and quality improvement are core components. Since 2011, 56 internal medicine residents and 15 adult gerontology nurse practitioner students with continuity clinic in SFVA primary care clinics have participated. Our primary care clinics are organized in the VA medical home model called Patient Aligned Care Teams (PACT). Physician and NP faculty and quality and safety chief residents facilitate the RCA sessions.

DESCRIPTION: RCA facilitators email trainees an overview of the RCA activity including a worksheet to complete which guides them through the RCA process. Trainees are paired together (members of the same PACT team when possible) and asked to choose a case of a medical error from their own primary care clinic experience that led to an adverse event or "near miss". With at least 2 weeks lead-in time, the pair, with support from RCA facilitators, reviews the chart for the chosen case and interviews involved healthcare personnel. Each trainee pair presents the timeline of the case and leads an interactive discussion analyzing the factors that contributed to the error(s) and potential solutions in a 1-hour session. Two to three pairs present per session. Faculty ensure learning objectives are met during the discussion and communicate some of the proposed solutions generated by the conference to related services.

EVALUATION: Post-session surveys revealed high marks from the trainees for this curricular activity ($n=125$). On a 1–5 scale (1=poor, 2=fair, 3=good, 4=very good, 5=excellent), trainees rated the overall quality of session as 4.6 (SD 0.64) and estimated likelihood of making changes in practice as a result of the session as 4.4 (SD 0.80). We performed a qualitative analysis of 33 RCA's from the past 3 years and identified 6 common contributing factors to the adverse events or near misses: poor communication between PACT members; poor communication between primary care providers (PCPs) and providers outside of PACT; poor provider-patient communication; missed follow-up appointments; lack of timely access to appointments or tests; and tests not followed up appropriately. Twenty-two RCA's had 2 factors identified, 7 had 3 factors identified, and 2 had 4 factors identified. The most prevalent contributing factors were poor communication between PCPs and providers outside the PACT (70 %) and poor provider-patient communication (58 %).

DISCUSSION / REFLECTION / LESSONS LEARNED: We developed a novel approach to patient safety education for interprofessional trainees in the outpatient setting that was highly rated and requires limited curricular time. Experiential learning is an ideal

medium to teach quality improvement and patient safety skills: concepts that come from a brief trainee presentation can lead to tangible systems improvements. Communication errors contributed significantly in the RCA cases we reviewed, further emphasizing for our trainees the importance of the communication and teamwork training which is also part of our COEPCE program. Our next steps will be to improve opportunities for systems-based practice learning and optimization of clinical learning environments by involving the medical center's patient safety leadership in the RCA sessions. We will also ask presenters to revise and submit their proposed solutions from the RCA activity to leadership after incorporating input from the conference attendees. We strive for this curriculum to be both educational and contribute to system improvement; trainees' lasting impressions of this activity will arise from their work contributing to real change.

PANEL MANAGEMENT AS A CURRICULAR TOOL FOR DEVELOPING COMPETENCY IN QUALITY IMPROVEMENT Pete Spanos³; Mary A. Dolansky¹; Gloria Taylor³; Alli Heilman³; Renee H. Lawrence³; Sarah Augustine²; Brook Watts²; Anne Rusterholtz³; Mamta K. Singh². ¹Case Western Reserve University, Cleveland, OH; ²Louis Stokes Cleveland VAMC, Cleveland, OH; ³Louis Stokes Cleveland VA Medical Center, Cleveland, OH. (Tracking ID #2198997)

NEEDS AND OBJECTIVES: Panel management, a key tenet of the Patient-Centered Medical Home model, is shown to be an effective practice strategy for improving patient outcomes (Feldstein, Perrin, et al., 2010). There is little guidance, however, on how best to connect panel management to a curricular framework, and despite longstanding and new efforts, health professions education programs still face challenges successfully integrating quality improvement (QI) knowledge and application opportunities into ambulatory care education such that systems thinking, quality improvement and patient safety become a sustained part of everyday practice. A structured panel management curriculum can effectively help learners achieve the core Practice-Based Learning and Improvement (PBLI) and Systems-Based Practice (SBP) competencies by providing opportunities for learning and improving via performance audit (PBLI) and working effectively with other care providers to improve health care delivery (SBP).

SETTING AND PARTICIPANTS: As one of five Centers of Excellence in Primary Care Education (CoE-PCE) funded by the Veterans Health Administration's Office of Academic Affiliations to develop new models for training healthcare professionals, we developed a longitudinal program called Transforming Out-Patient Care (TOPC) that provides an immersive PCMH training experience for MD residents, Nurse Practitioner (NP) residents and students, and Health Psychology residents.

DESCRIPTION: Within the TOPC program, we developed a longitudinal curriculum—Quality Care Improvement (QCI)—that provides experiential learning in QI using real-time access to trainee panel patient data. Trainees are given a dedicated panel management half-day each week to use a web-based registry tool that allows them to systematically analyze groups of patients for selected criteria then apply QI tools and methods to make evidence-based improvements to care. Additionally, each panel management half-day has a mix of trainee types to foster interprofessional team learning and are led by core clinical faculty from different disciplines (nursing, medicine and health psychology) to provide expertise and guidance on pathways for care and available system resources to help manage patients with chronic diseases.

EVALUATION: Trainees complete short Minute Paper evaluations (Cross, Angelo, 1988) as part of QCI that provide ratings on usefulness and confidence-building (Singh, Lawrence, Headrick, 2011). These sessions have received an average rating of 4.56 out of 5 (1–5; 5=high; $n=503$; mode=5) for usefulness and average rating of 4.35 out of 5 ($n=500$; mode=5) for increased confidence. Also, preliminary focus group and exit survey results show that this QCI/panel management component of the overall program is highly valued, and preliminary analysis of panel data across time has shown a move toward optimal evidence-based outcomes—we will provide specific trend results for patients with diabetes.

DISCUSSION / REFLECTION / LESSONS LEARNED: Health professions competencies like PBLI and SBP emphasize systematic analysis of practice by using information technology resources to optimize learning and effect improvement change and the ability to recognize a system context and use available resources to provide quality care. Traditional clinical venues with short block rotations and lack of interprofessional teams and faculty do not create favorable teaching conditions for these core competencies. A longitudinal ambulatory clinical experience in a PCMH model with interprofessional learners and a strong data registry are key structural components of a robust panel management curriculum. Additionally, connecting this curriculum to a larger QI conceptual framework has allowed opportunities for learners to demonstrate achievement of PBLI and SBP competencies through quick evaluations, competency essays and improvement in clinical work. In summary, a formal panel management curriculum allows for quality improvement to become part of daily decision making and clinical work, a critical learning objective of health professions education.

PATIENT OUTCOMES AND RESIDENT SATISFACTION DATA AFTER INSTITUTING A 4+2 PRACTICE MODEL Eileen Wang³; Lisa M. Vinci¹; Vineet M. Arora²; Wei Wei Lee¹; John McConville¹; Julie Oyler². ¹University of Chicago, Chicago, IL; ²University of Chicago Medical Center, Chicago, IL; ³University of Colorado, Denver, CO. (Tracking ID #2197843)

NEEDS AND OBJECTIVES: Many internal medicine programs have instituted an X+Y block scheduling model, such as the 4+2, for ambulatory training. Previous studies have shown improved resident satisfaction but mixed patient outcomes. Our aim was to evaluate the effect of the transition to the 4+2 model on both resident and patient outcomes.

SETTING AND PARTICIPANTS: On July 1, 2013, an academic internal medicine training program transitioned to a 4+2 model during which residents spend 4 weeks on inpatient rotations followed by 2 weeks of outpatient clinic.

DESCRIPTION: Resident satisfaction was measured using an annual ambulatory survey and patient outcomes data was pulled from the electronic medical record on residents' clinic patients who had been seen at least twice by the same resident, at least once of which was in the pre or post period. Pre 4+2 data from October 2012 to April 2013 was compared to post data from October 2013 to April 2014.

EVALUATION: Patient demographics including average age (pre 58.1, post 57.8), gender (female pre 67 %, post 68 %), and race (African American pre 82.1 %, post 81.8 %) were all unchanged during the 4+2 transition. A higher proportion of patients had tighter diabetes control (those with HgbA1c < 7 pre 29.6 %, n=96, post 36.9 %, n=136, p<0.05) and increased influenza vaccination rates (pre 37 %, post 45 %, p<0.001). This resulted in 307 more patients vaccinated. Residents saw more patients after the 4+2 transition (number of patient encounters/resident over 6 months, pre 127, post 144, p=0.02). However there was an increase in missed appointments (pre 24.4 %, post 27.3 %, p<0.001), an increased rate of ED visits/patient over 6 months (pre 0.51, post 0.58, p<0.001) and hospitalizations/patient over 6 months (pre 0.30, post 0.32, p<0.001) after the transition. On the annual survey, residents reported that they were much more likely to be able to focus on outpatient education while in clinic (pre 37.3 %, post 71.1 %, p<0.001), and that the pace and session scheduling were adequate (pre 33.8 %, post 58.9 %, p<0.001), but that the continuity of clinic preceptor had declined (pre 80.0 %, post 61.8 %, p<0.01). The average number of residents attending teaching conferences increased after the 4+2 transition (pre 13.0, post 26.3, p<0.001).

DISCUSSION / REFLECTION / LESSONS LEARNED: The transition to a 4+2 training model resulted in many positive patient outcomes including: increased rate of influenza vaccination and higher proportion with tighter HgbA1c control. This model also resulted in improved resident outcomes with increased conference attendance, resident satisfaction, and number of clinic encounters. The drawbacks of the 4+2 model included more patient missed appointments, increased ED visits and hospitalizations, and decreased resident perception of preceptor continuity. Despite these drawbacks, the 4+2 model improved ambulatory training.

PATIENTS AS TEACHERS IN PATIENT SAFETY: A NEW INTERPROFESSIONAL EDUCATIONAL MODEL FOR COLLABORATIVE LEARNING ABOUT MEDICAL ERROR DISCLOSURE AND PREVENTION Thorsten Langer²; William Martinez³; David Browning²; Pam Varrin²; Barbara Sarnoff Lee¹; Sigall K. Bell¹. ¹BIDMC, Boston, MA; ²Boston Children's Hospital, Brookline, MA; ³Vanderbilt University Medical Center, Nashville, TN. (Tracking ID #2201116)

NEEDS AND OBJECTIVES: There is growing interest in engaging patients and families (P/F) in patient safety efforts, and in patient- and family-centered medical education, but robust partnership opportunities have been limited. P/F experiences when things go wrong highlight an important gap in effective communication after adverse events. However, the potential role for P/F in safety education has not been well-developed. Medical error disclosure training programs are rapidly disseminating, yet opportunities for patients and providers to come together, reflect, and engage in collaborative learning about patient safety communication are generally lacking in most practice settings. We developed, implemented and assessed a new educational model that engages P/F as teachers and co-learners with interprofessional clinicians on medical error disclosure and prevention.

SETTING AND PARTICIPANTS: Interprofessional clinicians and P/F from 2 academic hospital patient and family advisory councils in Greater Boston volunteered to participate. P/F who participated in the workshops attended an orientation session that focused on principles of collaborative learning. Three workshops were consecutively held in 2012/2013; each involving 20–25 participants.

DESCRIPTION: The 4-h workshops included an in-depth simulation with professional actors portraying the role of patients and family members, and clinicians playing their own

role in disclosure of a team error. Facilitators included physician, psychosocial, and family faculty who are practicing professionals and educators. The simulation focused on medical error disclosure and both clinician and P/F challenges with speaking up about potential safety threats. Each enactment was immediately followed by debriefing including the actors, clinicians, patients/family, and facilitators.

EVALUATION: A pre-post-survey with closed and open-ended questions assessed the acceptability of the model to P/F and clinicians, and the potential benefits and risks of including patients and family in medical error disclosure and prevention training. It also queried participants' experiences and perceptions about medical error, and attitudes about patient engagement in safety and speaking up. SPSS (21.0) was used for statistical analysis. Responses to open-ended questions were coded according to principles of content-analysis. Of participants, 53/55 (96 %) clinicians and 71/88 (81 %) P/F completed pre-surveys, and 42 % clinicians and 39 % P/F reported experiencing a harmful error. Of those, about half (57 % clinicians, 48 % patients) reported the error was disclosed. The vast majority (94 % clinicians, 88 % P/F) held positive expectations regarding collaborative learning. Participants reported their hopes, fears, what was valuable and challenging (Table 1). Clinicians prioritized learning "what it is like on the receiving end" of a disclosure conversation, and compassionate communication skills. Patients hoped to learn "what clinicians experience in a medical error;" "my role as a patient in minimizing errors", and preventing recurrences, and how to engage clinicians to learn from patients. Among concerns, clinicians cited power dynamics dampening effective interaction, and that P/F would "learn just how fallible we are." P/F were concerned about jargon, defensive posturing by clinicians, and dynamics, hoping they "have the freedom to speak openly" and are "willing to be seen as fallible human beings." To date, 48/55 (94 %) clinicians and 9/9 P/F completing the training reported the participation of P/F and clinicians (respectively) was valuable. Clinicians specifically valued direct feedback from "real" patients—"great insights I don't normally have access to." They reported learning concrete patient-centered approaches to error disclosure ("patients need time to process - we go too fast"). P/F appreciated insights into emotional impact of errors on clinicians (I had never heard medical people acknowledge feeling before), learning communication skills, and the honesty and accountability of clinicians.

DISCUSSION / REFLECTION / LESSONS LEARNED: An educational paradigm that includes patients as teachers and co-learners with clinicians about patient safety is feasible and highly valued by clinicians and P/F, particularly to help P/F and clinicians appreciate each other's perspectives, improve compassionate communication, and empower patients as safety partners. However, sensitive facilitation is required as participants may be worried to talk openly about medical errors and medical culture, including fallible providers and systems. Learning alongside patients and family sets the stage for building more robust partnerships between clinicians and patients. The authors provide recommendations about how to develop a patient-teacher in patient safety program (Table 2).

PREPARING FOR THE PRIMARY CARE CLINIC: AN AMBULATORY BOOT CAMP FOR INTERNAL MEDICINE INTERNS Lindsay M. Esch; Amber Bird; Julie Oyler; Wei Wei Lee; Sachin D. Shah; Amber Pincavage. University of Chicago, Chicago, IL. (Tracking ID #2193547)

NEEDS AND OBJECTIVES: Fourth year medical students often have limited exposure to primary care education in their last year of medical school and interns often report being unprepared to start internal medicine continuity clinic. Although boot camps have been used at the beginning of post-graduate training programs to improve preparedness and clinical skills for clinical work, there has not been adequate research regarding how to best prepare interns for primary care clinic. Our objective was to implement and assess the impact of an intern ambulatory boot camp on primary care knowledge, confidence, and curricular satisfaction.

SETTING AND PARTICIPANTS: During July 2014, 38 internal medicine interns attended ambulatory boot camp prior to starting primary care clinic.

DESCRIPTION: The boot camp included one half day of clinically focused case-based didactic sessions on common ambulatory topics including diabetes, hypertension, hyperlipidemia, health maintenance screening, shoulder pain and knee pain. This was followed by another half day of orientation to the clinic, outpatient team and EMR. To evaluate the curriculum, interns anonymously completed a 15 question pre-test on topics covered in the boot camp and were re-assessed with an identical post-test after the boot camp. The interns were also surveyed regarding their confidence, satisfaction with the boot camp experience and exposure to ambulatory education in medical school.

EVALUATION: Thirty eight interns participated in boot camp and all completed tests and surveys. Prior to the boot camp, few interns reported confidence managing common outpatient conditions: 55 % for hypertension, 50 % for hyperlipidemia, 42 % for health maintenance screening, 32 % for diabetes, and 11 % for musculoskeletal complaints. Only 15 % of interns felt they had received sufficient training in medical school to manage primary care patients. On average, the interns reported 2.9 months of primary care clinic

rotations during medical school. The average duration between the boot camp and the participants' last primary care clinic was 15 months. The number of prior outpatient rotations and the amount of time since the interns' last primary care rotation had no effect on the pre-test scores. The average pre-test knowledge score was 6.95/15 (46.3 %). After the boot camp, the average post-test knowledge score significantly improved to 11.42/15 (76.1 %) ($p < 0.001$). After completion of the boot camp, 100 % of interns reported that the boot camp was good preparation for clinic, 100 % felt that ambulatory boot camp should be a required component of internship, and 97 % felt that the lectures boosted their confidence in managing common conditions encountered in primary care clinic.

DISCUSSION / REFLECTION / LESSONS LEARNED: The intern ambulatory boot camp improved knowledge of commonly encountered medical topics in the primary care clinic. The participants thought it was good preparation and it should be a required component of internship. The intern ambulatory boot camp may be an effective way to improve the preparation of interns for primary care clinic.

PREPARING MEDICAL STUDENTS FOR THE FUTURE, RATHER THAN THE PRESENT Golub Lucas; Daniel D. Dressler. Emory University, Atlanta, GA. (Tracking ID #2200075)

NEEDS AND OBJECTIVES: Every day a practicing clinician comes up with dozens of clinical questions. The ability to efficiently fill in these knowledge gaps over the course of a medical career is an important skill. Medical education can only provide knowledge as it currently exists, and it is difficult to systematically teach the skills necessary to be a lifelong learner. Thus our objective were to create curriculum for medical students which would help them 1) efficiently answer clinical questions, 2) interpret summary medical literature, 3) utilize mobile and web-based resources for these purposes.

SETTING AND PARTICIPANTS: Our institution's medical school curriculum contains a 'capstone' component during the final month of students' forth year. There are multiple selective courses from which students choose to build a customized curriculum; ours is one. Typically around 25 students take the course.

DESCRIPTION: This course occupies two separate half-days, roughly a week apart. Day 1 provides several interactive didactic sessions on topics including evidence hierarchy, finding evidence to answer clinical questions ("pull" tools), monitoring new evidence as it is published ("push" tools), and systematically evaluating summary evidence (both guidelines and meta-analyses, with a structured journal club format to discuss representative examples of each). As homework for the second session, students individually prepare 2-min talks on separate "push" and "pull" resources. They also form small groups wherein each group asks a clinical question, searches for a piece of relevant summary literature, and systematically evaluates the article. Day 2 of the course is student led and involves the 2-min talks on relevant push and pull resources followed by discussions of the specific guidelines and meta-analyses that the groups have selected.

EVALUATION: Pre- and post-tests are given to students to assess both their comfort level with the topics discussed subjectively (Likert scale) and also objectively test their knowledge of concepts presented via multiple choice questions. In the 3 years that this course has been offered, 80 students have taken it. On average, Likert scores for confidence to effectively utilize push and pull resources increased from 3.1 to 4.6, and 3.6 to 4.7, respectively. Similarly, scores for the ability to critically appraise both guidelines and meta-analyses increased from 3.2 to 4.5, and 3.1 to 4.5, respectively. Of note, the students varied broadly in their future field of practice: 38 % internal medicine, 17 % surgical subspecialty, 12 % pediatrics, 10 % general surgery, 7 % emergency medicine, 7 % radiology, 7 % psychiatry or neurology, and 3 % OB/GYN.

DISCUSSION / REFLECTION / LESSONS LEARNED: With only two half-day sessions, soon-to-graduate fourth year medical students were able to significantly improve their competence with a number of core skills required to be lifelong learners and keep abreast of future advances in medicine. They left with practical knowledge to efficiently search the medical literature to answer clinical questions (pull resources) and have cutting-edge clinical information automatically sent to them (pull resources). Students were also taught how to systematically evaluate and interpret some of the most clinically relevant evidence types, guidelines and meta-analysis/systematic review. Given the pace of modern medicine clinically, as well as the exponential rate of growth of knowledge and information, we feel that these are some of the most high-yield skills which could possibly be taught to students and trainees alike. Based on objective data from pre- and post-testing of the course, these are not subjects that students feel comfortable with, even at the conclusion of 4 years of medical education. However, a small investment of time significantly increases proficiency with tasks that will last a lifetime.

READMISSION M & M Joseph J. Ingrassia; Sidra Azim; Shiromini Herath; Jennifer Baldwin; Scott Allen; Wendy Martinson. University of Connecticut, Farmington, CT. (Tracking ID #2194457)

NEEDS AND OBJECTIVES: A common goal for all healthcare institutions is to decrease preventable readmissions. John Dempsey Hospital of the University of Connecticut developed a multidisciplinary Morbidity and Mortality (M&M) style conference to help determine the root causes of readmissions. The main goals of the conference are to educate residents about readmissions and to analyze the causes of readmission for process improvement.

SETTING AND PARTICIPANTS: Investigations are conducted by Internal Medical Residents on a 4-week inpatient hospitalist medicine rotation. Residents meet with faculty, chief medical residents and quality specialists of the hospital to discuss the case at the beginning of the rotation and are educated and guided on how to do a root cause analysis of the readmission through weekly meetings with the team.

DESCRIPTION: Residents then conduct the investigation through review of medical records, patient and family interviews, and feedback from staff that provided patient care during the index admission and the readmission. The staff include the hospitalists, residents, fellows, nursing staff primary care physician and other specialists who are involved in the care of the patient. Case managers, home care agencies, discharge coaches and extended care facilities are also interviewed. The residents present their finding and lead a discussion at the monthly Readmission M&M that is attended by hospitalists, specialists, emergency room physicians, members of the palliative care service, and other ancillary staff including nursing, case management and social workers. Hospital administration, quality, and patient safety representatives also attend. At the conclusion of each conference, the residents submit an 'Apparent Cause Analysis' of the readmission that was investigated to the quality and safety department. The findings are used to drive quality improvement and patient safety initiatives.

EVALUATION: The conference identifies system failures that have contributed to readmission. The following are areas that have been identified for improvement: inpatient care management, appropriate utilization of local resources, communication across provider groups, medication reconciliation, and post-hospitalization management and coordination of care. Examples of specific opportunities for improvement identified by the residents that have resulted in changes in the system of care include: · Implementing an antibiotic review process in conjunction with the pharmacy department, to reduce the incidence of *Clostridium difficile* infection. · Development and reinforcement of email communications that alert in-network primary care physicians and specialists of patients that have been admitted to the hospital. · Performance of D-test for inducible Clindamycin resistance on MRSA isolates. · Documentation of the method of urine collection for specimens sent to Microbiology testing. · Creation of a survey of regional skilled nursing facilities based on quality and capabilities for most appropriate referral of patients. · Development of individualized care plans for future admissions by the hospitalist, the patient's primary care physician, specialists, and emergency room physician for patients with recurrent readmissions that anticipate complex care management needs.

DISCUSSION / REFLECTION / LESSONS LEARNED: Residents who presented the conference report having gained an understanding of clinical and psychosocial care that needs to be present across the continuum of care for best practice. They also learn about the interplay between readmissions, hospital reimbursements, and patient satisfaction. This initiative addresses three of the six focus areas of the Clinical Learning Environment Review (CLER) where residents participate in hospital initiatives to improve quality and safety. Further, this conference is educating all providers of cognitive and system errors that lead to hospital readmissions, and is providing an opportunity to discuss them in an open forum enabling solutions at the same time.

SELF-REGULATED LEARNING AND STANDARDIZED TEST PERFORMANCE IN INTERNAL MEDICINE RESIDENTS Mary Andrews²; Anthony R. Artino¹; Kevin M. Douglas¹; Kent DeZee¹. ¹Uniformed Services University of the Health Sciences, Bethesda, MD; ²Walter Reed National Military Medical Center, Bethesda, MD. (Tracking ID #2195924)

NEEDS AND OBJECTIVES: Standardized tests are ubiquitous in medical education and residents who underperform on these tests require considerable faculty time and resources to remediate. Novel methods of identifying and assisting these residents are needed. Self-monitoring (the practice of accurately assessing one's performance) and causal attribution (a personal belief about the reasons why one's performance meets standards or not) are two components of self-regulated learning theory that may provide a useful framework for identifying and correcting test-taking deficits. In our academic medical center, we have used a structured, face-to-face assessment of self-monitoring and causal attribution as part of a multifaceted remediation plan for struggling internal medicine residents. We conducted a pilot study to collect validity evidence for our methods. Our objectives were to determine the feasibility of measuring self-monitoring and causal attribution among internal medicine residents by means of an online examination and to determine whether self-monitoring and causal attribution, as measured by this online examination, correlate with performance on the In-Training Examination (ITE) and the USMLE Step 2 Clinical Knowledge (Step 2).

SETTING AND PARTICIPANTS: We conducted a cohort study of internal medicine trainees at a single academic medical center. All residents who had not participated in the face-to-face assessment were invited to participate.

DESCRIPTION: Participants completed an online examination consisting of 10 expert-validated, multiple-choice, clinical vignette test questions, each of which was followed by a single item measuring confidence in the answer on a Likert-type scale and three free-response items assessing diagnostic reasoning and answer justification. The confidence scores and the answer status for each test question (correct or incorrect) were used to calculate a self-monitoring score that ranged continuously from zero to four, with zero indicating complete miscalibration (repeatedly either over- or under-confident) and four indicating perfect calibration (i.e., very confident when correct and not at all confident when incorrect). The free-response items regarding diagnostic reasoning and answer justification were scored independently by two board-certified general internists using prespecified criteria to generate a causal attribution score which ranged from zero to 10. The higher the causal attribution score, the better the participant explained his diagnostic reasoning and justified his answer choice. Interrater agreement for scoring free response items was assessed by the kappa statistic. Correlation between self-monitoring and causal attribution scores and ITE percentile rank and Step 2 three-digit scores were examined using Spearman's rank correlation coefficient. Power analysis was based on an estimated sample size of 50 residents, which would have resulted in 80 % power to detect a correlation coefficient of 0.4 or greater.

EVALUATION: 22/77 (28 %) of internal medicine trainees participated in the study. Half of participants (11/22) were interns, eight were PGY2s, and three were PGY3s. The average number of multiple-choice questions answered correctly was 7.7/10 (SD 1.5). The average self-monitoring score was 2.4 (SD 0.4) on a 4-point scale, with a score of 4 indicating perfect calibration of the trainees' self-confidence with their performance. The average causal attribution score was 4.6 on a 10 point scale (SD 1.4), with a score of 10 indicating that the resident mentioned all details that the expert reviewers considered necessary when explaining their diagnostic reasoning and justifying their answer selection. The interrater agreement for scoring the causal attribution questions was moderate to substantial (median kappa=0.58, IQR, 0.49–0.78). There was no statistically significant correlation between ITE rank score and self-monitoring ($r_s=0.22$, $p=0.22$) or between ITE and causal attribution ($r_s=0.19$, $p=0.40$). Likewise, there was no statistically significant correlation between Step 2 CK scores and self-monitoring ($r_s=0.27$, $p=0.28$) or causal attribution ($r_s=0.21$, $p=0.41$). Post-hoc analysis showed that a sample size of 124 would be necessary to achieve 80 % power to detect a correlation of 0.25 or greater.

DISCUSSION / REFLECTION / LESSONS LEARNED: Measuring self-regulated learning in internal medicine residents via an online examination is feasible. Although we did not detect statistically significant correlations between self-monitoring and causal attribution and standardized test performance, we did find small effect sizes and we were limited by low participation rates. Future efforts to measure self-regulated learning should utilize incentives and dedicated time within the workday to encourage resident participation. Self-regulated learning theory remains a feasible tool for assisting trainees who underperform on standardized tests.

ONLINE RESOURCE URL (OPTIONAL): https://www.surveymonkey.com/s/SRL_Instrument

SERVING THE COMMUNITY AND UNDERSTANDING THE AFFORDABLE CARE ACT: UNIVERSITY OF MIAMI MEDICAL STUDENTS TRAINED AS CAC ASSISTERS Alison Moody; Jennifer Shiroky; Joe Bennett; Karyn Meshbane; Angelica Melillo; Jeffrey Lin; Katelin Snow; Mark O'Connell. University of Miami, Boynton Beach, FL. (Tracking ID #2199362)

NEEDS AND OBJECTIVES: The Affordable Care Act (ACA) gives Americans the opportunity to purchase health insurance through Health Insurance Marketplaces. Miami and SE Florida has one of the largest uninsured populations in the US. Faculty and student leaders from University of Miami Miller School of Medicine's (UMMSM) Department of Community Service (DOCS) saw the ACA as an opportunity to expand access to care for uninsured members of the community and felt that students would benefit from the opportunity to learn about health insurance and the ACA by becoming involved in its implementation. To that end, a project was developed to train and certify UMMSM medical students as Certified Application Counselors (CACs) in order to provide assistance to consumers seeking health insurance through the Health Insurance Marketplace.

SETTING AND PARTICIPANTS: A partnership was formed between UMMSM and the Health Council of South Florida (HCSF), a community organization that was awarded federal funding for training and managing insurance Navigators and CAC assisters. Some enrollment events were conducted in partnership with Enroll America, the White House's ACA organizing entity in Florida. Enrollment activities took place at the UM/Jackson Health System medical campus, a large public safety net hospital and academic health center in Miami. Students also provided assistance to consumers attending DOCS

community health fairs in several underserved communities in South Florida and in a student-run weekly free clinic.

DESCRIPTION: The choice to train as a CAC was made available to all UMMSM students and participation was voluntary. Students who chose to participate completed a 5-h online course created by the federal government and attended an in-person 1-hour training session hosted by DOCS student leaders. Once trained and certified by HCSF, students were asked to allocate a minimum of 2 h each week to educating and enrolling insurance consumers. In the first year of the ACA initiative (2013–14), 64 students were credentialed as CACs. These CACs provided insurance enrollment assistance on the UM/Jackson Health System campus 4 h a day, 5 days a week for 2 months of the enrollment period. Student CACs also organized community enrollment events and established an "Enrollment Assistance Station" at five UMMSM DOCS health fairs and a student-run weekly free clinic. Student CACs assisted over 300 consumers with creating accounts on Healthcare.gov, exploring their insurance options, identifying federal subsidies, and enrolling in a health plan. The State of Florida enrolled more consumers through the federal marketplace than any other state, and enrollment in Miami-Dade County was the highest in the state. For this second year's enrollment season, 76 students from UMMSM's Miami campus have been credentialed as CACs. Also, the ACA initiative was expanded to UMMSM's Regional Medical Campus in West Palm Beach where 16 regional campus students have become certified CACs under the aegis of the Health Council of Southeast Florida, the partner organization to HCSF in Palm Beach County. These students have attended numerous community events, enrolling consumers in health insurance plans and providing education and assistance to many more.

EVALUATION: All participants and partners consider the medical student CAC project to have been a valuable experience. We are currently conducting a formal survey of our CACs to assess the educational benefit of the project for our students and their perceived community impact. Survey analysis will be completed in February. This year's CACs will complete the survey at the end of the enrollment period allowing us to assess our progress and continue to shape the initiative for future years.

DISCUSSION / REFLECTION / LESSONS LEARNED: Students gained valuable insight into health insurance and the impact of social and financial factors on access to health insurance and care. These issues are underemphasized in medical education. Students were able to gain a unique perspective on barriers to care and frustrations experienced by consumers who struggle to navigate the health insurance system. Many Floridians do not qualify for or cannot afford health insurance as a result of the State's failure to accept Medicaid expansion. Insurance was not available to consumers who fell in the "Medicaid gap." They were referred to sliding scale clinics and to legal aid services. Students struggled with language barriers, as many individuals seeking healthcare through the marketplace in South Florida were Spanish and Creole speaking-only. This year, HCSF is providing a Spanish and Creole-speaking navigator to work with the student CACs. Our student CACs provided insurance education and enrollment assistance to several hundred consumers. We feel this model can be expanded to other medical schools providing future physicians with an understanding of the ACA and to the benefit of the communities in which they train.

SIMULATION IN AMBULATORY EDUCATION: A CURRICULUM INNOVATION Alexander S. Rackman²; Emily Ryan³; Rebecca A. Mazurkiewicz¹. ¹Lenox Hill Hospital Medicine, New York, NY; ²Lenox Hill Hospital NS-LIJ, New York, NY; ³Lenox Hill, NSLIJ, New York, NY. (Tracking ID #2195774)

NEEDS AND OBJECTIVES: 1. To determine if use of a patient care simulator in ambulatory resident education increased Internal Medicine resident comfort with performing breast and pelvic exams. 2. To determine if use of a patient care simulator in ambulatory resident education increases Internal Medicine residents' intent to perform breast and pelvic exams in the future. 3. To determine the perceived quality of a curriculum utilizing patient care simulators to perform breast and pelvic exams by Internal Medicine residents.

SETTING AND PARTICIPANTS: Educational modules were run by the investigators for the categorical Internal Medicine Residents at Lenox Hill Hospital who rotated on the ambulatory service during the 2014–2015 academic year. Each session was comprised of 1 facilitator and 4 resident attendees, for a total of 66 resident participants of any PGY level 1 to 3.

DESCRIPTION: Residents underwent individual baseline skill assessment (pretest) for breast and pelvic exams via direct observation by the session facilitator using checklists derived from ACP recommendations for these procedures. Residents then participated in a 1.5-h education session featuring patient scenarios in which one would perform breast and pelvic exams on a patient simulator. The case for the breast exam featured a patient complaining of a breast lump while the pelvic exam case featured a patient complaining of vaginal discharge. As a group, residents discussed the case then the session facilitator performed a stepwise demonstration of the procedure. Lastly, residents were retested (posttest) for breast and pelvic exams using the same procedure as the pretest. After the

session ended, residents were asked to complete an anonymous electronic survey to elicit the residents' comfort with breast and pelvic exams before and after the educational intervention, their likelihood to perform these ambulatory procedures in the future, as well as the overall quality of the educational session.

EVALUATION: Procedure performance, comfort with the procedures, likelihood of performing the procedures, quality of ambulatory procedure training before the educational intervention were compared to that after the intervention using descriptive statistics and mixed method assessment using qualitative and quantitative methods. All of the 66 residents who participated in the educational session completed the post-session survey. On a scale of 1 to 5 (from very uncomfortable to very comfortable), resident comfort with performing breast exams went from an average rating of 3.38 to 4.42 and pelvic exams from 2.74 to 4.08 after the educational session. Residents reported that on a scale of 1 to 5 (from very unlikely to very likely), residents rated the likelihood that they would have perform a breast exam for an asymptomatic woman (i.e. as part of an annual physical after the educational session) as a 2.33 before the educational session to 3.51 after the session. The intention to perform pelvic exams for screening purposes rose from 2.35 before the session to 3.42 after the session. On a scale from 1 to 5, the average rating of the educational session by resident participants was 4.73.

DISCUSSION / REFLECTION / LESSONS LEARNED: Residents had tremendous positive feedback, including the following anonymous comments: "Excellent teaching session, my comfort level with breast and pelvic exams has increased significantly." "Very informative and helpful." "Excellent educational experience! Despite feeling very comfortable prior to my clinical chloe session I now feel both comfortable and confident with both pelvic and breast exams." This educational intervention proved to be a unique curriculum innovation and is, to our knowledge, the first comprehensive ambulatory simulation model. The education session was designed to help residents feel more comfortable in performing pelvic and breast exams, while proving that they will intend to perform more of these sensitive exam maneuvers in the future. In future directions, we will be analyzing a more objective way to evaluate resident performance by using pre and post direct observation evaluation forms, which can also be used for the ACGME requirements of direct observations.

STAR (SAFE TRANSITIONS ACROSS CARE): AN INITIATIVE TO IMPROVE RESIDENT AND FACULTY EDUCATION TO IMPROVE PATIENT CARE ACROSS THE HEALTHCARE CONTINUUM Nancy M. Denizard-Thompson²; Kirsten Feiereisel¹. ¹Wake Forest Health Sciences, Winston-Salem, NC; ²Wake Forest University School of Medicine, Winston-Salem, NC. (Tracking ID #2196008)

NEEDS AND OBJECTIVES: 1. To Integrate a resident transition of care curriculum and provide associated faculty development 2. To create a tool to standardize an approach to discharge planning and hospital follow up visits 3. To evaluate utilization and impact of the STAR transitions of care tool

SETTING AND PARTICIPANTS: The educational innovation was designed and implemented at a large academic medical center targeting Internal Medicine residents and General Internal Medicine faculty.

DESCRIPTION: This curriculum was developed for residents and faculty to improve the discharge planning process and reintegration of patients into their community and medical home. Residents participated in 2 STAR seminars which introduced use of a STAR Transitions of Care tool with a dual purpose of educating learners while enhancing patient safety. This pocket card identifies key elements of a safe and successful transition across the care continuum. One side is for hospital discharge planning and highlights key elements of a safe discharge while the other side focuses on elements of the hospital follow-up visit. The first seminar simulated the inpatient discharge process using the discharge planning side of the STAR tool. The second session introduced the hospital follow-up side for use in clinic to inform residents about issues that may prevent readmissions and ensure that patients have safely transitioned to their home. As faculty need to be proficient in engaging and training residents on this important skillset in both the inpatient and outpatient settings we provided faculty development sessions on use of the STAR tool. These seminars followed the same structure as the STAR Educational Seminars described above.

EVALUATION: Residents completed a pre, immediate post and 6 month post survey measuring knowledge and attitudes of transitions of care. Approximately 30 residents completed the training seminars. Of the residents surveyed 44 % percent reported having very little formal training on discharge planning. In contrast, 53 % reported very little training on hospital follow-up and 47 % reported having had no formal training. The pre and immediate post evaluation demonstrated an increase from 68 to 95 % of residents feeling highly skilled (4 to 5 on Likert scale) in the key components of discharge planning and an increase from 50 to 74 % of residents feeling highly skilled in their ability to teach learners about discharge planning. Immediately following training, residents reported a number of domains that they planned to start to address in their discharge planning process. There was a 15 to 24 % increase in pending referrals and results, and

transportation needs; 25 to 34 % increase in home equipment needs; 35 to 44 % increase in goals of care and communication with key providers, and social networks; 45 to 53 % increase in patient's ability to obtain medications, family support systems, and education needs. The pre and immediate post evaluation demonstrated an increase from 43 to 96 % of residents feeling highly skilled (4 to 5 on Likert scale) in the key components of hospital follow-up visits. Immediately following training, residents reported a number of domains that they planned to start to address in their hospital follow up visits as a result of the seminar. Specifically there was a 15 to 24 % increase in areas of assessing whether key follow-up appointments had been scheduled; 25 to 34 % increase in assessing patient's understanding of hospital course; 35 to 44 % increase in ADLs and need for home health; 45 to 54 % increase in goals of care, cognitive and functional status, barriers to medication adherence, and family support systems; 55 to 74 % increase in assessment of equipment needs, social networks, and transportation needs. Review of 6 month post survey showed that the majority of these areas were maintained at higher levels. Seventy-four percent reported having used both the discharge planning and the hospital follow up component of the STAR tool in clinical practice. Faculty completed a pre and immediate post survey. Faculty data revealed that 62 % and 69 % had received no prior training on how to teach discharge planning and hospital follow-up, respectively. The pre and immediate post evaluation demonstrated an increase from 38 to 78 % and 54 to 86 % of faculty feeling highly skilled (4 to 5 on Likert scale) in teaching residents the key components of discharge planning and hospital follow up visits, respectively.

DISCUSSION / REFLECTION / LESSONS LEARNED: There is need for training of residents and faculty in discharge planning and even more significantly in hospital follow-up visits. We demonstrated continued use of the STAR transition tool by residents six month following training and persistent retention of knowledge and skills learned during the seminar. This intervention required minimal training time and provides a simple tool that is easy to use and disseminate to other sites. Next steps will include evaluation of hospital follow-up visits following implementation of the tool to evaluate effect on readmission and patient outcomes.

TEACHING CLINICAL NUMERACY TO INTERNAL MEDICINE RESIDENTS Frank W. Merritt. University of Colorado, Aurora, CO. (Tracking ID #2198355)

NEEDS AND OBJECTIVES: There has been a recent emphasis on teaching principles of evidence-based medicine and high-value care in graduate medical education, as evidenced by the Choosing Wisely initiative and described by subsections of the Practice-Based Learning and Systems-Based Practice core competencies laid out by the ACGME. To competently practice evidence-based medicine, physicians must have a foundational ability to accurately interpret literature regarding both treatments and diagnostic tests and to translate these data into decisions for individual patients. However, most physicians-in-training—and most practicing physicians—have poor ability to understand medical statistics and, more importantly, have difficulty using those data productively to promote rationale clinical decisions. This set of skills, which has been termed "clinical numeracy," may not be adequately conveyed to learners through a traditional journal club curriculum.

SETTING AND PARTICIPANTS: A pilot curriculum was delivered to the entire intern class in Internal Medicine at our institution over the course of 6 months, with monthly interactive lectures and case-discussions. Each session was approximately 30 min long and included 10–12 interns.

DESCRIPTION: Our objective was to provide learners with the fundamental skills of clinical numeracy and the ability to apply these skills to limit unnecessary or harmful tests and interventions. The first half of the curriculum dealt with the accurate assessment of risks and benefits of treatments, including understanding the relationship between absolute and relative risk reduction and understanding the difference between patient-centered outcomes and less-helpful surrogate outcomes. Case-based teaching encouraged learners to use these skills to make difficult individualized clinical decisions, making recommendations for or against hypothetical medications. For instance, learners were asked to discuss how strongly they would recommend a drug with a statistically significant but very small absolute risk reduction of myocardial infarction to a patient in whom the drug was a considerable financial burden. The second half of the curriculum dealt with the rational use of diagnostic testing. We explored principles of Bayesian reasoning and the importance of understanding pre-test probability as well as a test's ability to change the probability of a diagnosis (usually best expressed as a likelihood ratio). These diagnostic probabilities were considered in the context of "treatment thresholds." Again, we used a case-based format and interactive discussion to encourage learners to determine whether a test would change management in a given scenario. We discussed how cognitive biases may hinder accurate interpretation of tests, particularly if test characteristics are not known by the ordering physician and if pre-test probability is not considered. Several key overarching concepts were woven throughout the course, including cost-effectiveness, effective communication of risk and benefits to patients, and dealing with uncertainty in medicine.

EVALUATION: The initial response from learners was positive. To the statement “This session significantly furthered my understanding of how to practice evidence-based medicine in a real world setting,” the average response was 4.6 on a 5-point Likert scale ($N=108$). Similarly, for the statement “I will be able to use skills from this session in my regular practice,” the response was 4.5 out of 5 ($N=108$). Additionally, we have preliminary data showing a trend towards improved scores on the Critical Risk Interpretation Test (CRIT), a previously validated assessment that uses brief clinical vignettes to assess clinical numeracy. The test was administered to 41 interns prior to the curriculum and 37 interns repeated the test 6 months later. There were significant differences in several specific skills measured by the CRIT, including rating morality as more important than 5-year survival rates in screening studies (87 vs. 53 %, $p<0.01$), recognizing that disease is unlikely when pre-test probability is extremely low, even with a positive diagnostic test (40 vs. 5 %, $p<0.01$), and recommending treatments that improve mortality rates more strongly than treatments that only improve surrogate outcomes (90 vs. 56 %, $p<0.01$) or composite outcomes (57 vs. 17 %, $p<0.01$).

DISCUSSION / REFLECTION / LESSONS LEARNED: Teaching fundamental clinical numeracy concepts may complement the traditional journal club curriculum in internal medicine residency programs and is perceived by learners to be beneficial. Ideally, these skills should be taught in a problem-based manner that gives learners skills that they can apply in a real-world setting. Future efforts will focus on encouraging learners to implement these ideas in practice and measuring changes in behavior and culture.

TEACHING VALUE-BASED CARE TO MEDICAL STUDENTS TO INCREASE HIGH QUALITY, COST CONSCIOUS CARE Sara-Megumi L. Naylor; Erin L. Duffy; Neveen S. El-Farra; Allison Diamant. UCLA Medical Center, Los Angeles, CA. (Tracking ID #2190985)

NEEDS AND OBJECTIVES: Ongoing changes to the healthcare system demand further education of physicians to consider the benefits, harms, and costs of their daily interventions for patients. Focusing on medical students early in their career can promote cultural and process change that will increase their likelihood of practicing value-based care. There is minimal data regarding the attitudes, knowledge, and skills of medical students regarding value-based care. Similarly, there is no data regarding the impact of educational interventions on the willingness or confidence of medical students to practice such care. We designed and evaluated an educational intervention that introduces value-based care to medical students.

SETTING AND PARTICIPANTS: A total of 33 students were included. Specifically we recruited 22 third year medical students from the UCLA David Geffen School of Medicine who were rotating on the inpatient internal medicine clerkship at Ronald Reagan UCLA Medical Center between January and June of 2014. Eleven third year medical students at different clerkship sites served as controls for the intervention.

DESCRIPTION: We designed a prospective survey-based cohort study of an educational intervention. The project received IRB approval. The educational intervention consisted of clinical cases, interactive activities, and resources that highlight value-based care. The material was generated from reviewing the literature and by using the available resources found through the ACP High Value Care initiative as well as the ABIM Choosing Wisely campaign. The intervention was conducted in a group setting and lasted 1 h. There was a concerted effort to generate personalized, concrete strategies for students to practice value based care in their current role as medical students on inpatient ward teams. We collected pre-intervention, post-intervention, and delayed (3 months) post-intervention survey data to measure attitudes, self-perceived skills, and knowledge regarding value-based care. All responses were on a 5 point Likert scale. Paired *t*-test were utilized to assess differences between pre-intervention and post-intervention surveys.

EVALUATION: Overall we found the educational intervention to be effective in promoting value-based care. We found that only 33 % of students either somewhat agreed or strongly agreed that they have a role as medical students in controlling healthcare costs prior to the intervention, but this increased to 81 % after the intervention. Interestingly, 90 % of students either somewhat agreed or strongly agreed that they will have a role in controlling healthcare costs as a physician even prior to the intervention, hinting that we likely need to empower and prepare our medical students more during the third year of medical school to practice value-based care. We found the educational intervention was most effective in encouraging students to think about cost. After the educational intervention, there was a significant increase in students' reported likelihood of looking up the cost of a specific test or procedure prior to recommending it as part of the treatment plan ($p<0.001$), discussing the cost of a specific test or procedure with a patient ($p<0.001$), and discussing how the cost of a specific test or procedure will impact the finances of the patient ($p=0.018$).

DISCUSSION / REFLECTION / LESSONS LEARNED: If providing high-value, cost-conscious care becomes a “critical seventh general competency for physicians” as proposed by SE Weinberger, MD, there will be a large need for defined curricula to

address these current gaps in our education. It is important to design and measure educational interventions that can meet the needs of medical students. We were reminded that teaching must be deliberate and purposeful as we found that approximately one-third of third year medical students reported never receiving any education on value based, high quality and/or cost-conscious care despite required classes on these topics during the first 2 years of medical school. Our data was limited by sample size as students were at various training sites and few students opted to voluntarily complete surveys online. We also found discussing cost to be challenging given the lack of transparency of charges and costs and the long-standing history of avoiding the discussion of money in medicine. Finally, we were unable to measure the impact of our intervention on the actual skills of medical students in practicing value-based care and the impact of our education on real patient and system outcomes. Our future goal is to optimize this teaching initiative through sequential, iterative changes and implement the project for all medical students prior to entering their third year clerkships.

TEAM QI: AN INNOVATIVE STEPWISE APPROACH TO INVOLVE RESIDENTS IN QUALITY IMPROVEMENT INITIATIVES IN THE OUTPATIENT SETTING Elena Lebduska³; Amar Kohli¹; Erika L. Hoffman⁵; Gary Fischer²; Carla Spagnoletti²; Jaishree Hariharan⁴. ¹UPMC, Pittsburgh, PA; ²University of Pittsburgh, Pittsburgh, PA; ³University of Pittsburgh Medical Center, Pittsburgh, PA; ⁴University of Pittsburgh Medical center, Pittsburgh, PA; ⁵VA Pittsburgh Healthcare System, Pittsburgh, PA. (Tracking ID #2199104)

NEEDS AND OBJECTIVES: ACGME recognizes that internal medicine (IM) trainees must achieve competence in systems based practices. The outpatient setting is an ideal place to teach these skills. With many residency programs going to an inpatient/outpatient “block system” achieving continuity for quality improvement (QI) projects in the outpatient setting becomes a challenge. With this in mind, we developed an educational initiative that aims to: 1) Increase resident interest and participation in QI projects in the outpatient setting by using a resident-driven team-based approach; 2) Improve the care of outpatients by addressing chronic disease management in the new “block system”; 3) Foster increased interaction and communication between residents and ancillary clinic staff.

SETTING AND PARTICIPANTS: Participants are the 140 residents affiliated with the University of Pittsburgh Medical Center. All residents follow a panel of continuity patients with faculty supervision in one of three hospital-based clinical sites: a university clinic ($n=52$), a community clinic ($n=36$) and a VA clinic ($n=52$). In the new block system, residents have clinic one full day each week (Monday-Thursday) every other month. Residents have been placed into QI teams based on their clinic day, for a total of 8 QI teams per site. Ancillary staff is also involved in the initiative (nurses, medical assistants, secretaries, and clinic directors).

DESCRIPTION: The pilot year for this initiative is 2014–2015. At non-VA clinic sites, the focus of the resident QI project is diabetes. Eye and foot exams were initially identified as the quality measures with the least compliance rates; thus, our focus this year is to improve these measures using a longitudinal, multistep, innovative approach. To date (September through December 2014) the following steps have been completed: Step 1) Residents received a short didactic session on principles of QI. Step 2) Using automated chart review, they identified their diabetic patients who have not received these exams. Step 3) They each used a worksheet to review their charts to identify key barriers and brainstormed interventions for improvement. Step 4) Residents joined together in their QI teams, and along with ancillary staff input, compiled their individual data using a worksheet and selected interventions for implementation. Step 5) A resident “team leader” from each group, along with ancillary staff, the clinic director, and faculty clinicians, convened to form a QI council. Interventions developed by the teams were voted on and the top 3–4 were selected to be clinic-wide QI interventions. The remaining steps will occur in January through June 2015: Step 6) Team leaders will work with ancillary staff to finalize protocols for the chosen interventions which will be launched in mid-January. Step 7) Teams will meet every other month to review progress and make adjustments. The VA-based clinic residents are following a similar 7-step approach but will be focusing their QI interventions on improving hypertension metrics.

EVALUATION: Worksheets were developed to assist individual residents and QI teams with Steps 1–4. Data derived from the university hospital site (52 residents), shows that 47 of 52 completed individual worksheets (participation rate (PR)=90 %) and all 8 teams completed worksheets (PR=100 %). Their QI council decided to focus on 4 interventions pertaining to the eye exam. Effectiveness of the QI interventions at all sites will be assessed through process measures and quarterly data through June 2015. QI methodology is also being used to evaluate this educational initiative. Throughout this process we have collected a running list of successes and failures, which has allowed us to make changes in the moment as we learn from our experiences. In addition, surveys will also be distributed to residents and ancillary staff bi-annually to assess participants' QI interest and knowledge, team dynamics, and resident leadership.

DISCUSSION / REFLECTION / LESSONS LEARNED: This is a team-based educational initiative to teach residents about QI and to improve patient care. It is unique in that it is resident-driven and utilizes an innovative stepwise approach that can easily be extrapolated to a variety of QI interventions at different clinical sites and institutions. To date, the initiative has successfully engaged nearly 140 residents in the QI process, and has fostered collaboration between residents and ancillary clinic staff. What we have learned so far: 1) The team structure allows for a collaborative, non-judgmental environment for residents to share information, discuss barriers and be creative. 2) Residents came up with meaningful interventions with minimal attending guidance. 3) Many interns have few continuity patients, so being part of a team is beneficial. 4) Scheduling time for QI projects into resident schedules is imperative for successful participation. 5) Transparent comparison of pertinent disease metrics, stratified by team, is expected to encourage healthy competition for improvement.

THE ADDICTION RECOVERY CLINIC: A NOVEL PRIMARY CARE-BASED APPROACH TO TEACHING ADDICTION MEDICINE Jeanette M. Tetrault²; Stephen Holt¹; Dana Cavallo¹; David A. Fiellin¹. ¹Yale University, New Haven, CT; ²Yale University School of Medicine, New Haven, CT. (Tracking ID #2199058)

NEEDS AND OBJECTIVES: Substance use is prevalent in the U.S. resulting in major public health burdens. Despite the high prevalence of substance use in Internal Medicine (IM) practice, little curricular time is devoted to training IM residents in Addiction Medicine (AM) and evaluating their skills in identification, diagnosis, treatment and prevention of substance use and substance use disorders. We developed and launched the Yale Addiction Recovery Clinic (ARC), intended to meet this educational deficit while also providing an outpatient clinical service to patients with addictive disorders, based upon the chronic disease management model. The educational objectives of the ARC include providing IM residents with knowledge of the biologic basis for addiction, and educating residents about available pharmacologic and behavioral interventions.

SETTING AND PARTICIPANTS: The ARC is embedded within our outpatient adult Primary Care Residency Clinic and is staffed by two to three IM trainees per block, two AM-certified attending physicians, one AM Fellow, one social worker and a licensed behavioral psychologist and provides comprehensive care to patients with addiction. During their ambulatory rotation, trainees spend ½ day per week for four consecutive weeks at the ARC seeing new and established patients.

DESCRIPTION: Patient referrals are made from both the outpatient Primary Care Residency Clinic, and the inpatient service. Inpatient consults are evaluated by the ARC team during the inpatient stay, treatment is initiated, and follow up with the ARC is then arranged. Once patients are stabilized at the ARC, residents are encouraged to transition the patients' care back into their longitudinal primary care practice, utilizing the skills obtained during their ARC rotation. Services provided within the clinic include: treatment of opioid use disorder with buprenorphine induction, maintenance therapy, and behavioral counseling; treatment of alcohol use disorder with pharmacotherapy (naltrexone, disulfiram, acamprosate) and behavioral counseling, outpatient management of alcohol withdrawal, consultative services for other drugs of abuse (e.g. marijuana, cocaine), smoking cessation pharmacotherapy and counseling, and direct referral to local addiction treatment facilities for patients who cannot be safely managed within the ARC.

EVALUATION: We developed a multi-level evaluation system. Clinical practice is evaluated by visit numbers and patient satisfaction surveys. Between August 2014 and December 2014, a total of 156 visits were seen with an average of 2 new patients and 7 follow-up patients were seen during each half-day session. Fifty percent of patients were treated for opioid use disorder, 30 % for alcohol use disorder and 20 % for other substance use disorder. Patient satisfaction surveys are currently being collected and analyzed. Residents are evaluated using a novel Entrustable Professional Activity (EPA) based system specifically designed for this rotation, which includes three specific EPAs across ten different domains. Overall, the rotation has been highly regarded by the residents as assessed by qualitative evaluation data.

DISCUSSION / REFLECTION / LESSONS LEARNED: The ARC offers a unique primary care-based approach to teaching IM residents the knowledge and skills to identify, diagnose, treat and prevent addiction throughout the disease spectrum, in keeping with the chronic disease management model. A multilevel assessment system is used to evaluate the overall clinical practice, resident performance and skill acquisition through an EPA based system, and resident satisfaction with the educational experience.

THE DANGER OF ONLINE MODULES? TESTING THE MULTI-PATIENT OBSERVED SIMULATED HANDOFF EXERCISE (M-OSHE) TO ASSESS ENTERING RESIDENTS PERFORMANCE IN DELIVERING HANDOFFS Vineet M. Arora²; Sean Gaffney¹; Jeanne M. Farnan¹; Kristen Hirsch¹; Michael McGinty¹. ¹University of Chicago, Chicago, IL; ²University of Chicago, Chicago, IL. (Tracking ID #2198619)

NEEDS AND OBJECTIVES: The new ACGME Clinical Learning Environment Review focus on care transitions benefits from enhanced standardized training and assessment across residency programs. Despite this, there are few validated resources to either teach or evaluate patient handoffs in a robust way. In addition, the AAMC has identified transfer of patient responsibility as a Core Entrustable Professional Activity for entering residency (CEPAER), which makes rigorous baseline assessment of handoff performance among incoming interns a priority. We aimed to assess whether prior training and prior handoff experience is associated with improved performance among entering residents in 4 programs (IM, Peds, OB, Surgery) during a novel multi-patient Observed Simulated Handoff Experience (m-OSHE).

SETTING AND PARTICIPANTS: A comprehensive handoff curriculum was embedded into the GME Orientation for four core residency programs (IM, Peds, OB, Surgery) at one institution.

DESCRIPTION: The curriculum featured an online training module completed prior to GME Orientation and a multi-patient Observed Simulated Handoff Experience (m-OSHE). Participants verbally "handed-off" a set of mock patients and then were evaluated and given feedback by a trained "handoff receiver" using an expert-informed, five-item checklist. Objective performance ratings and pre- and post- survey data were used to assess the effectiveness of the curriculum.

EVALUATION: Eighty-four interns completed the curriculum. Self-reported preparedness for conducting a verbal handoff increased after the online module (88 % post-module vs. 54 % pre-module, $p < 0.0001$ Wilcoxon sign-rank test) and after the m-OSHE (70 % post-mOSHE vs. 54 % pre-module, $p < .001$). There was a decline in self-reported preparedness after the m-OSHE compared to after the online training module. The mean checklist score was 3.23 (SD 1.09) and did not differ across residency programs. Self-reported preparedness at baseline and post m-OSHE was not associated with checklist scores. However, prior handoff experience in medical school was associated with higher checklist scores (23 % none vs. 33 % either 3rd OR 4th year vs. 58 % 3rd AND 4th year, $p = .021$, Trend Test). While all participants struggled with the prioritization of patients (30 % correct), prioritization did differ by residency program (8 % Pediatrics vs. 30 % Surgery vs. 33 % OB/Gyn vs. 44 % Medicine, $p = .016$, Chi2). Prior training was associated with the ability to prioritize patients based on acuity (12 % no training vs. 38 % prior training, $p = .014$, Chi2). All (100 %) participants agreed that the online training module was an effective review of handoffs and that the m-OSHE was a realistic portrayal of a clinical setting.

DISCUSSION / REFLECTION / LESSONS LEARNED: This study demonstrates that online training modules may invoke an inflated sense of preparedness among incoming interns that is adjusted when learners experience a realistic clinical simulation like the m-OSHE. The superior performance of residents with prior training and more handoff experience highlights the importance of considering formal handoff training prior to the start of residency. Positive learner-feedback indicates that this method is a promising strategy for teaching and evaluating handoffs that may be used at other institutions. Expanding and tailoring this curriculum to other programs and bolstering training in medical schools on handoffs is an important next step.

THE DAWN OF INTERPROFESSIONAL MEDICINE: EVIDENCE FOR INTERACTIVE SIMULATIONS WITH MEDICATION RECONCILIATION Melissa A. Gaines¹; Jason Foster¹; Maitri Patel². ¹University of Kansas SOM-Wichita, Wichita, KS; ²University of Kansas School of Pharmacy, Lawrence, KS. (Tracking ID #2192952)

NEEDS AND OBJECTIVES: Medical students need to have proficiency in reconciling medications during care transitions to improve patient safety. Medical students also have barriers to electronic medical records during their training which precludes active order writing. Currently, medical students have parallel learning in patient care during inpatient rotations, but no interprofessional opportunities during their MS3 year. Our objectives were: (1) to identify medications that should be avoided or used with caution in older adults and explain the potential problems associated with each, (2) to document the dose, frequency, indication, benefit, side effects, and an assessment of adherence for each patient's complete medication list, including prescribed, herbal and over-the-counter medications, and (3) to improve their teamwork skills by engaging in collaborative communication (ICS-D3), considering alternative solutions provided by other team members (SBP-B3), working effectively in interprofessional teams to ensure safe patient care, and responding productively to feedback from all members of the team.

SETTING AND PARTICIPANTS: The MS3 medical students and the P3-4 pharmacy students met in a classroom during the medical students' required 4 week geriatric clerkship. There are 8-10 students per workshop with one faculty facilitator.

DESCRIPTION: This workshop was a brown bag medication review utilizing a care transition from hospital discharge to office follow-up highlighting medication reconciliation. Multiple prescription bottles were collected and labels made to indicate the

instructions. One was dosed too high and there were several different prescribers and pharmacies utilized. The students were given the case history and general conceptual ideas of how to evaluate a medication list. The hospital medication reconciliation form was given to students with the case example. The brown bag contents included bottles marked with name, dose and frequency with duplications and incorrect dosing. Students were asked to suggest 5 changes to the list. Possibilities included, but were not limited to, safety, duplication, indication, serious side effect profile, dosing schedule, cost, and prescribing cascade. At the end of the workshop, students wrote a new medication order for the patient.

EVALUATION: A post-test survey was administered with 6 questions that were answered based upon a Likert scale and area for comments. The questions reflected teamwork and interprofessional competencies when mapped to internal medicine residency competencies including flexibility and respect for team communication. Students were given written feedback about their written medication orders by the preceptor.

DISCUSSION / REFLECTION / LESSONS LEARNED: Most students strongly agreed that the interprofessional workshop enhanced their learning experience. They also agreed that they felt comfortable writing a new medication list for a patient recently discharged from the hospital. There were comments such as "Have not done a med review case before, so was a good experience"; "It was good to learn how pharmacy students learn and their view about care". For future experiences, the students asked for more time and cases using standardized patients which would be an opportunity for a simulation interprofessional experience using a hospital dismissal care transition. This workshop increased medical student's awareness of information sources regarding medications to avoid, correct dosing of medications, and how to assess drug interactions in the elderly.

THE EDUCATIONAL HANDOFF: BLENDING DIGITAL LEARNING AND STANDARDIZED PATIENT-BASED ASSESSMENT TO MEASURE AND ENHANCE CORE ENTRUSTABLE PROFESSIONAL ACTIVITIES (EPAS) FOR ENTERING RESIDENCY Adina Kale²; Steve Yavner³; Hyuksoon Song⁴; Demian Szyld¹; Martin V. Pusic¹; Grace Ng¹; Mike Nick¹; Thomas Riles¹. ¹NYU School of Medicine, New York, NY; ²New York University School of Medicine, New York, NY; ³Fairfield University, Fairfield, CT; ⁴Georgian Court University, Lakewood, NJ. (*Tracking ID #2198652*)

NEEDS AND OBJECTIVES: UME and GME Medical Educators must ensure that new interns both demonstrate competence in 13 core Entrustable Professional Activities (EPAs) recently defined by the AAMC and are able to recognize and safely manage common "coverage" conditions among hospitalized patients on day of residency, one as defined by the ACGME. However, there is no consensus on how this should be addressed, assessed, and documented. Our goals in this project are to 1) understand and maximize the readiness for internship of our graduating medical students (MS4s) 2) develop and benchmark high quality and clinically meaningful, educationally responsive measures and methods to assess core EPAs 3) pilot and evaluate an efficient and scalable blended digital learning and performance based assessment strategy to address gaps in readiness for internship.

SETTING AND PARTICIPANTS: In the week prior to medical school graduation we recruited 52 MS4s to participate in a 3-h "readiness for internship" event held in our simulation center. The study of this event was IRB approved.

DESCRIPTION: For this pilot we assessed intern's readiness to assess and manage oliguria in the acute care setting and designed two Standardized Patient/Standardized Nurse simulation cases and built measures of 10 of 13 core EPAs. Students then saw one case before (post-operative) and one after ("rule out MI") spending up to 40 min interacting with the Oliguria MD on Call module (MDOC). In each SP/SN case the student, playing the covering intern returned a page to the SN (5 min), evaluated the SP with the SN in the room (20 min) then wrote a "coverage note" (10 min). Students could request lab values, ECGs and imaging results and simple bedside procedures (foley placement, IV fluids) from the SN. Student EPA assessment data was captured in 3 ways; SPs completed checklists measuring Communication Skills and PE both scored as % of items well done (interrater reliability .55-.81); SNs completed checklists measuring Care Quality and Safety, Collaboration and Interprofessional Communication Skills (interrater reliability .47-.52); Clinical Reasoning was assessed based on the "coverage note" and scored using R.I.M.E. Framework (reliability assessment underway). MDOC, a series of case-based multimedia digital modules, aims to prepare interns for common clinical coverage issues. It is designed to promote clinical reasoning of novice clinicians by building and refining diagnostic schemas or scripts. To assess students' oliguria schema before completing MDOC we gave them a blank piece of paper with the following prompt; "In the next 5 min, please write or draw how you think about oliguria". Two clinicians scored the results using a 3 level rubric (Kappa .78).

EVALUATION: Baseline core clinical skills of these motivated volunteer MS4s were highly variable; Communication skills (73 %, SD 27.5 %) and physical exam (51 %, SD

15.5 %), SN ratings (36 % SD 14.5 %) and clinical reasoning (.94, SD .52 on a 3 point scale). Before viewing the oliguria MDOC modules 59 % of students were able to present a clear and organized semantically sophisticated schema for oliguria (e.g. Pre-Renal, Renal, Post-Renal) with mention of related key features, diagnostic and management implications; 21 % represented only a basic set of diagnostic categories; and 17 % of these students could not convey an organized structured approach. We observed moderate to large gains in all clinical competency areas measured pre/post MDOC- communication (Cohen's d .41), physical exam (1.5), communication with the nurse (.61) and clinical reasoning (.64)). Supporting both the immediate educational impact of MDOC on performance and the sensitivity of our measures to instruction. In general, students appreciated being able to practice skills and reported that this 3-h event was highly educational, time well spent and challenging but enjoyable and asked us to host more on other topics.

DISCUSSION / REFLECTION / LESSONS LEARNED: We were able to assess 10 of 13 core EPAs and demonstrate that MDOC used in this manner addresses significant skills gaps. Although they need to be refined, our assessments were reasonably reliable measures, with the advantage of being authentic and synthetic. All core EPAs and many of the common topics required for transition from UME to GME can be assessed and addressed using this style of blended assessment/learning experiences. This spring we plan to study various blending strategies to determine best practices and work on an appropriate assessment report. This work will inform meaningful educational handoffs and optimal use of web-based instructional materials in the service of optimizing health professions education and patient safety and quality.

TRAINEE EVALUATION IN THE HEAL INITIATIVE: A MULTIDIMENSIONAL FRAMEWORK FOR A NOVEL GLOBAL HEALTH FELLOWSHIP Alanna Stone¹; Madhavi Dandu¹; Sriram Shamasunder¹; Phuoc Le¹; Robin Tittle². ¹University of California, San Francisco, San Francisco, CA; ²Santa Clara Valley Medical Center, San Jose, CA. (*Tracking ID #2194689*)

NEEDS AND OBJECTIVES: The Health, Equity, Action & Leadership (HEAL) Initiative is a unique fellowship training opportunity developed at the University of California, San Francisco (UCSF) to build Global Health work force capacity in the United States (US) and abroad. The mission of the fellowship is to equip US physicians as well as domestic and global partner fellows with the ability to be leaders in global health while making a sustainable impact on health equity and disease burden in resource poor settings. The fellowship has the following overarching objectives for trainees: 1. Provision of high quality care focused on local burden of disease 2. Effective engagement in local health systems 3. Demonstration of leadership and interprofessional team management skills 4. Development of strong and diverse teaching skills 5. Advocacy for communities, health systems, and patients 6. Adherence to principles of health equity and ethics in clinical and academic work. The present proposal describes a plan for trainee evaluation to meet the needs of a diverse group of learners who are expected to achieve competencies within the defined objectives.

SETTING AND PARTICIPANTS: Eight UCSF HEAL Initiative fellows will be selected from accredited US-based Internal Medicine, Pediatrics, Family Medicine, Psychiatry and Emergency Medicine residencies. There will be a total of 8 partner sites—4 through the Indian Health Service (IHS) in the Navajo Nation (AZ and NM) and 4 in developing countries (Liberia, India, Haiti, and Mexico). Each partner site will nominate and select locally-based HEAL Initiative fellows (can be any healthcare provider) to participate in training for a total of 16 trainees per year.

DESCRIPTION: UCSF HEAL fellows are paired and will alternate clinical responsibilities in 4 month blocks between IHS and developing country sites over a period of two years. The fellowship will begin with a one month intensive curriculum in July 2015 for both UCSF HEAL fellows and HEAL fellows selected by partner sites. All fellows have the option of obtaining an online Master in Public Health (MPH) degree from the University of California, Berkeley over the two year period. Each cohort of fellows will be assigned a faculty mentor from UCSF who will conduct periodic site visits and oversee evaluation. Each site will also have a designated mentor for trainees to provide feedback and support.

EVALUATION: A multidimensional framework for evaluation of fellows in the HEAL Initiative is necessary because the trainees are multi-specialty, interprofessional, and cross-cultural. The evaluation is structured around competencies developed from the core objectives of the Initiative. These competencies were defined through an iterative process involving fellowship leaders, curriculum committee, and partner sites. The evaluation framework will be housed within a portfolio that can be accessed by both trainees and mentors. The center of the framework is an individual development plan (IDP) created by the trainee with assistance of their mentor at the start of the fellowship. The IDP will encompass competencies from all six core objectives, but can be tailored to meet the

diverse backgrounds and experiences of the fellows. The trainees will also undergo biannual standardized evaluation on meeting the fundamental competencies of the fellowship utilizing a milestones rubric representing development from novice to expert. These evaluations will be completed by both UCSF and site mentors. In addition to these formalized assessments, fellows will do periodic reflective exercises to assess their own progression in their development plan and will provide feedback to their peers on these reflections.

DISCUSSION / REFLECTION / LESSONS LEARNED: The HEAL Initiative is a novel fellowship that involves training in resource-poor settings both domestically and in developing countries. It will involve learners who come from diverse educational and experiential backgrounds and who will have unique training experiences based on their site of practice. Thus, a multidimensional framework of evaluation is necessary to meet the needs of all of the trainees. The evaluation will be learner specific with input from longitudinal mentors as well as from peers. As all health professions training becomes interprofessional, it will be necessary to develop innovative means to assess learners with diverse backgrounds. This framework uses established evaluation tools but creates a flexible and easily adaptable format that may be applied to evaluate interprofessional learners and curricula in other settings.

TRAINING INTERNAL MEDICINE RESIDENTS IN CARE OF PATIENTS WITH DISABILITIES: DEVELOPMENT OF A NOVEL CURRICULUM
Bliss Temple; Sharad Jain. UCSF, San Francisco, CA. (Tracking ID #2198807)

NEEDS AND OBJECTIVES: Despite about 20 % of the US Population having a disability, physicians in training receive little education about how to care for these patients.[1] In studies of health care trainees[1], PM&R residents[2], and Family Medicine residents[3], residents have reported a lack of skills for caring for patients with disabilities and a need for training. There are no specific ACGME requirements for education of Internal Medicine residents in this area. Literature review and web searches did not identify any Internal Medicine residency program with a formal curriculum in caring for patients with disabilities. We saw a need to develop such a curriculum to provide residents with a sense of the health and health policy issues specific to patients with disabilities, improved clinical skills for working with these patients, and knowledge about resources for this population.

SETTING AND PARTICIPANTS: The curriculum was developed for use as part of the UCSF Internal Medicine—San Francisco General Hospital Primary Care residency, which focuses on care for underserved and vulnerable populations. Categorical residents electing to participate in the Health Equity: Academics and Advocacy Training (HEAAT) track were also included in the course. It was given twice for different groups of about 12 residents in 2014 and will be repeated in 2016.

DESCRIPTION: A novel curriculum was developed consisting of: – a general didactic session, – small-group clinical case discussions about patients with a variety of disabilities, – an experiential workshop on caring for patients with low vision, – a talk by a local disability expert on working with patients who are Deaf or hard of hearing, and—a site visit to visit local and national organizations working with people with disabilities, which also included a health policy talk by a national expert. The course was broken into four half-day sessions given during a 1-month ambulatory care block.

EVALUATION: Course participants were surveyed on each sub-component's relevance to practice, contribution to knowledge, and effectiveness of the presentation and associated learning materials using a 5-point Likert scale, with one being least and 5 being most useful. For the site visit, they were also asked to compare this field trip with others that are part of their training using a 5-point Likert scale ranging from "one of the worst" to "one of the best". Mean scores for relevance to practice and contribution to knowledge (respectively) for the general didactic session were 4.3 and 4.3; for the small-group case discussions were 4.7 and 4.7; for the low-vision workshop were 4.0 and 3.5; and for the local expert session on caring for patients with hearing impairments were 4.0 and 3.7. All participants rated the field trip as a 5. Participants also provided free-text comments with significant themes being the usefulness of this training for practice and a perceived need for similar training at all levels of medical education.

DISCUSSION / REFLECTION / LESSONS LEARNED: There is a need for Internal Medicine residency programs to include formal training on caring for patients with disabilities, who are a significant population group with specific health needs. UCSF residents regarded a new disability curriculum as being relevant to practice and contributing to knowledge. Didactic sessions, case discussions, and especially a site visit with disability organizations were particularly helpful. Other Internal Medicine programs should consider introducing similar curricula as part of residency education. 1. Holder, M., H.B. Waldman, and H. Hood, *Preparing health professionals to provide care to individuals with disabilities*. Int J Oral Sci, 2009. 1(2): p. 66–71. 2. and attitudes of PM&R residents: a comparison group trial. Med Teach, 2010. 32(8): p. e360–4. 3. Jain, S., et al., *Patients with disabilities as teachers*. Fam Med, 2013. 45(1): p. 37–9.

TRANSITIONS OF CARE CURRICULUM FOR INTERNS: PILOTING FORMAL DISCHARGE EDUCATION Christopher Bruti; Christine Tsai; Jansi Maganti. Rush University Medical Center, Chicago, IL. (Tracking ID #2192184)

NEEDS AND OBJECTIVES: Effective coordination of care within and across healthcare delivery systems is a national patient safety priority and an important competency for Internal Medicine residents. Residents are expected to work in teams and transmit clinical information that ensures proper transition of care between health care settings. Current evidence suggests that residents often do not receive and would like formal education on how to appropriately discharge patients. Our objectives were to teach interns the importance of evaluating discharge needs on admission, describe the roles of other professionals in the discharge process, explain the differences between different post-discharge care settings, and identify the importance of proper medication reconciliation in an effort to enable interns to efficiently and effectively discharge patients.

SETTING AND PARTICIPANTS: In spring 2014, we interviewed case managers, nurses, pharmacists, residents and faculty for topics and tips essential to teach interns regarding discharge. We then created an innovative presentation outlining our institution's multidisciplinary approach to discharge planning that highlighted the intern's role in this process. We encouraged interns to understand the patients' discharge needs from time of admission and throughout hospitalization, emphasizing the importance of collaboration in creating a safe, personalized, and effective plan. We also developed a teaching handout organized as a timeline. Beginning July 2014, we presented our curriculum monthly to new interns on the second day of their rotation on the general medicine floor, timing the class to maximize applicability.

DESCRIPTION: The presentation was done in an interactive small group format using a *Prezi*. It covered how to assess discharge needs on admission, a basic introduction to various insurance types and their importance, the types of post-acute care settings, home health services available, the role of case managers and other interprofessional staff, and the importance of proper medication reconciliation. The discharge timeline was an outline of questions to ask and things to consider at various points in the hospitalization (admission, during hospitalization, the day before discharge, and the day of discharge).

EVALUATION: We conducted five sessions and administered a survey immediately after the lecture, surveying 56 interns in total. Forty-one ranked the session helpful, 15 somewhat helpful. None ranked it neutral, somewhat unhelpful, or unhelpful. On qualitative analysis, the most helpful aspects included providing a framework for preparing discharge, teaching the importance of medication reconciliation, and the creation of a handout for future reference. All surveyed recommended the curriculum be given to future interns. Several Interns thought the sessions would benefit from specific images of the electronic medical record discharge screens.

DISCUSSION / REFLECTION / LESSONS LEARNED: We believe that our curriculum provided our Interns with tools to enhance efficiency and patient safety during transitions of care. Our Interns found the program valuable, and we will continue to improve the curriculum based on feedback. We plan on enhancing the curriculum by adding screenshots from the electronic medical record to make it even more practical. This curriculum can be easily adopted by other programs, providing a framework for teaching safe transitions of care.

USE AND IMPACT OF AN OBJECTIVE STRUCTURED TEACHING EXERCISE (OSTE) TO IMPROVE DIRECT OBSERVATION SKILLS AND ATTITUDES AMONG FACULTY Jeremy Smith; Amy Smith; Mary Thompson; Maryam Heydari. University of Wisconsin, Madison, WI. (Tracking ID #2188597)

NEEDS AND OBJECTIVES: Direct observation (DO) of trainees has been shown to identify clinical deficiencies otherwise unrecognized, enhance learner skill and confidence, and increase frequency of feedback. At our institution, however, DO was not being performed regularly. We recognized that faculty development is inherent to the success of DO. Therefore, we designed and implemented a faculty development program, which included the use of an OSTE, with the overall goals of increasing the amount and quality of DO of learners. Our objectives for our faculty participants were to: 1. Appreciate the educational utility of DO 2. Improve attitudes about the burden of DO 3. Improve confidence in skills of observation, evaluation, and feedback

SETTING AND PARTICIPANTS: Nine 4-h workshops were conducted over a 6 month period, each with 15–20 participants. A total of 161 Department of Medicine faculty attended a workshop. Faculty were invited based on the extent of involvement with clinical teaching, and were strongly encouraged to participate, with a specific

recommendation from the Department Chair. The workshops were facilitated by 3 persons, consisting of one physician and two educators, all of whom had some prior experience with faculty development.

DESCRIPTION: The program began with the definition and subsequent group discussion of pertinent terms related to DO. A fishbowl activity was then conducted, which consisted of two facilitators role-playing a clinical encounter between a patient and a resident, in front of the assembled group of participants. Workshop participants were instructed to act as faculty conducting DO of that resident's clinical performance. Group discussion then ensued about what feedback might be given to the resident. This discussion enabled the facilitators to expound on certain concepts, such as the difference between evaluation and feedback, the use of self-assessment questions, formative versus summative evaluations, and the characteristics of effective feedback. The participants then broke into small groups, and discussed logistical barriers to DO. Facilitators guided the groups to troubleshoot these problems. The large group reconvened, and these proposed solutions were then discussed and shared among all participants. This section of the program took approximately 2 h. The second half of the program consisted of an Objective Structured Teaching Exercise, which is a simulation tool for evaluating and providing feedback for teaching skills. The faculty were divided into groups of 3–4, and rotated through each of 4 stations. Each station contained a standardized learner (a medical student or resident volunteer), and 3 of the 4 stations included a standardized patient. The stations consisted of a learner taking a history from a patient, a learner performing a physical exam on a patient, a learner counseling a patient about a treatment plan, and a learner receiving end-of-rotation feedback. At each station, 1 of the faculty was the Teacher, observing the encounter and providing the learner with feedback. Feedback to the Teacher was then provided by the standardized learner, the other participating faculty, and a facilitator. After the completion of the OSTE, the large group was reconvened for final debriefing and take-home points.

EVALUATION: Survey data was collected by participants at the beginning of the workshop, at the end, and approximately 6 months after completing the workshop. Six month follow-up data is currently being analyzed, but immediate post-intervention surveys showed improvements in faculty attitudes and self-assessed skills in several domains. Participants' perception of the value and utility of DO increased significantly. There were also significant improvements in participants' attitudes about the burden of DO. Participants reported significantly improved confidence in several skills related to DO and giving feedback. Narrative evaluation data suggested that most participants felt the OSTE to be the most impactful aspect of the program, while others felt uncomfortable in role-play, and desired more didactic and less interactive teaching.

DISCUSSION / REFLECTION / LESSONS LEARNED: With this program, we were able to successfully train over 160 faculty in the skills of DO, and improve their attitudes about the feasibility and utility of conducting DO. One of our initial concerns was whether we would be able to have our faculty find the time to participate in the program. We found that with specific encouragement from the Department Chair (in the form of a group email), and follow-up emails from the facilitators, 161 of 163 targeted faculty actually completed the workshop. Most participants found great value in practicing the skills of DO in the OSTE. Facilitators reported that this part of the program was highly successful in getting participants comfortable doing DO, and in obtaining high-yield feedback for participants. However, there remained a proportion of faculty who noted the artificiality of role-playing, and did not perceive great value in that exercise.

USE OF A GROUP OSCE IN TEACHING DIFFICULT COMMUNICATIONS Gita Mehta¹; Neil J. Farber²; Simerjot K. Jassal²; Peggy Wallace¹; Robert MacAulay¹. ¹UCSD, La Jolla, CA; ²UCSD/VASDHHS, San Diego, CO; ³University of California, San Diego, La Jolla, CA. (Tracking ID #2200663)

NEEDS AND OBJECTIVES: Residency training usually does not provide adequate structured training for developing communication skills, particularly in difficult situations. We evaluated the use of a Group Objective Structured Clinical Exam (GOSCE) based workshop using Standardized patients (SPs) in improving resident confidence in difficult communications, and as a method to provide feedback to medical residents about such communications.

SETTING AND PARTICIPANTS: Forty-two R1-R3 residents in Medicine participated in a structured interview that involved communication with 4 SPs: in 2 cases, Residents were asked to give bad news to 2 SPs, deal an angry SP, and disclose a medical error to a 4th SP. Residents moved as pairs from one case to the next, alternating as participant or observer, while faculty were assigned to a specific case. Faculty members viewed each interaction remotely in a monitoring room, and then joined the residents and SP to debrief on each interaction and provide feedback.

DESCRIPTION: Forty-two R1-R3 residents participated in 2 separate sessions. Prior to the workshop, residents and faculty were given a tutorial on giving bad news and dealing with medical errors. Residents were given 15 min to communicate with each SP, and as they were paired, residents interacted with 2 SPs and gave feedback on 2 interactions.

Immediately following each interaction, 15 min was spent in giving feedback to each resident by an observing colleague in the room, the SP and the observing Faculty member. All residents completed an evaluation form after concluding the workshop.

EVALUATION: Measures of success: Prior to attending the workshop, 8/42 (19 %) had significant experience delivering bad news, 13/42 (30 %) had experience working with an angry patient, while only 2/42 (<10 %) had experience dealing with a litigious patient. 15/42 (71 %) residents reported previously being directly observed and given feedback while delivering bad news, 26/42 (69 %) when working with an angry patient, and 12/42 (28 %) when dealing with a litigious patient. Over 85 % (36/42) of residents felt the workshop was valuable, and they learned specific ideas they could implement. 31/42 (73 %) felt they acquired new and/or advanced skills, and had more confidence upon which to base difficult communications in the clinical setting. All residents felt the overwhelming strength of the workshop was the feedback from the faculty, SP and a colleague.

DISCUSSION / REFLECTION / LESSONS LEARNED: Our data supports the utilization of a group structured exercise in improving resident confidence in difficult clinical interactions. This setting also permits immediate feedback to the resident from various sources including peers, SPs, and faculty members. The unique opportunity to have 15 min of constructive feedback from three different people was felt to be particularly valuable. A group OSCE can be used at a Medical Resident level to teach communication skills in difficult situations, and also provide an environment for constructive feedback for all participants

USE OF COMMUNITY HEALTH WORKERS TO TRAIN MEDICAL STUDENTS IN THE SOCIAL DETERMINANTS OF HEALTH AND CROSS-CULTURAL COMMUNICATION Shreya Kangovi³; Pratyusha Yalamanchi³; Casey R. Chanton¹; Tamala Carter¹; Robyn A. Smith²; Horace Delisser². ¹Penn Medicine, Philadelphia, PA; ²University of Pennsylvania, Philadelphia, PA; ³Perelman School of Medicine, Philadelphia, PA. (Tracking ID #2193185)

NEEDS AND OBJECTIVES: Medical students often lack training in how to assess and address the psycho-socioeconomic determinants that shape the health of vulnerable populations. To address these gaps, we created a medical student clinical elective rotation called the IMPaCT Teaching Service. In this externship, fourth year medical students served as apprentices to community health workers (CHWs). CHWs are trusted members of the community, hired and trained by the University of Pennsylvania Health System to support low-income patients in reaching health goals. The objectives of the course were for students to: • Understand challenges low-income patients face in maintaining health • Develop cross-cultural communication and negotiation skills • Learn health care and community resources available to low-income patients • Learn to advocate in the healthcare setting for patients to obtain needed care and services

SETTING AND PARTICIPANTS: This was a 2–4 week clinical elective rotation open to fourth year medical students. CHWs and students served patients who: 1) were admitted to the inpatient general medical service, 2) were uninsured/insured by Medicaid, and 3) resided in a 5-ZIP code low-income community of West and Southwest Philadelphia.

DESCRIPTION: Students worked closely with senior CHWs to conduct the four stages of the IMPaCT intervention. 1) Meeting the patient: On the day of admission, students conducted an in-depth interview exploring patients' psycho-socioeconomic histories. Students worked with their patients to develop patient-centered goals for care. 2) Hospital Discharge: Students advocated for low-SES patients during the discharge process, ensuring that they could afford discharge medications and perform discharge instructions. Students learned about the use of low-cost formularies, prescription assistance programs, Medical Assistance, and health coaching skills such as teach-back. 3) Return to the Community: After discharge, students provided tailored support to patients using home visits and calls. Students connected patients to community-based services and used motivational interviewing to support health behavior change. 4) Primary Care: Students facilitated and attended PCP follow-up appointments for their patients, particularly those who received care in community health centers. In addition to the patient care described above, students participated in weekly discussions designed to create dialogue between students and CHWs on controversial topics such as "the difficult patient", disability and entitlement programs and institutional racism.

EVALUATION: Between January 13, 2014–December 14, 2014 we conducted 7 in-depth semi-structured interviews with students and CHWs to explore their perceptions of the course and obtain suggestions for improvement.

DISCUSSION / REFLECTION / LESSONS LEARNED: Three key themes arose from the qualitative interviews. First, the course allowed students to appreciate the lived experience of their patients. The CHW reflected on a student's reaction when a cab refused to pick them up from a low-income neighborhood: "and then it was so frustrating get a cab for the patient who was on crutches. [The student] couldn't believe it. And this is what I'm saying. In our community, when you ask for a cab, and they say where you at? Oh no,

we don't come there." Second, despite challenges, students realized that many psychosocial barriers could be addressed. "[The medical team] often feels like, oh this is something that we're not gonna be able to solve. In the very bottom [of the note] is discharge and it usually just says, like 'talk to social work and discharge planner' Watching [CHW] look at this problem, I saw her come up with creative solutions." Finally, it was sometimes challenging for patients to transfer the trust from CHWs to the students. "[The patient] told me briefly what was going on, but she didn't want to tell me in front of the med student." CHWs dealt with this by coaching students on empathy and active listening skills in order to foster trust. "Teaching the med student how to understand patients from their view...wait on the paperwork. Get to know that person first, get that wall down." A student concurred, "And she would just let the patient talk. It's amazing what they can tell you that no one ever knew, because there's just this open space, it's a safe space, the patient will just tell - talk about all the things in their lives that a lot of doctors are not able to get." Based on our pilot experience, the Perelman School of Medicine has decided to make the IMPaCT Teaching Service a permanent course offering. The Center for CHWs is also exploring the option of opening this elective course to nursing students.

WORK LIFE BALANCE IN RESIDENCY, HOW TO MAKE IT POSSIBLE
Delaram Moazami, Capital Health, Trenton, NJ. (Tracking ID #2199181)

NEEDS AND OBJECTIVES: One of the core requirements in the ACGME Program Requirements for Internal Medicine states "the program must be committed to and responsible for promoting patient safety and resident well-being in a supportive educational environment." Resident well-being is essential for optimal resident learning as well as competent and compassionate patient care. It is estimated that 27–75 % of residents are burned out at any given time depending on the medical specialty.

SETTING AND PARTICIPANTS: To promote a culture of wellness, our program developed the Wellness Curriculum to assess and improve resident well-being during their training. Goals: To increase coping skills and strategies to manage stress. To identify and recognize burnout symptoms and signs in themselves and others. To introduce the concept and importance of wellness at the beginning of residency. To create and maintain a supportive educational environment in which wellness is a mindful value.

DESCRIPTION: In a series of didactic sessions, residents were educated about the importance of recognizing symptoms of fatigue and burnout in themselves and among their peers. Wellness goals were added to the agenda of monthly faculty advisor meeting. The Program and the GME Department monitors resident duty hours and teaches residents ACGME Duty Hour requirements. The Program has a referral system in place for residents to seek help confidentially. A series of monthly Resident Well-being topics was added to the Noon Conference agenda throughout the year, once a month: Video and discussion of "Struggling in Silence: Physician Depression and Suicide" (American foundation for Suicide Prevention) Debriefing sessions Lectures about healthy diet, substance abuse, fatigue and sleep deprivation. Lectures and interactive sessions about professional competence and relationship: difficult patient, conflict management, social media, team building exercise, job satisfaction, insurance companies, medical health reform. In addition, innovative wellness activities took the place of traditional Noon Conference lecture format. Some of these included the value auction game, simulated calls to a loved one and reflections on thankfulness. Through these activities residents were able to focus on issues that are important outside of residency training. A variety of group activities were added throughout the year as "stress relievers" and team building activities. Some of these included: fundraising for AHA, holiday and birthday celebrations, off-site social gatherings, community activities (volunteering at NYC Marathon, local flu vaccine event) Residents have been involved in different activities to increase a sense of control: Hospital committee, curriculum committee, and Program Evaluation Committee. Faculty members were encouraged to provide positive feedback and to use praise card. The Maslach Burnout Inventory (MBI) was administered to 32 residents.

EVALUATION: Thirty-two out of 32 residents took the MBI. The group average scores for Emotional Exhaustion and Depersonalization were less than general population and for Personal Accomplishment was more than general population. 15.6 % (5/32) resident had severe burnout and 28.1 % (9/32) had moderate burnout. The results were provided to residents and will be monitored by the program and faculty advisors.

DISCUSSION / REFLECTION / LESSONS LEARNED: Through the Wellness Curriculum, our residents have a greater understanding of the relationship between their well-being and the provision of high quality, and safe patient care. Methods of identifying residents with increased stress and burnout are implemented, as well as avenues for relief and treatment of burnout symptoms. Elements of the curriculum will be implemented earlier in the PGY1 year including during orientation. Wellness issues will be discussed during semiannual resident evaluation meetings and resident-faculty meetings.

WORKING TOGETHER TO TAKE THE PAIN OUT OF CHRONIC PAIN: AN INTERPROFESSIONAL EDUCATIONAL EXPERIENCE IN GRADUATE MEDICAL EDUCATION Bennett Lee; Allison E. Phillips; Steven Bishop; Rachel R. Waller; Laura Morgan; Bryan Jensen; Benjamin D. Lord; Brigitte L. Sicut; Bruce Rybarczyk. Virginia Commonwealth University, Richmond, VA. (Tracking ID #2184824)

NEEDS AND OBJECTIVES: Interprofessional education and collaboration is critical to medical education and practice and is being increasingly integrated into undergraduate medical education. While graduate medical education (GME) trainees do interact with pharmacists and psychologists to complete parallel patient care activities, they rarely collaborate to learn from one another. We developed a series of team-based learning (TBL) activities with learning teams composed of medical residents, pharmacy residents, and clinical psychology graduate students. We describe the development and evaluation of an interprofessional education (IPE) TBL module on Chronic Non-Cancer Pain in the ambulatory setting. At the end of this TBL, we expected learners to be able to do the following: 1. Assume responsibility as a provider for assuming a non-biased attitude towards patients on chronic opiates 2. Encourage the use of cognitive behavioral therapy (CBT) and recognize its value 3. Embrace and recognize the necessity of a team-oriented approach toward patient management 4. Recognize risk factors for prescription drug misuse in patients treated with chronic opioids 5. Identify common differential diagnoses for aberrant medication use behavior 6. Administer common practice tools for monitoring patients treated with opioids 7. Explain CBT to a patient and prepare him/her to participate in CBT as an adjunct to pharmacologic therapy 8. Assess an initial management plan for effectiveness, tolerability, and safety

SETTING AND PARTICIPANTS: Participants included 59 medical residents, 10 pharmacy residents and 7 psychology graduate students in a single TBL session.

DESCRIPTION: The TBL module was developed collaboratively by faculty from all three disciplines. To prepare for the module, facilitators sent participants pre-reading assignments in advance (preparatory work). Readings consisted of guidelines or review articles. Facilitators ensured that all teams included at least one pharmacy and one psychology trainee. During the session, teams completed a quiz on the reading, first individually and then as a team (readiness assurance test), followed by facilitated discussion of interactive cases requiring complex patient care decisions (group application exercises). Each case was constructed to require input from all professions in order to develop an appropriate answer.

EVALUATION: At the conclusion of the session, learners assessed, on a 4-point scale, with 1=never, 2=sometimes, 3=often and 4=always, their likelihood of developing team-oriented attitudes, performing team-based tasks related to caring for patients with chronic non-cancer pain, and applying new medical knowledge. The first two response levels 'never' and 'sometimes' were combined due to small numbers reporting 'never' to any of the survey items. The survey asked learners to assess their ability both before and after training (retrospective pre-post design). Wilcoxon signed-rank tests were used to determine if mean differences between pre- and post-test scores were significantly different from zero. Generalized estimating equations were used to determine how profession and gender affected participant responses. All survey questions had a statistically significant increase in mean score between the pre- and post-assessment ($p < 0.0001$). The largest increases were seen in participants' likelihood of explaining cognitive behavioral therapy (CBT) to a patient to prepare him/her to participate in CBT as an adjunct to pharmacologic therapy (1.06), their likelihood of encouraging the use of cognitive behavioral therapy (CBT) (0.90), and their likelihood of identifying common differential diagnoses for aberrant medication use behavior (0.76). Reported scores differed by profession with psychology graduate students reporting higher scores in their likelihood of encouraging the use of CBT compared to both medical and pharmacy residents. Pharmacy residents were more likely to report higher scores in the likelihood of assessing an initial management plan for effectiveness, tolerability and safety when compared to both medical residents and psychology graduate students.

DISCUSSION / REFLECTION / LESSONS LEARNED: This IPE TBL experience in GME appears to have had a positive effect on all learners, with increases not only in perceived knowledge of how to manage chronic non-cancer pain, but also in attitudes toward team-based care. The data appear to show an overall increase in participants' likelihood of explaining CBT, and also encouraging its use. Perhaps not surprisingly, psychology graduate students were more likely to encourage the use of CBT. TBL is a potentially powerful way to leverage interprofessional learning experiences; however, the module did take significant time to plan and implement (10–15 h of planning). The session is also most fruitful if all participants are able to do the pre-reading of material, which can be a challenge. Further study is needed to determine if changes in attitudes seen here are sustained and if they lead to actual changes in team-oriented behavior.

***INNOVATIONS IN CLINICAL PRACTICE (ICP)**

“IT’S BIGGER THAN JUST THE VISIT”: A HOSPITAL FOLLOW-UP INITIATIVE TO ADDRESS SOCIAL DETERMINANTS OF HEALTH AND PROMOTE HIGH QUALITY TRANSITIONS OF CARE Nancy M. Denizard-Thompson; Kirsten Feiereisel. Wake Forest University School of Medicine, Winston-Salem, NC. (Tracking ID #2200370)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Although much work has been done to improve time to hospital follow up visit the quality and breadth of these visits is often lacking.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Decrease variability of hospital follow up visits among residents in clinic through a standardized template 2. To improve quality of hospital follow-up visits by addressing key issues that affect readmission and safe transition back to the community and medical home 3. To simultaneously train residents on the key components of a hospital follow-up visits and social determinants of health

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The intervention was implemented at two outpatient internal medicine resident clinics at an academic medical center. The clinics serve an underserved patient population. The intervention is a hospital follow up template created for the electronic medical record and developing isolated hospital follow-up clinics at the resident clinics. The template incorporates elements that are often lacking in a hospital follow-up visit such as access to medications, functional status, social support, and home care needs. It also emphasizes areas such as medication reconciliation, pending labs, and key studies that are areas that prior research has shown can lead to hospital readmission. It also meets standards and contains prompts for the transition of care billing codes. In addition many residents reported that there was not enough time in a regular visit slot to address the complex issues in a hospital follow up visit. There for hospital follow up clinic schedules were created at both clinic sites. The clinic schedule template was adjusted to allow 40 to 45 min for hospital follow up visits depending on the clinic site given the complexity and importance of the visit to improve the health of patients and readmission rates.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): 1. Increase use by residents in their clinic sites of the hospital follow up template 2. Recognition by the residents and faculty preceptors that the hospital follow up template caused them to discover missed items that they would not have discovered using a regular visit note template 3. Realization by residents that issues such as transportation, functional status, family support, and social networks are key to patients having a safe transition back to the community 4. Residents reported that having the hospital follow up visits separated from the continuity visits allowed them to focus on the hospitalization and key issues that would prevent further hospitalizations

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Preliminary chart audit comparing previous hospital follow up visits to visits incorporating the template revealed that things such as functional status, social networks, transportation, and ability to access medications were reported in a higher number in those who did use the template. In addition those who used the template had a higher rate of routing the document to the primary care provider or other key providers in the care of the patient. A more formal chart audit is in process.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): 1. The residents demonstrated steady growth in usage of the template and it is gaining persistent attending and resident enthusiasm. 2. A standardized template incorporating key social determinants of health and highlights clinical areas of concern for patients with high readmission rates promotes safe transitions of care and improves patient’s outcomes. 3. Having a separate hospital follow up clinic with longer appointment times allowed residents to perform higher quality hospital follow up visits 4. Attending physicians also reported that the quality of the hospital follow up visit notes had improved.

A COLLABORATIVE PHARMACIST-MANAGED CHRONIC PAIN CLINIC IN A PRIMARY CARE SETTING Katy E. Trinkley¹; Carmen L. Lewis³; Huong M. Lam²; Chelsea Mitchell¹; Jessica Norman¹. ¹University of Colorado, Aurora, CO; ²University of Colorado, Denver, CO; ³University of Colorado, Denver, NC. (Tracking ID #2200605)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Chronic opioid users are a complex and high risk population who are high utilizers of primary care services; however, providers are often not comfortable managing these patients or do not have adequate time to assess/address their needs.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): An interdisciplinary team including a pharmacist is best equipped to address the needs of the growing population of chronic pain patients. Currently, there is limited literature describing the role of a primary care pharmacist collaborating with primary care providers (PCPs) to improve patient-centered (e.g., patient satisfaction with pain control, adverse effects, impact on daily life) or other clinically significant (e.g., pain scores, opioid burden) outcomes for patients with chronic pain. Therefore, we have developed and implemented a collaborative pharmacist-managed chronic pain clinic (CPC) in a primary care setting to meet the following objectives: 1) Improve patient reported satisfaction with pain control (e.g., pain scores, overall satisfaction, adverse effects, impact on quality of life); 2) Decrease opioid burden and increase use of appropriate non-opioid adjunctive pain medications; and 3) Improve patient understanding of how to adhere to pain medication regimen (e.g., timing of administration).

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The CPC is a collaborative service between PCPs and the clinical pharmacy team at the University of Colorado’s Anschutz Internal Medicine Clinic (UMA). The pharmacy team consists of one pharmacy attending, and rotating medical students, pharmacy students and pharmacy residents. The pharmacy team screens an electronically generated list of chronic opioid users and reviews their medical records to determine eligibility. Eligible patients receive primary care at UMA and have taken opioid medications for at least 3 months. Patients are not eligible if they have a terminal diagnosis, are pregnant, followed by a pain management specialty clinic, or have active cancer. All patients deemed eligible are reviewed by their PCP who accepts or denies a referral to the CPC. Accepted referrals are contacted by the pharmacy team to schedule an appointment. Appointments occur at UMA during a time their PCP is also in clinic to allow for close collaboration and signature of opioid prescriptions. During the visits, the clinical pharmacy team comprehensively evaluates patients’ pain and impact on activities of daily living and manages pain medications per protocol. Patients are discharged from the CPC when the patient has deemed their pain control satisfactory, or the pharmacist and PCP determines it is not appropriate to escalate therapy further.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Outcome measures will be recorded before and after the intervention and include 1) patient reported pain scores, satisfaction with pain control regimen, adverse effects, timing of and how they take their pain medications in comparison to the prescribed instructions, and impact on activities of daily living; 2) total daily dose of opioids in morphine equivalents; and 3) number of non-opioid adjunctive pain medication changes. To compare pre- post-intervention differences, the McNemar Test will be used for discrete data and Wilcoxon Rank Sum for continuous data.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): From November 3, 2014 to January 2, 2015, 332 patients were determined to be eligible by the pharmacy team. Of the eligible patients, 30 % of referrals were accepted by the PCP, 5 % denied and 64 % awaiting referrals. A total of 42 calls to schedule appointments have been made and 21 appointments have been confirmed; 4 patients denied appointments with the CPC, 13 did not answer and 4 asked for a call back later or their phones were disconnected. Of the 6 patients who have attended their first CPC visit, 7 changes were made to their pain regimen; 2 included adding a long acting opioid and 5 involved optimizing non-opioid adjunctive medications. Only one patient has had a follow up visit and 4 patients either cancelled or no showed to their initial visit.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): A small pilot with patients of 3 providers was critical to problem solving logistics to ensure feasibility and efficiency. The logistics of obtaining written prescriptions for opioids evolved over the course of the pilot. The pilot also served to solidify data collection tools that were feasible to complete during office visits. Close communication with providers regarding clinic flow and processes was very helpful. Careful messaging to patients about the CPC to ensure acceptability and early buy in from stakeholders, including clinic and institution leadership and providers was key to the early successes of this service. Continued process mapping and PDSA cycles will be conducted as the CPC clinic expands. Additional efforts are needed to identify and address barriers to PCP acceptance and patient engagement. Further, careful monitoring of appointment cancellation and no shows will be performed to ensure patients are seen.

A SURVEY TO ASSESS PATIENT EXPERIENCES IN PATIENT-CENTERED MEDICAL HOMES FOR PATIENTS WHO ARE HOMELESS AND FORMERLY HOMELESS Stefan Kertesz^{2, 3}; Erika L. Austin¹; Calvin Elam²; Nancy Johnson². ¹Birmingham VAMC, Birmingham, AL; ²Birmingham VA Medical Center, Birmingham, AL; ³University of Alabama at Birmingham, Birmingham, AL. (Tracking ID #2198318)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Public funders such as the US Department of Veterans Affairs (VA) and the Department of Health and Human Services (HHS) fund primary care medical homes for homeless individuals, but a practical method to assess this population's health care experiences has not been demonstrated.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): Patient experience surveys ask whether the care received embodies core expectations such as accessibility, coordination, continuity and trust. This team has published a 33-item survey based on qualitative and quantitative psychometric research with 563 homeless primary care patients (Primary Care Quality-Homeless, PCQ-H). The PCQ-H is shorter than the Consumer Assessment of Health Plans (CAHPS) PCMH battery, easier to read (7th vs 9th grade), and offers 4 scales (Relationship, Accessibility/Coordination, Perceived Cooperation among Caregivers, Homeless-Specific Needs). Each scale has similar or better internal reliability to comparable CAHPS scales and reflects tailoring for homeless-experienced patients. However, practical deployment of this survey outside a research context requires answering key questions related to feasibility and acceptability, including: 1. For homeless and formerly-homeless patients, what response rates result from mailed surveys compared to surveys handed out by clinic staff? 2. How do patients experience the survey with regard to: time required to respond; ease of responding; privacy concerns; and, who they think about when asked about their "primary care provider" in a multi-provider system such as VA? 3. Do care ratings differ when surveys are mailed (with no remuneration offered) compared to responses obtained from face-to-face administration in the research setting (with remuneration)?

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Setting: Birmingham VA Medical Center's Homeless Patient-Aligned Care Team (H-PACT), one of 50 specialized VA primary care teams for the homeless. The PCQ-H survey (33 items and 10 supplemental questions regarding feasibility/acceptability) was mailed two times (one month apart) to 296 patients using the last-available address. Clinical staff were also asked to distribute the same survey in clinic.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): We recorded response rates and feasibility/acceptability responses; we also compared care ratings among the current H-PACT respondents to 150 homeless and formerly-homeless veterans surveyed previously under research conditions (face-to-face after informed consent, with remuneration) in 2012.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Response rates were 15 % ($n=45$) for the first mailing and an additional 10 % ($n=28$) for the second mailing. Clinical staff reported it was impractical to hand out surveys, and only 13 completed surveys were obtained from the clinic. The 86 total responses comprised 29 % of the eligible patient panel. Most patients reported the survey required <10 min to complete (64 %) and preferred to receive it by mail (78 %). Just 7 % reported "frequently" feeling confused by the questions, although 32 % said they did not trust that responses were confidential. For questions about a "primary care provider," 54 % reported that they thought about "several persons working on a team" when responding. When compared to mean scores obtained through surveys administered by a research assistant, mean care ratings obtained on the mailed survey were not significantly different (all $p>0.10$).

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): A recently-published survey of homeless patients' primary care experiences was easily deployed in a clinical, non-research setting. A 29 % response rate, in the absence of remuneration, is lower than what is obtained from non-homeless veterans in VA's standard primary care (47 %, according VA's Director of Surveys). However, it is higher than is obtained after VA psychiatric hospitalization (22 %). Most respondents preferred the opportunity to respond by mail, while clinical staff found it impractical to hand out surveys. Interpretation of results requires considering that some patients will consider a team rather than a single individual when answering questions about "your primary care provider." Dedicated homeless clinics such as those funded by VA and HHS should consider this instrument as a practical tool to assess primary care for homeless and recently-homeless patients.

AVOIDING AVOIDABLE CARE: WEEKLY "M&M" REVIEW REDUCED ED VISITS IN A PACE PROGRAM Uma S. Tadepalli^{1, 2}; Maren Batalden^{1, 2}; Anne Fabiny^{1, 2}. ¹Cambridge Health Alliance, Cambridge, MA; ²Harvard Medical School, Boston, MA. (Tracking ID #2198664)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Comprehensive care processes are ill-described, and their effectiveness in reducing utilization is unclear.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): The objective of this innovation was to describe and evaluate a new process for individual patient care plan development that would reduce ED and hospital utilization.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): At a single-center Program for All-inclusive Care of the Elderly (PACE) in urban Massachusetts, we implemented a weekly interdisciplinary "Morbidity and Mortality" review of all program participant ED visits and hospital admissions using a root cause analysis instrument, and developed individual care plans based on this review. Participants included a rolling panel of approximately 290 community-dwelling, nursing home eligible, Medicare/Medicaid patients aged 55 and older.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): We measured ED visits and hospital admissions per member per quarter for 1.5 years before and after implementation of "M&M". We trended mean risk score of the rolling patient panel during this time as a measure of overall population complexity.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): The mean ED visit rate decreased from 9.9 % prior to the intervention to 6.0 % after the intervention was begun; the mean hospital admission rate decreased from 7.1 to 5.0 %. The mean risk score increased, but did not change significantly. Focus group analysis with M&M committee members suggests several mechanisms by which this intervention led to improvements and changed the program culture: (1) illumination of the gap between the theory of the program and actual program operations, including several ways in which patients, families and staff lacked basic understanding of care alternatives, (2) an expanded ability to see patients as whole people and identify novel ways to add value to patients' care within the larger context of their lives, (3) increased confidence in improvement capacity of program staff, and (4) development of a shared mental model of the program through cultivation of relationships among interdisciplinary program staff.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Using formal root cause analysis to inform care plan development significantly reduced ED utilization in a very complex patient population. Although developed within a PACE site, this method of review and intervention would apply to any primary care practice working to avoid avoidable care for complex patients.

DEVELOPING A LANGUAGE ACCESS CLINIC (LAC) FOR PATIENTS WITH LIMITED ENGLISH PROFICIENCY (LEP) Lucero C. Chueca Villa¹; Cheryl Miree²; Christine L. Joseph². ¹Henry Ford Hospital, Detroit, MI; ²Henry Ford Health system, Detroit, MI. (Tracking ID #2200336)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Improving health care access and quality of care for patients with Limited English Proficiency requires implementing language access services within health care settings.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): Explore the feasibility of establishing a Language Access Clinic (LAC) for Hispanic/Latino patients with limited English proficiency (LEP) and patients who prefer to communicate about their healthcare in Spanish.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The LAC was developed as part of the Internal Medicine outpatient clinic and Henry Ford hospital Main campus in Detroit Michigan. It started initially as a 4 h block every other week, but given demand it was increased to 4 h block every week and currently is an 8 h block every week.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): We established a Spanish LAC for patients who indicated LEP or a preference to receive their healthcare in Spanish. To evaluate the LAC, we collected data from 3 sources: **Staff Survey:** Clinic staff of Henry Ford Hospital (HFHS), Internal Medicine, Central Campus, were asked to complete a 37-questions survey about interpreter services used and needed. **Patient Survey:** Patients visiting the LAC were asked to complete a survey that asked about experiences before and after being seen in the LAC. **Convenience Sample (Non-LAC):** For a comparison group, encounter databases were used to obtain a listing of patients who had identified themselves as being of Hispanic/Latino descent and had been seen by a HFHS physician. Patients were mailed a survey that was identical to the two-part survey completed by patients in the LAC. **Financial Analysis:** A financial analysis was also performed.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): **Staff Survey** A total of 33/54 (61 %) staff members responded to the survey. Results are shown in Table 1. Seventy-nine percent of respondents reported encountering a patient with LEP at least once a month, and 64 % reported requiring an interpreter. A total of 24 % of respondents reported miscommunications with patients due to language differences occurring at least once per month, with 30 % asking a patient's adult friend or relative to interpret. **Patient Survey: (before LAC)** A total of 78 patients visited the LAC between September 19, 2012 and January 29, 2014 10 % of LAC patients versus 5 % of non-LAC patients reported previously (pre-LAC) having a "bad reaction" to medication due to language problems. Seventeen percent of LAC patients versus 3 % of non-LAC patients reported previously having trouble understanding medical instructions and advice. **Patient Survey: (After LAC)** LAC patients were more likely to feel comfortable, understand materials, and communicate during their visit when compared to non-LAC patients. LAC patients also reported feeling that they were treated with respect more so than non-LAC patients

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Results of our evaluation suggest that patients drawn to the LAC may have been those that had experienced problems with healthcare-related communications previously. Compared to a convenience sample, LAC patients reported better communication and satisfaction in the LAC experience than non-LAC patients. Increasing the number of bilingual staff at HFHS could make our healthcare system more attractive to Latino patients with LEP or who prefer to receive their healthcare in Spanish. A more rigorous study is needed for further exploration and to confirm these preliminary results. There is need as the LAC clinic started initially as a 4 h block every other week, but given demand it was increased to 4 h block every week and currently is an 8 h block every week. Sustaining and expanding the LAC at HFHS is feasible with minimal resources. Required are bilingual providers and support staff. Factoring in staff and supplies, the approximate cost of each clinic (4 h time slot) was \$98.00. Approximate revenue generated is \$450 per 4 h clinic slots (6 patients @ \$75 each), for a financial gain of \$351.00. More patients can be accommodated into existing schedules without increasing staff hours which would generate more revenue. In addition, the LAC patient navigator and nurse assistant were hired on a contingent basis. With the addition of bilingual fulltime staff for General Internal Medicine, perhaps a cost savings could be realized.

ENHANCING RESILIENCE TO PROMOTE VA PATIENT-CENTERED MEDICAL HOME TRANSFORMATION AND THE UNTOWARD EFFECTS OF THE NATIONAL ACCESS CRISIS Carole Warde^{1,3}; Wendell T. Ching^{2,3}; Robin Sohmer². ¹Greater Los Angeles VA Health System, North Hills, CA; ²VA Sepulveda Amb Care Ctr, North Hills, CA; ³David Geffen School of Medicine at UCLA, Los Angeles, CA. (Tracking ID #2194553)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): While successful transformation to a patient-centered medical home necessitates that front-line care teams possess resilience to thrive during ongoing change and avoid burnout, little attention is paid to this aspect of system transformation.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): The site quality council initiated a 6-step practice innovation to identify and implement interventions to maintain or improve PACT teamlet members' job stress, personal burnout and job satisfaction.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Setting and Participants: A large VA multispecialty outpatient clinic with 12 primary care teamlets. Each teamlet is responsible for caring for approximately 1200 Veterans and consists of a full-time primary care provider (PCP), a RN/care manager, a LVN and a medical services assistant (MSA). The site is currently in the third year of transformation to a patient-centered medical home called PACT (patient aligned care teams). Many quality improvement (QI) initiatives to promote primary care practice transformation are initiated by the Quality Council (QC), which is an interdisciplinary team of site leaders, clinicians and patient representatives. This pilot innovation is planned to continue for a year. The process includes: **1. Form a Resilience Steering Committee (RSC):** the QC invited volunteer PACT teamlet members from each discipline to lead the program. A facilitator and practice coach were also part of this group and they met weekly or biweekly. Statistical support was provided by the Veterans Assessment and Improvement Laboratory (VAIL). **2. Conduct a Needs Assessment:** the RSC used a short survey and focus group to conduct the needs assessment. Survey questions were selected from previously validated surveys (Linzer et al.). The RSC reviewed and categorized results into three categories (demand, control and support). **3. Create Buy-in:** Results and potential first improvements were presented to all 12 teamlets and the site leadership team at 2 large practice meetings. The facilitator moderated a large group discussion for feedback and selection of targeted interventions. **4. Initiate Improvement**

Processes: The QC and RSC and interested staff members voluntarily initiated improvements identified at the all staff meetings and at the RSC meetings. **5. Share Information:** In addition to serving as a venue to implement resilience initiatives, the monthly all-staff meetings were planned to share resilience-related resources, stories and best practices. **6. Assess Improvement:** surveys similar to those used in the needs assessment were collected quarterly to assess staff burnout, job satisfaction and stress and reactions to interventions. RSC members also collected qualitative feedback informally from their teamlet colleagues.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): We used previously validated tools to measure our success: job stress, job satisfaction and burnout were our primary indicators. We also measured perceived control over interruptions and pace of work, teamwork efficiency and leadership values alignment with staff.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Needs Assessment Results: Workload demands related to panel size and walk-in patients. Control needs related to work interruptions and pace, staff job accountability, missing staff, and equipment maintenance. Support needs related to teamlets covering for each other, values alignment and communication with leadership, professional growth opportunities, and change management. Improvement Processes: First quarter interventions related to demands and control included: the creation of a daily walk-in teamlet to cover unscheduled patient visits; initiation of protected time for MSAs; and leadership attention to equipment maintenance. Support needs were addressed by scheduling monthly all-staff meetings to communicate with site leaders and conduct teamlet-communication exercises. Anonymous suggestion boxes were placed in clinical areas and input reviewed by the RCS and QC. Unexpectedly, during the second quarter of this innovation, the nationwide VA access crisis occurred, which led to the cancellation of the all-staff meetings and the first quarter interventions. Baseline rates of high job stress and satisfaction were 63 and 46 %; high job satisfaction rates trended toward improvement to 67 % during the first two quarters. Burnout rates decreased with the initiation of the first quarter's interventions from 57 to 25 % ($P < .01$) and perception of control over work interruptions improved from 24 to 50 % ($P = 0.05$). After the cancellation of the main resiliency-related interventions, the second quarter burnout rates and perceived control returned back toward baseline.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): The process to improve PACT teamlet resiliency in this innovation was successful at involving front-line PCMH care team members in improvement efforts. Teamlet member burnout rate and perceived workplace control appear to be sensitive measures to monitor the initiation and withdrawal of practice improvements related to resilience.

MEDICAL STUDENT INSULIN TITRATION PROGRAM: A PHONE-BASED OUTREACH FOR PATIENTS WITH UNCONTROLLED DM Emily Knudsen²; Ingabire Balinda²; Emily Richardson²; Svetlana Goldman¹; Donna M. White¹; Mohan Nadkarni¹; Joel Schectman¹; Ira Helenius². ¹UVAHS, Charlottesville, VA; ²University of Virginia, Charlottesville, VA. (Tracking ID #2194639)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Does a medical student run telephone-based outreach program that includes insulin titration improve glycemic control for ambulatory patients with DM?

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): We initiated a quality improvement project with the objectives of 1) improving hemoglobin A1c (HbA1c) in patients with poorly-controlled diabetes and 2) fostering relationships between medical students and patients.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): We developed a telephone based insulin titration program in a large outpatient general medicine clinic that provides care to a primarily underserved and indigent population of patients at University of Virginia Medical Center. Medical students were recruited to design and run the program with oversight from two Internal Medicine attendings and a pharmacist/DM educator. Prior to starting the program the students attended training sessions on diabetes and its management run by DM educators. Students received training in motivational interviewing skills and became more comfortable utilizing these skills in engendering lifestyle and behavioral changes with patients. A previously used insulin titration protocol was adapted for the program to allow students to adjust patients' insulin doses over the phone. Patients with uncontrolled DM (HbA1c > 8 %) on long acting insulin were referred to the program by providers in the clinic. Three medical students began enrolling and calling patients in July 2014. In the weekly telephone conversations with patients, student volunteers discussed trends in blood glucose (BG) readings, diet and exercise. Healthy lifestyle modifications were stressed in the conversations, and potential barriers to improved DM selfcare were addressed. Volunteers also used the insulin titration protocol to adjust doses as needed based on weekly average BGs.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Pre- and post-program HBA1c, initial age and BMI, number of weeks enrolled in the program and number of weeks of successful calls were determined for each patient.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Program data from July 1, 2014 through November 1, 2014 were analyzed. Forty-seven patients were included in the analysis. The mean BMI was 36 kg/m² ($n=47$), mean age was 57 years ($n=45$), mean initial HBA1c was 10.2 % ($n=44$) and mean follow-up HBA1c was 8.8 % ($n=31$). The mean time between initial and follow-up HBA1c was 135 days. Among the 28 patients with pre and post values, the difference between initial and follow-up HBA1c was -1.57 % ($p=0.0007$). Students' attempts to reach patients per phone were successful 47 % of the time. Patients were successfully reached an average of 6.9 out of 14.6 weeks enrolled. Univariate regression showed that the magnitude of the reduction in HBA1c was significantly associated with the number of times the patient was reached by phone ($p=0.01$), but not associated with the number of weeks enrolled in the program ($p=0.91$). To date we have only anecdotal data on the effect of the program on medical students. Students report that they felt more comfortable with adjusting insulin and more importantly, that they have a better understanding of the struggles facing underserved patients. Some students have voiced frustrations about how difficult it is to reach patients per phone.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): A medical student run, phone-based outreach program for patients with uncontrolled DM using an insulin titration protocol can improve glycemic control. The patients who reap the most benefits from the program are those who are reached by phone most frequently; those patients who were not reached often did not get the benefit of reduced HBA1c even if they were enrolled in the program.

MULTIDISCIPLINARY APPROACHES TO IDENTIFY CAUSES FOR READMISSION FOLLOWING CORONARY REVASCULARIZATION Vishal Patel¹; Daniel J. Elliott². ¹Christiana Care, Newark, DE; ²Christiana Care Health System, Newark, DE. (Tracking ID #2195944)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Despite intense focus on the need to reduce readmissions, surprisingly little is known about the factors which lead to readmissions. Understanding these factors could help more appropriately target interventions to improve care transitions.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): To identify factors leading to all-cause non-elective 30 day readmissions following coronary re-vascularization; and to use these findings to implement interventions to circumvent these readmissions.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): We conducted a structured review of readmitted patients at a single tertiary care institution from May 2013 to present. All patients were participating in an integrative care management program. A multi-disciplinary team reviewed chart audits and patient interviews using standardized tools. A physician team determined preventability and factors that contributed to the readmission; and lessons learned were used for ongoing quality improvement.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Information from the index visit, discharge process, outpatient course, and readmission were collected and this was used to create a readmission model. A quantitative model was created to determine readmission risk potential and this information was distributed to the case managers to help allocate resources appropriately during and after discharge. In addition, other measures such as patient quality of life and symptoms were monitored.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): We reviewed 134 patients with an unplanned 30 day readmission. Thirty-five percent of the patients had CABG and 65 % had PCI. The chief complaint on readmission was chest pain or shortness of breath for 75 % of the cases. Thirty-eight percent were judged as potentially preventable. Of the preventable readmissions, 60 % could have been prevented with actions prior to the initial discharge. The major factors contributing to readmission for all cases by percentage include difficulty managing symptoms at home (61 %), continuity of care including appropriate follow-up (40 %), and lack of disease monitoring (20 %). In 25 % of the cases, we identified an opportunity for the care management team to improve engagement with the patient.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): A significant portion of readmissions were considered to be preventable with intervention,

many of which relate to improved systems of care delivery across the spectrum of care. This type of multi-disciplinary structured case review can identify opportunities for ongoing improvement of care delivery following coronary revascularization. Since implementation, we are now focusing on improvements in care transitions and placing a greater focus on home health care. We have incorporated more tele-health into the home to have greater meaningful contact with the patient and will continue to monitor if this will improve patient outcomes and readmission rates for preventable hospitalizations.

POST-DISCHARGE CARE COORDINATION FROM THE SAFETY NET MEDICAL HOME: A HEALTH WORKER PHONE CALL INTERVENTION Elizabeth Imbert⁵; Jessica Beaman⁵; Susan Wlodarczyk⁵; Claire K. Horton⁵; Hali Hammer⁵; Anna Robert¹; Ellen Chen¹; Catherine James¹; Lydia Leung²; Michelle Schneidemann⁴; Pineda Iveh¹; Karishma Oza²; Larissa Thomas⁶; Anne Rosenthal¹; Marina Mancillas¹; Elizabeth Davis⁵. ¹San Francisco Department of Public Health, San Francisco, CA; ²San Francisco General Hospital, San Francisco, CA; ³UCSF SF General Hospital, San Francisco, CA; ⁴UCSF/SFGH, San Francisco, CA; ⁵University of California San Francisco, San Francisco, CA; ⁶University of California, San Francisco, San Francisco, CA. (Tracking ID #2199401)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): There are 35.1 million discharges annually from hospitals around the US and approximately 18 % of these result in readmission.¹ Safety net hospitals have higher readmission rates likely attributable to serving patients with lower socioeconomic status and higher levels of comorbidities.² Many studies have evaluated preventability of readmission and on average only 23–30 % of 30-day readmissions appear to be avoidable.³ With the new Medicare penalty for readmissions, hospitals have focused on improving care coordination as patients transition from inpatient to outpatient settings in an effort to reduce readmission and improve patient outcomes.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): At San Francisco Health Network Primary Care, we implemented a primary care based post-discharge phone call by a health worker to 1) improve care coordination upon discharge from San Francisco General Hospital; 2) increase the percentage of post-hospital discharge appointments attended within seven days of discharge; 3) and decrease readmission rates. To meet these goals, we iteratively refined the health worker workflow and script at four primary care clinics and then spread it to eight other primary care clinics.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): In late 2013, a needs assessment was performed to identify rates of admission, readmission, and post-hospital discharge appointments for patients in pilot primary care clinics. In October–December 2013, our first Plan-Do-Study-Act (PDSA) cycle piloted a post-discharge phone call at four primary care clinics. Each business day, the health worker at each clinic queried the electronic medical record to identify patients who were discharged from San Francisco General Hospital, made them a follow up appointment if they did not already have one, and called the patients. The phone call script content varied among the four pilot primary care clinics. In February 2014, PDSA cycle #2 took lessons learned from one of the sites and modified the phone script to include questions regarding medication issues, which triggered nursing involvement if positive, and information about how to access the clinic should symptoms worsen. In July 2014, PDSA cycle #3 focused on ensuring follow-up appointments were made within 7 days of hospital discharge. In July–August 2014, we integrated scripts across all four sites creating a uniform script and protocol that we then disseminated to eight additional health centers through a network-wide training. In October 2014, patients were surveyed over the telephone regarding their experiences with the post-discharge follow up phone call. Using this information, in December 2014 PDSA cycle #4 involved a revision of the script to include a review of medications and clarification of whether the patient has enough medication to last until the follow appointment; a screening for red flag signs, which triggers nursing involvement if positive; a teach back component reviewing content of phone call; and a description of the purpose of the post-hospital discharge appointment.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): The metrics used to evaluate this program include percentage of primary care clinic patients attending post-hospital discharge appointments within 7 days of discharge; percentage of readmissions to SFGH; and percentage of post-discharge phone calls requiring nursing involvement.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): During the 1 year since implementation, there has been a steady increase in the percent of patients attending post-hospital discharge appointments within 7 days from 36 to 42 % in General Medicine Clinic and 33 to 52 % in Family Health Center.

Percentage of patients attending post-hospital discharge appointments did not change at the other two pilot sites due to staffing issues which limited implementation of phone calls. Overall, percentage of patients attending post-hospital discharge appointments has increased by 32 to 42 % across San Francisco Health Network. The readmission rate has been unchanged since our implementation. The percentage of post-discharge phone calls requiring nursing involvement is 0.05 %.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Post-discharge phone calls by health workers can improve post-hospital discharge appointment attendance in the safety net setting. Although our readmission rate has not changed, we suspect this is due to a rise in readmission rates at San Francisco General Hospital as well as the fact that our data for readmission rates is only current as of June 2014 and does not reflect our most recent PDSA cycle which included our telephone script modification. Our low nurse involvement reflects that this intervention can be done by a health worker however our last script modification was performed with a focus on triggering nurse involvement when appropriate. The telephone call protocol implemented in this study could be easily transferred to other outpatient settings and may serve as one method of improving safety and ensuring close follow-up for patients during their transition from the inpatient to outpatient setting.

THE BUDDY SYSTEM IN DIABETES SELF-MANAGEMENT: A PILOT PROJECT Natasha Parekh²; Rachel Hess³; Marcus A. Poindexter¹; Elena Jiménez Gutiérrez²; Gary Fisher². ¹University of Pittsburgh, Pittsburgh, PA; ²University of Pittsburgh Medical Center, Pittsburgh, PA; ³University of Utah, Salt Lake City, UT. (Tracking ID #2196224)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Prior work has examined the use of support programs with hired or volunteer peers for the management of chronic diseases including diabetes, tobacco abuse, HIV, obesity, and depression, but the use of patients' existing social support has not been well-investigated; with this in mind, could an outpatient program that takes advantage of patients' existing social support (i.e., a Buddy System) improve diabetes self-management?

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): We designed a single-center, prospective feasibility project called the "Buddy System" for high-risk patients with diabetes in our general internal medicine clinic. The goals of this pilot project were: 1. To assess the feasibility of such a system in terms of (a) patient satisfaction with and desire to continue the program, (b) challenges and barriers for program success, and (c) possibility of expanding this to a larger diabetic population. 2. To assess the impact of such a system on (a) hemoglobin A1c (HbA1c), (b) blood pressure, (c) body mass index (BMI), and (d) health care utilization (emergency room visits/hospital admissions).

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The Buddy System is an outpatient-based intervention conducted by internal medicine residents, a clinic social worker, and a clinic diabetes educator. The study team enrolled patients with uncontrolled diabetes (HbA1c > 8.5 in the previous year) from our clinic population. Patients participating in this trial identified a "buddy" within their social support network who was trusted to be a supporter of their health. The patient and buddy then attended an education session by the study team on diabetes self-management, challenges, and goals. They chose from a "menu" of support options on ways that the buddy could help the patient with self-management. Some examples included time commitments to exercise together, cook fresh meals together, and assist with obtaining medications and attending medical appointments. The patient and buddy were then followed up at 1 month (by phone), 3 months (in person), and 6 months (in person) to assess outcomes.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): The study team used patient and buddy survey data to assess how the buddy system functioned and to evaluate for areas of improvement, satisfaction, and challenges to system implementation, as well as perceived effects on stress, diet, exercise, and the patient-buddy relationship. The team also used medical chart review to assess objective outcomes including HbA1c, blood pressures, BMI, emergency room visits, and hospitalizations.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Seventeen patient-buddy pairs initially enrolled in the project (mean age 53 years old, 82 % female patients). Ten pairs (59 %) completed the program. Of those who completed the program, 100 % of patients and buddies were very much or mostly satisfied with the Buddy System and would be willing to continue it in the future. Reasons for not completing the program included 1 patient death, 3 buddy hospitalizations, and 1 patient transportation issue; only 2 patients were not willing to continue. Among those who completed the project, there was a decrease in median HbA1c from 9.3 to 8.7 at 6-months, though not statistically significant ($p=0.095$). There was no significant difference

in BMI ($p=0.59$), perceived stress score ($p=0.75$), and hospitalizations/ER visits ($p=0.50$).

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Interventions that address health outside of the clinic are necessary to improve our patients' health. This pilot project suggests that a Buddy System is feasible for high-risk patients with diabetes in our clinic. Considerations to prevent dropouts in the future include the use of technology to remind patients/buddies of their goals, more logistical support with appointments, and exclusion criteria for buddies to ensure that buddies are functionally able to support patients. Although a decrease in HbA1c was not statistically significant, this data can be utilized to calculate power calculations and inform future work in this area. Thus, taking advantage of patients' existing social support systems could be of value to self-management in a high-risk population of patients with diabetes.

THE USE OF SNAP SURVEYS TO EVALUATE, IMPROVE AND ENGAGE RESIDENTS IN CLINICAL OPERATIONS, TEACHING AND QUALITY IMPROVEMENT Scott Joy¹; Anjali Dhurandhar². ¹The Colorado Health Foundation, Denver, CO; ²University of Colorado School of Medicine, Denver, CO. (Tracking ID #2195029)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): It is important for faculty and administrators in academic medical practices to obtain routine, timely feedback from residents on their satisfaction with clinical operations, faculty teaching and quality improvement efforts that are ongoing within the clinical training environment to make meaningful changes to improve the resident experience and perceptions of the practice of general internal medicine.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): In the era of online, web-based status updates and instant feedback, "pulse surveys" or "snap polls" are gaining more widespread use in places of employment. The purpose of these short monthly, weekly or daily polls is to collect data on how team members actually feel about their work environment and to recognize problems promptly and address common issues of concern. It has not been reported how these types of surveys could be applied within the outpatient clinical practice environment in a general internal medicine training program.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): We sought to identify key measures that were often areas of past concern for GIM residents which included team huddle, clinic rooming process, medical assistant performance, access to attendings for patient sign-outs, quality and content of pre-clinic educational conferences, overall perception of the quality of faculty teaching, and the perceived value of participating in ongoing QI projects. Our GIM residents are on a 4+1 schedule, rotating in the GIM outpatient clinic for 1 full week out of 5 weeks. On the Friday of each clinic week, a faculty member leads a group discussion, asking each residents to provide a specific number regarding how they feel about each of the areas of evaluation described earlier on a 1–10 Likert scale (0-poor, 10 excellent). If the value is not a 10, residents are asked to provide a specific suggestion for improvement that would have made the area of evaluation become a 10. These values and comments are documented by the faculty member leading the survey session and entered into an excel spreadsheet for analysis. These feedback sessions on average take less than 15 min to complete as a group. Findings and observations gleaned from the resident feedback are discussed at regularly weekly faculty/staff meetings, and solutions to areas of concern are addressed and appropriate changes are made in clinical operations or teaching efforts.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Create a culture of openness and trust within the clinic and between residents and clinic leadership. Proactively demonstrate to residents, on a weekly basis, that their feedback is welcome and valuable suggestions will be acted upon by clinical leadership to improve their learning experience and the patient experience of care. Provide faculty with an opportunity to train residents on how to provide constructive comments and feedback related to clinical operations and teaching effort, insisting upon specific suggestions to improve performance in any category that is not scored a 10.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Summary data from 07/18/2014 to 12/15/2014: Metric: Average Score (Range of Scores) Huddle: 8.3 (7–10) Rooming: 8.9 (8–10) MA/Front Desk Performance: 9.8 (9–10) Access to Faculty: 9.0 (6.5–10) Quality of Pre-Clinic Conference: 9.1 (8–10) Overall Quality of Teaching: 8.8 (6–10) Value of QI Project: 7.8 (1–10)

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): A weekly, brief, "snap survey" is a simple tool that is an effective means for gathering feedback from residents on their perceptions on clinic operations and teaching experience

within a GIM academic practice. The residents are also given an opportunity to voice and discuss concerns and or make suggestions with a faculty member on a regularly scheduled and timely basis to improve their overall clinical and teaching experience. A potential limitation is that the snap surveys are not anonymous, are administered by a faculty member and are held as a group. As a result, residents may not always feel comfortable expressing some of their thoughts. However, this provides a teachable moment for the resident to learn how to provide feedback as a group and to hear what their peers comments/suggestions are, and to provide the faculty member an opportunity to teach principles of effective feedback generating constructive comments that can be acted upon by administration to add value to the overall teaching experience for the residents. Because of the frequent feedback sessions, suggestions for improvement can be quickly addressed and applied to enhance the clinical and teaching experience for GIM residents.

USING AN EVIDENCE-BASED, SYSTEMATIC APPROACH TO IMPROVE BLOOD PRESSURE CONTROL IN STAGE 2 HYPERTENSIVE PATIENTS THROUGH A MULTIDISCIPLINARY TEAM-BASED MODEL Sarah Schenck; Pooja Dogra; Edward Ewen; Julie Silverstein. Christiana Care Health System, Newark, DE. (Tracking ID #2195948)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Clinical management of patients with hypertension is often complex, particularly in an urban population with a high burden of chronic illness due in large part to fragmented care, lack of incorporating evidence-based guidelines into practice, patient non-adherence and social barriers.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): To reduce systolic blood pressure by 10 mmHg in 20 % of Adult Medicine Office (AMO) and Internal Medicine Family Practice (IMFP) patients with Stage 2 hypertension

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The AMO, the Internal Medicine residency teaching clinic, and the IMFP take care of 7500 patients who are mostly underinsured, under-resourced and suffer a high burden of chronic disease. In the AMO and IMFP, 48 and 30 % of the patients respectively have hypertension. We designed a program, AMO-HTN, to address patients with Stage 2 hypertension (blood pressure >160/100 based on rolling 12 month time-averaged blood pressures) who had been seen in the office at least once in the previous 12 months. Our program was developed based on 3 principles: o Population health approach: to use clinical staff in roles appropriate for their training. o Evidence-based medicine: to determine best practice (STITCH chosen over JNC-7) to develop clinical algorithm. o Patient engagement in self-management: aided by distribution of home blood pressure monitors. We developed a clinical algorithm based on guidelines, literature review, relevant medication formularies and costs. We incorporated resident and faculty education into the Preclinical Pearls curriculum. AMO-HTN patients were given dedicated appointments for hypertension evaluation and management, and standardized hypertension templates were used for documentation of these visits. Our multidisciplinary team included faculty and resident physicians, a clinical pharmacist, a nurse and medical assistants. The intervention period was 6 months (10/1/2012-4/30/2013).

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): • To reduce systolic blood pressure by 10 mmHg in 20 % of Adult Medicine Office (AMO) and Internal Medicine Family Practice (IMFP) patients with Stage 2 hypertension in 6 months. • Comparison of results by visit type o No visit o AMO-HTN visit o Other visit type

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): • A total of 209 patients were enrolled in the AMO-HTN program • A 10 mmHg reduction in systolic blood pressure was seen in 26.8 % of the overall enrolled population • The average reduction in systolic blood pressure was 5.04 mmHg • Patients who had an office visit during the intervention period were 2 (AMO) to 4 (IMFP) times more likely to achieve a 10 mmHg reduction in blood pressure

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): • Blood pressure can be reduced in patients with Stage 2 Hypertension by a multidisciplinary team-based approach utilizing an evidence-based algorithmic model of care and patient self-management. • Having an office visit, whether it was designated for hypertension or not, was associated with blood pressure reduction. • The study period was short and BP management is an iterative process that requires time for sequential interventions and follow-up measurements.

A MULTIDISCIPLINARY EFFORT TO IMPROVE UTILIZATION OF RESOURCES FOR PATIENTS WITH MORBID OBESITY IN THE PRIMARY CARE CLINIC Stephen C. Chow. Carolinas Medical Center, Charlotte, NC. (Tracking ID #2196726)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): This quality improvement project aimed to increase morbid obesity counseling and referrals to relevant resources in those with a BMI of 40 or higher seen at Myers Park Internal Medicine Clinic during January 2014.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): To increase awareness of morbid obesity and the resources to address it in the outpatient setting amongst residents. To increase the amount of morbid obesity counseling and referrals to resources for patients with BMI of 40 or higher in clinic. To address morbid obesity during clinic visits in hopes that weight loss will improve longterm clinical outcomes of other chronic diseases.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): This project was conducted at Myers Park Internal Medicine Clinic in Charlotte, North Carolina, which is the outpatient training site for the Carolinas Medical Center internal medicine residency program. It is an urban clinic with a high percent of patients who are either uninsured, have Medicaid, or have Medicare. Patients were included if they were seen in the general internal medicine clinic by either a resident or attending and had a BMI of 40 or higher. Patients were excluded if they were there for a hospital follow-up visit. In January 2014, we introduced a brightly colored handout to physicians to use with their patients with BMI of 40 or higher. The handout included counselling on diet and exercise, multiple referral options, and space to write in additional recommendations. After collaborating with our quality improvement team, clinic nurse manager, clinic physician director, and clinic nurses, we developed a system where nurses would pull this handout on all patients they roomed with a BMI of 40 or higher. The physician would then fill it out and place it back in the chart. The nurse then copied the handout, keeping the copy for us, and giving the original to the patient to take home.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): We measured obesity counseling, dietitian referrals, YMCA referrals, aquatic therapy referrals, and bariatric clinic referrals in January 2013 (pre-intervention) and again in January 2014 (during intervention). Electronic charts of all patients with BMI of 40 or higher seen at Myers Park Internal Medicine during these months were identified through use of the electronic medical record. Chart reviews and data extraction were performed to look for the counselling and referrals listed above.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): One hundred forty-seven patients in January 2013 and 135 patients in January 2014 met our inclusion and exclusion criteria. Obesity counseling rose from 53.1 % (78/147) to 72 % (97/135) of patients in the pre-intervention and intervention groups respectively. This increase was highly significant, with p-value of 0.001. Dietitian referrals nearly tripled from 6.8 % (10/147) to 18.5 % (25/135), also with highly significant p-value of 0.003. Aquatic therapy referrals increased from 2 % (3/147) to 6.7 % (9/135), with a trend toward significance with a p-value of 0.056. YMCA referrals did not significantly change, at 6.8 % (10/147) in 2013 and 7.4 % (10/135) in 2014 (p-value 0.843). Bariatric Clinic referrals also did not significantly change, from 3.4 % (5/147) in 2013 to 1.5 % (2/135) in 2014 (p-value 0.450).

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): We were able to increase obesity counseling, dietitian referrals, and aquatic therapy referrals for our morbidly obese clinic patients, by using a simple one-page handout that addressed obesity counseling and referrals to resources through a nurse-physician collaboration. In our initial survey of residents, 90 % (26/29) identified time constraints as a barrier to addressing obesity with patients in clinic. We believe this intervention provided an efficient and low-cost way to address obesity with patients. Although this was a relatively small sample size in one clinical setting, we believe it could be implemented in a wide variety of primary care practices. As the majority of our obese patients have medical problems associated with their obesity, such as diabetes, hypertension, heart disease, and osteoarthritis, every intervention we can make to decrease obesity is a step toward preventing and treating these diseases.

A MULTIDISCIPLINARY TEAM-BASED MODEL UTILIZING THE DIABETES EDUCATOR TO IMPROVE DIABETES OUTCOMES IN PRIMARY CARE

Georgia Kulina¹; Victoria L. Mayer¹; Laurie Edelman¹; Jonathan Arend¹; Brett Ives³; Maria E. Rodriguez²; Carol Levy¹; Ronald Tamler¹; Carol R. Horowitz¹; Abby L. Schwartz²; Eva Waite¹; Theresa Soriano¹. ¹Icahn School of Medicine at Mount Sinai, New York, NY; ²Mount Sinai Diabetes and Cardiovascular Alliance, Mount Sinai Health Network, New York, NY; ³Boston University, Boston, MA. (Tracking ID #2197919)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Management of Type 2 Diabetes Mellitus (T2DM), a disease affecting over 29 million people in the United States, poses a significant challenge to health systems, resulting in the need to formulate highly effective primary care delivery models in order to improve diabetes-related outcomes.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. To optimize management of patients with diabetes by improving Hemoglobin A1c (HbA1c), blood pressure, and weight, and to increase adherence to diabetes-related health maintenance guidelines, such as retinopathy, neuropathy, and nephropathy screening and pneumococcal vaccination. 2. To train resident physicians and other practitioners in the multidisciplinary, collaborative management of diabetes in order to expand knowledge and improve future care of patients with diabetes. 3. To utilize the expertise of various team members, including certified diabetes educators (CDEs), general internal medicine attendings, endocrinologists, nurses, residents, community health workers, and care coordinators to provide a scalable, generalizable experience where patients feel equipped and motivated to improve diabetes self-management.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Internal Medicine Associates is an urban academic internal medicine primary care practice with approximately 29 % of patients suffering from T2DM. We provide care to the diverse community of East Harlem, predominantly Latino and African American residents suffering the highest rates of diabetes and diabetes-related complications and mortality in New York City. In order to improve outcomes, we implemented a novel, multidisciplinary, team-based program which places the Registered Dietitian (RD)/CDE at the center of the care team. Patients with HbA1c $\geq 8\%$ can be referred to our program by their primary care providers, and care coordinators facilitate enrollment. Patients subsequently meet for individual sessions with a RD/CDE who provides nutritional counseling, assesses disease management and risk of complications, identifies barriers to adherence, delivers intensive self-management support, and refers to other team members as needed, such as depression care specialists and community health workers. A unique aspect of our program is that the RD/CDEs are fully integrated into our existing clinic practice, and consult with faculty physicians in real-time for medication management. We collaborate regularly with endocrinologists to review difficult cases and ensure our general internists and CDEs are qualified to deliver the most up-to-date care for T2DM. In an effort to engage resident physicians in diabetes management, first year internal medicine residents rotate through our program during their ambulatory blocks. Residents are provided with didactic sessions that improve knowledge of diabetes therapies, motivational interviewing techniques, and instruct how to promote patient self-management. These skills are then applied during diabetes-focused visits with patients referred to our program. Finally, care coordinators facilitate pre-visit planning and follow up, and use specially designed clinical decision supports and feedback of quality metrics enabled through our electronic health record to optimize care and communication with patients and other team members.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Using the electronic medical record, we are gathering demographics, comorbidity, and longitudinal data on diabetes-related biometric outcomes for participating patients before and after enrollment, including blood pressure, weight, HbA1c, LDL cholesterol, hospitalizations and ED visits, and adherence to quality metrics such as retinopathy, neuropathy, and nephropathy screenings. We will compare HbA1c trends among those enrolled in the program to other patients in the practice with similar glycemic control and demographics at the first time point.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): During the first 12 months of our program we saw 164 patients for two or more visits. The number of patients with HbA1c values $\leq 9\%$ increased from 29 to 50 % ($p \leq 0.005$ %). The number of patients with HbA1c values less than 8 % increased from 4 % at enrollment to 23 % ($p \leq 0.005$ %).

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Utilizing the CDE in a team-based approach to diabetes management has been shown in the literature to improve outcomes while reducing cost; our findings to date further support this model. Our novel physician-extender program has been successful in improving glycemic control in a high-risk population utilizing physician extenders. Our program is integrated into the existing clinic workflow, engaging faculty physicians in diabetes co-management. We have found that it is feasible to involve residents and build an educational component around a multidisciplinary chronic care model. The strength of our model lies in the central role of the RD/CDE, the real-time collaboration with physicians, and robust care coordination. We believe this model is generalizable to other institutions and practice models, and can provide another dimension for chronic care management.

A PATIENT-CENTERED APPROACH TO ADDRESSING WOMEN'S HEALTH IN A REFUGEE POPULATION Jessica E. Murphy³; Chiamaka Onwuzurike¹; Aba Barden-Maja². ¹University of Pennsylvania, Philadelphia, PA; ²Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA; ³Hospital of the University of Pennsylvania, Philadelphia, PA. (Tracking ID #2190396)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Since 2010 our clinic has cared for refugees who have recently resettled in Philadelphia, and women's health was identified by both physicians and patients as an area in need of improvement.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): A refugee women's clinic was created in July 2013 with the objectives of (1) improving patient education about cervical cancer screening and contraception, (2) improving family planning counseling, and (3) screening for sexual violence.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Patients are seen in the women's clinic soon after their initial comprehensive refugee in-take exam. To create a comfortable environment, the clinic is staffed by only female providers and includes in-person female interpreters. Prior to being seen by the physician, patients participate in a group educational session led by medical students. These sessions address various women's health topics, including Pap smears and contraception, while providing patients with the opportunity to ask questions and learn from the experiences of other members of their community. Subsequently, the physician performs a comprehensive women's health assessment. All providers use a standardized template within the electronic medical record. Providers screen for gynecologic complaints and perform appropriate bone and breast health screening. Providers discuss family planning, specifically the patient's history of contraceptive use, their reproductive plan, and their current interest in contraception. Finally, providers screen for any history of physical or sexual violence and for symptoms of depression or PTSD. All patients of reproductive capability receive a pregnancy test, and if indicated, a Pap smear is performed. Patients who are prescribed a new method of contraception are referred to our contraception adherence program where they will follow-up with our clinical pharmacist at 1 month and 4 months, with the goals of ensuring proper use of each method, addressing any side effects, and reducing discontinuation rates.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Quantitative data from the visits will be analyzed, including the rates at which women of appropriate age are receiving Pap smears and contraceptive education, how well we are meeting the contraceptive needs of our patients, and how frequently we are uncovering positive sexual violence screens. In addition, patients will be surveyed regarding their experiences in the clinic to determine whether we have achieved our goal of establishing a comfortable and secure environment for such an intimate visit.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Since the initiation of our clinic through December 31, 2014, we have had 11 clinic sessions and seen 34 women at a total number of 37 clinic visits. Patient ages range from 19 to 37 years with a mean of 39.5 years. The top three nationalities represented have been Bhutanese (20.6 %), Burmese (29.4 %), and Iraqi (17.6 %). In terms of cervical cancer screening, 82.4 % of patients had never previously had a Pap smear, however after our educational sessions 76.5 % of patients said they were knowledgeable about Pap smears. Pap smears were performed on 25 of the 27 patients with an indication for testing. In terms of contraception care, 73.5 % of patients were premenopausal, and 64.7 % were currently sexually active. 64.7 % of patients had a history of birth control practices, with Depo-Provera and oral contraceptive pills equally most utilized and together making up 72.8 % of previously used methods. 44.1 % of patients were interested in birth control and all of these patients left the visit with a contraceptive plan, most commonly oral contraceptive pills. Overall, our unmet need for contraception has decreased from 29 % prior to beginning our women's clinic to 11 %, and 3 patients have enrolled in our contraception adherence program. In terms of safety and violence screening, we did uncover several patients who had been victims of violence, including 1 patient with a history of female genital cutting and 2 with a history of sexual assault, however all patients asked about safety at home reported feeling safe.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Refugees are a unique and challenging population. Their previous experiences are often traumatizing and can make this population particularly sensitive to vulnerable situations including invasive office exams and screening questions. Our model of a women's clinic that is staffed by women, involves group educational sessions, and includes a comprehensive history and exam with the assistance of in-person interpreters is a novel approach to address this problem. Other institutions attempting to provide culturally sensitive but comprehensive women's care may find this model helpful, particularly if caring for a vulnerable population.

A PHARMACIST BASED INTERVENTION TO PREVENT MEDICATION ERRORS AT DISCHARGE Navneet K. Sidhu¹; Christopher T. Bunn²; Tiffany Montoya³; Bart Cox¹. ¹University of New Mexico, Albuquerque, NM; ²University of New Mexico, Albuquerque, NM; ³University of New Mexico, Albuquerque, NM. (Tracking ID #2199419)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Medication errors at the time of hospital discharge are common and can lead to preventable adverse drug events (ADE's). Over 40 % of all medication errors are believed to result from inadequate reconciliation. Of these errors about 20 % result in patient harm. Hospitalized patients are subject to at least one medication error per day.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): The goal of the project is to identify and correct medication errors before a patient is discharged from an inpatient cardiac unit. Types of error are tracked over time and educational interventions are created to target errors that occur frequently.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): After physicians complete discharge medication reconciliation, a pharmacist trained in cardiac and chronic disease state management evaluates the discharge medication list. If discrepancies are identified they are corrected before the patient is discharged. These interventions are categorized and tracked over time. Critical interventions are defined as those which are likely to lead to readmission or ADE's. Critical errors are defined as: duplicate, omitted, incorrect doses of medications, inappropriate medications, or missing dose, route, or frequency on the medication list. Non-critical interventions are those that are less likely to cause a readmission or ADE's. Changing medication therapy for cost savings, physician failing to sign the discharge documents in the electronic medical record (EMR), eliminating abbreviations from the patient medication list, assistance from a pharmacist for drug-drug/disease interaction, clarification of complex medications regimens, or other prescription assistance were defined as non-critical interventions.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Percentage of discharges intervened on by a pharmacist. Number of errors identified at discharge. Types of errors identified by the pharmacist. Categories of error as they change over time.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): From 10/2012-102014 a pharmacist intervened on 69 % of 2530 discharges that were reviewed. Over a ten month period in 2014, 1414 interventions on the discharge documents were identified and corrected by a pharmacist. Six hundred and thirty of these errors (44.6 %) were categorized as critical interventions. Categories and rates of critical errors were: omission of medications (33 %), missing dose, route, or frequency (22 %), inappropriate medications (20 %), incorrect dose of medication (16 %), and duplicate medication (8 %). Based on the initial information regarding types of errors, a medication reconciliation orientation was created for residents rotating through the cardiology service. The attached figure demonstrates the changes in the types of error that occurred following the educational intervention.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Using a pharmacist based intervention can identify and prevent critical medication errors at discharge. Omission of medications from the discharge list is an error that occurs at a high rate despite educational interventions. A special folder of medications organized by disease state is being created in the EMR for easy access to discharge prescriptions. The folder will contain prepopulated evidence based dose, route, frequency and indication of common medications. We will continue to track interventions and hypothesize that this will decrease omissions of medications and missing dose, route, frequency of medications from the discharge list. Categorizing and tracking errors over time can be used to create novel educational and technological innovations to reduce potential ADE's.

A QUALITY IMPROVEMENT PROJECT TO IMPROVE DIABETES CARE IN A TRAINEE CLINIC Anuradha Phadke²; Nazima Allaudeen¹; Nicole Grant¹; Steven Asch¹. ¹Palo Alto VA Healthcare System, Palo Alto, CA; ²Stanford University School of Medicine, Palo Alto, CA. (Tracking ID #2194859)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Teaching chronic disease management to internal medicine residents is challenging—while individual case presentations are at the core of clinical teaching, sharing registry data with residents teaches them crucial population based management skills.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): The goals of our intervention were 1) to increase the rate of residents reporting exposure to diabetes practice patterns and 2) to decrease the rate of diabetic patients in our clinic with suboptimal blood pressure control and missing diabetes labs.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The project took place in a Veterans Affairs hospital general internal medicine teaching clinic with 493 diabetic patients. Baseline rates of adherence to diabetes quality metrics were suboptimal. Thirty-five percent of patients had a most recent blood pressure greater than 140/90. Eighteen percent of patients did not have an annual hemoglobin A1c on record and 25 % did not have an annual urine microalbumin. In the last Accreditation Council for Graduate Medical Education (ACGME) survey, 44 % of affiliated residency program residents reported that data had not been provided to them regarding their clinical practice patterns. We conducted chart review of a convenience sample of patients to determine the principle root causes for missing labs and suboptimal blood pressure control. 10/29 (35 %) patients who lacked annual hemoglobin A1c had not scheduled or had missed recommended follow-up appointments and 5/29 (17 %) patients had not had ordered labs drawn. 6/27 (22 %) patients had high blood pressure documented at a non-primary care, medical specialty clinic visit and 5/27 (19 %) patients with elevated blood pressure had not followed up in clinic as recommended. We presented these results to clinic leadership to devise a population management and process improvement based solution. We conducted numerous plan-do-study-act (PDSA) cycles testing generated change ideas. Ultimately, we devised an intervention that coupled quarterly trainee-directed audit and feedback about diabetes care performance with academic detailing regarding team-based registry management and institutional diabetes management resources. As an adjunct, we implemented a process improvement and checklist intervention to encourage pre-clinic lab ordering and patient reminder phone calls. In combination, these interventions targeted the main root causes and our educational gap. As our clinic was already divided into distinct sides, we devised a quasi-experimental intervention, where residents on one side of the clinic participated in the intervention and the other side served as a comparison group.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): The process and educational measures are the percent of residents who participate in this intervention, initiate a plan of care, and report receiving clinical performance data during their annual program survey. The clinical outcome measures are the percent of registry patients missing annual hemoglobin A1c, missing annual microalbumin, and with blood pressure greater than 140/90. We will compare the rates between control and intervention groups adjusting for clustering by provider.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): The checklist intervention was started 2 months ago with all but a few residents having participated. The audit, feedback, and academic detailing intervention began approximately 1 month ago and 14 of 22 intervention-group residents have participated with qualitative data reporting good acceptance of the intervention. At present, rates of missing hemoglobin A1c on the intervention side have decreased to from 18.1 to 16.9 % with rates on the comparison side increasing from 17.3 to 20.0 %. No change has been noted in blood pressure or rates of missing microalbumin, but we anticipate changes may lag interventions by months. Clinical measures will be collected every 2 weeks for the remainder of the academic year.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Limited clinic attendance and lack of familiarity with established clinic processes prevent residents from optimally managing the chronic diseases of their patients outside of clinic encounters. Using a combination of modalities - (1) audit and feedback with peer comparison (2) academic detailing regarding team-based registry management and diabetes care resources (3) and implementation of a lab preordering reminder checklist- we have started to bridge this gap. Through our PDSA cycles, we have learned that trainees prefer performance data to be pushed to them rather than pulling data from a registry and that data is less overwhelming to trainees if curated and presented with specific improvement suggestions regarding performance gaps. Feedback regarding improving performance should also emphasize the importance of using a team-based approach and leveraging existing methods of communication used in clinic.

A QUALITY IMPROVEMENT PROJECT: OPTIMIZING INPATIENT DISCHARGE FLOW Erin Lundberg¹; Meghan M. Lyman³; Anne Tomolo^{1, 2}. ¹Emory University School of Medicine, Atlanta, GA; ²Atlanta VA Medical Center, Atlanta, GA; ³Centers for Disease Control and Prevention, Atlanta, GA. (Tracking ID #2196154)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Peaks in hospital discharges throughout the day impact the availability of resources, including inpatient beds, contributing to increased ED boarding time.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. To evaluate discharge smoothing by determining the percent of

patients discharged from medicine teams before noon from a baseline period through multiple Plan-Do-Study-Act (PDSA) cycles of change. 2. To determine the impact of the quality improvement interventions on inpatient length of stay and Emergency Department (ED) boarding time

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The Atlanta Veterans Affairs Medical Center (AVAMC) is a tertiary care facility that has 273 inpatient beds. From June through October 2013, the peak discharge time at AVAMC was 2–3 pm and the percent of ED patients waiting for a hospital bed more than 4 h from the decision to admit time was 20.8 % compared to 7.2 % in VA nationally. Studies suggest that prolonged ED boarding time increases hospital length of stay and costs, increases mortality, and decreases patient satisfaction. ED boarding time depends on bed availability, which is affected by the flow of hospital admissions and discharges. To smooth the timing of inpatient discharges throughout the day and improve availability of resources, a continuous quality improvement project was started in November 2013. The aim was to increase the percent of inpatients discharged before noon from a baseline of 13.8 % (June through October 2013) to 30 %. The first three PDSA cycles of change focused upon engaging inpatient nurse practitioners (NP), educating medical residents about early discharge planning and related tools, and using team-based report cards that included the percent of patients discharged before noon and use of discharge planning tools. In April 2014, a fourth cycle of change was instituted to enhance communication about discharges. The intervention was a brief interdisciplinary huddle and included representatives from inpatient teams (physicians and NPs), utilization management, bed control, radiology, cardiology, physical therapy, home health, and transportation. Team representatives presented information about patients ready for discharge in an effort to resolve impediments to discharge and expedite pending tests and evaluations necessary for patients to be discharged home later that day and the following day.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): The percent of medicine patients discharged before noon was measured weekly and graphed on a Statistical Process Control (SPC) P-chart. Data was collected from May 2013 through November 2014, including a 20 week baseline (June–October 2013). Balancing measures, such as hospital length of stay and ED boarding time, were evaluated from February through November 2014 in a run chart.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): The 20 week period following the initiation of the report cards and the huddle (February–May 2014) represents special cause variation on the P-chart as indicated by data points above the upper control limit. These points show a larger variation than one expects to occur randomly, suggesting that the interventions did have an impact on the mean percent of discharges before noon, increasing from 13.8 to 22.4 %. The manual data collection required for the report cards was too time-consuming and the process was discontinued by June 2014. The previous improvements were not sustained by the huddle alone, and special cause was again noted. The P-chart showed two out of three successive values more than two standard deviations below the centerline (a line indicating the mean percent discharged before noon). This 24 week period (June–November 2014) following discontinuation of the report cards represents a new stable process with a mean of 14.2 % (pre-intervention period level). There was no special cause variation identified in the run charts of hospital length of stay and ED boarding time from February to November 2014.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): This study emphasizes the importance of monitoring performance measures in real time to inform quality improvement projects and the role of SPC in examining time series design. Timely and accessible performance data delivered to stakeholders, such as inpatient teams, resulted in significant improvement in discharge smoothing, which was not maintained with the implementation of the huddle alone. The most recent cycle of change is the development of an automated report of team-based inpatient flow metrics to facilitate the timely audit and feedback of data to the inpatient teams.

A SHORT MINDFULNESS-BASED INTERVENTION DECREASES PERCEIVED STRESS AND MEDICAL VISITS Lisa M. Grant. University of Wisconsin-Madison, Madison, WI. (Tracking ID #2191976)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Adults are not receiving the help they need to manage the stress in their lives.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Provide patients with tools to mobilize their own internal resources to optimize health and wellbeing. 2. Decrease patients' perceived stress. 3. Decrease healthcare utilization, (number of medical visits)

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Chronic stress can result in serious health problems. We hypothesized that a 5 week "Mindful Movement for Stress Management" Program, (MMSM), could decrease patients' perceived stress and decrease their number of medical visits. Subjects were patients in a university-based primary care clinic. "High-utilizer" patients were defined as those having four or more medical visits within a six month period. One thousand three hundred such patients were invited to attend a MMSM class. The first 28 patients to respond were enrolled. The program is modeled after the Mindfulness-Based Stress Reduction Program, (MBSR), developed by Dr. Jon Kabat-Zinn. It is an abbreviated version with the addition of an educational component about how stress commonly manifests in the body. The class met for one hour on 5 consecutive weeks. The objectives were for patients to better recognize stress when actually experiencing it, and to build resilience through the cultivation of an awareness practice. Each class included a didactic component about the anatomic and physiologic aspects of the stress response and an experiential component, focusing on the progressive acquisition of mindful awareness. Participants were given daily reading and homework assignments.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Participants self-administered the Perceived Stress Scale, (PSS), prior to the start of the classes, at the conclusion of the fifth class, and again 6 months after completion of the program. The PSS is a validated short questionnaire. It is the most widely used psychological instrument for measuring peoples' perception of stress and whether situations are predictable and controllable, or overwhelm the respondent. A lower score on the PSS represents lower perceived stress. Healthcare utilization was determined by the number of medical visits in the electronic health record for the 6 months prior to the class and the 6 months after. Medical visits were defined as outpatient visits with a physician or NP/PA. ER visits and procedures were excluded. Changes in PSS scores and medical visits were analyzed using paired t-tests.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Twenty-five patients completed the program. One person never attended and two subjects discontinued after the first class. All 25 completers reported that the class objectives were met and that this specific intervention provided them with concrete tools to help manage their stress and to find their own capacity for ease. The mean baseline PSS score was 23.1 out of a maximum of 40 points. The mean PSS score upon conclusion of the class was 19.4 with a mean difference of -3.7 . ($p=.010$). Nineteen subjects completed the 6 month PSS, with a mean PSS score of 15.4. This represents a 7.4 mean decrease for subjects who completed the survey. ($p<.001$). The mean number of medical visits in the 6 months prior to the class was 5.8. This decreased to a mean of 4.7 at six month follow up. This is a mean decrease of 1.2 visits. ($p=.077$). A subgroup analysis via paired t-test also looked at those patients who had six or more visits prior to the class, ($n=12$). This group showed a mean decrease of 2.7 visits, ($p=.016$). Larger, randomized controlled studies comparing this limited intervention to usual care are warranted.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): A relatively brief MMSM program was feasible in a primary care setting. The program showed a significant sustained improvement in patients' perceived stress and also decreased clinic visits in the highest healthcare utilizers. The program is a time-limited, low-cost intervention, intended to provide relief of suffering; empowering patients while aiming to also lower costs for the system that cares for them. Chronic stress brings numerous symptomatic complaints and is also a driver of chronic disease and healthcare utilization. Stress reduction could thus lead to improved chronic care outcomes and decreased healthcare costs. The electronic health record can readily identify those patients that are the highest utilizers of the healthcare system. These patients may have the most to gain by learning the self-care strategies explored in MMSM programs. While this particular program was taught by a physician, it may be more cost-effective to have another member of the healthcare team lead the class. Experience in leading mindfulness groups can often be found in psychologists, social workers, and yoga teachers. A PA/NP could also combine their medical expertise with a different professional providing the mindfulness piece. Further consideration could be given to offering stress reduction techniques as a group medical visit.

A SUCCESSFUL INTER-PROFESSIONAL TRANSITIONAL CARE MANAGEMENT (TCM) IMPROVEMENT STRATEGY AT AN ACADEMIC PCMH Kathy Salter²; Beverly Barrineau²; Christine Wheeler²; Sherry Doniphan-Davies²; Sarah Ball²; Elisha L. Brownfield¹; Kimberly S. Davis². ¹MUSC, Charleston, SC; ²Medical University of South Carolina, Charleston, SC. (Tracking ID #2198778)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): To successfully deliver a high rate of TCM services, clinics need a relatively complex clinical and

support strategy including rapid follow-up contact by staff, increased clinic access for hospitalized patients, and coordination within the PCMH team including clinical staff, scheduling, clinic registration, pharmacists and physicians.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): Transitional Care Management (TCM) service is a new Medicare payment policy instituted in an effort to improve care coordination and reduce hospital re-admissions. TCM requires a systematic clinical and support strategy to maximize impact. TCM billing requirements include patient contact by a staff member from the practice within 2 business days of hospital discharge, and a primary care clinic visit within 7 or 14 days. If the patient is readmitted within 30 days, a TCM service will not be paid. The goal of the PCMH team was to maximize TCM service delivery to improve care coordination and reduce risk of hospitalization.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): University Internal Medicine (UIM) developed a multi-step process to implement and refine our TCM management strategy using a data-driven quality improvement strategy. After an automated electronic notification of the patient discharge (limited to University Hospital only), the nurse case manager (CM) uses a scripted telephone follow-up tool focused on assessing clinical stability, medication reconciliation, and scheduling an appropriate physician follow-up appointment within the time interval. If a patient is uncertain about the medication regimen, the CM can consult a pharmacist of physician for clarification. Once the phone contact has been completed, the CM generates a paper 'TCM notice' that is attached to patient intake packet at registration pending the day of the visit. This 'TCM notice' serves to remind the physician/provider that the patient visit is for a Transitional Care Management, the appropriate patient contact had been completed, the patient is eligible for TCM service and includes the visit codes for TCM billing. If the patient does not complete the first scheduled visit, the notice serves as a trigger for the CM to follow-up with the patient and to reschedule the patient with provider. Using rapid cycle improvement process, we tracked rates of completion of each step of the process in the TCM service and calculated the monthly completion rates of TCMs over time.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): With total monthly hospitalizations as the denominator, the PCMH team calculated monthly rates of successful patient contact by a CM within 2 business days of hospital discharge, contacts outside the 2 day window, completed clinic visits within 7 days, 8 to 14 days, and successful TCM coded and billed visits within 7 and 8–14 days. Data source for CM phone contacts was the electronic record (Epic) and for TCM service code was the practice billing data.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): UIM is a faculty and internal medicine practice serving a population of 12,000 patients with a mean age of 57 years (SD 16.6), 37 % male, 47 % African-American, and provides over 30,000 annual visits. The population averages about 200 hospital admissions per month at University Hospital. Over the 12 months of the study, the PCMH team increased the rate of nurse follow-up phone calls from approximately 50 to 75 % and the rate of completed TCM-coded visits from 18 to 25 %.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): TCM services require rapid follow-up contact by the PCMH team improved clinic access for hospitalized patients, as well as coordination between CM, scheduling, clinic registration, pharmacists and physicians. The most common reason for not completing the phone calls after discharge was CM staff availability and the most common reason for failure to complete TCM physician visits was patient nursing home or rehabilitation placement. In response to the high rate of post-hospital placement, CMs now set a 20 day reminder to re-contact patients and schedule TCM services at discharge from that facility. We are assessing impact on admission and readmission rates.

A TEAM APPROACH TO IMPROVE CONTROL OF HYPERTENSIVE PATIENTS IN A HOSPITAL BASED AMBULATORY CARE PRACTICE

Lisa Rucker¹, Eleanor Weinstein², Katalin Macs¹. ¹Albert Einstein College of Medicine/Jacobi Medical Center, Bronx, NY; ²Jacobi Medical Center, Bronx, NY. (Tracking ID #2184956)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Management of chronic diseases like hypertension require a team approach, outreach and adequate access to care.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. To utilize a team approach engaging all levels of staff to improve performance. 2. To utilize population management strategies and a chronic disease registry to track progress and trends and outreach to patients who need care. 3. To improve hypertension control to >60 %.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS):

HHC (Health and Hospitals Corporation), a large public hospital system and the safety net provider for NYC, developed a registry to track control of patients with hypertension. At Jacobi Medical Center, a teaching hospital in the Bronx, about 37 % of hypertensive patients were controlled in 2012. An HHC, team-based PI initiative set >60 % control of hypertension as the goal. Team members include primary providers, RNs, patient care associates, population managers, dietitians, pharmacists, call center staff, social workers, and practice administrators. The following are examples of interventions implemented as part of the program. 1. Housstaff a. Group Visits- A faculty physician, 2 residents, dietitian, pharmacist and nurse lead these ½ day sessions. Twelve patients with uncontrolled hypertension are scheduled. The didactic content is patient driven and each patient is also seen individually. b. Planned visits- Each resident has one session during his/her outpatient block to schedule two patients with uncontrolled hypertension for extended time to teach, counsel, and explore issues of non-adherence. These visits also include time with the RN or social worker depending on the barriers to control. c. Peer Review- Resident physicians participated in a chart review of patients with uncontrolled hypertension to assess for systems, process or provider issues as barriers to control. 2. Patient Care Associate (PCA) and RNs a. PCAs were re-educated on the proper technique for measuring BP and observed to assure competency. b. Treat-to-Target Program - RNs see uncontrolled, complex hypertensive patients referred by their providers. The RNs assess and counsel patients and adjust medications according to pre-written orders using motivational interviewing techniques. They also distribute sphygmomanometers for home monitoring. c. Team RNs see less complex uncontrolled hypertensive patients referred by their providers for a BP check after medication adjustment—generally within 2 weeks of the initial appointment. 3. Practice Administrators a HTN Task Force- An administrative group of team leaders meets weekly to discuss all aspects of the hypertensive challenge, following trends and tracking progress. b. Access- By the guidelines of the registry, patients who had not had a BP checked in the previous 6 months, were “uncontrolled.” About 1/3 of our registry had not been seen in > 6 months. Given our persisting issues with access, we created “HTN sessions” for all providers to create appointment availability for these patients. c. Call center -The call center contacts “uncontrolled” patients from the registry to schedule appointments. This is the first experience with targeted outreach for the practice. 4. Faculty Providers and NPs. a. Performance Feedback- Providers are given their registry data relative to other providers so they can track their own progress. b. Focus on hypertension—While precepting learners in the practice, the faculty reinforces tighter BP control and timely changes in therapy and f/u for the uncontrolled.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): We measured the number and percentage of patients whose hypertension was controlled.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED):

Of the 4080 hypertensives, we have achieved target BP according to HHC guidelines in 64.3 %. Were we to follow the less-stringent recent guidelines with BP target <150/90 in patients aged 60 or older, the yield would be even higher. Chronologically, the last two interventions we instituted—increasing the number of available appointments with primary providers and with the team nurses—had the biggest impact, raising the percent controlled from 42 to 64.3 %. (Figure 1 shows timeline of intervention and % effect). However, success comes at a cost. In a system that is chronically oversubscribed, the waits for appointments for non-hypertensive patients escalated.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?):

Key Lessons for Dissemination—The use of a patient registry is instrumental to track patients, chronic disease indicators and performance. Population management with targeted outreach is key to success when access to care is limited. Nurses play a vital role in collaboration as they educate, motivate and follow the patient to their goal BP. Chronic disease management strategies using planned visits, group visits and all members of the health care team (pharmacists, dietitians, PCA's) result in improvements in outcomes.

AN INTEGRATED TAI CHI INTERVENTION FOR FALL PREVENTION AND WELLNESS PROMOTION AMONG ELDERLY PATIENTS AT BOWDOIN STREET HEALTH CENTER

Hsiang-Wen Wang¹, Connie R. Shi², Gordon Keir³. ¹Harvard School of Public Health, Brookline, MA; ²Harvard Medical School, Boston, MA; ³Harvard Business School, Boston, MA. (Tracking ID #2194140)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Falls are a major source of morbidity and mortality among adults aged 65 and older; here we describe the design and implementation of a novel holistic fall prevention intervention incorporating regular Tai Chi exercise and fall risk education for a cohort of elderly patients at Bowdoin Street Health Center (BSHC).

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1) Falls Prevention: Reduce risk of falling among elderly patients at BSHC, measured by improved balance and mobility, reduced number of falls, reduction in participants' fear of falling. 2) Patient Education: Educate patients on fall risk factors via discussion sessions led by clinical staff and promote health literacy in a socioeconomically challenged patient population facing multiple co-morbidities. 3) Patient Engagement: Create a community focused around health education, motivating elderly patients to improve their health through regular group exercise.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Our intervention is a 6-month, multi-component program featuring 1) twice weekly Tai Chi instruction led by an experienced Tai Chi instructor, and 2) a longitudinal, comprehensive fall prevention curriculum led by BSHC clinical staff covering a variety of fall risk topics such as home safety, stretching and flexibility, and nutrition. The program provides an environment for health engagement for a population of elderly patients challenged by multiple chronic co-morbidities, isolation, social inequality, low health literacy, and lack of access to wellness resources. We collaborated with Bowdoin Street Health Center (BSHC), a community health center and NCQA Level 3 Patient Centered Medical Home located in Dorchester, MA. Seventeen percent of patients at BSHC (1253 individuals) are aged 65 and older. BSHC primary care providers referred their patients aged 65 and older to the program if the patients had a history of falls or multiple fall risk factors. Program participation was voluntary, with recruitment conducted by phone call and mailings. Transportation assistance for participants was provided as necessary. The program was implemented with support of the Harvard Medical School Center for Primary Agents of Change Challenge Grant.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Qualitative metrics collected include patient surveys assessing fear of falling, functional status (activities of daily living), and knowledge of fall risk. We conducted focus groups to elicit feedback about program structure, progress, and perceived effects / benefits. Quantitative metrics collected include two validated clinical assessments of fall risk. The Timed Up and Go test, which measures the time it takes to walk 20 ft, and the Tinetti Balance & Gait Assessment, which evaluates ability to safely perform a variety of tasks including walking, turning, and maintaining balance, were performed pre- and post-intervention. We will assess actual falls using chart reviews and participant self-report.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Nineteen patients have participated in the program, of whom 58 % (11) are female and 42 % (8) male. The participants' average age is 73 years. Average attendance per class is 12. The program is still in progress until late Jan 2015. Based upon initial and midpoint balance and gait assessments, we have found the following: Pre-Intervention (Aug. 2014), $n=12$ Avg. Timed Up and Go: 13.5 s (range 8.4–27 s) Avg. Tinetti Balance score: 11.8 (out of 14); Avg. Tinetti Gait score: 10.25 (out of 12). Program Midpoint (Nov. 2014), $n=10$ Avg. Timed Up and Go: 12.67 s (range 10.3–16.7 s) Avg. Tinetti Balance score: 13.3 (out of 14); Avg. Tinetti Gait score 11.7 (out of 12). A lower Timed Up and Go time indicates participants are able to more quickly complete a walk of 20 ft. Higher Tinetti Balance and Gait scores indicate participants are able to better complete a variety of balance and mobility tasks. These results suggest that even after only 3 months of twice weekly Tai Chi practice, program participants experienced objective improvements in mobility and gait. Participants reported improvements in back, shoulder, and knee pain. Other qualitative improvements in mobility and strength include no longer needing to use walking sticks and assistive devices, and greater ease in walking up and down stairs.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): By combining regular group exercise with comprehensive patient education led by clinical experts, this intervention has targeted the multifocal risk factors associated with falling. Participants report the importance of social group interaction and the positive benefits of working to reduce fall risk in a supportive community of peers and instructors. Consistently high attendance, positive participant feedback, and objective improvements in participant balance and mobility after only 3 months demonstrate that a robustly designed longitudinal and multi-component fall prevention intervention can successfully engage socioeconomically disadvantaged elderly patients in the community health center setting.

ATTRIBUTES OF AN OUTPATIENT GERIATRICS CONSULT SERVICE IN THE SAFETY NET Anna H. Chodos^{1, 4}, Janet Myers², Alain Takane⁵, Edgar Pierluissi⁶, Christine Ritchie³. ¹UCSF, San Francisco, CA; ²University of California, San Francisco, CA; ³University of California San Francisco, San Francisco, CA; ⁴Division of Gen Int Medicine, SFGH, San Francisco, CA; ⁵Univ of Hawaii, Honolulu, HI; ⁶UCSF, SFGH, San Francisco, CA. (Tracking ID #2199466)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): In safety net primary care, there are rarely adequate geriatrics specialists to address assessment and management needs for older adults with geriatrics issues.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): Implement a geriatrics consult service to: 1) Provide a spectrum of consultative services for older patients referred by primary care providers (PCPs) including electronic consults (e-consults), care coordination services and comprehensive evaluations in an in-person consultation clinic. 2) Perform a chart review to understand the service's patient population, consult activities, PCP satisfaction, and impact on patient's medication use.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The outpatient geriatrics consult service is delivered in an urban safety net health care system: San Francisco General Hospital's primary care clinics. The SFGH system uses a web-based platform, called eReferral, that interfaces with the electronic health record and allows primary care providers to submit referrals to specialty services. Through eReferral, specialists can then submit responses with clinical management suggestions or request further work-up and can schedule patients into their clinics. During the pilot phase, two geriatricians spent four hours per week reviewing consults submitted via eReferral and provided various levels of service based on the clinical scenario: an e-consult reply only, and e-consult reply and some care coordination (e.g. ordering physical therapy, discussing with patient's social worker and creating a care plan), or seeing the patient in-person for comprehensive geriatrics assessment in a monthly 4-h clinic. A pharmacist was available later in the pilot to staff the clinic. The pilot clinic served two large primary care clinics, an adult internal medicine clinic and a family practice clinic. Both clinics are training sites for residents.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): To understand how this service could be most effectively targeted and expanded, we performed chart review on the pilot period from October 2012 to November 2013 to characterize the patient population served and the nature of the service's consult activities. We recorded 1) patient characteristics, medical conditions, and changes in their medication use; and 2) consult triage outcomes (e-consult, etc.), questions submitted by PCPs and geriatricians' recommendations. We measured provider satisfaction with surveys. We compared pre and post-consult number of medications using paired t-tests.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Primary care providers consulted the service on a diverse patient population. Sixty-nine providers referred 101 patients, 5 were under 65 and excluded from the chart review. Of the remaining 96, the mean age was 78.5 years (± 6.9 , range 65–95); 63.5 % were women; 12 % were white, 13 % black, 44 % hispanic, and 31 % asian. The majority were foreign born (73 %), poor (84 %), and lived with family (58 %). The mean number of chronic conditions was 5.4 (± 2.2). Consult service activities were varied: 17 % received e-consult, 21 % received e-consult and care coordination activities, and 63 % received comprehensive assessment. Providers often submitted more than one question per consult, with a median of 3. The most common were: cognitive evaluation (64 %), medications (38 %), comprehensive evaluation (38 %), falls (31 %), and social service needs (26 %). Median number of recommendations was 10, which was the max recorded in our chart review (mean 7.2). The most common related to: medications (87 %), cognitive evaluation (80 %), falls (58 %), social service needs (56 %), and goals of care (55 %), which were all higher than the prevalence of these conditions in consult questions. Most users reported being satisfied: 94 % agreed or strongly agreed that the consult "addressed their concern to a satisfactory level". Six months post-consult mean number of medications decreased (9.5 to 8.8, $p=0.056$).

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): A Geriatrics Consult Service with a small geriatrics staff served safety net providers seeing complex, vulnerable older adults. Overall, 38 % of consults did not require an in-person consultation by a specialist to adequately address the PCPs question, suggesting there is potential for a small geriatrics staff to help many PCPs with clinical geriatrics questions. The consults detected unaddressed clinical geriatrics issues, particularly cognitive impairment and medications, suggesting there is an on-going need for geriatrics services. Further evaluation of its impact are needed and on-going monitoring of its activities will help inform its clinical utility as it expands to more primary care clinics.

BRIDGE-TO-CARE: IMPLEMENTING A QUALITY IMPROVEMENT INITIATIVE TO TRANSITION PATIENTS TO A PERMANENT PRIMARY CARE PROVIDER (PCP) THROUGH INTERPROFESSIONAL COLLABORATION IN THE CRIMSON CARE COLLABORATIVE-INTERNAL MEDICINE ASSOCIATES (CCC-IMA) CLINIC (2012–2015) Jolene M. Singh; Julia Pian; Xiaoli Mi; Barbara A. Quaraglia; Meaghan O. Cloutier; Thalia M. Krakower. Massachusetts General Hospital/Harvard Medical School, Boston, MA. (Tracking ID #2200904)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): The CCC-IMA practice started as a student-faculty collaborative clinic in 2010 with a dual aim—to provide top-notch care and to transition patients to a permanent PCP within 1 year of receiving services in our clinic, but an evaluation of the bridging rate at the end of 2011 showed that a significant proportion of patients were “lost-to-follow-up.”

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Assess the needs of the clinic and resolve cases lost-to-follow-up through convening a Bridge-to-Care (BTC) Task Force 2. Construct and implement an algorithm for bridging patients within 1 year of starting to receive services in the clinic 3. Promote higher rate of bridging within the 1 year term and lower rate of loss-to-follow-up by performing audits at regular intervals to monitor and improve the bridging process

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The CCC-IMA clinic is a student-faculty collaborative which serves two types of patients: those requiring urgent care in an evening clinic and those who do not have a PCP. The clinic also aims to bridge patients who have not established a PCP to a permanent PCP within one year. However, during the 2010–2011 period, there were many patients who had been “lost-to-follow-up” and whose bridging status was unknown. As a result, there was a need for a) follow-up in these cases (called “the olds”) and b) institution of a system to avoid losing track of current/future patients. The BTC Task Force included Resource Center (RC) volunteers, medical/nurse practitioner (NP) students, full-time clinic staff and the physician director of the clinic. The task force met approximately monthly to assess the needs of the clinic and to brainstorm mechanisms for following up with the patients whose status was unresolved after being seen in the clinic for more than one year, as well as, to construct an algorithm for bridging patients in the future. Call scripts and guidelines were devised for following up with “the olds” patients and a new algorithm was put in place for following up with current/new patients in the clinic. To bridge patients within one year, we found it beneficial to have RC volunteers explain the bridging program to patients at their first clinic visit. Medical/NP students, full-time clinic staff and physicians would work with the RC to ensure that all BTC patients interacted with RC volunteers and the option to bridge to Internal Medicine Associates (IMA) primary care residents was made available. Finally, an auditing procedure was implemented to ensure compliance and to provide regular follow-up phone calls and letters to patients who would likely be lost-to-follow-up due to missed appointments, etc. The audit tracking system reports can be cross-validated by electronic medical record (EMR) tracking because we place a Crimson Care Collaborative (CCC) logo/tag in the EMR of patients whose bridging status has not been resolved.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): The BTC Task Force introduced an algorithm and scripts for following up with “the olds” patients. As a result the bridging status of all patients seen between 2010 and 2011 was tracked through follow-up at clinic visits, by phone and/or by mail. Every current/new patient is tracked in two ways—(1) a CCC tag is attached to the EMR until the patient has successfully bridged to PCP or declines the bridging service and (2) the patients are tracked in a spreadsheet shared with clinic staff where bridging interactions are logged. Quantitative measurements such as time to bridging and bridging rates within 1 year of the first clinic visit are being recorded and monitored in the tracking system.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): The BTC Task Force constructed and implemented an algorithm for reaching patients whose bridging status had been unresolved for one year or more. As a result, the status of 2/3rds of “the olds” patients was resolved and the remaining 1/3rd were marked lost-to-follow-up after three phone calls and one letter were sent over the span of at least six weeks. An algorithm was implemented for placing patients with PCPs within one year and many current/new patients have been matched to PCPs within the one year timeline. Several patients elect to bridge to residents in the IMA clinic. Patients decline bridging due to out-of-state moves, nursing home placement, and lack of insurance coverage. Interprofessional teamwork helps provide coverage outside of evening clinic hours, improving patient tracking.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): The BTC Task Force was successful in its aim to resolve the status of “the olds” patients. In addition, its recommendations improved the clinic’s compliance with its goal of bridging patients to a permanent PCP within one year. Many patients have bridged to IMA residents. Regular audits, interprofessional teamwork, and increased communication between clinical and nonclinical professionals and volunteers about the bridging status of patients has improved the quality of our service, which can be quantified by decreased time to bridging, increased rate of bridging and decreased rate of loss-to-follow-up.

BRIDGING SILOS: SAN FRANCISCO GENERAL HOSPITAL’S CARE TRANSITIONS TASKFORCE Karishma Oza¹; Larissa Thomas¹; Elizabeth Davis^{1, 3}; Anna Robert^{2, 3}; Jeanette Cavano²; David Smith²; Jack Chase¹; Michelle Schneidermann¹. ¹University of California, San Francisco, San Francisco, CA; ²San Francisco Department of Public Health, San Francisco, CA; ³San Francisco Health Network, San Francisco, CA. (Tracking ID #2196065)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Complex medical and psycho-social conditions and limited resources create challenges in the transition from hospital to community for patients at San Francisco General Hospital (SFGH) and within the San Francisco Health Network (SFHN).

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): In 2012, the SFGH Care Transitions Taskforce was chartered to create a comprehensive, systems-based care transitions program that would provide patients with the proper care and tools they need to stay out of the hospital. The Taskforce grew through grassroots relationship-building into an organized, multidisciplinary working group comprising of inpatient and outpatient providers. Our collective goal is to reduce readmissions by 15 % and standardize and improve processes of care.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The SFHN has a commitment to serving San Francisco’s most vulnerable populations and encompasses a wide array of services across a continuum of care, including: primary care, specialty care, acute care, home care, long-term care, and emergency care. SFGH, the only public safety net hospital in San Francisco, plays an essential role as the primary acute care hospital in the system, providing 20 % of the city’s inpatient care. Its patient population is diverse and particularly at risk for readmission. On average, 8–10 % of admitted patients are marginally housed or homeless. Approximately 30 % of patients are uninsured, 40 % Medicaid and 20 % Medicare beneficiaries (FY 12–13). During this time period, the all-cause, 30-day readmission rate to SFGH was 13.5 %. Among higher risk patients such as those with heart failure, the readmission rate was 27 %. Since the Taskforce’s creation, we have successfully developed a multidisciplinary team including inpatient and outpatient physicians, nurses, pharmacists, social workers, utilization managers, and members of community-based organizations. The group meets biweekly to review data dashboards, discuss readmission cases, and present results of pilot projects to plan for dissemination. Some of the projects initiated through the Taskforce’s efforts include standardization of electronic discharge documents, creation of a data dashboard and network-wide discharge worklist, development of a process to improve linkage to post-discharge follow-up care, post-discharge pharmacist medication reconciliation visits, and enhancement of communication between inpatient and outpatient providers. Ongoing innovations promoted by Taskforce members include a hospital-based nursing program similar to Project RED (the Transitional Care Nursing program), a post-discharge follow-up clinic, and several new types of post-discharge visits in the medical home: health worker phone visits and clinic-based pharmacist and nurse visits.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): The Taskforce has increased the proportion of patients attending post-discharge follow-up appointments, reduced duplication of services, allowed for more effective communication between providers, and streamlined access to medical information. Our wide reach has allowed for more rapid expansion of pilot projects with stakeholder input.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): As a result of Taskforce initiatives, the proportion of patients attending a follow-up appointment within 7 days of discharge has increased from 34 to 42 %; the 30-day readmission rate among patients attending appointments is 5 %. Although we have not yet achieved our targeted reduction in overall 30-day readmission rate, among patients over 55 years old with CHF, COPD, MI or pneumonia seen by the Transitional Care Nursing program, the average 30-day readmission rate has fallen from 18 to 11 %.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): A multidisciplinary, cross-continuum working group is essential to successfully improving care transitions while avoiding duplication. The SFGH Care Transitions Taskforce has developed a model for strategically building a collaborative working group of key stakeholders that can innovate, disseminate care transitions improvements, and optimize efficiency and quality. The Taskforce’s strategy has led to targeted programs that have improved processes of care and reduced readmissions among a subset of high risk patients. Our challenges in achieving our target reduction in overall readmission rate speak to the complexity of the hospital-to-home transition and highlight opportunities to further target interventions that are tailored to each aspect of the transition.

BUPRENORPHINE GROUP MEDICAL VISITS: TEAM-BASED OPIOID ADDICTION TREATMENT IN PRIMARY CARE Aaron D. Fox^{1, 2}, Mariya Masyukova². ¹Montefiore Medical Center, Bronx, NY; ²Albert Einstein College of Medicine, Bronx, NY. (Tracking ID #2193235)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Opioid addiction is increasingly treated in primary care, but health system fragmentation has prevented collaboration between medical and behavioral specialists who treat addictions.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. To develop a team-based opioid addiction treatment intervention for primary care by applying the model of group medical visits to buprenorphine maintenance treatment (BMT). 2. To implement the intervention in a federally qualified health center (FQHC).

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Based on the model of group medical visits, we developed and implemented a multi-disciplinary intervention (group BMT) combining BMT, group counseling, and peer support. The setting was an academic health center-affiliated FQHC in a neighborhood deeply impacted by opioid addiction in the Bronx, NY. Before implementation, 10 general internists (PCPs) routinely provided BMT during primary care visits without collaboration with behavioral specialists. Development of group BMT involved literature review, observation of group medical visits for other conditions (e.g. diabetes), meeting with key stake holders, patient focus groups, design of materials, and formal request for administrative approval. The team included a general internist, clinical social worker, and a fourth year medical student who conducted group BMT, and a receptionist and nurse who registered and prepped patients before sessions. PCPs at the FQHC referred BMT patients with ongoing substance abuse. BMT prescribing was transferred to the twice monthly group BMT sessions, but patients continued to see their PCP for primary care. Group BMT included 30 min for registration, urine collection for drug testing, completion of self-assessment forms, and nursing assessment; and 90 min for open discussion and feedback, a facilitated harm reduction activity, psychoeducation, relaxation exercises, and BMT prescribing. The physician was available for 30 min following sessions to provide individual attention (e.g., BMT dose changes). Lunch and transit passes were provided as incentives. Clinicians met in between group sessions to discuss patient progress and plan activities.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): During development and preliminary evaluation, we assessed: 1) interest; 2) feasibility; and 3) patient satisfaction. The primary measure of success was patient attendance, which was used to confirm feasibility. We reviewed electronic health records and patient self-assessment forms to assess feasibility. Measures were sociodemographics, health insurance, co-morbidities, and attendance. During development, we conducted five focus groups with BMT patients to assess interest in combining BMT and group counseling. One focus group occurred after implementation and included participants of the group BMT pilot to assess patient satisfaction. Focus groups were audio-recorded, transcribed, and qualitative analysis used a grounded theory approach to elicit key themes. We will conduct an RCT in the future to assess effectiveness of group BMT at reducing substance abuse.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Between Feb and Aug 2014, the group BMT pilot included 13 sessions. Overall, 33 patients were referred by PCPs. Of these, 20 attended at least one session and 13 attended two or more sessions. Median attendance per session was 6 patients (range: 4–10) who attended a median of 3 sessions each. Participants were mostly middle-aged (median: 53), male (15/20), Hispanic (10/20) or non-Hispanic Black (10/20), publicly insured (20/20), and had at least one chronic medical (18/20) or mental health (16/20) comorbidity. Of the 33 participants in the 5 focus groups (range: 3–11 participants), most were middle aged (median: 50), male (28/33), and Hispanic (20/33). Key themes relating to interest included the desire for peer support to be part of BMT and concerns about confidentiality, time commitment, and loss of individualized physician time. Themes relating to patient satisfaction among the 3 participants who had also participated in the pilot were that group BMT delivered valuable lessons and imparted a sense of hope. A representative quote from a group BMT participant was, “every other Wednesday, I know I’m gonna be here, I’m gonna feel safe, I’m gonna learn something, and be around people I feel comfortable with.”

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): 1. There is interest in group medical visits for BMT. Our group BMT pilot was feasible and valued. 2. Patient concerns about confidentiality, time commitment, and loss of

individualized physician attention must be addressed. We start group BMT sessions by reviewing confidentiality rules; we only target patients who need increased treatment intensity; and we ask patients before each session whether they need to see the physician individually. 3. Our biggest challenge has been communicating treatment plans to PCPs and ensuring that patients with chronic health conditions also see their PCP for preventive care and chronic disease management. 4. Logistical challenges, such as clinical space, nursing support, and funding for incentives, required significant attention prior to implementation.

CARE PLUS: ADDRESSING MEDICAL AND PSYCHOSOCIAL NEEDS THROUGH TEAM BASED PRIMARY CARE AND CARE COORDINATION Melanie Martin; Kirsten Feiereisel; Nancy M. Denizard-Thompson. Wake Forest University School of Medicine, Winston-Salem, NC. (Tracking ID #2200209)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Psychosocial challenges are a driving force for readmissions and frequently cannot be adequately addressed in usual outpatient care settings.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Identify and characterize frequently readmitted patient population from urban safety net practices. 2. Implement *Care Plus*, a multidisciplinary care model to address patient engagement and improve satisfaction in this superutilizer population. 3. Significantly reduce admissions and emergency department (ED) utilization in this challenging population

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): *Care Plus* was launched in October 2013 to provide team based primary care and care coordination to frequently admitted adults and high emergency department utilizers from two safety net practices at a large academic medical center. A multidisciplinary team consisting of a lead physician, a nurse practitioner, a licensed clinical social worker with experience in mental health and substance abuse, a community health worker and an RN were assembled to develop and implement an individualized care plan for each patient addressing the unique medical and psychosocial needs of the patients. The team collaborates very closely with clinical pharmacists, a psychologist, a psychiatrist, pastoral care, palliative care and home health. Enrollment is blind to insurance status, however the practices traditionally serve high numbers of Medicaid, Medicare and dually eligible patients. At the time of patient enrollment, a comprehensive intake is conducted consisting of a survey of previous healthcare access, medication access, food and housing, educational background and habits to better identify individual challenges. Through steps of increased frequency of visits, home visits, addressing transportation and medication access challenges, and integrated behavioral health care, the goal of this program is to reduce admissions and ED utilization in this challenging population.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): *Care Plus* compares enrolled patients to their historical selves to determine the impact of the program on hospital and ED utilization. An initial goal was established as a reduction of admissions by 20 % and a reduction of ED utilization by 20 %. A greater understanding of the characteristics and psychosocial challenges of this population was desired to better understand the unique needs and most appropriately target resources and interventions.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Demographic data demonstrate a predominantly African-American population (73 %). The majority of patients have Medicaid (25 %), Medicare (40 %) or are dually eligible patients with both Medicaid and Medicare (21 %) with a smaller percentage being self pay (14 %). The participants have a high degree of psychosocial challenges, with preliminary data revealing 100 % unemployment, 90 % qualifying for food stamps and 31 % having not completed high school. In addition, 37 % report substance use (primarily alcohol or cocaine) and 65 % screen positive for depression (mild to severe) on PHQ-9. Preliminary data on the first 178 patients who had been enrolled for at least 6 months show that through this interdisciplinary team based approach that addresses both medical and psychosocial concerns, *Care Plus* has been able to decrease admissions in this patient population by 50 %, reduce 30 day readmissions by 40 % and reduce ED visits by 35 %.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): It is often psychosocial challenges such as food insecurity, low literacy, mental illness, substance use, lack of access to transportation and difficulty obtaining medication that drive readmissions. We provide a multidisciplinary care model that includes social work, integrated behavioral health and frequent patient touches that has successfully reduced readmissions and ED utilization in this challenging population.

CARING WISELY: A PROGRAM TO SUPPORT FRONTLINE PROVIDERS AND STAFF IN IMPROVING HEALTH CARE AND REDUCING COSTS Ralph Gonzales¹; Christopher Moriates¹; Alvin Rajkomar¹; Priya A. Prasad¹; Victoria Valencia¹; Christy K. Boscardin¹; Deborah Grady¹; J. Claiborne Johnston². ¹UCSF, San Francisco, CA; ²UT-Austin, Austin, TX. (Tracking ID #2199331)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Strategies that align frontline providers and staff with organizational leadership are needed to reduce health care costs and improve care within health care delivery systems.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. To identify “hot spot” areas of low-value care/waste that frontline providers, staff and trainees have under their direct control. 2. To implement intervention strategies developed through collaboration between frontline project teams, implementation scientists, and organizational leaders. 3. To achieve a positive return on investment for the health care organization.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The Caring Wisely™ program was conceived by the UCSF Center for Healthcare Value (CHV) in partnership with the UCSF Medical Center. The program consists of 3 stages: 1) The Ideas Contest (2–4 weeks)—a campus and medical center-wide open call to all staff, providers, faculty and trainees to bring forward their best ideas for identifying hot spots or problem areas that could be targeted with focused efforts to reduce inefficiencies and health care costs; and 2) The Request for Proposals stage (4–6 weeks)—related to the top ideas selected from the Ideas Contest; and 3) The Project Implementation stage (12 months)—project and implementation science teams meet regularly to develop and implement an intervention strategy with the first test of change within 3–6 months, and final evaluation of effect at 12 months. Each project has a maximum budget of \$50,000. Project support plus implementation science faculty and staff support amounted to about \$200,000 for these 2 projects. A key feature of the Caring Wisely program is the partnership between project teams, the Caring Wisely implementation team (consisting of a director, program manager, data analysts, and implementation scientists) and the Caring Wisely steering committee (comprised of executive health system leaders in quality, operations, finance and information technology). Each project team designed multidimensional interventions that addressed predisposing (such as knowledge, attitudes and social norms), enabling (such as audit or environmental barriers and facilitators) and reinforcing factors (such as rewards, audit/feedback and opinion leader endorsements) that were relevant to the primary behavior change target.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Primary outcomes: utilization of red blood cell transfusions per 100 discharges and proportion of total respiratory therapies due to nebulizers. Return on investment is based on direct material costs (and respiratory therapist labor costs for nebulizers) divided by the cost of the program (\$200,000) at year 1. Appropriate statistical procedures accounting for clustering by specialty, provider and patient, as well as interviews and surveys with project team members, will be completed in time for presentation at the annual meeting.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): There were 132 ideas, from which 20 complete project proposals were submitted in year 1. Submitters included doctors, nurses, pharmacists, administrators, and IT staff from a range of levels including residents, clinical fellows, assistant professors and full professors. During the Caring Wisely project period (July 2013–June 2014), average RBC transfusion rates per 100 hospital discharges per quarter declined 10.0 %. Using the first 2 quarters as a baseline period, there were an estimated 790 transfusions saved over the subsequent 6 months attributable to the Caring Wisely program. There was a general increase in transfusion rates among non-intervention units during the same time period. Median hemoglobin levels prior to transfusion during the project period were 7.5–7.8 mg/dl across both groups, and did not vary significantly over time. In the year prior to Caring Wisely, the nebulizer project team had completed a version of their intervention with the hospital medicine service. This resulted in a significant decline in the proportion of treatments due to nebulizers from 0.9 to about 0.7 among target services, and maintained during the Caring Wisely period. Among non-targeted services, the nebulizer proportion showed a small decline to 0.85. Based on the observed (0.69)-to-expected (0.85) nebulizer utilization during the Caring Wisely period, one estimates approximately 3988 nebulizer treatments saved. Based on an average cost per unit RBC of \$260, and the average cost per nebulizer treatment (labor+materials) of \$66.19, the estimated ROI in year 1 was 2.34.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Applying implementation science principles to the intervention design strategies was a key factor in the success of Caring Wisely. These principles included stakeholder engagement, tailoring and adaptation of the intervention to the target audience, and rapid-cycle process

measurement and feedback. In each project, the PRECEDE-PROCEED was used to insure that each intervention design included complementary elements of effective behavior change—intended to increase awareness and motivation to change, to make change “easy”, and to reward/reinforce change.

CHOOSING WISELY IN PRIMARY CARE: RE-DESIGNING DARTMOUTH-HITCHCOCK’S GENERAL INTERNAL MEDICINE (GIM) PREOPERATIVE EVALUATION PROCESS TO DECREASE UN-NECESSARY TESTING AND IMPROVE EFFICIENCY John Matulis. Dartmouth-Hitchcock Medical Center, Lebanon, NH. (Tracking ID #2198203)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Routine preoperative testing persists as a wide-spread practice despite strong evidence suggesting this service provides little value to patients.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): Specific Aim # 1: Reduce the rate of unnecessary preoperative testing, defined by published guidelines, in patients undergoing preoperative assessment for all low risk surgeries in the Dartmouth-Hitchcock GIM clinic from 36 to 10 % by June 2015. Specific Aim # 2: Decrease the average, scheduled appointment time for preoperative visits from 47 to 30 min by June, 2015.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Dartmouth-Hitchcock Medical Center, an academic tertiary care center in rural New England, operates a GIM clinic staffed by 16 internists, 7 associate providers (physician assistants and nurse practitioners) and 39 internal medicine residents providing primary care for approximately 20,000 patients. Annually, the clinic performs around 850 preoperative evaluations. All of these visits are completed in anticipation of low or intermediate risk surgeries. Prior to this intervention, there was no standardized approach in scheduling or performing these evaluations. **Description:** A multi-disciplinary improvement team was created in May of 2014. PDSA cycles consisted of creation of a dedicated associate provider run preoperative clinic, operationalizing a scheduling scheme, educational interventions, and employment of electronic medical record tools to facilitate reliable completion of these visits. At the time of submission about 25 preoperative visits per month, or 33 % of preoperative visits are being seen in the preoperative clinic. Process changes were informed by a clinical microsystems approach and tools such as cause and effect diagrams, process mapping, and qualitative methods were used to inform the interventions. Statistical Process Control (SPC) methods were employed in data collection and analysis.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Outcome Measure: Percentage of patients receiving unnecessary diagnostic testing. Patients who received at least one unnecessary preoperative test were counted in the numerator. Total number of patients undergoing preoperative evaluation composed the denominator. An unnecessary test is one that is ordered and associated with the visit and is not in concordance with the 2014 ACC/AHA perioperative guidelines for evaluation of non cardiac surgery. Data Source: manual chart extraction Outcome Measure: Number of unnecessary tests ordered. Patients who received unnecessary EKG, CBC, or metabolic testing were counted using the above mentioned guidelines. Data source: manual chart extraction Process Measure: Average scheduled visit time for preoperative visits. The numerator was the total number of minutes of scheduled clinic time dedicated to preoperative visits while the denominator was the total number of preoperative visits performed. Data Source: Electronic Medical Record Query

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Compared to the baseline rates of 36 % of preoperative patients receiving unnecessary testing in the GIM clinic, the newly designed Associate provider preoperative clinic showed rates of 5 % within 3 months of implementation. This difference in rate of unnecessary testing was statistically significant by accepted rules of SPC. Numbers of EKGs, CBC and metabolic blood tests ordered similarly showed statistically significant decreases while numbers of imaging and other cardiac tests showed non-statistically significant decreases. Overall, the time of scheduled visit showed a significant decrease from 48 to 40 min.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): A dedicated clinic directed towards providing a particular subset of primary care can improve reliability, guideline concordance, efficiency and patient access. These clinics may also function as a powerful tool in minimizing provision of low-value services. In our academic, GIM practice a preoperative clinic was effectively staffed with associate providers. Tools in the electronic medical record, particularly template directed documentation and patient completed questionnaires can be powerful tools in directing clinicians towards guideline focused care while simultaneously improving efficiency. Identifying

appropriate patients for inclusion in these clinics while optimizing primary care provider collaboration are important challenges moving forward. Our preoperative clinic showed promising gains in reducing rates of unnecessary testing while simultaneously improving efficiency. It is our hope that with continued use of established quality improvement methods and collaboration with surgical and anesthesia services this clinic can be expanded to include a larger percentage of preoperative appointments across all primary care service lines.

COLLABORATIVE APPROACH TO OBESITY COUNSELING IN PRIMARY CARE: JUMPSTART TO WELLNESS Melissa M. Page; Jillian Regan; Laura K. Snyderman; Caitlin Toomey; Deborah Blazey-Martin. Tufts Medical Center, Boston, MA. (Tracking ID #2198362)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Primary care doctors are in an opportune position to identify obese patients; however, time constraints and lack of experience in weight management make it difficult to treat obesity in the primary care setting. How can primary care physicians collaborate with other specialties to solve this problem?

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. To identify barriers to effective weight loss counseling in the primary care setting and to referrals for weight loss. 2. To create a collaborative pilot program that makes it easier for primary care providers to refer morbidly obese patients with a BMI of 40–45 to weight loss counseling, and to assess the efficacy of this program.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): General Medical Associates (GMA) at Tufts Medical Center is a large academic, outpatient primary care practice with 34,000 patients, 30 attendings, 6 nurse practitioners and 72 residents. The Tufts Weight and Wellness Center (WWC) provides nutrition counseling, meal replacement programs, behavioral health counseling, pharmacologic treatment and bariatric surgery. Our collaborative pilot served GMA patients seen 2/14-9/30/14 with BMI 40–45. The Jumpstart to Wellness (JSW) Program was created to provide referral-based weight loss counseling to primary care patients and overcome physician-identified barriers to such referrals. Physicians identified concerns over lack of time, prematurely sending patients for bariatric surgery, prohibitive copayments, lack of clarity about appropriate referrals, and a desire to make referrals in a sensitive, patient-centered manner. JSW was developed with two primary components: an easy referral mechanism during a primary care office visit and a dietitian-initiated weight loss program. During a primary care visit, medical assistants identify patients with a BMI of 40–45 and alert the PCP by leaving a JSW brochure on the exam room door. The provider can then initiate a conversation about weight management and refer the patient to JSW if deemed appropriate. Patients referred to JSW receive three dietitian visits designed toward understanding the patients' needs and challenges, providing education, initiating food and exercise logs, and reviewing barriers and progress. The dietitian and patient then identify together which program track is most appropriate: medical weight loss, meal replacement, or bariatric surgery. The dietitian communicates the decision to the PCP and facilitates transition to the appropriate program.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Program effectiveness will be evaluated by tracking weight loss, patient attendance, length of time between visits (days), ending weight, BMI, and weight loss track chosen.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): During the pilot period, 624 patients with a BMI 40–45 were seen in GMA, 246 (39.4 %) were referred to JSW, and 139 (56.5 %) attended at least one visit. Of these patients, 39 (28 %) continued on a WWC weight loss track: 79 % of patients chose medical weight loss or meal replacement and 21 % chose a bariatric surgery path. Of the patients who attended all three visits ($n=37$, 26.6 %), the average weight loss was 3.98 lbs over an average period of 64 days (range of +6.4 to -30.4 lbs, median of 3.6 lbs).

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Jumpstart to Wellness is an effective way for primary care physicians to refer obese patients to appropriate and effective weight loss counseling. While participants successfully achieved weight loss, weight loss remains a sensitive issue and a large percentage of patients referred did not complete the program. Further investigation revealed that those who did complete the program were more medically complex, as evidenced by higher BMI, older age, more office visits to their PCP and specialists, and more co-morbidities. We will determine if these differences are statistically significant once we have a larger patient population. We will use this information to target patients in our primary care practice who may benefit the most from the Jumpstart program and to better understand barriers to completion.

COMPLETE CARE MODEL FOR DIABETES CARE WITHIN A PATIENT CENTERED MEDICAL HOME—PRE-VISIT PLANNING, AT-VISIT EFFICIENCY AND INTER-VISIT CARE Jaishree Hariharan²; Natasha Parekh²; Jacqueline Mihm²; John Donehoo²; Cynthia Murphy²; Deborah Simak²; Gary Fischer¹. ¹University of Pittsburgh, Pittsburgh, PA; ²University of Pittsburgh Medical Center, Pittsburgh, PA. (Tracking ID #2197838)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Diabetes care is challenging and despite multiple interventions to aid physicians in caring for patients, and the presence of a diabetes educator, the clinic persistently had 15 % of diabetics with A1C \geq 9.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. To redesign diabetes care to be patient-centered, proactive and team-based, engaging patients throughout the continuum of care with an emphasis on managing poorly controlled diabetics (A1C \geq 9) 2. Increase appointment show rate, maximize visit efficiency and intensify inter-visit care using standardized protocols and medication titration. 3. Incrementally improve all diabetes outcomes, especially mean A1C in this cohort.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): University of Pittsburgh Physicians- General Internal Medicine (UPP-GIM) is a large urban academic primary care practice with approximately 1523 diabetes patients. These patients are cared for by 34 faculty and 52 residents who are grouped into four firms in a PCMH. In January 2014, a need for diabetes redesign was recognized as 15 % of patients had A1C \geq 9. A multi-disciplinary diabetes team was created to redesign diabetes care. The team met regularly, reviewed best practices, current literature, created protocols, standardized documentation, obtained software for glucometer downloads and established a care model to be implemented in phases. Phase 1 (March 2014) involved pre-visit planning. All patients with A1C \geq 9 scheduled for a PCP visit the following week were identified from the provider schedules. They received an outreach phone call from their firm nurse reminding them of their appointment, encouraging home glucose and blood-pressure monitoring, and requesting that they bring their logbook /glucometer to their appointment. Medication and transportation needs were assessed and appropriate referrals were placed based on patient needs. Phase 2 (June 2014) involved improving at-visit efficiency. MD huddles with MA to review schedule for any patient needs at start of clinic. The medical assistants (MA) prepares patients by having their glucometer downloaded, feet exposed and point of care A1C performed if due prior to exam. MD creates the care plan and refers to diabetic educator/pharmacist /nurse as needed for inter-visit care. Phase 3 (July 2014) involved inter-visit care by diabetic educators to coach, troubleshoot and manage patients using a medication-titration protocol. Phase 4 (Jan 2015) involves detecting and addressing mental health challenges in diabetes. Future goal is to include patients with A1C $>$ 8.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Process measures include percentage of patients reached by phone for pre-visit planning; improvement in appointment show rate for patients with A1C \geq 9, increase in glucometer downloads at-visit and percentage of patients following up with diabetic educators. Outcome measure is improvement in mean A1C and A1C \geq 9 rates in a year.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): In January 2014, the clinic had 1523 unique diabetic patients of whom 229 (15 %) had an (A1C \geq 9) which formed our cohort. Our cohort had a higher percentage of African-Americans compared to all diabetics (50 %, vs 38 %) and 59 % of them were between (40–64) years old. Through September 2014, on average, 75 % of scheduled patients were reached by our nurses for pre-visit planning. The appointment show rate improved from 70 to 76 % for this cohort. Glucometer downloads averaged 28 per month. When comparing encounter rate for our cohort with usual care, we found 4.0 office visits per cohort patient (vs 3.3) and 9.8 telephone encounters per cohort patient (vs 6.4). Increase in encounter intensity was provided primarily from non-MD members of the team. In addition, 54 % of cohort patients encountered the Diabetes Educator (vs 20 %). There is suggestion in the literature that increasing intensity of encounters and team care will improve compliance. Mean A1C reduced from 10.8 to 9.7 over the last 6 months. More outcome data is expected by March 2014.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Diabetes care requires a coordinated proactive multi-disciplinary team-effort at different points within the healthcare system and continued effort to engage patients and improve outcomes. Targeted interventions can be implemented in phases and integrated into clinic workflow. Sustaining improvements remains a challenge.

COPILOTS: A COLLABORATIVE PAIN INTERVENTION FOR LONG-TERM OPIOID TREATMENT SAFETY Serena L. Roth¹; Sarah Ricketts²; Naum Shaparin²; Charleen Jacobs¹; Darlene Desantis²; Laila Khalid¹; Lorlette Haughton²; Joanna L. Starrels¹. ¹Albert Einstein College of Medicine & Montefiore Medical Center, Bronx, NY; ²Montefiore Medical Center, Bronx, NY. (Tracking ID #2194876)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Patients with chronic pain frequently have comorbid mental health and substance abuse problems leading to poor pain outcomes and greater risk for opioid analgesic misuse, yet primary care providers may lack the time and training to optimally manage these complex issues; a collaborative care model can integrate pain care management and behavioral health into primary care settings.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): The objectives of this project are: 1) to develop and pilot a collaborative care model for chronic pain management in primary care; and 2) to determine whether the collaborative care model is associated with: improved screening for mental health and substance use problems, improved use of safer opioid prescribing practices (written controlled substance agreement, drug testing), and improved patient pain, functional, and substance use outcomes.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): This program is being implemented in the Montefiore Family Care Center's Internal Medicine Practice, a teaching clinic in Bronx, NY serving predominantly low-income and racial/ethnic minority patients. Eligible patients are adults prescribed long-term opioids (≥ 3 prescriptions in prior 6 months) for a chronic pain condition, who have suboptimally controlled pain and/or psychosocial challenges, and completed ≥ 2 visits with their PCP in the past year. Exclusion criteria are prescription of long-term opioids solely for treatment of opioid use disorder (addiction) or prescription of long-term opioids by an outside provider. The Collaborative Pain Intervention for Long-term Opioid Treatment Safety (CoPILOTS) engages a multidisciplinary team to improve patients' pain, function, and behavioral health. The CoPILOTS team includes a pain care manager (nurse practitioner), behavioral health manager (psychologist), two primary care champions (PCPs), a psychiatrist and a pain specialist. Key program components include: 1) monthly assessments with the pain care manager focusing on pain, opioid use, and screening for mental health and substance use problems; 2) team-based recommendations to the PCP; 3) a 6-week patient self-management program; 4) evaluation and treatment with the behavioral health manager if indicated; and 5) care management including facilitated referrals for specialty services. After being referred to CoPILOTS by the PCP, each patient is invited for a comprehensive intake visit with the pain care manager. Patients are referred to the behavioral health manager for evaluation if they screen positive during the intake or subsequent visit for depression (PHQ-9), anxiety (GAD-7), trauma, or substance misuse (AUDIT-C, COMM, and NIDA quick screen).

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): We are using EMR data, interrupted time series analysis and non-FCC controls, to determine whether CoPILOTS is associated with: 1) improved screening for mental health and substance use problems among patients prescribed opioids for chronic pain; 2) improved use of safer opioid prescribing practices; and 3) improved patient pain, functional, and substance use outcomes. Feasibility outcomes will include patient and provider acceptability and satisfaction.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): In the first 3 months, 36 patients were referred to the CoPILOTS program; referring PCPs cited suboptimal pain control in all 36, and psychosocial issues in 35 patients. Of the 36 referred, 26 (72 %) completed the initial intake evaluation; 65 % were female. Of the 10 who did not complete an intake, 8 were not interested, 1 was ineligible, and 1 was unable to complete the intake due to distress. Among the 26 who completed intakes, 21 (72 %) had a positive mental health or substance use screens; of these, 12 (57 %) completed a behavioral health evaluation within 30 days. Patients had a high severity of pain, poor physical and general function, significant pain catastrophizing, and high rates of psychological symptoms and exposure to trauma.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): After only 3 months of the intervention, we have identified many patients with significant mental health and substance use problems of which PCPs were not fully aware. Many patients on chronic opioid therapy considered themselves too physically or psychologically disabled to participate fully in the self-management program. Patients reported severe pain with significant impact on their physical and psychological wellbeing. Collaborative care for chronic pain management has potential to improve care for complex patients with chronic pain and behavioral health problems. Linking patients to behavioral health care is particularly important. Self-management programs may be more successful

with patients who are less severely disabled. We will continue to revise and examine the CoPILOTS program, and if successful, it may be a model for care delivery in other primary care settings.

CREATION AND EVALUATION OF A PROCESS FOR FALLS RISK ASSESSMENT AND INTERVENTION IN AN ACADEMIC GENERAL INTERNAL MEDICINE CLINIC Kathryn A. Brennan³; Emily K. Sturkie³; Brooke B. McGuirt²; Shana Ratner¹. ¹UNC Chapel Hill, Chapel Hill, NC; ²UNC Internal Medicine, Chapel Hill, NC; ³University of North Carolina, Chapel Hill, NC. (Tracking ID #2193611)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Falls in the elderly population are associated with significant morbidity and mortality, and patients at risk for falling often go undetected in the outpatient setting.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1) To create a standardized and streamlined approach for detecting patients who are at risk for falling. 2) To implement evidence-based interventions to reduce injury and fracture risk for patients at risk of falling.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Falls in the elderly population occur frequently and remain a public health problem in the outpatient setting. The Centers for Disease Control and Prevention (CDC) estimate that one out of every three patients over the age of 65 have fallen in the past year but less than half of these patients discuss this with their healthcare professional. The University of North Carolina Internal Medicine Clinic (IMC) is a general academic clinic with a patient population of approximately 14,000 patients, 31 % of whom are over the age of 65. Prior to our intervention, the clinic had no standardized method of assessing a patient's risk of falling. We utilized multiple Plan, Do, Study, Act (PDSA) cycles to develop a fall risk screening process that could be integrated into a busy outpatient clinic setting. We developed a protocol consisting of a single nurse administered screening question during the patient rooming process: "Have you had any falls in the past year?" If a patient screened positive based on this initial question, the nurse would be prompted to offer the provider a clinical decision support tool. The clinical decision support tool is a bright orange double sided paper form that is intended to both notify the provider that this patient may be at risk for falling and also prompt the provider to consider specific evidence-based interventions such as physical therapy referral, Fracture Risk Assessment Tool (FRAX) calculation to assess for need for bisphosphonate, vitamin D supplementation and medication review. We initially began by working with two nurses who were familiar with the clinic workflow. They were taught the steps to the screening process and how to document patient's fall risk in the electronic medical record system. Physicians working with these nurses were contacted and informed about the screening process. After this initial trial, participating nurses and physicians were interviewed and charts were reviewed to evaluate the process. We then performed a second and third trial with the addition of more nurses and providers. Each trial incorporated feedback and lessons learned in the previous trials. By the end of the third trial, we had six nurses participating with a plan to transition to clinic-wide screening.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Our primary outcome was the number of patients age ≥ 65 years old who were screened for fall risk. Secondary outcomes included the percentage of patients who screened positive and the number and type of provider interventions delivered.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): A total of 76 patients age ≥ 65 years old were screened during a pilot of about 3 weeks. The majority of patients were screened in the final week (46 patients). Twenty-nine patients (38.2 %) screened positive to falling in the last year. Of these 29 patients that screened positive, 16 patients had at least one documented evidence-based intervention (range 1 to 3 interventions, mean 1.8 interventions). Documented interventions included vitamin D supplementation (9 patients), physical therapy referral (6 patients), medication review with an aim to reduce delirigenic medications (6 patients), FRAX Calculation +/- DEXA scan (5 patients), community exercise program referral (2 patients). Feedback was obtained from both nursing staff and physicians. Nurses overall were satisfied with the simplicity of the one-question screening tool. Provider decision support forms were placed in patient rooms based on nurse feedback to ensure all nurses had easy access to these documents. Physicians were satisfied with the bright color of the form, which served as an effective reminder. Physicians suggested other interventions to be incorporated into the decision tool. Based on these suggestions, we added information regarding county-specific community-based exercise programs to the form. Physicians

also suggested that we build automated best practice advisories within the electronic health record (EHR).

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Using a single question screening protocol to assess whether patients age ≥ 65 years old have fallen in the past year is a simple way to incorporate fall risk screening into busy clinic workflow. The addition of a clinical decision support tool in this setting can promote the use of evidence-based interventions to prevent falls and fractures. Using multiple small tests of change, we were able to modify and improve the process over the course of three weeks. Future efforts will be geared towards integration in the EHR and resident curriculum development.

DEVELOPMENT OF A PATIENT EMPOWERMENT PROGRAM (PEP) BASED ON STANDARDIZED PATIENT (SP) METHODOLOGY Lisa Altschuler; Joseph Plaksin; Sarita Kundrod; Sondra Zabar; Adina Kalet. NYU School of Medicine, New York, NY. (Tracking ID #2184475)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Can Standardized Patient (SP) training methodology be adapted into a Patient Empowerment Program (PEP) that activates underserved minority, low literacy “real” diabetic patients in the medical encounter?

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): To determine: 1. If PEP increases patient activation, preferences for medical decision-making, and diabetes self-management behaviors in diabetic patients. 2. The acceptability, feasibility, and replicability of implementing PEP across three urban hospital centers serving underserved populations in NYC. 3. If PEP leads to a measurable difference in hemoglobin A1c.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): We recruited patients with type 2 diabetes (DM) to participate in PEP, a 4-hour, two-session workshop run by a Health Psychologist (L.A.) with extensive experience in HCP education. In the first session, participants discuss shared decision-making (SDM) in the medical encounter, view trigger videos of patient-HCP interactions, and rate both parties using a behaviorally anchored SDM checklist. In the second session, participants role-play several scenarios with Standardized Healthcare Providers (SHPs). After each scenario, participants rate the performances and practice giving feedback to each other and the SHPs. Following the standardized role-play scenarios, participants apply what they have learned in a role-play scenario with a SHP, created specifically for each participant based on self-reported difficulties with DM. Finally, participants debrief as a group with SHPs and research personnel to create a SMART goal based action plan targeted to improve SDM in future medical encounters and DM self-care.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): We survey patients to assess for change in activation, preferences for control in medical decision-making, and self-reported DM self-management behaviors at baseline, immediately after the intervention, and 3 months after the intervention. Hemoglobin A1c is obtained by chart review at baseline and after 3 months. Program evaluation includes participants’ opinions on the acceptability and feasibility of PEP as well as which specific parts of the intervention they felt were most beneficial.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): To ensure the curriculum and materials were patient-centered and appropriate, we held focus groups with DM patients to elicit their experiences and opinions. Overwhelmingly, participants stated that they would volunteer to be a part of PEP and believed they would learn a lot from the experience. A pilot of the PEP intervention was then held with six of these patients. They were able to complete the role-playing scenarios and give appropriate feedback to their peers and the SHPs. Participants reported that the intervention gave them specific tools to interact with their HCPs and get the most out of their appointments, including being honest about health beliefs and behaviors, speaking up about preferences, asking HCPs to slow down and explain more clearly, and voicing difficulties with the intent to come up with a plan together. Participants reported that the completion of the action plan made them feel much more prepared for their next medical encounter, supported by the other members of the group, and motivated to follow through on their specific goals. Based on their feedback, we revised the scripts and re-filmed the patient-HCP trigger videos, amended the standardized role-playing scenarios to be more clear and realistic to patient experiences, and created additional individualized role-play scenarios. Currently, participants are being recruited from clinic to participate in further pilot testing of the PEP intervention. Our goal is to recruit 120 participants across three sites in order to have 40 participants complete the intervention over the next year.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Using SP training methodology to create PEP is feasible, acceptable, and enjoyable to volunteer patients with DM from an underserved, minority, and low literacy population at a large urban safety-net hospital center. Active patient participation in the design of the program maximizes relevancy and engagement and allows fine tuning for cultural differences and low literacy. Practical barriers to implementation across all three sites include limited institutional and patient resources. We found that providing support for transportation to and from the sessions for patients is key. Identifying appropriate space—including a conference room in the clinic at each site and a simulation center which enables role-plays in authentic environments and videotaping for later review—are difficult. Guided by the outcome data we will refine PEP so that it can be delivered with maximum impact in pragmatic ways including creating flexible, technology supported blended versions (e.g. session one as an interactive webinar) and convenient times and locations (e.g. immediately following DM group visits).

E PLURIBUS UNUM: INTERDISCIPLINARY BEDSIDE MORNING ROUNDS ON THE GENERAL MEDICINE WARDS Michael F. Krug¹; Andrew A. White²; Naomi L. Maxey²; Christy McKinney². ¹The University of Washington, Seattle, WA; ²University of Washington, Seattle, WA. (Tracking ID #2194941)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Insufficient coordination between doctors and nurses on our inpatient medicine floors has, at times, resulted in inferior patient care and frustration among patients and providers.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1) Optimize communication between physicians, nurses, and pharmacists 2) Make patient care more proactive and efficient 3) Promote a culture of teamwork and safety

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The inpatient medicine service at our urban academic medical center is a major teaching site that is primarily staffed by resident-led teams. Historically, physician teams rounded in the mornings independently of pharmacists or nurses, and interprofessional communication was ad hoc. We implemented a pilot whereby bedside morning rounds would be coordinated to include the physician team, the nurse for the day, and a pharmacy representative. During the pilot, two of the four physician teams coordinated rounds in this fashion (intervention group), and the other two teams did not (control group). Nurses cared for patients in both groups. Pharmacy presence was expectation during morning rounds in both the intervention and control groups. Rounds were coordinated via a posted rounding schedule filled out by the physician teams and “heads up” phone calls from the physician team to the nurses. Rounds were expected to last 15 min per patient or less in the intervention group. Bedside communication was not structured, but open exchange of concerns was encouraged.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): We conducted an anonymous survey of physicians and floor nurses after they had worked extensively during the pilot. The survey assessed teamwork attitudes using questions from the validated Safety Attitudes Questionnaire (SAQ) and solicited perspectives on morning rounding. Most survey questions used a 5-item Likert scale ranging from “strongly agree” to “strongly disagree.” Because too few participants reported negatively, we combined “strongly disagree,” “slightly disagree,” and “neutral” into one category. We compared the responses of the intervention group physicians to the control group physicians, and we also compared the responses of the doctors to the responses of the nurses. Using electronic paging data, we evaluated whether there was a difference in number of pages to physicians in the intervention versus the control groups. We used t-tests and chi-square analysis to compare survey responses and paging data.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): We collected survey data from 79 physicians (34 attendings, 45 interns/residents) and 22 nurses. Based on Likert scale responses, 76 % of physicians and 87 % of nurses strongly preferred coordinated morning rounds. There was no statistically significant difference in teamwork attitudes between the intervention and control physicians (all p-values > 0.05), although the results seem to suggest a trend toward more favorable teamwork attitudes in the intervention group. There was no significant difference in morning report attendance, time for teaching during rounds, or time for management discussion during rounds between intervention and control physicians (all p-values > 0.05). Nurses were less likely than physicians to feel that they were working as a well-coordinated team together ($p = .05$). Physicians were more likely to know the first name of the nurses they worked with than vice-versa ($p = .04$). The number of pages sent to physicians was statistically different between intervention and control groups, though this difference is unlikely to be clinically meaningful (28.1 pages/team/day in the intervention group vs. 28.7/team/day in the control group) ($p < 0.0001$).

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?):

Implementing interdisciplinary bedside morning rounding was achievable on the general medicine ward of a major academic medical center and was strongly preferred by doctors and nurses. This intervention did not statistically improve teamwork attitudes or dramatically reduce the frequency of pages during the initial 6-month pilot, however we are optimistic that tangible benefits will be seen as we optimize our rounding system moving forward. Interdisciplinary rounding did not negatively influence time for teaching during rounds, time for management discussion during rounds, or resident morning report attendance.

EARLY HOSPITALIST SCREENING AND ANTIBIOTIC RECOMMENDATION INTEGRATED WITH ANTIBIOTIC STEWARDSHIP PROGRAM

Andrea Porrovecchio²; Priya Nori²; William Southern¹. ¹Montefiore, Bronx, NY; ²Montefiore Medical Center, Bronx, NY. (Tracking ID #2191694)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): To ensure appropriate antibiotic choice, dose and duration our antibiotic stewardship team (ABS) makes recommendations 72 h after admission, however, earlier screening and intervention by a hospitalist might lead to more appropriate antibiotic regimens and improved patient outcomes.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1) Develop a process in which a hospitalist can, on hospital day one, screen, make recommendations, and refer cases to the antibiotic stewardship team. 2) Develop a standardized tool for hospitalists to use to screen and make early antibiotic recommendations for admitted patients with pneumonia, urinary tract infection, and skin/soft tissue infections.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): In a community hospital associated with a large urban academic medical center, the Directors of Hospital Medicine and the Antibiotic Stewardship Program collaborated to create the Early Hospitalist Screening and Antibiotic Recommendation program. Before the intervention the antibiotic stewardship team would screen and make antibiotic recommendations 72 h after admission. The intervention consisted of trained hospitalists acting as extensions of the antibiotic stewardship team to intervene on patients with pneumonia, urinary tract infection, and skin/soft tissue infection, on hospital day one. The multifaceted intervention included: 1. **Hospitalist screening:** A hospitalist representative was present at interdisciplinary team rounds each morning. New admissions for the diagnosis of PNA, UTI, and SSTI were flagged and subsequently screened by the hospitalist using a standardized tool. Comorbid illness, risk for nosocomial infection, appropriateness of diagnosis, appropriateness of initial antibiotic choice and dose were considered. 2. **Hospitalist recommendations:** Based on the screen and using a standardized algorithm for empiric antibiotic regimens tailored to local epidemiology, the hospitalist contacted the primary team and made recommendations for change of antibiotics choice, dose regimen, or work up if appropriate. 3. **Early Referral to ABS:** If Infectious Disease consultation had already been made, if the primary team disagreed with hospitalist recommendations, or if the case was judged by the hospitalist to warrant early ABS involvement, these cases were immediately referred to the ABS for recommendations on hospital day one. All cases screened were referred to the ABS so that they could follow up as per routine on hospital day three. To standardize the intervention and to aid the hospitalists with screening and recommendations a standardized screening tool was developed collaboratively by the Directors of Hospital Medicine and the Antibiotic Stewardship team.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): We measured the number of patients reviewed, the proportion that resulted in a hospitalist recommendation, and the proportion of the hospitalist recommendations that were adhered to by the primary care team. In addition, we examined each hospitalist recommendation to determine the nature (eg broaden coverage, narrow coverage, dose adjustment, further work up). In a before-after study, we will be comparing the length of stay (LOS) for this population against the LOS of the similar diagnosis in the same geographic unit in the same months (Aug-Oct) one year prior.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): One hundred seventy-five cases were eligible for screening based on admission diagnosis over a three month period. Of those cases screened, 70 % had recommendations made by the hospitalist representative on hospital day one. Examples of recommendations made include change in antibiotic dosing based on GFR or age, further work ups recommended, expansion or change of regimen based on clinical factors and microbiology history. Of those cases where recommendations were made, 75 % of the time the primary team adhered to the recommendations.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?):

Early hospitalist screening and recommendations for antibiotic stewardship are feasible. In addition, the majority of the time, the recommendations are adhered to by the primary team.

ENHANCED CARE PROGRAM: A MODEL FOR COMPLEX CARE MANAGEMENT

Swati Shroff²; Jodie Bryk¹; Dr. Gary S. Fischer¹; Deborah M. Simak¹; Dennis Wickline²; Pamela Peele²; Dr. Wishwa Kapoor¹. ¹University of Pittsburgh, Pittsburgh, PA, PA; ²UPMC Health Plan, Pittsburgh, PA. (Tracking ID #2181886)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Medically complex individuals with multiple comorbidities often have unplanned care, resulting in frequent ED utilization, high admission and readmission rates, and high healthcare expenditures.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): Our innovation is the design and implementation of an Enhanced Care Program (ECP) to meet the needs of complex, high-utilizing individuals. In line with the Institute for Healthcare Improvement's triple aim, the program aims to: reduce unnecessary healthcare utilization, improve the continuity and quality of care, and improve the patient experience of complex, high-utilizing individuals.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The ECP is being implemented in the University of Pittsburgh Physicians General Internal Medicine practice in Oakland (UPP-GIMO) in collaboration with UPMC Health Plan (UPMC-HP), a major insurer in western Pennsylvania. Individuals are invited to participate in the ECP if they meet the following criteria: 1) "Care Needs Index" score of 3 or greater on a scale of 0-5 (a risk score based on prior avoidable utilization, gaps in care, medical condition resource intensity, and predicted utilization calculated by the UPMC-HP for every patient) or >1 inpatient hospitalization or >5 ED visits in the previous year; 2) 18 years of age or older; 3) UPMC-HP member; 4) Receive primary care at UPP-GIMO; and 5) Agreed to participate. The ECP is embedded within a patient centered medical home primary care practice. The ECP team consists of one full-time physician, two part-time physicians, a full-time nurse care manager, a full-time medical assistant, a part-time psychologist, and a part-time psychiatrist. After a comprehensive assessment, a care plan is developed and agreed upon by the patient and the ECP team. Patients have regular face-to-face and phone call follow up with the ECP team, including 24/7 direct access to the ECP team via the ECP Direct Cellphone. The ECP team follows patients in the hospital and communicates with the ED when patients present to the ED. Patient care and service needs are discussed by the ECP team during weekly huddle meetings, at which time individual care plans are modified as needed.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Data will be obtained from an electronic ECP database, the electronic health record, and the UPMC Health Plan. Process measures include number of patients screened, enrolled, and refusing to participate in the ECP, and number of visits and phone calls per actively enrolled patient with the ECP team. Our primary outcome of interest is the number of hospitalizations per patient over the course of the intervention. Other utilization measures include number of ED visits, specialist visits, and ECP primary care provider (ECP-PCP) visits per patient. Continuity measures include the proportion of patient visits with the ECP-PCP out of all providers and number of unique providers who see the patient. Quality of care outcomes include adherence to HgbA1C goals, blood pressure goals, and age-appropriate preventive care services. Finally, patient satisfaction will be assessed through patient satisfaction surveys. We will compare outcomes with both pre/post measurements and propensity-matched controls from the same geographic area insured by the same insurer.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): From the start of the program in July 2014 to October 2014, 60 individuals were enrolled and 5 dropped out, leaving 55 actively enrolled patients. Average age of actively enrolled participants is 49 years. Seventy-six percent of participants are female. Common co-morbidities include: asthma (25, 45.5 %), diabetes (25, 45.5 %), mental illness (19, 34.5 %), osteoarthritis (19, 34.5 %), and congestive heart failure (11, 20 %). In the 12 months prior to enrollment, 34 % of ECP participants had an ED visit per month and 7 % of ECP participants had an unplanned hospitalization per month. Average number of ED visits and hospitalizations per patient in the 12 months prior to enrollment were 7.5 and 0.9, respectively. We plan to evaluate all process and outcome measures discussed above in July 2015.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Thus far the team has learned it takes time and frequent interactions to build trusting

relationships with these patients. It is essential to keep patients engaged through continuous contact, a large portion of which has been occurring via 24/7 telephone access to the team. Behavioral health resources are essential given the high rate of mental health illnesses in these patients. Highly coordinated care and a multi-disciplinary team are required to care for these patients, and each of these patients has complex, individual care needs. Continual consideration of the optimal composition of the ECP team will be required.

ENHANCED SMOKING CESSATION SERVICES VIA ON-SITE NICOTINE REPLACEMENT THERAPY (NRT) IN AN OPIOID TREATMENT PROGRAM (OTP) Melinda M. Katz; Shomari M. Harris; Soteri Polydorou; Markos D. Emmanouel; Ellie Grossman. New York University School of Medicine, New York, NY. (Tracking ID #2192491)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): What are effective methods for enhancing smoking cessation among a high-risk population of patients in treatment for opioid dependence?

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Promote interest in smoking cessation among patients and staff at an opioid treatment program 2. Enhance confidence in addressing smoking cessation among patients and staff 3. Provide patients with short-term access to free nicotine replacement therapy and optimize use of the state telephone quitline service

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The program targeted patients enrolled in an opioid treatment program ($N=375$) at an urban safety-net hospital with a current smoking prevalence of approximately 85 %. The program provides methadone and buprenorphine and offers a wide range of daily group and individual counseling activities to support patients' recovery. For this pilot initiative, a part-time staff member approached patients in public program areas, group counseling sessions, and via word-of-mouth among patients and staff. Patients were asked if they had smoked even a puff of a cigarette in the past 30 days, and if so, were offered nicotine replacement therapy (NRT) patches on-site and given educational brochures about local smoking cessation services. Smokers were encouraged to accept referral to the New York State Smokers' Quitline; for those interested, staff helped patients complete the referral form and faxed it to the quitline. Smoking cessation program staff also provided informal education on tobacco treatment for interested OTP counselors. The part-time smoking cessation staff member was available on a limited basis for brief sessions of motivational interviewing; however, this service was not intended to provide comprehensive counseling on-site for smoking cessation. Its purpose was to optimize access to NRT and the state quitline service as a means to 'kickstart' local discussion and focus on smoking cessation.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Quantitative measures of success include the number of patients given NRT and referred to the quitline; number of patients reached by the quitline, and use of NRT and change in tobacco use assessed at one month follow-up. Qualitative measures of success include patients' acceptance of NRT and reports of discussions about smoking cessation.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Initial enrollment included 55 participants who all received NRT. The average number of cigarettes smoked per day was 14.5. Nine individuals (16 %) used e-cigarettes in the past 30 days, 3 (6 %) smoked hookah in the past 30 days, and 6 (11 %) used other forms of tobacco in the past 30 days. Forty-eight (87 %) previously attempted to quit smoking. We reached 30 participants to conduct a 1-month follow-up survey. Twenty-one (72 %) used the NRT patch from OTP, and the patch was used for an average of 11 days (range 0–28). Ten patients reported problems associated with NRT use: inadequate dose and ongoing cravings (2), difficulty finding sites to apply (1), sweating and difficulty sticking on (1), and the remainder with nausea, palpitations, and pruritus. Four patients used other quit-smoking medications during this time (2 NRT gum, 2 unknown medication). At follow-up, patients reported smoking an average of 7 cigarettes per day (range 0–20), and a majority (72 %) reported a change in their smoking pattern since they received the NRT. Many had discussed quitting smoking in the past month: 52 % talked to their OTP counselor; 56 % talked to family or loved ones; 44 % talked to other OTP patients; and 33 % talked to the OTP physician or another health-care professional. Fifteen (56 %) reported they had received a call from the NYS Quitline, and 6 actually had a conversation with a quitline coach. Patients were generally supportive of the program, and offered suggestions for other ways the OTP could promote smoking cessation. These ideas included incentives for quitting (e.g. movie tickets, gift certificates), on-site tobacco cessation support groups, and help with insurance issues for cessation medications. We received follow-up reports for 42 patients from the NYS Quitline. Twelve patients were successfully contacted by the Quitline; of these, 10 had quit smoking, 1 was sent additional NRT by the quitline, and 1 was not ready to quit.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Patients enrolled in opioid treatment programs have high rates of tobacco use and are interested in quitting smoking. Distribution of NRT on-site seems to correlate with a reduction in cigarette use over a short-term time interval and was an effective means of engaging patients to work on improving this health behavior. Connecting patients with the state quitline is useful for the relatively small number of patients who are successfully reached; perhaps a better counseling strategy is to build tobacco treatment into already-existing counseling services and use the energy of the group milieu of the treatment program.

ENHANCING PATIENT ENGAGEMENT AND PROVIDER AWARENESS OF SAFETY VULNERABILITIES USING A MULTIDISCIPLINARY DISCHARGE TIMEOUT CHECKLIST Brian Eiss¹; Paul Martin¹; Laura F. Gingras¹; Julius Motal²; Michael Gao¹; Nadine Rosenthal²; Megan E. Maikoff². ¹Weill Cornell Medical College/ New York Presbyterian Hospital, New York, NY; ²New York Presbyterian Hospital, New York, NY. (Tracking ID #2199313)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Transitioning a patient from acute hospitalization to home is a complex process with varying levels of patient engagement and high rates of adverse events; we believe that a discharge "timeout" checklist that actively engages patients, posed by physicians and nurses after standard discharge instructions, would decrease medication reconciliation errors, improve patient satisfaction and improve provider recognition of potential transitional care associated safety vulnerabilities.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): – To improve patient engagement in and satisfaction with communication efforts from medical and nursing staff at the time of discharge, as reflected by a 50 % improvement in corresponding HCAHPS scores and by self-reported patient satisfaction—To increase self-reported medical and nursing staff awareness of crucial vulnerabilities at the time of discharge care transition, including the unintended presence of central lines or catheters and key changes made to patient medication lists during the hospitalization—To improve self-reported physician and nursing satisfaction with communication at the time of discharge

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Over a several month period at our institution, three medicine patients were unintentionally discharged home with central lines in place, highlighting the need for strategies to increase provider awareness of safety vulnerabilities. Within the past year, efforts have already been undertaken by our institution to improve processes surrounding medication reconciliation and patient engagement. After buy-in was secured on multiple levels, from nursing management and hospital administration to medicine housestaff and staff nurses, focus groups were conducted to inform the creation of a 6-item discharge timeout checklist. During an initial pilot phase on a single medicine unit, this discharge timeout checklist is being administered by both staff nurse and resident physician together at the bedside after standard discharge instructions are provided to patients being discharged directly home. Utilizing rapid-cycle methodology, mini-focus groups are being conducted with involved providers to determine whether the checklist or process should be modified and to recognize any other unanticipated issues. During the pilot, feedback is being sought from providers regarding satisfaction with communication during the discharge process. Feedback is also being obtained from patients directly via satisfaction surveys and indirectly through review of unit-based HCAHPS scores. From the initial pilot phase we will move to prove sustainability and generalizability by expanding to include other medicine patient units with a different mix of patients and different provider types (physician assistants, NPs). We will again utilize PDSA rapid cycle innovation to help us adapt the process and will continue all evaluation processes to optimize engagement.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): – Number/types of "Safety Issues" identified by providers and patients (tracked by paper checklists) - Patient satisfaction, self-reported after discharge timeout and via standard post-discharge phone calls - HCAHPS/Press-Ganey scores for questions relating to discharge and follow-up instructions, medication reconciliation and multidisciplinary collaboration - Provider self-reported satisfaction with interdisciplinary communication (from surveys administered at interval focus groups) - Provider self-reported ability to recognize safety vulnerabilities at hospital discharge (pre- vs post-timeout participation, from surveys) - Readmission rates Process: – Percentage of eligible patients who have discharge timeout completed - Time used for timeout (minutes) - Delays in discharge time because of timeout (minutes)

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): We have created our checklist and, to date, approximately 20 discharge

timeouts have been conducted. Housestaff and nursing report success with the current process with only minimal logistical difficulties related to arranging a time to meet for conducting the timeout. The first round of interval focus groups revealed high levels of patient engagement with a majority of patients reporting that they saw potential benefit with the timeout checklist ranging from possible prevention of adverse events to improvement in their understanding of their medical conditions, medications and follow up plans. Resident physicians have reported that they are performing more thorough physical exams on the day of discharge than they did previous to exposure to the timeout to ensure that patients are not unintentionally discharged with lines, tubes or catheters that were meant to be discontinued.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): If successful, this project can improve communication and patient engagement in the discharge process and help increase awareness of potential safety issues at the time of discharge, potentially leading to prevention of adverse events. If we can successfully show generalizability and sustainability, the impact could include full integration of the multidisciplinary discharge timeout into standard hospital discharge processes.

ENHANCING VALUE THROUGH STANDARDIZATION OF NON-MEDICATION REFILL MESSAGES IN A LARGE ACADEMIC MEDICINE OUTPATIENT PRACTICE Stacey E. Jolly; Holly M. Moster; Deborah Burton; Giavanna Russo-Alvarez; Andrea L. Sikin. Cleveland Clinic, Cleveland, OH. (*Tracking ID #2181969*)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Considerable amount of time is spent processing outpatient messages, going back and forth with patients and healthcare team members to obtain needed information, and then additional time trying to track a patient down for resolution of their message.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1) Add value to patient non-medication refill messaging process through standardization 2) Improve satisfaction with non-medication refill messaging

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Setting: Outpatient clinic with an integrated electronic health record (EHR) and personal health record (PHR) with ongoing value-based care initiatives to create change through rigorous quality improvement projects Intervention: Standardization of non-medication refill patient messaging Significance: Impacts all team members: medical secretaries, medical assistants, nurses, clinical pharmacists, physician assistants, and physicians; refills already standardized Preplanning: Generated potential causes for wasteful time spent processing patient messages and why no standardization existed. Made a decision matrix and asked people to help us identify top root causes. Created a current and future process map of how non-medication refill messages were being handled and the vision of how they could be handled. Development: Categorized non-medication refills into 4 groups: results, forms, medical question/symptom, other. Found existing electronic templates for outpatient calls and modified for our project needs. Determined a minimum amount of information needed for each encounter and then created algorithms to follow depending on the category and circumstance. Through this method it became clear that our triage procedure also needed to be standardized as calls to the doctor's office are first answered by medical secretaries. Thus, we worked closely with our nursing staff to create algorithms for the medical secretaries on when patients should speak with a triage nurse immediately vs. it could be handled by a clinical team member that same or next day. Implementation: Standardization process vetted at respective meetings for all team members. Training manual was created and distributed. Medical secretaries underwent individual training sessions over 1 month via a "go live" format following the new standardization procedure with actual patients.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Evaluation: Mixed methods electronic survey given pre-/post-intervention to health care team members. Additionally, we conducted a pre-intervention and will conduct a post-intervention random chart audit of telephone encounters to determine the non-medication refill message category, number of days to resolve, number of people involved, and total calls.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Pre-Intervention: survey April 2014; 52 % response rate (46/89). Fifty percent were not satisfied with current non-medication refill messaging process. Sixty-four, 43, and 29 % responded that they always or often would have to call back or bounce back a non-refill message for medical symptoms/questions, test results, or forms, respectively because of missing information. Random chart audit of 24 telephone encounters; Categorized: results 34 %, medical questions/symptoms 25 %, forms 25 %, and other 16 %. To resolve it took an average of 3.2 days (range 1-10) and involved >2 people

(range 1-5) and average of 2 calls (range 1-3). Post-Intervention: survey Sept 2014; 49 % response rate (39/80). Seventy-nine percent were satisfied with the new standardization for non-medication refill messaging. Twenty-eight percent, and 15 % responded that they often would have to call back or bounce back a non-refill telephone message for medical symptoms/questions, test results, or forms, respectively because of missing information. Feedback: medical secretaries appreciate the ability to communicate to patients a time-frame of when to expect resolution of their message; nurses appreciate getting complete information and correct numbers to call patients; team members vested increasing use of the PHR to communicate test results and appropriate issues electronically; physicians appreciate more clarity/detail around what patient is asking for or wanting, that many messages can be handled by other team members.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Lessons Learned: Required a committed team and dedicated time for the necessary planning, implementation, and evaluation. Considerable undertaking to create standardization for each of the 4 non-medication refill categories, however, wanted to minimize confusion around when it should or should not be used and so chose to make it a standard for all practice teams. Medical secretaries, a pharmacist, and physicians were on our team and utilized consultants in nursing, information technology, and administration. Imperative to work with EHR personnel early to know what is possible with EHR platform. Crucial to pilot with EHR test patients and slowly roll out through an iterative process; make changes based on feedback as needed. Challenges measurement and what EHR data can be queried automatically vs. manual chart review. This is adaptable to other outpatient primary care sites, especially those that utilize an EHR.

EYES ON THE PRIZE: IMPROVING DIABETIC RETINAL SCREENING AT AN URBAN SAFETY NET HOSPITAL Claire Horton. UCSF/VASFCM, San Francisco, CA. (*Tracking ID #2198040*)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Long wait times lead to low screening rates for diabetic retinopathy in our urban, safety net population.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): Diabetic retinopathy is the leading cause of blindness among adults 20-74 in the U.S. Most people with diabetes will develop diabetic retinopathy within 20 years of diabetes diagnosis (90 % of patients with type 1 and 60 % of patients with type 2).^{1,2} With early detection and treatment, the risk of blindness can be reduced by 90 %.³ Unfortunately, screening rates average 50 % nationally. Our screening rates were even lower: only 18 % of patients with diabetes in our two clinics received routine screening. Objectives: To introduce a system of teleretinopathy screening for patients with diabetes at San Francisco General Hospital To facilitate access to teleretinal services by developing a warm handoff system between primary care and ophthalmology To increase diabetic retinopathy screening rates from 18 to 50 % by December 31, 2014 1. Klein et al. The Wisconsin Epidemiologic Study of Diabetic Retinopathy. IX. Four-year incidence and progression of diabetic retinopathy when age at diagnosis is less than 30 years. Arch Ophthalmol 107:237-243, 1989 2. Klein et al. The Wisconsin Epidemiologic Study of Diabetic Retinopathy. III. Prevalence and risk of diabetic retinopathy when age at diagnosis is 30 or more years. Arch Ophthalmol 102:527-532, 1984 3. Garg, S. Diabetic Retinal Screening Update. Clinical Diabetes, vol 27 no 4, 2009

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): San Francisco General (SFGH) is an urban safety net hospital staffed by residents and faculty of the University of San Francisco, California. The overwhelming majority of our patients are poor, uninsured or publically insured, with multiple medical problems and significant psychosocial comorbidities. The Family Health Center and General Medicine Clinic provide full-spectrum primary care to patients in the SFGH system. Our current combine patient population is 18938 primary care patients. Of these, 3216 (17 %) have diabetes. Prior to this intervention, approximately 20 % of our patients received routine retinal screening. Due to low staffing numbers and inadequate resources, wait times for a visit to ophthalmology clinic were 6-12 months. Additionally, the workflow at ophthalmology clinic included full ophthalmologic exams by an ophthalmologist for most referred patients, without the time-saving assistance of technological support. In 2011, we formed a primary care / ophthalmology partnership to address this issue. Teleretinal screening is an innovation that has helped other systems increase screening rates significantly, and we hoped to introduce this system at SFGH. We purchased teleretinal cameras and trained staff on proper use. After introducing the cameras, we found referral rates remained low. A new workflow was developed in which medical assistants assess every patient with diabetes for up-to-date retinal screening and refer patients directly to teleretinal services if screening is due.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/

INTERVENTION): Our primary metric is the rate of diabetic retinal screening in patients with diabetes. Secondary metrics of success include the impact of the warm handoff system on medical assistant and clinic workflows, the acceptability of teleretinal screening for our diabetic patients, and the ease of tracking results of teleretinal screening in our electronic health record.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): We have found minimal impact on medical assistant and clinic workflow with the warm handoff system. Our medical assistants have given feedback about the new system at every step of development, which has helped minimize workflow impact. Patients find the new system acceptable and have expressed appreciation for the decrease in wait times to ophthalmology screening. The rate of diabetic retinal screening has risen from 20 to 60 % over the 3 years of program implementation. Tracking results remains a challenging issue. We are currently developing a system by which results are brought forward into a section of the electronic medical record that is routinely used by providers and staff and can serve as a decision support tool to spur referral.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): The introduction of teleretinal screening and a warm handoff system can improve rates of screening for diabetic retinopathy in vulnerable populations. This intervention is relatively cheap and easy to implement with existing staff. In overstretched, underresourced settings, technology can reduce wait times and maximize the ability of highly trained specialists to focus on high risk patients rather than routine screening.

GROUP DISCUSSIONS ABOUT FUTURE CARE PLANNING Nathalie Bloch; Alyse C. Krantz; Aftab Iqbal; Abigail Frydryk. Harvard Medical School, Boston, MA. (Tracking ID #2195063)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Will a targeted and tailored approach to end-of-life discussions at the primary care clinic result in higher satisfaction, a greater proportion of participants making end-of-life choices, and higher PAM scores amongst participants as opposed to individuals who did not have such an intervention?

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): . Provide a safe space where patients and their loved ones can explore their preferences, values and goals related to end-of-life care . Educate patients about end-of-life care planning and options and empower them to take an active role in their health care . Increase proportion of patients who have a signed health care proxy on file

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): This project, supported by the Harvard Medical School Innovation Fellows Program, explores the capacity of the primary care physician to initiate end-of-life planning among non-terminally ill patients age 65 and older through a structured peer group discussion. We are currently up-scaling our pilot study to involve ~10 primary care physicians. Based on the results of a pilot, we estimate that each PCP will be able to recruit 20 patients. Patients are randomly assigned to control and intervention groups. The intervention includes a structured, peer led end-of-life conversation facilitated by members of the research team, which includes a video, values & satisfaction surveys, conversation regarding advance directive and health care proxy forms.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): This qualitative, comparative experiment uses multiple semi-structured questionnaires in a prospective fashion. The questionnaires include knowledge surveys on end-of-life care and satisfaction surveys for participants and family members. Patient activation and involvement in his/her own care is assessed using a validated questionnaire PAM (Patient Activation Measure). The intervention will be evaluated through a comparison of the proportion of advance directives (health care proxy and DNR/DNI forms) that are submitted by participants in treatment and control groups. Additionally, we try to quantify how many people are "touched" by these discussions, as each participant talks to more people about their experience in the discussion.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Our study included 15 treatment patients, 7 family members, and 11 control patients. We held four group discussions. • 100 % of patients and family members reported feeling comfortable throughout the group discussion ($n=22$) • 73 % of treatment patients showed increased knowledge about end-of-life care planning issues, compared to 27 % of control patients ($n=26$) • The proportion of study patients with a health care proxy on file increased 40 %, compared to a 0 % increase among control patients ($n=26$) • On average, participants reported sharing their discussion experience with four people outside of the study ($n=15$) • 86 % of patients and family members reported that the group discussion helped them recognize values and goals about end-of-life care ($n=22$) • The

PAM scores increased slightly from 68.6 to 69.1 in the treatment group and 63.5 to 66.3 in the control group ($n=26$). The majority of the participants in the treatment and control group entered the study at a PAM level 3 or 4 (93 % of treatment patients and 91 % of control patients)

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Our results proved that peer group discussions are an effective method for educating patients about end of life care and planning. We determined that patients felt more comfortable having end of life discussions with their loved ones following the intervention, and that the group discussion allowed them to explore and identify their values around end of life care. Additionally, health care proxy forms submission data suggest that the intervention had a positive impact on patient advance care planning behaviors. Finally, patients in the intervention group were eager to share their experience at the group discussion with members of their social community, leading to a "network effect."

HIGHLAND HEALTH ADVOCATES: A RESIDENT-LED, MULTIDISCIPLINARY ADVOCACY PROGRAM ADDRESSING SOCIAL DETERMINANTS OF HEALTH Michael Wang¹; Dennis Hsieh¹; Deborah Son¹; Lia Losonczy¹; Kimiko Tahara¹; Harrison Alter¹; Blake Gregory². ¹Alameda Health System—Highland Hospital, Oakland, CA; ²Highland General Hospital, San Francisco, CA. (Tracking ID #2194323)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Patients in the safety net struggle with barriers such as food insecurity and unstable housing that may undermine health and wellbeing.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Collect data on patients' social needs to better allocate hospital resources. 2. Assess impact of intervention on healthcare utilization metrics including hospital admissions, clinic no-show rates, establishment of patient centered medical home, and emergency room visits

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Social determinants of health are an increasingly recognized target for improvement in healthcare and have been associated with premature mortality (Cheng, et al.), among other unfavorable outcomes. This is especially true at safety net hospitals like Highland General Hospital (HGH) in Oakland, California. At HGH, we created an outpatient, resident-led low acuity social work service to serve the needs of clients who are at risk of food insecurity, unstable housing, legal problems, and other issues that impact wellbeing. This program, Highland Health Advocates (HHA), connects clients to available resources depending on the specific needs of the patient. HHA staffs numerous service desks located in the Emergency Department waiting room and near multiple outpatient clinics. The desks are open 9 AM to 5 PM Monday through Friday and accept both patient self-referral and HGH provider referrals by phone or in-person. The service desks have been staffed by 75 volunteers recruited from both nearby colleges and the community at large. One hundred twelve volunteers will be active starting January 2015. They are organized into ten four-hour shifts per week and managed by specially trained volunteer leads, who are in turn supervised and led by a full-time social worker. Our program uses a resident-built Microsoft Access database for client management and a Google Drive datasheet as a resource database.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Our program evaluates process measures including number of client referrals, percentage of patients satisfactorily helped, patient demographics, and need assessments. Hospital utilization metrics as described in the objectives will also be incorporated into the evaluation of program effectiveness.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Since formalized data collection started June 20, 2014 through December 31, 2014, we have served 571 clients. Of these clients, 166 reached an endpoint of being discharged from the program for having needs met, not desiring further resources, or being lost to follow-up. Among this cohort of discharged clients, 44 % (73) had needs satisfactorily met or required no further assistance. The remaining 405 clients continue to be actively enrolled in the program. Among all clients, the top need was housing, affecting 52 % of clients served. Food insecurity was the next highest ranking need, affecting 21 % of clients. Initial comparison of discharged clients who had needs met versus clients who were lost to follow-up showed no significant differences in gender or average age. There was a trend towards more Spanish speaking clients in the group of clients who had problems addressed (16 % vs 8 %), but this difference was not significant.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Our preliminary data described above have already begun to inform policy change at our institution. The recognition of food and housing as top priorities in the clients we serve has

led to outreach and partnership with food resources and homeless advocacy groups. Meanwhile, further characterization of the types of clients we are able to help will identify opportunities to improve and expand upon our current service offerings. This project continues to be in the early stages of its validation and development. However, it has already been a great benefit to our clients and has been instrumental in matching institutional resources to the needs of clients with significant barriers to achieving health and wellbeing. As such, we plan to publish a toolkit as a resource for other institutions to replicate. Critical components to success include a core of dedicated volunteers, full-time social work staff for managing volunteers, executive level institutional support, integration within existing social service offerings, active clinical champions, and flexible information systems that adapt to changing program needs. Properly staffed and equipped, an advocacy program based on our model should be replicable at any institution with a high social need burden and can have the capacity to make an immediate impact on policy decisions to improve patient care.

IMPLEMENTATION OF A MEDICATION MANAGEMENT PLAN FOR PATIENTS DISCHARGED TO SKILLED NURSING FACILITIES

Amanda S. Mixon^{3, 2}; Susan P. Bell^{4, 2}; Amy P. Myers¹; Julia M. Jacobsen²; Kathryn Goggins²; Avantika A. Saraf²; Sunil Kripalani^{2, 2}; Joseph Ouslander⁵; Sandra Simmons^{2, 3}; John F. Schnelle^{2, 3}; Eduard E. Vasilevskis^{2, 2}. ¹Vanderbilt University Hospital, Nashville, TN; ²Vanderbilt University Medical Center, Nashville, TN; ³VA Tennessee Valley Healthcare System, Nashville, TN; ⁴Vanderbilt University, Nashville, TN; ⁵Florida Atlantic University, Boca Raton, FL. (Tracking ID #2184380)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Hospitals often send multiple medication lists for patients transferred to skilled nursing facilities (SNFs), which can contribute to medication errors and often lack guidance for prospectively managing medications at SNF.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): To implement a medication management plan which consolidates medication information and provides prospective guidance for patients being transferred from hospital to SNFs.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Vanderbilt University Hospital (VUH) is a private, non-profit, quaternary care teaching institution located in Nashville, Tennessee. Funded by a CMS Innovations award, VUH has implemented IMPACT (Improved Post-Acute Care Transitions). IMPACT is a quality improvement intervention for Medicare patients who are transferring to 23 SNFs in middle Tennessee and southern Kentucky for post-acute care services. IMPACT focuses on improving communication of the patient's care plan between the family, the acute care setting, and the SNF. A key component of the intervention is transfer-oriented medication reconciliation and documentation by a clinical pharmacist. Pharmacists reconcile prehospital medications with the transfer orders and clearly mark which are to be continued, changed, held, or discontinued on the Medication Management Plan. The plan also includes the indications, comments for prospective management, and the last administration date/time. Documentation of selected high-risk medications, such as warfarin, insulin and diuretics, includes recent doses and relevant clinical data. The pharmacist reviews the plan for potentially inappropriate medications (PIMs), and, if necessary, contacts the discharging team about clinically relevant medication errors and recommends changes prior to the plan being sent with the patient to SNF.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Pharmacists record medications and PIMs throughout hospitalization, as well as clinically relevant medications errors identified, communicated and resolved prior to SNF transfer.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Preliminary data from January 2013 to July 2014 on 564 patients transferred to SNFs with a medication management plan demonstrates that on average patients took 12.8 medications on admission and 14.2 on discharge. Patients were prescribed on average 2.4 PIMs on admission, 1.2 initiated during hospitalization, and 2.3 at discharge. On average 1.0±1.3 PIMs were stopped or held at discharge per patient. Pharmacists identified an average of 1.5 clinically relevant medication errors per patient, communicated them to the discharging team, and were able to resolve an average of 0.6 errors prior to transfer.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Implementation of the medication management plan has improved the quality of documentation of patient's medications prior to SNF transfer. Future work will be to integrate the medication management plan into the electronic medical record, so it will be sent

automatically to the SNF for this patient population. An important lesson learned is that despite implementing the medication management plan containing anticipatory guidance, there was no decrease in the number of total medications or PIMs prescribed at transfer to SNF. While this intervention is important, it is not enough to simply reconcile medications without trying to discontinue more of those that are problematic or perhaps reducing polypharmacy altogether. Subsequent interventions will target reducing overall medications and PIMs in order to further reduce the risk of medication errors for patients transferring to SNFs.

IMPLEMENTATION OF AN ELECTRONIC REFERRAL SYSTEM IN A LARGE ACADEMIC MEDICAL CENTER Michael Barnett^{1, 3}; Ateev Mehrotra³; Joseph P. Frolkis¹; Melissa Spinks²; Brandon Hehir²; Casey Steiger²; Jeffrey Greenberg². ¹Brigham and Women's Hospital, Brookline, MA; ²Brigham and Women's Physicians Organization, Boston, MA; ³Harvard Medical School, Boston, MA. (Tracking ID #2193544)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): There are many well-documented problems with the specialty referral process and at our institution, Brigham and Women's Hospital (BWH), prior work showed that 63 % of PCPs were dissatisfied with the referral process and making significant number of referrals outside of our system.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): To improve the referral process we set out to design and implement an electronic specialty referral ordering system ("eReferral") to 1) increase PCP satisfaction with the referral process, 2) improve referral tracking and enable effective triage of urgent referrals, and 3) reduce referrals to specialists outside of the BWH system.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): This innovation was implemented at BWH, an academic medical center with ~135,000 primary care patients seen by 162 PCPs at 14 clinics. In 2013 there were approximately 105,000 new specialist visits at BWH, with about 32,000 of those from this primary care population. The new eReferral system was integrated within the EMR for point of care referral ordering. To make a referral, the referring physician enters the following in a screen accessible through the patient's chart: desired specialty, specific physician vs first available specialist, brief reason for referral, and urgency level (<3 days, <7 days, <30 days, or patient convenience). The referral is then sent to an electronic queue managed by the specialty department's administrative staff, who calls the patient within one business day to book an appointment. This step bypasses the need for the primary care office to serve as an intermediary in the process of scheduling a referral. The eReferral program was rolled out in January 2014 to all primary care sites.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): We conducted a prospective cohort study of all BWH PCPs and primary care population. We measured physician outcomes using electronic surveys pre- and post-intervention (satisfaction with process and perceptions on access, 65 and 63 % response rate in pre and post surveys, respectively) and patient outcomes using internal billing and scheduling data (specialty visit volume, time to appointment and percentage of specialist referrals outside BWH).

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): The eReferral process was rapidly adopted by BWH PCPs: by August 2014, 93 % of all new specialist referrals from BWH PCPs were made via eReferral. The percentage of PCPs agreeing or strongly agreeing that they were satisfied with the overall referral process increased from 21 to 69 % ($p<0.001$). The fraction of PCPs agreeing or strongly agreeing that they could confidently track referrals increased from 20 to 45 % ($p<0.001$). PCPs reported increased ability to obtain timely access to ten common specialties with 5 of those increases statistically significant ($p<0.05$). The distribution of triage urgency requests through eReferral was heavily skewed towards non-urgent referrals, with only 19 % of the requests for an appointment within one week or less. After eReferral implementation the fraction of first appointments that occurred within 7 days or less decreased from 26 to 24 % ($p=0.003$), while first appointments occurring 31 days or more from the date of referral increased modestly from 33 to 34 % after eReferral ($p=0.07$). The average number of monthly new specialist visits per BWH primary care patient increased from 2.25 to 2.75 new specialist visits per 100 patients per month ($p<0.001$). There was a non-statistically significant decrease in percentage of specialist referrals outside of BWH from 28 to 23 % ($p=0.054$).

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): The implementation of the eReferral system at BWH was a success with several key caveats. PCP satisfaction with the referral process and referral tracking increased dramatically.

PCPs also reported improved access to across several departments in specialty care. In addition, we observed a notable decrease in percentage of specialist referrals outside of BWH. However, despite PCP perceptions, we observed little change in actual access times, which could reflect better “sorting” of patients into nonurgent referrals with longer waiting periods. We also found an increase in the number of specialist visits per month in the BWH primary care population, which could mitigate the benefit of eReferral in a health system trying to minimize unnecessary referrals. This growth likely reflects the greater ease and transparency of the new referral system which creates less of a barrier to referral than the prior system. Further study of eReferral across a wider diversity of health systems will help to quantify the impact of such systems on the specialty referral process.

IMPLEMENTATION OF TEAM-BASED CARE FOR DIABETES FOR SAFETY-NET POPULATION WITH COMPLEX MEDICAL AND PSYCHOSOCIAL COMORBIDITIES

Sara L. Jackson¹, Lydia Chwastiak³, Lisa Chew², Meghan M. Kiefer¹, Kathy Mertens¹, Pam Dekeyser¹, Elizabeth Lin⁴. ¹University of Washington, Seattle, WA; ²University of Washington - Harborview Medical Center, Seattle, WA; ³University of Washington School of Medicine, Seattle, WA; ⁴Group Health Research Institute, Seattle, WA. (Tracking ID #2200825)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Diabetes prevalence is disproportionately high among patients treated in safety-net settings, and with Medicaid expansion under national health care reform, there is a critical need to develop interventions to improve medical outcomes in these high-risk, vulnerable populations.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Describe the feasibility and acceptability of adapting and implementing an evidence-based multi-condition collaborative care intervention for the treatment of diabetes and cardiovascular risk factors in an academic primary care clinic serving a safety-net population. 2. To identify patient characteristics (demographics, medical and psychosocial) associated with “engagement” in the Diabetes Treatment Team, by comparison of patients who were referred but did not establish with the program, to those who attended more than two visits and were not lost to follow up.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): TEAMcare is an evidence-based multi-condition collaborative care model that was shown to improve diabetes disease control and depression symptom severity among primary care patients in a randomized controlled trial in a large health maintenance organization (Katon, N Engl J Med. 2010 Dec 30;363(27):2611–20). We describe the implementation of the TEAMcare model in an urban safety net primary care clinic in Seattle for a target population with high rates of serious mental illness, substance abuse and dependence, and social vulnerabilities. There was no external funding to support this implementation, and all services were provided utilizing existing resources. Harborview Medical Center (HMC) in Seattle, WA is a safety-net teaching hospital, and provides over 45 % of all charity hospital care delivered in King County, WA. The Adult Medicine Clinic is HMC’s largest primary care clinic serving roughly 4500 patients; approximately 1000 of patients have diabetes, with 30 % having poor glycemic control (HbA1c > 9 %). All clinic patients with HbA1c > 9 % were eligible to enter into the Diabetes Team program, there were no exclusion criteria. Referrals came from primary care providers. The program consisted of the following components: 1) an individualized health plan with specific and measurable targets; 2) frequent contact with care manager for support of diabetes self-care; 3) treat-to-target pharmacotherapy intensification; 4) weekly team-based systematic case review using a registry of enrolled patients (Chwastiak, Int Rev Psychiatry. 2014 Dec;26(6):638–47). Our multi-disciplinary team includes 4 diabetes care managers (an advanced nurse practitioner, 2 RNs and a nutritionist/certified diabetes educator), a medical assistant, a social worker and a consulting psychiatrist and internist.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Diabetes disease control was measured with respect to Hemoglobin A1c, systolic blood pressure and LDL. Depression symptoms were evaluated with PHQ-9. Alcohol use and substance use disorders were identified through chart review. Engagement was defined as attendance at two or more care manager visits. Descriptive statistics were used to evaluate demographic and clinical characteristics of all patients referred to our Diabetes Team, and for those patients who engaged in treatment and those who did not.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Since March 2013, 156 patients have been referred to our clinic Diabetes Team, 68 have attended two or more visits, while 88 did not engage or were lost to follow up. Patients who engaged with the Diabetes Team were similar to those who did not in terms of: age (mean 57.5 years for those who engaged, 53.3 years for non-engaged); ethnicity (white 38.2 % compared to 35.2 %, black 26.5 to 34.1 %, hispanic 22.1 to 18.2,

API 7.4 to 10.2 %, and American Indian 4.4 to 1.1 %). Mental health disorders were common, and similar between those who engaged and those who did not: depression (45.6 % engaged compared to 47.7 % non-engaged); post traumatic stress disorder (5.9 to 13.6 %); bipolar disorder (0 to 6.8 %); psychotic disorder (5.9 to 1.1 %); and other psychiatric diagnosis (15.1 to 14.8 %). Patients with substance abuse diagnoses were less likely to engage with the Diabetes Team: alcohol abuse (7.6 % for those who engaged compared to 18.2 % for those who did not); opiate use (4.5 to 15.9 %); methadone use (1.5 to 4.5 %); cocaine and/or methamphetamine use (1.5 to 9.1 %); and marijuana use (7.6 to 15.9 %). Similarly only 4.5 % of engaged patients were documented to be homeless, compared to 11.4 % of those who did not engage.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?):

It is feasible to implement an evidence-based multi-condition collaborative care in an academic teaching clinic serving populations with significant psychosocial vulnerabilities, without external funding. Given the limited resources in safety net settings, the current pilot provides critical information to identify patients who are most likely to engage in and benefit from this resource-intensive intervention. Next steps include evaluation of preliminary effectiveness.

IMPLEMENTING ROUTINE INTER-PARTNER VIOLENCE SCREENING AT LGBT HEALTH CENTER

Catherine Basham¹, Dana King¹, Cara Presley-Kimball¹, Jennifer Potter². ¹Fenway Health, Boston, MA; ²Harvard Medical School, Boston, MA. (Tracking ID #2194556)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Domestic violence or inter-partner violence (IPV) is a significant social and health concern, resulting in 5.8 billion dollars in medical costs annually. The U.S. Preventive Services Task Force recommends IPV screening for women of childbearing age, and screening interventions tested among women show that those who talk to their health provider about partner violence are four times more likely to use an intervention. Research shows that lesbian, gay, bisexual and transgender (LGBT) people experience IPV at rates similar to or higher than heterosexual women; therefore, some have also recommended routine screening in these communities. Despite these recommendations, rates of IPV screening remain low nationwide. At our own health center, pre-intervention data collected prior to implementation of the universal screening protocol described below demonstrated a screening rate of approximately 30 % in women ages 18–50 who had been prescribed birth control in the previous 3 years, with 6 % of those screened reporting past or current abuse. Although we did not ascertain baseline screening rates among older females, males, or transgender individuals specifically, we suspect that we would have observed even lower pre-intervention screening rates in these groups.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): The goal of this intervention was to institute universal IPV screening in order to identify all patients in need of support and to facilitate connection to violence recovery and prevention services. A systems-based screening strategy was created that included 1) development and administration of a gender-neutral screening survey; 2) implementation of electronic health record (EHR) reminders and forms to promote effective documentation/tracking; and 3) construction of a referral network.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Fenway Health, a community health center specializing in LGBT health, provides an ideal venue in which to study the feasibility and effectiveness of IPV screening across all genders and sexual orientations. All patients presenting for primary care appointments are considered eligible for screening. Universal screening was implemented in February 2014. The screening survey is administered via tablet or paper version to any patient who has not been previously screened within the last 12 months. Screening is prompted by an EHR alert that reminds the medical assistant to offer the screener to each eligible patient. A provider then reviews survey results with the patient during the visit and documents responses on an electronically extractable tracking form. Patients who screen positive are offered a referral to Fenway’s on-site Violence Recovery Program for LGBT-identified patients, an on-site behavioral health specialist, or to apropos support services in the community.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Following implementation of universal IPV screening, we have assessed screening effectiveness quarterly by measuring rates of overall screening, disclosure, and referral uptake via the electronic health record.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): The first two quarters of screening from February to August 2014 estimated an overall screening rate of 52 % across primary care appointment types, with 10 % of patients disclosing emotional, physical, or sexual abuse within the past year. Fifty

percent of patients who were offered a referral to an in-house violence recovery program were seen within 6 months of screening, suggesting that use of this screener and immediate referral may help clients connect to needed services. Demographic data suggest that this screening is effective in reaching groups who are underserved by traditional violence recovery programs, including men and LGBT-identified people. In terms of gender, approximately 56 % of those who disclosed current violence were male, 27 % female, and 17 % transgender. In terms of sexual orientation, 32 % of those reporting current violence identified as lesbian or gay, 11 % as bisexual, and 23 % as heterosexual. Approximately 6000 patients were screened in the first 6 months of implementation.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Initial findings indicate that EHR prompts and paper-based surveys result in higher rates of IPV screening and detection. Gender-neutral screening that is appropriate for people of all genders and sexual orientations may play an important role in reducing health equity gaps for LGBT communities. Fenway's universal IPV screening strategy may inform screening practices in other primary care settings.

IMPROVING A HEALTH CARE SYSTEM'S CRITICAL LAB VALUE REPORTING PROCESS THROUGH A MULTI-DISCIPLINARY QUALITY TEAM David McCollum; Daran Brown; Joshua Gunnin; Vicki Hale; Trevor Lever; Leslie Hayes. University of Alabama at Birmingham, Birmingham, AL. (*Tracking ID #2195788*)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): A University Hospital System's special process which alerts clinicians of critical lab values has become unwieldy and dysfunctional.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): -Review the medical literature, nationwide best practices, and regulations related to the reporting of critical lab values -Make recommendations to hospital administration for improvements in our institution's process of reporting of critical lab values -Implement the changes and track associated metrics including cost-savings

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): This quality improvement project took place in a large urban University Hospital System that includes both inpatient and outpatient settings. The community served by this hospital includes the mid-sized city where it is located and serves as a referral center for the region. Patient safety cases involving critical lab values were reported to the hospital's patient safety committee. The patient safety committee identified the critical lab value notification special process to be in need of improvement. A multi-disciplinary quality improvement team was formed out of members taking part in the University Hospital's onsite quality improvement academy. The team was made up of an internal medicine physician, two nurse managers of hospital wards, a nurse member of the patient safety committee, a pediatric critical care physician, and the manager of the hospital's paging network. The team made a process map of the critical lab value notification special process. The team collected available hospital data related to the process. The team discussed the process with the key frontline staff involved in the process. The lab manager responsible for the process identified the following issues: "too many critical lab tests, poor documentation, and lack of reviews of critical lab policies." Review of data showed that there were 47 different laboratory tests with over 6000 results per month that were required to undergo the special process. Interview of key frontline clinical laboratory staff and clinicians discovered the sense that many of the labs being reported were not in fact critical. They were not felt "critical" because they did not require urgent action and could be dealt with using routine clinical processes. These interviews also raised the concern for "alarm fatigue" in which the vast number of critical lab values might dilute the response to those lab values which truly did require urgent action. Review of the literature and other institutions critical lab value notification systems discovered much variability and no gold standard in regards to which labs and parameters were considered critical. Review of regulations by The Joint Commission revealed a requirement for a critical lab value reporting process but that the values included were up to the institution. The team next gathered a multi-specialty committee of ten physicians known for their clinical expertise and leadership within the institution. The committee reviewed the findings of the quality improvement team and then discussed each critical lab value and made recommendations for a modified list. The modified list was then presented to the hospital administration's operational effectiveness committee. The committee approved the changes (with one exception) and formed a task force to implement the change. Currently the modified critical lab value list is being coded into the electronic health system. The change will be fully implemented in 1 to 2 months.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Quantitative Measures -A decreased number of labs-per-month requiring use of the critical lab value special process -Less time spent by laboratory staff

finding and alerting clinicians of critical lab values Qualitative ->With the decrease in required calls, the critical lab value process will become a more functional patient safety process -Frontline participants in critical lab value special process (lab techs and nurses) will have less distraction and be better able to perform their core duties

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): -The changes to the critical lab value list includes removing 18 labs of the original 47, and hence the new list will include 29 labs -Of the 29 remaining labs on the list, 9 labs had the parameters changed which require activation of the critical lab value process -The projected change will be a 52 % decrease in number of labs requiring the special process -Projected savings of laboratory technician time will be 1.8 FTE's -Feedback from the lab director was very encouraging including "The work the team did was simply amazing!"

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): -A critical lab value reporting system requiring too many notifications can lead to the process becoming dysfunctional and becoming a patient safety hazard -A multi-disciplinary quality improvement team is an effective approach to this problem -An internal medicine physician's clinical expertise and professional relationships is an invaluable asset to the team.

IMPROVING CLINIC FLOW IN AN ACADEMIC GENERAL INTERNAL MEDICINE CLINIC UTILIZING PATIENT-CENTERED LAYOUT AND SIGNAGE Brooke B. McGuirt; Betsy B. Shilliday; Tamrah Parker; Derek Cain; Shana Ratner. University of North Carolina at Chapel Hill, Chapel Hill, NC. (*Tracking ID #2198593*)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): The University of North Carolina (UNC) Internal Medicine Clinic (IMC) Press Ganey scores showed patient dissatisfaction with moving through the visit, and employees were stopped over 380 times a day by unnecessary interruptions related to patient flow.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1) To improve patient satisfaction in moving through the visit 2) To identify areas in clinic where signage was lacking or needed to be improved 3) To reduce staff interruptions by improving IMC signage to allow patients to more easily self-navigate through the clinic

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The UNC IMC is an academic general internal medicine clinic with 13,958 active patients and approximately 44,000 visits per year. It is recognized as a Level 3 Patient Centered Medical Home. The clinic has a newly formed patient advisory committee and is working to solicit more patient feedback in its longstanding quality improvement work. The clinic is staffed by faculty physicians, resident physicians, and advanced practice providers. The nurses are predominantly LPNs. With over 200 patient visits a day, clinic staff reported frequent interruptions by patients requiring assistance navigating through the clinic. IMC formed a multidisciplinary Lean Six Sigma purple belt team to conduct a week-long Kaizen event to investigate patient flow problems of the clinic and test solutions. Administrative and nursing staff completed brainstormed patient flow problems. The team worked with the staff to complete a root cause analysis to determine the deeper causes of reported problems. Patients external to the clinic (from the cancer patient advisory board) walked through the clinic and gave feedback about patient flow and signage. The team compiled this information and broke the root causes into: confusion caused by the 2 desk check-in system, lack of signage to checkout, poor signage for check-in, and lack of 3D signs to the restrooms. The team created temporary paper signage and directly observed front desk and internal clinic flow, shifting placement, style and size of the signs based on staff and patient feedback. We tested several methods to direct patients to the correct check-in desk and to the correct provider room during the visit. Once new temporary signs were in place, we checked for clarity by walking the route to and from every room in the clinic. In doing so, we recognized and changed signs that were still not clear. Patient advisors were brought back to tour the clinic once signs were tested during the week to ensure patient satisfaction before finalizing the new signage order.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Our team conducted observations of patients and staff before, during, and after implementation of the new signs. Observers were dispersed throughout the clinic to be able to watch every area for 1 h at a time. They tallied interruptions during that time and categorized the types of interruptions. Hourly interruptions were multiplied by 8 to approximate the number of interruptions per day. Counts were collected for the number of times patients inquired about the exit, the restroom, the number of patients checking in at the wrong desk, and the number of wandering patients and families. These interruptions were classified as either being a nurse or front desk interruption. We also noted our Press Ganey scores relating to moving through the visit being before and after

the changes. Finally, our team tracked the number of new signs added to the clinic, signs removed, and patient safety issues that were identified and resolved throughout the process.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): By improving IMC signage, our team was able to reduce total interruptions per day by 60 % (384 to 152), nurse interruptions by 40 % (160 to 96), and front desk interruptions by 75 % (224 to 49). The team was able to add 39 news signs to our clinic and eliminate 12 signs that were misdirecting patients or causing inefficient patient flow. Press Ganey scores related to moving through the visit improved from satisfaction levels of 84.7 % before to 92.9 % after our intervention. Staff were surveyed and were highly satisfied with the improved flow. Throughout the process we identified and resolved 4 patient safety issues. The small tests of change with the temporary signs led to multiple changes in the placement and content of signage during the kaizen week. Data from this project led to a switch to a 1-desk from a 2-desk check-in model.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): By gathering patient and staff feedback and performing a root cause analysis, our team was able to improve signage, improve patient flow, and reduce non-value added interruptions in IMC. Utilizing the patients' perspectives we were able to fix the signage to better meet their needs. Staff satisfaction improved by decreasing unnecessary interruptions leaving them more time for clinical care. Using rapid cycle improvement and testing different front desk layouts and temporary signs, the team was able to provide data to support development of more patient-centered and staff friendly flow for the clinic.

IMPROVING CMS QUALITY METRICS: INNOVATION THROUGH A TEAM-BASED APPROACH Janet R. Zolli²; Huy Hoang²; JoAnne Gottridge¹; Maansi D. Amin²; Joseph Conigliaro². ¹Hofstra North Shore LIJ School of Medicine, Great Neck, NY; ²Hofstra-NS/LIJ School of Medicine, North Shore University Hospital, Great Neck, NY. (Tracking ID #2198017)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): With quality metrics becoming the standard measure for quality of care and the measure for reimbursement, it has been a challenge for physicians to improve quality metrics on their own.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): We undertook a quality improvement project that involved all members of the practice including medical assistants, IT technicians, data analysts and physicians in a large, suburban outpatient practice which included a resident-run practice. The objective of the project was to improve quality metrics such as mammogram screening, colorectal screening, diabetes management, pneumococcal vaccination, and smoking cessation counseling.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Starting in 2011, we began to use a team-based approach to improve quality metrics in a faculty and resident-run, suburban outpatient practice. This approach included the following changes: 1. Medical assistants, nurses, and physicians participated in daily huddles to help identify patients who needed to be screened or counseled for that day. 2. Standing protocols were made for ordering the FIT colorectal screening test and pneumonia vaccine so that physicians would not have to be reminded to order the test or vaccination. 3. Data analysts drew up reports for eligible patients who had not been screened for mammogram, colorectal cancer, and the pneumonia vaccine. 4. Reminders were sent to patients so that they could discuss screening with physicians. 5. Vaccinations and the results of screening tests were electronically uploaded so that they could be easily tracked. 6. Rates for each physician were posted and shared to other physicians to develop a friendly, but competitive atmosphere for improving quality metrics. 7. Quality measures were assessed on a monthly and yearly basis. The Plan-Do-Study-Act cycle was used to help develop and test changes to protocols to improve quality measures.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): The quality measures for mammogram screening, colorectal screening, diabetes management, pneumococcal vaccination, and smoking cessation counseling are measured on a monthly and yearly basis. The quality measures are compared from year to year to measure success of the team-based approach.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Over the 3 years since initiation of the program, quality metrics in mammogram screening, smoking cessation counseling, colorectal screening, diabetes management, and pneumococcal vaccine have improved year over year, and in most cases have exceeded goals. Baseline data was established in 2011. For mammogram screening, the rates of screening have improved from 45.0 % in 2011 to 64.4 % in 2012 to

77.8 % in 2013 to 82.5 % in 2014. The rates of colorectal screening improved from 45.5 % in 2011 to 47.3 % in 2012 to 50.4 % in 2013 to 57.6 % in 2014. For the resident practice, colorectal screening rates improved from 24.2 % in 2012, to 28.5 % in 2013, to 43.5 % in 2014. The rates for the pneumonia vaccine were 82.0 % in 2011, 90.3 % in 2012, 84.3 % in 2013, and 85.8 % in 2014. The rates of people with diabetes with A1Cs of more than 9 % was 24.0 % in 2011, 14.8 % in 2012, 14.2 % in 2013, and 14.5 % in 2014. The patients who received smoking cessation counseling improved from 50.0 % in 2011 to 52.0 % in 2012 to 69.0 % in 2013 to 88.5 % in 2014. Overall, there was a significant improvement in all quality measures using the steps outlined above. The effectiveness of the team-based approach is most apparent when comparing year to year quality measures for colorectal screening in the resident practice. Because of the financial cost of colorectal screening and patients in the resident practice comprising of uninsured populations, colorectal screening rates were 24.2 % in 2012. Using the PDSA cycle, cost as a major barrier to colorectal screening was identified. The FIT test was identified as a low cost alternative. Data analysis was used to identify and remind physicians of patients that required colorectal screening. This led to an improvement of screening rates to 28.5 % in 2013. In 2014, using standing protocols, medical assistants started handing out FIT tests to patients at the beginning of a well visit. This gave both the medical assistant and the physician an opportunity to discuss the importance of colorectal screening. This led to an increase in colorectal screening rates in the resident practice from 28.5 % in 2013 to 43.5 % in 2014. This significant increase most clearly outlines the effectiveness of the team-based approach.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): The team-based approach involving all members of a practice can improve quality measures. By working with data analysts, IT technicians, medical assistants, and nurses, barriers to improving patient care can be addressed and overcome. Using daily huddles with all members of the healthcare team, having medical assistants hand out screening materials and tests, having all screening and tests results in an easily trackable EMR, and having friendly competition among colleagues can all help to improve quality measures. These methods can be adapted and applied to outpatient clinical practices to improve patient quality measures and outcomes.

IMPROVING DEPRESSION ASSESSMENTS AND TREATMENT IN A HOSPITAL FOLLOW-UP CLINIC TO DECREASE READMISSIONS Genevieve G. Embree²; Jamie Cavanaugh⁴; Brooke B. McGuire²; Shana Ratner¹. ¹UNC Chapel Hill, Chapel Hill, NC; ²UNC Health Care, Chapel Hill, NC; ³UNC Internal Medicine, Chapel Hill, NC; ⁴University of North Carolina at Chapel Hill, Chapel Hill, NC. (Tracking ID #2196389)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Readmitted patients at the University of North Carolina (UNC) Internal Medicine Clinic (IMC) had high rates of depression, and lack of treatment at the time of discharge may contribute to their readmissions.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Improve recognition of depression in recently discharged patients using the 9-item Patient Health Questionnaire (PHQ9). 2. Provide interventions (anti-depressant medication, counseling, or Psychiatry referral) to those with moderate to severe depression utilizing standard protocols. 3. Decrease hospital readmission rates by treating a common driver of readmission.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The University of North Carolina Internal Medicine Clinic is an outpatient academic general Internal Medicine practice serving about 13,000 patients. In 2012, the clinic designed an innovative multi-disciplinary dedicated hospital follow-up clinic to specifically meet the needs of patients transitioning out of the hospital with the goal of preventing readmission. The dedicated clinic is staffed by a clinical pharmacist, care manager, and physicians. We provide 108 hospital follow-up appointments monthly. Previous root cause analyses of readmitted patients from our clinic noted high rates of depression in these patients. As a result, in July 2013 we began administering the 9-item Patient Health Questionnaire (PHQ9) to screen for and assess severity of depression among all patients seen in the hospital follow-up clinic. For patients with moderate to severe depression (PHQ9 score ≥ 10), we offered interventions including medications, referral for counseling, and/or Psychiatry referral based on standard protocols. An embedded social worker provided most of the counseling for these patients. Patients then followed up and received usual care from their primary providers including ongoing depression treatment.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Our primary measure was presence of absence of depression assessment with PHQ9. Secondary measures included depression severity, presence of

evidence based treatments, and presence or absence of 30-day hospital readmission. We determined the percentage of patients with moderate to severe depression by PHQ9 score at hospital follow-up visit who received a subsequent PHQ9 assessment once they returned to usual care. Based on these paired data, we calculated whether depression assessment is associated with improvement in depression severity. We will also calculate correlation coefficients to see whether absolute PHQ9 score and/or change in PHQ9 score are associated with readmission risk.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Of 545 patients seen in our hospital follow-up clinic between July 1, 2013 and April 3, 2014, we successfully screened 325 patients (60 %). Mean PHQ9 score was 7.0 with a standard deviation of 5.8. The breakdown of depression severity was as follows: 136 (42 %) had no depression (PHQ9 score 0–4); 87 (27 %) had mild depression (PHQ9 score 5–9); 59 (18 %) had moderate depression (PHQ score 10–14); and 43 (13 %) had severe depression (PHQ9 score ≥ 15). Based on a chart review of 160 patients, among those with moderate or severe depression, 22 % were offered medication, 22 % were offered counseling, none were offered new Psychiatry referrals (many were already followed by Psychiatry), 30 % were recommended to continue or restart their previously recommended therapy, and 39 % did not have treatment recommendations documented. Based on a chart review of the first 47 patients with moderate to severe depression, 29 (62 %) had documented subsequent PHQ9 scores after returning to usual care. Paired *t*-test calculations for those with documented subsequent PHQ9 scores revealed a clinically and statistically significant decrease in PHQ9 score. Those with PHQ9 score ≥ 10 (combined moderate and severe depression) had an average decrease of 5.1 points at the subsequent encounter ($p < 0.0001$). The effect was strongest among those with severe depression (PHQ9 ≥ 15) who had an average 6.1 point drop in PHQ9 at the subsequent encounter ($p = 0.01$).

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Depression has been documented as a risk factor for hospital readmissions and seems a fruitful target to reduce readmission rates. We have been able to demonstrate improvement in depression severity among recently hospitalized patients by incorporating depression assessment with PHQ9 and offering standard depression treatments which could be replicable in other clinics. We are hopeful that the improvement in depression severity will lead to reduced hospital readmission rates.

IMPROVING IDENTIFICATION OF HIGH-RISK PRIMARY CARE PATIENTS FOR INTERNAL MEDICINE RESIDENTS' YEAR-END HANDOFFS Maya H. Dulay^{1, 2}; Melissa Bachhuber^{1, 2}; Rebecca L. Shunk^{1, 2}; Bridget C. O'Brien². ¹San Francisco VA Medical Center, San Francisco, CA; ²University of California, San Francisco, San Francisco, CA. (Tracking ID #2199524)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): At the end of each academic year, PGY3 internal medicine residents identify patients from their continuity clinic panel who they deem sufficiently high-risk to warrant a comprehensive handoff without the benefit of an objective metric to assist in high-risk patient identification.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): • To critically review residents' processes for selecting which panel patients need a handoff and why. • To compare residents' selection to an objective indicator of patients' risk for hospitalization or death - the Care Assessment Need (CAN) Score. • To evaluate the utility of providing residents with patients' CAN scores when they select patients for handoff.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): At the end of each academic year, 18 PGY3 internal medicine residents who have continuity clinic in a San Francisco VA primary care clinic receive a list of all patients currently assigned to them. They are asked to review their panel patients and identify high-risk/high-complexity patients who should be transferred to a PGY2 or faculty provider rather than to a new PGY1. The residents are then expected to complete a written and an optional oral handoff to the new primary care provider. At the end of the 2014 academic year, we introduced an intervention in which PGY3 residents received CAN scores for all patients on their panels prior to transfer. CAN scores are a validated metric developed within VA to identify patients at high risk of death or hospitalization within 1 year. After first identifying patients for a handoff based upon their own assessment, the PGY3s reviewed their panel patients' CAN scores to compare their own selections with objective metrics. In one-hour small group sessions a faculty member explained the CAN score metric to residents, then asked them to review their panel data / handoff selections, make any changes based on CAN scores and explain what factors led them to select patients for handoff.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/

INTERVENTION): PGY3 average panel size was 75 (SD 18.1) and panels had an average of 6 patients (SD 3.7) with a high CAN score (≥ 95 out of 100). Prior to the CAN score review, PGY3's selected 10 patients on average (SD 5.6) or 13 % of their panel for a handoff. Of these, an average of 3 patients (SD 2.3) had CAN scores ≥ 95 (58 % of high risk patients identified by CAN score). We conducted small group discussions with residents to explore their thought processes.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): PGY3's made few adjustments to their list of handoff patients after viewing CAN scores (3 residents, 10 patients added for handoff). They listed several reasons why patients who had high CAN scores were not selected for handoffs, including patients having: many issues that are well-controlled, one or two major issues that are relatively easy to manage, a strong support system, significant improvements in health, or co-managed care by a non-VA provider. There were 12 patients who had high CAN scores and had never been seen by the PGY3. This prompted discussion of how best to approach care for these patients to ensure quality and safety. PGY3s identified several reasons for selecting patients for handoff despite not having a high CAN score. These included: personality, behavioral or mental health concerns; management challenges despite low risk for morbidity and mortality; patient engagement in risky behaviors; or a complex situation that is difficult to glean from the chart.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): PGY3s made few changes to their handoff choices after reviewing CAN scores and identified several factors that are important for handoff selection but are not well reflected in CAN scores (e.g. psychosocial and behavioral issues). Nonetheless, they indicated that CAN scores provided helpful information to incorporate into their decisions and recommended including these or similar risk-related metrics with their panel for year-end review. Utilizing an objective risk indicator to augment clinical judgment may particularly help residents reduce reliance on availability heuristics when identifying high risk/high complexity patients.

IMPROVING PATIENT AND PROVIDER COMMUNICATION THROUGH MULTIDISCIPLINARY ROUNDING WITH THE USE OF A DISCHARGE PLAN TASK LIST Sarvenaz Alibeigi; Sunita Mistry; Blake Gregory. Alameda Health System - Highland Hospital, Alamo, CA. (Tracking ID #2192563)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Does a unit-based, multidisciplinary model of rounding improve patient satisfaction and communication between providers and the patient?

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. To improve communication of the care plan and discharge plan between health care providers and the patient. 2. To improve patient satisfaction and understanding of the care and discharge plans. 3. To reduce re-admission rates by enhancing patient understanding of discharge plan.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): An inpatient pilot was conducted over a three week period on Mondays through Fridays, with a total number of 16 patients enrolled in the pilot. The intervention implemented a multidisciplinary team rounding approach. The members of the team included: attending physician, senior resident, a designated unit social worker, a designated unit care coordinator, a designated unit clerk, the bedside nurse, and the patient. The setting for this pilot was a 9-telemetry bed unit with a 3:1 patient to nursing ratio. This unit was chosen specifically for the variety of patients that are admitted there and the geographic layout of that unit. Medicine patients were assigned overnight to that unit based on their level of acuity and estimated length of stay, they were then transferred over to the "pilot team" the following morning. The "pilot team" continued to care for all assigned patients until discharge. The intervention consisted of twice daily rounds with the multidisciplinary team at the patient's bedside. The morning rounds were more comprehensive and detailed, while the afternoon sessions involved reviewing a checklist. The morning rounds were scripted and focused on the patients care plan and discharge plan. The discharge task list was continuously referred to by the care coordinator and the designated tasks were acknowledged by the various team members. The focus of the morning rounds was to confirm the patient's awareness and agreement of their discharge plan. The focus of the afternoon rounds was to confirm all the necessary tasks for the day were being completed by the appropriate provider in a timely manner by referring to standard of work on the discharge task check list.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/ INTERVENTION): To measure improvements in communication, we surveyed the providers involved in the pilot and asked them to compare the "pilot rounds" with conventional rounding. To measure patient satisfaction we administered a survey to all

16 pilot patients and 16 control patients and focused the questionnaire on patient understanding of their discharge plan and their overall satisfaction with their hospital stay. We measured patient re-admission rates to our hospital at 30 days and 90 days and compared it to our current hospital average 30 and 90 day readmission rates. Successful transition of care to the patients' medical home was a major focus, with a goal of connecting patients to a primary care provider within two weeks of discharge. To measure this we contacted the medical home within two weeks from discharge to verify that the patient was evaluated.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Survey results revealed that patients in our pilot had a greater understanding of their medical condition and discharge plan compared to a control group that used conventional rounding. Patients in the study group also reported a preference to return to our hospital for future care, compared to the control group. Based on our survey results, we were able to show that providers involved in the pilot program felt the process was more patient centered and their tasks were more appropriate compared to our current usual practice. Patients involved in the pilot had a zero percent 30-day readmission rate and a 7 % 90 day readmission rate. This is a marked improvement compared to our current hospital average 30 day readmission rate of 10 % and our 90 day readmission rate of 25 %.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Our pilot program improved patient and provider satisfaction while enhancing communication amongst all members of the patients care plan. We achieved this without additional resources or staffing increases. With enhanced communication and a standard format for discharge tasks, the discharge process became more streamlined and tasks were done in a timelier manner compared to current practice. In an attempt to preserve the benefits of our pilot, we have restructured our social workers and care coordinators into a unit based model. Our next phase is to pilot a "huddle" involving several medicine teams, the care coordinator, and social worker in each unit. We plan to focus these huddles on individual patients' discharge planning needs while following the outline of the discharge task list that we have created.

IMPROVING THE ACCURACY AND EFFICIENCY OF THE MEDICATION RECONCILIATION PROCESS AT INTERNAL MEDICINE OUTPATIENT APPOINTMENTS Wendy Fiordellisi¹; Chris Goerd²; Cheryl Alberhasky¹; Sue Behrle¹; Krista M. Johnson². ¹University of Iowa Hospitals and Clinics, North Liberty, IA; ²University of Iowa, Iowa City, IA. (Tracking ID #2178875)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Can the accuracy and efficiency of the medication reconciliation process at internal medicine outpatient appointments be improved?

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Assess the accuracy and efficiency of the medication reconciliation process at internal medicine outpatient appointments at the University of Iowa. 2. Identify and implement potential improvements to the process. 3. Measure the change in accuracy and efficiency of the medication reconciliation process post intervention.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The University of Iowa Internal Medicine Outpatient Clinic is an academic primary care practice located in Iowa City, IA, staffed by 15 medical assistants (MAs), 5 nurses, 12 staff physicians, and the University of Iowa Internal Medicine residents. In order to assess the accuracy and efficiency medication reconciliation, we surveyed MAs, residents, and staff physicians about their perceptions of the process. We performed direct observation of MAs during their portion of medication reconciliation. We also interviewed patients after their appointments and reviewed the medication lists their "After Visit Summary" (AVS) to identify errors. Our pre-intervention data (see below) showed that neither the MAs nor physicians thought the current process was accurate or efficient. There were a surprisingly high number of medication errors on patients' AVS, which reflected the medication reconciliation performed by the physician. We found that the reconciliation performed by the MA, in a separate part of the medical record, was more accurate than the AVS. On survey, physicians admitted that they rarely used the information from the MA medication reconciliation when updating medication lists in their portion of the medical record. With this information, we formed an interprofessional task force, including staff physicians, residents, nurses, MAs, pharmacists, and information technologists, to create a process map, review the current medication reconciliation process, and identify potential improvements. Based on the recommendations of the task force, the following interventions were implemented: -MAs stopped recording the "date of the last dose" of each medication during their portion of the medication reconciliation process. -Physician medical record screen settings were adjusted to more easily view the medication reconciliation information entered by the MAs. -A "Welcome Encounter" report was printed for physician review for each patient appointment. This report differed from the report used prior, as it displayed not only the medication list but also the medication reconciliation notes made by the MA. -All clinic staff were educated

regarding the complete medication reconciliation process as well as their individual responsibilities in the process. The importance of medication reconciliation was stressed. Staff were encouraged to seek the help of clinic pharmacists for complicated cases.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): -MAs and physicians were surveyed to assess 1) their perception of the efficiency of the medication reconciliation process both pre and post intervention and 2) whether each intervention implemented was helpful in the medication reconciliation process (Likert scale). -Medication lists were reviewed with patients and the accuracy of medication reconciliation performed by both MAs and physicians was measured both pre and post intervention (student's *t*-test and chi square).

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): -Rating of efficiency of the medication reconciliation process (on scale of 1-5 with 5 being most efficient) improved from 2.4 to 3.6 (MA, $p=0.001$), 2.4 to 3.7 (residents, $p=0.002$) and 2.5 to 3.0 (staff physicians, $p=0.2$), (total, $p<0.001$). -The total number of errors on AVS decreased from 102 to 44 ($p=0.006$). The number of patients with at least one error on AVS decreased from 41 to 20 ($p<0.001$). -The number of errors noted by MAs that were not updated by physician on AVS decreased from 32 to 18 ($p=0.2$). The number of patients with at least one error noted by the MA but not updated by the physician on the AVS decreased from 20 to 11 ($p=0.1$).

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): -Improvements in medication reconciliation require the involvement of the entire healthcare team (medical assistants, nurses, physicians, pharmacists, and information technologists). -Communication amongst all members of the team is crucial to accurate medication reconciliation. The electronic medical record must be used appropriately so that it is a help, not a hindrance, to this process.

IMPROVING THE REACH AND ADOPTION OF SCREENING, BRIEF INTERVENTION, AND REFERRAL TO TREATMENT (SBIRT) SERVICES IN A PATIENT CENTERED MEDICAL HOME (PCMH) USING A MULTIMODAL IMPLEMENTATION INVOLVING PRACTICE REDESIGN Jeanne Morley⁵; Sandeep Kapoor^{3, 4}; Megan O'Grady¹; Jennifer Verbsky²; Nancy Kwon³; Mark Auerbach⁶; Jon Morgenstern³; Charles Neighbors⁷; Joseph Conigliaro⁵. ¹National Center on Addiction and Substance Abuse at Columbia University, New York, NY; ²North Shore LIJ Health System, Great Neck, NY; ³North Shore Long Island Jewish Health System, New Hyde Park, NY; ⁴The Feinstein Institute for Medical Research, Manhasset, NY; ⁵North Shore Long Island Jewish Health System, Manhasset, NY; ⁶North Shore Long Island Jewish Health System, Bay Shore, NY; ⁷The National Center on Addiction and Substance Abuse at Columbia University (CASA/Columbia), New York, NY. (Tracking ID #2196756)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Can SBIRT services be successfully integrated into a busy urban/suburban PCMH with parallel Faculty and Residency Internal Medicine Practices?

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1) Establish a robust SBIRT program in a PCMH with no preexisting protocol for alcohol/substance misuse screening or treatment. 2) Use the Reach, Effectiveness, Adoption, Implementation, Maintenance (RE-AIM) model combined with a Rapid-Cycle Improvement strategy (Plan-Do-Study-Act) to guide workflow changes and interventions to improve Reach of SBIRT services and enhance provider acceptance (Adoption). 3) Utilization of SBIRT services as an educational tool to improve Adoption among physicians in training (Residents), increase their awareness of alcohol/substance misuse among patients, demonstrate the value of brief interventions (BI)/motivational interviews in this population, and increase appreciation for a team based approach by leveraging the SBIRT care model.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): In 2013 a partnership (NYSBIRT-II) was established between the North Shore-Long Island Jewish Health System, the National Center on Addiction and Substance Abuse at Columbia University (CASA/Columbia), and the Office of Alcoholism and Substance Abuse Services (OASAS), funded by Substance Abuse and Mental Health Services Administration (SAMSHA), to build a sustainable SBIRT program within an integrated Hospital System focusing on Hurricane Sandy affected areas in the New York metropolitan area. By the end of the 5-year funding, the model developed for Emergency Departments and Primary Care will serve as the basis for subsequent dissemination of SBIRT services throughout New York State. This abstract outlines the implementation process during year one of NYSBIRT-II, at the alpha Primary Care site. Initial implementation occurred as follows:1) Medical Office Assistants (MoA) administered a 5-question SBIRT Prescreen for alcohol, drug, and tobacco use during vital

sign measurement at each provider visit; 2) a SBIRT Health Coach (HC) reviewed prescreens in real time to identify at risk patients; 3) the HC approached prescreen positive patients to complete a full screen (AUDIT and/or DAST-10); 4) after completion of the physician visit the HC performed a BI and/or referral to treatment based on full screen scores. We performed repeat PDSA cycles to facilitate timely identification of problems and rapid testing of workflow modifications. Intervention examples include: staff/physician education, staff engagement via feedback sessions for workflow adjustments, Industrial Engineering evaluations and practice redesign. One recognized concern was the significantly lower prescreen rate among patients roomed by Residents compared to MoAs.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Quantitative Measures: 1) Reach: Completion of SBIRT prescreens in patients arriving for office visits (% of patients receiving SBIRT prescreen among all patients seen). Benchmark set at 80 %; 2) Effectiveness: Delivery of intended services (% of patients receiving a full screen and intended services among all prescreen positive patients). Qualitative Measures: Adoption: We used standardized surveys, as well as feedback sessions with MoA's, Residents, and Attendings to assess engagement and attitudes towards SBIRT services.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Year 1: A total of 20,292 patients were prescreened yielding a Reach of 75 % with 2540 positive prescreens (13 %). A total of 1567 full screens were administered, yielding an Effectiveness of 62 %. Full screen positive patients totaled 460 resulting in 457 BI with 69 patients referred to further treatment. Average Prescreen Rate (PSR) was 80 % for Faculty Practice (FP) and 55 % for Resident Practice (RP). Strategies piloted to improve Reach within the RP were unsuccessful in achieving sustained benefit. Example Interventions: 1) Resident Training (PSR 31 %→56 %); 2) Individual Feedback Sessions (PSR 48 %→61 %, drop-off to 52 % after sessions ended). Unrelated to SBIRT, our Industrial Engineering Department evaluated the practice design, concluding that exam room utilization/allocation provided suboptimal practice efficiency (ie. excessive patient wait time). Based on their report, a "POD" system was implemented in August 2014 and directly impacted SBIRT Prescreen completion rates by changing workflow so all patients were roomed by MoAs. POD Implementation (PSR 47 %→85 %) – *Benchmark achieved and sustained

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): The PCMH is a suitable model for delivery of SBIRT services with greater Reach amongst FP patients compared to RP patients. Using the RE-AIM model and a Rapid-Cycle Improvement strategy (PDSA), delivery of SBIRT services were improved with practice redesign yielding the greatest and most sustained improvement. Intervention strategies should be tailored to individual practice preferences and conditions, to insure maximum reach into target populations. Encouraging a collaborative team approach by appreciating and eliciting input from front-line staff (via feedback sessions) can yield informed workflow changes and prove to be a successful strategy in improving Reach and Adoption.

IMPROVING THE SAFETY OF ICU TO FLOOR TRANSFERS—"TICKET TO RIDE" Faisal Siddiqui^{1, 2}; Morgan Jones²; R. Neal Axon^{1, 2}. ¹Charleston VAMC, Charleston, SC; ²MUSC, Charleston, SC. (Tracking ID #2197518)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Facilities with 'closed' intensive care units (ICU) often experience delays in bed availability spanning work shifts which complicate communication and can result in missed patient handoffs.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Prevent delays in floor team notification when patients are transferred from the ICU (i.e. missed handoffs). 2. Reduce delays in initiating ICU transfer orders. 3. Prevent transfer of medically unstable patients from ICU.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Patient handoffs have been the subject of increased study in recent years. Nevertheless, handoff quality often remains poor; a recent systematic review found a 13 % information error rate. Additionally, handoffs are ineffective when they are simply not performed. Transfer of patients from the ICU to ward is less well studied, but these handoffs are arguably more important given patient complexity. In response to a series of near-miss episodes where ICU patients were transferred from our ICU without proper handoffs, we sought to improve facility performance. A multi-stakeholder team of physicians, nurses, and clerical personnel mapped transfer/handoff processes and analyzed performance gaps. Our Internal Medicine program already had a well-established handoffs curriculum/system in place, but a critical area of delay was identified between the time of initial bed request and the actual time of bed assignment and patient transfer. In some cases, this delay was over 12 h and spanned

multiple work shifts. There were also instances of delayed initiation of transfer orders with the potential for missed medications or treatments. We devised a simple checklist, called the "Ticket to Ride" (TiR), which forces a face-to-face, standardized interaction between the transferring and accepting physicians and other team members at the time of bed assignment.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): We performed intermittent audits of TiR forms to track implementation. We also reviewed charts of consecutive ICU transfer patients comparing 3 months pre-intervention ($n=71$) to 3 months post ($n=80$). Mean times (in minutes) were examined using Students t test, and proportions were compared using Pearson chi square.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): We observed no further episodes of 'missed handoffs' after TiR implementation. Post implementation, the proportion of accept notes written before transfer increased significantly (41 vs. 22 %, $p=0.01$). Among transfer notes written after ICU transfer, mean time to first accept was not significantly changed (113 vs. 103 min, $p=0.53$). Only 2 patients required ICU readmission pre-implementation, and none post-implementation. Finally, we observed a significantly lower proportion of in-hospital deaths among ICU transfers (5 vs. 15 %, $p=0.03$) post-implementation.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): 1. Use of a standardized checklist requiring signatures is a simple, seemingly effective means for prompting providers to complete patient handoffs at the time of ICU transfer. 2. Early accept note completion improved post implementation indicating more prompt ward team evaluations. 3. Observed differences in mortality after implementation are intriguing and may be the subject of future study. Nevertheless, we do not interpret these results as causal as it relates to the TiR without analysis of a larger sample with adjustment for potential confounders.

INCREASING VALUE ACROSS FOUR HOSPITALS THROUGH A HOSPITALIST-LED QUALITY IMPROVEMENT PROGRAM: TOP-DOWN SUPPORT FOR BOTTOM-UP CHANGE TO DECREASE LENGTH OF STAY AND COST OF CARE Henry J. Michtalik^{1, 2}; Bishara Bates⁴; Robert E. Hody²; Phillip Phan^{3, 2}; Melinda Kantsiper⁵; Jodi Rennert-Ariev⁶; Laura Winner²; Daniel Brotman¹; Patricia Wachter²; Eric J. Park⁷; Eric Howell^{6, 2}. ¹Johns Hopkins Hospital, Baltimore, MD; ²Armstrong Institute for Patient Safety and Quality, Baltimore, MD; ³Johns Hopkins University, Baltimore, MD; ⁴Johns Hopkins Medicine, Baltimore, MD; ⁵Howard County General Hospital, Columbia, MD; ⁶Bayview Medical Center, Baltimore, MD; ⁷Johns Hopkins Community Physicians, Bethesda, MD. (Tracking ID #2199163)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): In multi-site health systems, hospitalist programs in different hospitals may not directly interact or even use the same metrics to evaluate quality of care, leading to high variability in both the cost and quality of care. In an environment focused on maximizing value to patients, strategies to align incentives, share knowledge, and empower change are desperately needed.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): To develop an inter-hospital collaborative program of hospital administrators, hospitalist program directors, hospitalists, lean sigma experts, and data analysts to: (1) develop consistent performance metrics across sites and identify high-value targets for intervention; (2) provide analytic and lean sigma support while empowering local staff to make changes; and (3) measure and disseminate improvements.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): In 2013, four separate hospitalist programs in the Johns Hopkins Medical Institutions collaborated with the Armstrong Institute for Patient Safety and Quality to increase hospitalist-driven value. A multi-level strategy involving front-line providers, hospitalist program directors, and hospital administrators was used to perform a needs assessment, garner financial support, and develop performance metrics. Metrics were selected based on ability to have a positive impact on both quality and cost, required consensus, and were reviewed via quarterly meetings with all parties. Two key metrics were length of stay and cost per patient admission, around which a data-driven dashboard, known as the A3, was created for each site. The one-page A3 for each hospitalist program communicated a common goal, data and observed trends; identified potential causes and interventions; documented completed and future steps; and assigned specific benchmarks, roles, responsibilities, and due dates. Local, customized solutions to achieve metric targets were encouraged at each site. Barriers and progress were assessed through the use of monthly hospitalist "clinical communities" meetings consisting of all hospitalist program directors, weekly on-site meetings, monthly project champion meetings between site leaders, and quarterly performance reviews with system leaders.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Success was measured by (1) engagement of front-line staff; (2) implementation and maintenance of individualized interventions; and (3) achievement and sustainment of individual site length of stay and cost benchmarks.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Local teams consisting of over 100 hospitalists, 30 administrators, 7 program leaders, 4 lean sigma experts, and 2 data analysts developed and evaluated 12 customized interventions to decrease length of stay and cost of care and improve quality of care, including orthopedic co-management, early patient ambulation, and a high intensity discharge protocol for selected patients. Length of stay targets were exceeded at 3 of the 4 hospitals, with year over year reductions of at least 0.1 days per case. Because hospital day costs in the state of Maryland can vary both by time period and site, adjustments were needed to harmonize cost comparisons. Additional methods were developed to differentiate cost savings from reduced length of stay versus more efficient use of resources. In the first year of the program's inception, a net \$759,000 was saved.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): This program aligned the goals of 4 diverse hospitalist programs while encouraging the development of local solutions. By sharing metrics, system-wide access to data, and using strict reporting procedures, the program provides powerful oversight without micro-management and accelerates learning and innovation at the local and system levels, resulting in a significant return on investment.

INTEGRATING LONG-ACTING REVERSIBLE CONTRACEPTION INTO AN ACADEMIC PRIMARY CARE PRACTICE Lydia E. Pace³; Brigid M. Dolan⁴; Lori W. Tishler²; Holly Gooding¹; Deborah Bartz³. ¹Boston Children's Hospital, Boston, MA; ²Brigham and Women, Boston, MA; ³Brigham and Women's Hospital, Boston, MA; ⁴Northwestern University, Chicago, IL. (Tracking ID #2198772)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Long-acting reversible contraceptive (LARC) methods are highly effective at decreasing unintended pregnancy and are safe in most chronic medical conditions, but remain underutilized in general internal medicine practices, largely because few internists are trained in device placement.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): The goal of this Innovation in Clinical Practice was to facilitate patients' access to LARC in the primary care setting by: 1) creating a training model to allow general internists to attain competence in intrauterine device (IUD) and implant placement, 2) developing a clinical protocol and system to provide LARC services on-site, and 3) building the educational infrastructure and foundation for internal medicine resident training in LARC.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): We implemented this program in an academic general internal medicine practice in an urban Boston teaching hospital. For the past 3 years, this practice has been undergoing transformation toward team based care, with a goal of achieving National Center for Quality Assurance Patient-Centered Medical Home status. The practice has 18,000 unique patients and over 50,000 patient visits per year. Many patients are medically underserved and socially complex. Development of an on-site LARC program involved multiple steps: 1) engagement of clinic leadership; 2) development of a collaborative relationship with an obstetrician-gynecologist at our institution willing to advocate for this project and train an internist in LARC placement; 3) commitment of clinic funds to purchase LARC devices, needed equipment and consumables to make them available on-site; 4) development of a training program for the internist that overcame the challenges of unpredictable LARC opportunities and the competing imperative of teaching ob/gyn residents; 5) launch of a biweekly LARC clinic within the primary care practice, including identifying support staff; developing a stock strategy for devices; creating templates for referral, notes, billing, scheduling, and consents; and developing practice protocols; and 6) patient recruitment.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Initial measures utilized include the numbers of procedures completed during training, number of patients served in the LARC clinic, and preliminary information on costs and revenues for the clinic. Future measures will include patient satisfaction, detailed assessment of clinical outcomes and complications, and number of internal medicine residents trained.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): The training in IUD placement involved 7 half-day sessions, including sessions with models, with patients in the hospital's Family Planning and gynecology

clinics; 10 IUD insertions were completed during training. For implant training, the internist completed a pharmaceutical company-sponsored training and then was observed placing implants by the ob/gyn. Following launch of the dedicated LARC clinic, 24 patients presented for LARC services in our primary care practice over 8 months. Eleven patients received an IUD, 6 received an implant; 2 of these were provided by residents under supervision. Four patients had an IUD removal. For 3 patients requesting an IUD the device could not be placed in the clinic, requiring referral to the ob/gyn service. One patient had an IUD expulsion 5 months after placement; we are not aware of any other complications. Initial costs to the clinic for materials and extra malpractice coverage for the internist provider were about \$1800. Up-front purchase costs for a levonorgestrel IUD and etonorgestrel implant were approximately \$650 each. Indirect costs included medical assistant time and office space. Procedure charges were approximately \$1100 for IUD insertion and \$2500 for implant placement.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): LARC training and service integration into an academic general internal medicine practice are feasible but require strong multidisciplinary collaboration, administrative support, clinician commitment, and up-front financial investment. Further evaluation will determine whether patients are satisfied with this service and perceive that it lowers barriers to LARC use. In-depth analysis of costs and revenues will also be performed. As the program continues, incorporation of internal medicine resident training is a primary goal. By eliminating cost-sharing for contraception among privately-insured women, the Affordable Care Act is expected to increase demand for LARC. Increasing the number and types of providers able to provide LARC, and integrating services into primary care, have the promise to further decrease barriers to these methods, reducing unintended pregnancies and improving women's health.

LAG BETWEEN PUBLICATION AND IMPLEMENTATION: JOURNAL CLUB TO BEDSIDE EXAMINING PRACTICING PHYSICIAN BEHAVIORS IN PRESCRIBING AZITHROMYCIN: A QUALITY IMPROVEMENT STUDY Midhun Malla; Libu Varughese; Byron Reichert; Huong Nguyen; Natalie Como; Gerard Hoatam; Tam Chu; Priya Radhakrishnan. St.Joseph's Hospital and Medical Center, Phoenix, AZ. (Tracking ID #2199529)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): As part of our antibiotic stewardship and patient safety initiative, we examined the physician Z-pak prescribing patterns and whether there was assessment of cardiac risk prior to prescribing the medication.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Reduce the lag time between latest body of evidence and its implementation 2. Assess antibiotic prescription behavior patterns of physicians 3. Increase physician's awareness of potential toxicity of prescribing Z-pak

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Data was extracted from the Ambulatory database from the adult primary care clinics from May 2011 to August 2014. We compared the Z-pak physician prescription behavior patterns and assessment of cardiac risk by ordering electrocardiograms (EKGs). We used 2012 as a milestone year (based on study publication). We analyzed whether there was an increase in the number of EKGs ordered to assess if physicians checked a baseline QT interval prior to prescription especially in patients who were on arrhythmogenic medications or had a diagnosis of QT prolongation. As a secondary outcome, we compared the percentage of Z-pak prescriptions with that of other antibiotics like Amoxicillin, Levofloxacin, and Ciprofloxacin.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): 1. Follow the trends of Z-pak prescriptions after the publication of NEJM study in 2012 2. Increase in the number of cardiac risk assessments (EKG) prior to prescribing Z-pak 3. Encourage physicians at our academic institution to have a lower latent period between publication of literature to clinical practice

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): A total of 7415 antibiotics were prescribed during the study period (2011–2014). Of these, 34 % were Z-Pak, 22 % Ciprofloxacin, 35 % Amoxicillin and 9 % Levofloxacin. Of the 2499 Z-Pak prescriptions, 381 patients were identified as having potential risk for cardiac events (arrhythmogenic medications, or documented long QT). Only 77 (3.08 %) had an EKG performed in the previous 30 days. Of note, none of the 4 patients with a history of QT prolongation had an EKG ordered. We also looked at whether there was an increase in cardiac risk assessment after the publication of the NEJM study in 2012, as a marker of increased awareness for the need to assess QT interval.

The percentage of EKGs increased from a baseline of 1.92 % to 3.64 and 4.19 within the first and second year respectively, after the study was published.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): At the conclusion of the first part of our QI project, we have identified a significant need for development of processes to enhance patient safety. While the number of EKGs performed has doubled since May 2011, there is still a significant number of at risk patients (documented QT prolongation or on arrhythmogenic medications) who did not receive the risk assessment. This lag between publication of the article and lack of clinical translation is consistent with the published literature. This is concerning given the point of care alerts displaying recommending caution with prescription in most EHR. Our study raises questions on optimal safety processes in regards to the prescription behavior that can endanger patients. While it is a QI project and not powered to assess a statistical significance, it raises alarm about the ability of the EHR to pick potential medication side effects and provider's ability to change behaviors. It is important for physicians to be aware of these dangers while taking care of patients with cardiac conditions presenting with 'simple' illnesses. It is important to develop a process to ensure up to date evidence based medicine is being practiced at the point of care. This study also highlights the use of 'big data' to assess practicing behaviors of physicians at a time where maintenance of certification is a hotly debated topic.

MULTIDISCIPLINARY INTERVENTION TO IMPROVE CARE TRANSITIONS Tafadzwa Muguwe; Nathalie Bloch; Orissa Viza. Mount Auburn Hospital, Cambridge, MA. (Tracking ID #2198587)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Evaluating the efficacy of a low cost multi-disciplinary intervention package in the hospital and primary care offices in order to improve healthcare quality while reducing healthcare costs as well as urgent care visits and re-hospitalizations within 30 days of discharge.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): Aim 1: To develop and implement a multi-disciplinary transitions intervention with contributions from hospital and primary care personnel. Aim 2: To evaluate the effects of this intervention on post-discharge adverse events, functional status, patient satisfaction, as well as urgent care and hospital utilization within 30 days of discharge.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The study will compare 30-day re-hospitalization rates between patients admitted during a six month period in 2014 (prospective intervention arm) and patients admitted during a similar time period in 2013 (retrospective non-intervention arm). The intervention in the hospital will consist of a discharge process that includes: obtaining updated contact information to be accessed within 48 h after the discharge; scheduling a follow up appointment with the primary care provider before discharge; and updating the patient and the patient advocate with a phone number to call in case of a medical issue before the primary care physician resumes care. After the discharge, the intervention will include: a follow up phone call to patient/advocate within 48 h of discharge from the primary care provider; and follow up appointment with the primary care provider within 7–14 days of discharge depending on the acuity of the medical condition. The hypothesis is that implementation of the intervention described above will reduce 30-day urgent care or hospital use. Data regarding the retrospective non-intervention arm (2013) will be obtained from medical records. These data will include any visit to an urgent care center or hospitalization during 2013.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Thirty day re-hospitalization rates Percentage of 48 your phone calls completed post-discharge Percentage of patients making scheduled 1–2 week outpatient appointments post-discharge Qualitative survey of patient satisfaction

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Uptake of the intervention has been largely successful, with almost all patient discharged with a follow-up appointment scheduled within 1–2 weeks of discharge. On the outpatient side there has been greater than 50 % adherence to the 48 h phone call by all outpatient practices, with some practices approaching 100 % adherence. Almost all patients that receive the 48 h call do show up to the scheduled appointment, proving the efficacy of the call. We are now in the process of calculating 30-day re-hospitalization rates for 2014, which will then be compared with pre-intervention rates from 2013.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): The hypothesis is that implementation of the intervention described above will enhance overall patient satisfaction and lead to a reduction in 30-day urgent care or hospital use. The

intervention is low-cost and simple, including a thoughtful discharge process and a follow up phone call at 48 h post-discharge to ensure that any patient issues are addressed prior to a scheduled follow appointment. Timing of follow up appointment is based on predetermined acuity of patient's medical condition, and this is vital to meeting the project objectives. If proven to work, the intervention described here can be easily up scaled to other services in the hospital and lead to reduction in readmissions and immense cost-savings across the healthcare system.

POST DISCHARGE INTENSIVE CARE TO REDUCE READMISSION RISK FOR HIGH RISK PATIENTS Geoffrey C. Lamb¹; Mary Conti²; Hope Benthien³; Susan Dummer²; Sandra S. Green³. ¹Medical College of Wisconsin, Milwaukee, WI; ²Froedtert Hospital, Milwaukee, WI; ³Froedtert Health, Milwaukee, WI. (Tracking ID #2199426)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): A review of patients readmitted to our hospital from primary care practices affiliated with our system revealed that the majority had complex illness and were readmitted despite having seen a primary care provider (PCP) within 7 days of discharge.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): To reduce 30 day readmissions among high risk patients utilizing a multidisciplinary intensive management program within the context of a medical home.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The project focused on patients admitted from a single internal medicine clinic affiliated with the hospital and certified as a NCQA level 3 medical home. Patients were risk stratified on admission using a tool derived from Project BOOST and tested within our hospital population. Patients at highest risk for readmission (predicted readmission rate 35 %) were invited to participate. Eligible patients were interviewed using a standard tool addressing social, financial, disease knowledge, self-care ability, medication, and transportation issues. Patients were excluded if they were receiving chemotherapy, discharged to a nursing facility or in hospice. An APNP in the clinic was contacted prior to discharge to initiate the handoff process. A home care referral was initiated and the patient seen at home within 24 h by an RN and social worker. The patient was scheduled in clinic within 72 h, evaluated by the PCP or APNP and met with a pharmacist to review medications. A weekly huddle was held with the APNP, home care RN, and a care coordinator. The patient also received a weekly phone call from the care coordinator. After hours, patients were instructed to call the home care nurse.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): The principle outcome measure was rate of readmission within 30 days following the index admission. True costs and direct margin (combined hospital and out-patient) for 60 days prior and 60 days after enrollment in the program were calculated. Performance was compared to 2 affiliated internal medicine clinics with a similar demographic.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Sixty-three patients were flagged as high risk by the tool. Twenty-seven were excluded, 14 declined and 22 agreed to participate. Prior to the intervention targeted patients had a readmission rate of 34.6 %. During the intervention the readmission rate among participants dropped to 11.9 % while nonparticipants remained at 36.4 %. Over the same period, comparison clinic A went from 20.5 to 21.6 % and clinic B went from 31.3 to 36.4 %. Total cost per case in the study group decreased 44 % after the intervention (\$6860 to \$3839). However the margin per case dropped (\$1789 to (–) \$1922). In contrast, clinic A cost went up (\$5053 to \$19,509) and margin went up (\$1321 to \$5520). All eligible patients qualified as home bound allowing the home care agency to cover their costs by billings.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Intensive management of patients at very high risk for readmission can lead to significant reductions in the readmission rate and a net reduction in costs. However, under current payment structures, loss of income from the second hospitalization can lead to a net negative margin unless costs can be recouped by other means or lower cost providers utilized.

PRIMARY CARE—SPECIALTY CARE ROUNDTABLES: A CASE-BASED DISCUSSION SERIES TO IMPROVE REFERRALS AND CO-MANAGEMENT Nathaniel Gleason¹; Sara Ackerman²; Ralph Gonzales². ¹UC San Francisco, Nathaniel Gleason, CA; ²UCSF, San Francisco, CA. (Tracking ID #2199704)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Major deficiencies in the Primary Care—Specialty Care interface, including insufficient information

in referrals, mismatched expectations, poor care coordination, and insufficient communication from specialist back to primary care providers (PCPs). Serendipitous interactions between PCPs and specialists have decreased in many settings with the introduction of electronic health records and the loss of physical proximity in the hospital as PCPs increasingly work exclusively in outpatient settings.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. To develop a structured forum in which PCPs and specialists can review the evaluation and management of the conditions most frequently referred or co-managed 2. To identify gaps in mutual understanding of appropriate timing of referral, pre-referral evaluation, and of the return of clinical management to the PCP 3. To use the case-based forum to develop and improve diagnosis-specific, local guidelines for referrals and electronic consultation (eConsult).

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): A lunchtime conference series features a single specialty with three 1-h sessions to optimize PCP attendance. Two specialists join PCPs, invited from across the organization. Cases are elicited from PCPs with individualized lists of recently-referred patients. Introductions are made by all participants to stress relationship building. With brief case presentations by PCPs, the group defines high-yield clinical and care-delivery questions to address. These are captured for later dissemination to all PCPs. Internal referral guidelines and the utility of eConsult are reviewed in conjunction with relevant cases. A laptop-mediated video conference connection was offered to PCP practices at other physical sites.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): A goal of delivering 15 conferences (5 specialties) per year was set. A survey was sent to all PCPs ($n=172$) after the first 12 conferences with 3 questions about the usefulness and desired frequency of the conferences. Sixteen PCPs and 10 specialists were interviewed about referrals and care coordination broadly, including a question about the utility of the Roundtables.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Participating specialties to date include cardiology, endocrinology, gastroenterology, hepatology, rheumatology, nephrology, pain management, neurology, orthopedics, psychiatry, and urology. Forty-one PCPs returned surveys (24 %), with the PCPs at other sites representing the majority of non-responders. Seventy-six percent of respondents found the conferences to be “very useful for improving your disease management strategies and referral decisions in Primary Care?” 88 % felt that the topic of co-management was “very important” to primary care. Thirty-nine percent desired monthly conferences and 42 % desired every-two-month conferences. Qualitative comments to the survey were strongly positive, finding the sessions to be “very high-yield.” The value of both the clinical and the care-delivery information frequently cited. “Putting a face to a name” is among the most frequently cited strengths.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): PCPs and specialists cite the in-person interaction – in a care delivery environment in which nearly all co-management communication takes now place electronically—as a fundamental strength of these conferences. Inclusion of remote primary care sites via low-quality video conference had low participation and low survey response. The case-based format provides a familiar structure, and the premise of the conference allows discussion of both clinical and care delivery topics. This format provides a unique opportunity to address a growing problem in care coordination.

PRIMARY CARE PHYSICIAN-PHARMACIST COLLABORATIVE MEDICATION MANAGEMENT SERVICE THROUGH A BENZODIAZEPINE OUTREACH CLINIC AT A UNIVERSITY-BASED INTERNAL MEDICINE CLINIC

Danielle F. Loeb¹; Carmen L. Lewis²; Huong M. Lam¹; Katy E. Trinkley³. ¹University of Colorado Denver, Aurora, CO; ²University of Colorado, Denver, NC; ³University of Colorado School of Pharmacy, Aurora, CO. (Tracking ID #2188200)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Inappropriate use of benzodiazepines increases known risks of falls, asthenia, impaired cognition and memory, substance abuse, and the potential to worsen anxiety.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): **Objective 1:** Decrease the proportion of patients inappropriately prescribed benzodiazepines in a university-based internal medicine clinic. **Objective 2:** Decrease anxiety symptoms through improved medication management. **Objective 3:** Improve primary care provider (PCP) understanding of appropriate benzodiazepine use.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): We are implementing a PCP-pharmacist

collaborative medication management service through a Benzodiazepine Outreach Clinic (BOC) at University of Colorado Anschutz Internal Medicine Clinic for patients with inappropriate benzodiazepine use. Based on National Institute for Health guidelines, we define inappropriate benzodiazepine use as: 1) “as needed” use for diagnoses other than insomnia, seizure disorder, or an acute anxiety; 2) scheduled use as monotherapy for anxiety disorders without documented evidence of failure to preferred, safer alternatives; and 3) suboptimal choice of benzodiazepine or dosing regimen. All patients are screened for inappropriate benzodiazepine prescriptions. The clinical pharmacy team includes an attending clinical pharmacist, medical students, and pharmacist interns and residents. This team recruits patients into the BOC using a phone script, assesses patients’ benzodiazepine use, and works collaboratively under protocols to optimize the safe and effective use of anxiety and insomnia medications. The protocols incorporate symptom assessments with validated scales, including the Generalized Anxiety Disorder-7 (GAD-7), Insomnia Severity Index (ISI) and Panic Disorder Severity Score (PDSS). All patients will receive education on non-pharmacological therapies and offered referrals to psychology and/or psychiatry. PCPs are updated on patients’ progress and any treatment questions or concerns will be managed collaboratively between PCP and clinical pharmacist. PCPs are educated directly through a one-time, formal, evidence-based review session guided by the treatment algorithms. They are educated indirectly through review of the BOC documentation in patient charts.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Our primary outcome is the change in the percent of clinic patients with inappropriate benzodiazepine prescriptions. Secondary outcomes include: 1) Pre- and post- intervention patient symptoms measured with the GAD-7, ISI, and PDSS 2) post-intervention patient satisfaction surveys, 3) post-intervention PCP satisfaction surveys, 4) Pre- and post- intervention PCP knowledge measured with a knowledge test. We have conducted cognitive testing of the PCP satisfaction survey and knowledge test with PCPs in another internal medicine clinic associated with the same university. We will conduct process mapping at 6 months to improve BOC clinic processes.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Chart reviews of a random sample of patients found that 11 (21 %) of 52 patients taking benzodiazepines had received inappropriate prescriptions. In a feasibility and acceptability pilot of patient panels from 3 PCPs, 24 patients were eligible; of those 19 (79 %) were referred to the BOC clinic by their PCP. Of those referred, 14 patients (74 %) scheduled an appointment and 11 patients (58 %) completed their first appointment. Of patients who completed their first appointment, benzodiazepines were optimized in 3 (27 %) patients and benzodiazepine regimens were determined appropriate in 4 (36 %) patients. In the patients determined to be on appropriate regimens, the indication for benzodiazepine prescription had not been documented accurately. We had planned to transition phone recruitment to clinic staff during the pilot study. However, during the initial calls patients were frequently reluctant to discuss benzodiazepines. Thus, we decided clinicians needed to continue to make these calls with careful messaging.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): **Referral Tracking:** The pilot pointed to a need to track patients referred to the BOC clinic and repeat outreach to patients who scheduled but did not complete appointments. **Early stakeholder engagement:** Influential PCPs, one of UC-A’s clinical teams, UC-A’s scheduling team, and the hospital’s Pharmacy and Therapeutics Committee were engaged in the planning and development of the BOC clinic. **Pilot intervention:** Conducting a small-scale pilot led to clinic-wide acceptance of the BOC clinic. **Patient Messaging:** Careful messaging from the pharmacy team was essential to patient acceptance of this potentially sensitive clinical intervention. **Documentation:** The pilot finding of inaccurate documentation of indication for benzodiazepine prescription points to the importance of clinic processes to ensure accurate prescription information.

REDUCING READMISSIONS WHY PATIENT AND PROVIDER PERCEPTIONS MAY MATTER MORE THAN YOU THINK Jocelyn A. Carter²; Deborah Wexler²; Karen Donelan¹; Charlotte Ward²; Courtney L. Kaiser². ¹Massachusetts General Hospital, Lebanon, NH; ²Massachusetts General Hospital, Boston, MA. (Tracking ID #2200333)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Do patient and provider perceptions about inpatient care reveal how to prevent readmission within 30 days

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): To identify perceptions of patients admitted to a single medical unit that are then readmitted within 30 days To identify perceptions of primary care/post-acute care providers of patients admitted to a single medical unit that are then readmitted within 30 days To analyze differences between and among patients admitted and readmitted

within 30 days with regard to demographic, clinical, socio-economic, and behavioral factors

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): A 20 item index questionnaire (administered to 533 inpatients on the day of discharge) and a 30 item readmission questionnaire (administered to 101 inpatients on the day of discharge) were developed by a team of survey experts as adapted from prior cognitively tested surveys. All patients included were admitted to a single medical unit in our academic center that admits ~1200 patients per year and is cared for by an internal medicine hospitalist paired with a nurse practitioner and two fourth year medical students. The index admission questionnaire included perceptions of physical and mental health, confidence in their own ability to take care of themselves outside the hospital, satisfaction with inpatient care received, likelihood to be readmitted in 30 days, understanding of care plan, basic demographic information (language preference, highest year of education and racial/ethnic identity) and whether or not patients have someone to help with their health at home. The readmission questionnaire included perceptions of why patients were being readmitted to the hospital (worsening of old symptoms, development of new symptoms, trouble getting a PCP or specialist appointment, trouble getting medications or taking medications, trouble with transportation, etc.), and the degree to which the understood the discharge plan. Index questionnaire participants were also asked if there was anything they could think of that would help them stay healthy outside the hospital. Readmission questionnaire participants were also asked about their living situation (living in their own home, with a roommate, staying with a friend, living with family, etc.), life changes (having to move or difficulty finding or keeping a job due to health issues, family stress, recent trauma or falls, worry about being alone or how to get help), financial difficulty (paying for medications, bills, food, shelter, etc.), degree to which assistance is needed to complete activities of daily living. Readmission questionnaire participants were also asked if they have someone to assist them with health care at home, if they need more assistance at home and what their biggest challenges were to staying healthy outside the hospital. A chart review was completed for all index and readmission questionnaire respondents and included basic demographics, reason for readmission, associated disease co-morbidities, as well as clinical and historical factors associated with admission or readmission. Focus groups of primary care clinic and post-acute care facility providers were completed for six hospital affiliated community clinics and eight commonly utilized post-acute care facilities, respectively. All chart reviews and surveys were entered into a REDCap database. Institutional Review Board approval was obtained

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): 1) Greater than 50 % response rate of patient index admission questionnaire 2) Greater than 50 % response rates of the patient readmission questionnaire 3) Completion of 100 % of provider focus groups at 6 community clinics and 8 commonly utilized post-acute care facilities

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): 1) Community clinic providers and post-acute care providers identified a lack of communication from hospital providers and unfavorable variation in the quality discharge summaries as a factor leading to increased readmission 2) Patients who rated their health as at least good were less likely to have a readmission (OR=0.62, $p=0.023$) 3) Patients who were very satisfied with their overall care that they received were less likely to have a readmission (OR=0.60, $p=0.027$) 4) Patients who said they were very likely to have a readmission were more likely to have a readmission (OR=1.98, $p=0.019$) 5) Responses from patients classified by their main clinical diagnoses during hospitalization (congestive heart failure, pneumonia, alcoholism, etc.) produced disease specific themes with regard to what would help them stay healthy outside the hospital.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): 1) Patient perceptions of health, satisfaction, and likelihood of readmission may predict rates of readmission 2) Provider perceptions may assist in discovering unidentified quality gaps 3) Clinical reasons for hospitalization may drive patterns of associated unmet patient needs related to readmission 4) Ongoing analysis of this data with implementation of interventions to address patient and provider identified quality gaps is underway 5) Additional studies are needed to confirm these results in other settings

SUCCESSFUL IMPLEMENTATION OF A CELLULITIS AND CUTANEOUS ABSCESS TREATMENT GUIDELINE AT AN ACADEMIC CENTER Keri Holmes-Maybank; John M. Hurst; Danielle Scheurer; Sean Boger. Medical University of South Carolina, Charleston, SC. (Tracking ID #2198961)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): A recent study reviewing treatment of cellulitis and cutaneous abscess at an academic hospital revealed extensive overprescribing of antibiotics and excessive treatment duration which is of

particular relevance in light of the strong statements released by the Centers for Disease Control and Prevention, Infectious Diseases Society of America (IDSA), and World Health Organization regarding the critical threat of antibiotic resistance caused in part by the inappropriate use of antibiotics in treatment of infections including cellulitis and cutaneous abscess.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): Create institution-specific clinical pathway, order set, and clinician education program for treatment of acute bacterial skin and skin structure infection (specifically cellulitis and cutaneous abscess). Improve antibiotic prescribing to increase compliance with clinical guidelines for cellulitis and cutaneous abscess. Decrease the length of antibiotic utilization for treatment of cellulitis and cutaneous abscess.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): An internist, Chief Quality Officer, and Antibiotic Stewardship Committee at an academic hospital collaborated to develop a guideline for treatment of adult inpatient cellulitis and cutaneous abscess based on recommendations from IDSA guidelines and the institution's antibiogram. For cellulitis with intact skin (uncomplicated), cefazolin was recommended for empiric therapy, with vancomycin reserved for cephalosporin allergy. For purulent (complicated) cellulitis or abscess >3 cm, empiric vancomycin was suggested. Source control was recommended for all cutaneous abscesses. Criteria were provided for de-escalation to oral therapy. The clinical guideline was presented at a mandatory resident conference in July 2013 to four general internal medicine teaching teams, each comprised of an internal medicine attending, upper level resident, and two interns, as well as two hospitalist services each with one internal medicine attending. For reference, the clinical order sets were made available to all practitioners on institutional computers, additionally internal medicine residents and attendings received a guideline pocket card. All interns, residents, and internal medicine attendings on a general internal medicine team or hospitalist service during July, August, and September 2013 received an email at the beginning of the month reminding them of the guidelines and resources for assistance with cellulitis and cutaneous abscess treatment.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): A chart review of patients with confirmed cellulitis or cutaneous abscess on the general internal medicine and hospitalist services prior to implementation of the clinical guideline (January to March 2013) and post-implementation of the guideline (July to September 2013) was performed recording antibiotic selection, antibiotic days of therapy (DOT), and days to antibiotic de-escalation.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Chart review of patients ($n=50$) with confirmed cellulitis or cutaneous abscess prior to implementation of the clinical guideline revealed 74 % would have been compliant. Post-implementation review of patients ($n=31$) demonstrated 93.55 % compliance with antibiotic selection. There was a significant increase in the use of cefazolin, the recommended antibiotic for uncomplicated cellulitis (pre 4 %, post 19 %, $p=0.03$). There was a significant decrease in the utilization of the broad spectrum gram-negative agent piperacillin-tazobactam (pre 36 %, post 6 %, $p=0.002$). There were non-significant decreases in use of vancomycin (76 % of cases pre, 61 % post, $p=0.12$), linezolid (4 % pre, 0 % post, $p=0.49$), and cefepime (8 % pre, 6 % post, $p=0.59$). Total antibiotic DOT decreased significantly post-intervention (pre mean days 13.79, range 2–51, post mean days 8.58, range 3–14, $p=0.009$). Intravenous DOT were significantly decreased (pre mean days 7.88, range 0–51, post mean days 3.64, range 0–8, $p=0.07$). There was a significant increase in appropriate de-escalation of antibiotics after implementation of the guideline (pre 78 %, post 94 %, $p=0.05$).

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Implementation of an institution specific antibiotic guideline for treatment of cellulitis and cutaneous abscess with repeated education resulted in a significant increase in appropriate antibiotic utilization and de-escalation. Additionally, a significant decrease in inappropriate utilization of broad spectrum gram-negative antibiotics and duration of antibiotic exposure was observed. This was achieved by combining the efforts of the internists caring for the patients, the Antibiotic Stewardship Committee, and the hospital's Chief Quality Officer.

TEAM-BASED CARE IN TEACHING CLINICS: WHAT DO HIGH-FUNCTIONING TEAMS HAVE IN COMMON? Marianna Kong; Kate Dube; Rachel Willard-Grace; Thomas Bodenheimer; J. Nwando Olayiwola; Reena Gupta. UCSF Center for Excellence in Primary Care, San Francisco, CA. (Tracking ID #2199867)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Well-designed team-based care is an essential building block of high-functioning primary care, but is faced with unique challenges in residency practices.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): We sought to understand how team-based care is implemented in teaching practices, where the presence of many part-time providers and inconsistent scheduling are common challenges. By identifying themes of successful team-based care in teaching clinics, the goal was to disseminate best practices in delivering collaborative and sustainable primary care in teaching clinics.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): We conducted site visits at sixteen primary care teaching clinics nationwide. Data was collected using a structured site visit guide and semi-structured interviews with clinic leadership, providers, trainees, and clinic staff. Site visit reports were coded and analyzed by two independent researchers using an iterative process, and the research team collaborated in identifying major themes in team-based care.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Not applicable

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Five major themes were identified as important to successful team-based care in the teaching clinics visited. Having small teamlets with providers and staff that consistently worked together was essential to creating care teams that were able to adapt well to day-to-day demands of functioning in clinic. A culture of empowerment of all team members was also important to truly share the care of a patient panel and allow each team member to perform at the maximum level of their training. Adequate staffing ratios to allow expanded team member roles, consistent team meetings and huddles for team/teamlet communication, and effective co-location were additional common elements in strong team-based care.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Despite obstacles faced by teaching practices in providing team based care, such as irregular provider schedules and staffing ratios, high functioning teams in teaching clinics were able to deliver effective team-based primary care by prioritizing a core set of themes. Understanding these themes may help other teaching practices improve their delivery of team-based primary care as well.

TESTING MEASURES FOR PHYSICIAN TIME AND TASKS IN AN ACADEMIC INTERNAL MEDICINE PRACTICE Matthew J. Moles; Carmen L. Lewis; Mary W. McCord; Huong M. Lam; Wagner Schorr-Ratzlaff; Laurence Williams. University of Colorado, Denver, CO. (Tracking ID #2191930)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Primary care is in a state of chaos with overburdened providers spending time doing non-clinical duties and working far outside of their clinical hours, with the upcoming incorporation of population management that will lead to additional demands on provider time.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): Objective 1: Identify feasible measures of providers' time spent on care and task Objective 2: Accurately measure providers' time spent working on specific tasks Objective 3: Expand measurement to staff

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The University of Colorado is actively working on changing the structure of their outpatient primary care clinics to be able to provide the care that is necessary in a pay-for-performance system and accommodates new demands related to population management. Currently, providers are asked to do the majority of direct patient care and care-coordination. In order to have a better idea of the current workload and to facilitate a better allocation of resources in the redesign of the primary care clinics, we attempted to quantify the time spent on activities by providers. The project was carried out at two large academic outpatient internal medicine practices. The practices were comprised of physicians and mid-levels working in a traditional fee-for-service model. They were supported by registered nurses and medical assistants performing in a traditional model of care. Patients were primarily insured. All clinical documentation was performed on an electronic medical record. Four PDSA cycles were conducted over the course of project. Before commencement we determined a list of tasks that were to be measured. PDSA cycle one used reports within the electronic medical record to look at the number in-basket tasks generated on a monthly basis for five internal medicine teams composed of physicians, registered nurses, and medical assistants. Tasks were compiled and analyzed based on subject matter. PDSA cycle two evaluated the time spent by providers during normal business hours by way of direct observation, sorting time based on predefined categories. Providers were observed during half day clinic sessions averaging 3.5 h with manual counting and time analysis of their activities. PDSA

cycle three involved provider reported time, utilizing Toggl, a manual counting and timing application for the computer and smart-phone. Five providers were asked to record their time spent on performing predetermined activities throughout each day. PDSA cycle four utilized a provider survey through email asking how much time was spent before, during, and after clinic on the electronic medical record performing patient care and care-coordination tasks per half day clinic sessions.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Tasks were measured by count and time and grouped into the following categories: patient visit, documentation, in basket, in basket - triage, in basket—results, in basket—other, email/Outlook, paperwork, preparing for the patient visit, and work outside of clinic.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Overall, providers spent 51 % of their time performing direct patient care and 41 % of their time on electronic medical record based documentation and in basket tasks. The remainder of the time was spent on email/outlook and paperwork. Per each 3.5 h clinical session, providers spent 2:09 h:min measured by direct observation and 3:21 h:min measured by physician input into Toggl on direct patient care. Providers also spent a significant amount of time performing documentation and in basket tasks. Utilizing Toggl, this amounted to 1:12 h:min and 1:31 h:min respectively. This was similar to what providers reported in the email survey, with the average time spent documenting of 1:48 h:min. This shows that for each 3.5 h clinical session, providers are performing approximately 2.5–3 h of additional time after direct patient care is over.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): 1. Providers spend a significant amount of time outside of direct patient care performing in basket tasks and documentation. This time occurs outside of normal business hours or designated clinical time. 2. Determining provider utilization of time requires concrete fields of measurement. 3. Long term scalability of measurement is best performed via direct observation and provider email. 4. Significant task redistribution will be necessary to facilitate population management and prevent provider burnout during the transition to a pay-for-performance model of care.

THE IMPACT OF OPEN ACCESS SCHEDULING ON INTERNAL MEDICINE RESIDENT-PATIENT CONTINUITY Shilpa M. Shah¹; Ryan Laponis²; Radhika A. Ramanan¹; Katherine Julian¹. ¹UCSF, San Francisco, CA; ²University of California San Francisco, San Francisco, CA. (Tracking ID #2198793)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): In an effort to provide access to timely and well-coordinated primary care, many practices have become certified as patient-centered medical homes (PCMH). One requirement for certification is open access scheduling, in which appointment slots are reserved for same-day or same-week patient access however little is known about the effect of open access scheduling on a resident continuity practice.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): Given the positive associations between patient continuity, resident satisfaction and patient outcomes, we sought to understand how open-access scheduling impacts patient continuity in a resident clinic. We examined patient continuity with their primary care provider before and after implementation of open-access scheduling in an internal medicine resident continuity clinic practice.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Resident physicians at the University of California, San Francisco (UCSF) participate in a 50/50 block model, alternating 2 months of inpatient rotations with 2 months of outpatient rotations. The Mt. Zion General Medicine Clinic is a mixed faculty-resident practice at UCSF, which is the continuity clinic site for between 21 and 24 internal medicine residents per class. Prior to October 2013, appointments were scheduled based solely on provider availability. In October 2013, open access scheduling was implemented for all providers. For residents, open access scheduling was limited to their outpatient blocks where, for each clinic session, one out of six appointment slots was reserved for same-week access.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): We examined patient continuity among second- and third-year residents at the Mt. Zion General Medicine clinic from October 2012 to March 2013 (FY13) as compared to October 2013 to March 2014 (FY14). First, we identified all appointments between residents and patients established in the practice including, but not limited to, their own primary care patients (FY13 n=3247, FY14 n=3218). Next, we identified all appointments that the primary care patients of residents had with any provider including, but not limited to, their own primary care provider (FY13 n=2457,

FY14 $n=2647$). We then assessed continuity using two methods: (1) the continuity physician method, which reflects the percentage of appointments during which providers see their own patients and (2) the usual provider method, which reflects the percentage of appointments during which patients see their own provider.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Using the continuity physician method, continuity among second-year residents increased from 59 to 60 % ($p=0.65$) following implementation of open access scheduling. Among third-year residents, continuity increased from 58 to 67 % ($p<0.05$) using this same method. Using the usual provider method, continuity among second-year residents increased from 76 to 81 % ($p<0.05$) with open access scheduling while in third-year resident providers, continuity decreased from 77 to 73 % ($p<0.05$).

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Implementation of open-access scheduling was associated with increased resident-patient continuity by the continuity physician method. The improved continuity was most substantial for third-year residents, which may reflect their larger panel size despite having the same appointment template as second-year residents. The decrease in resident-patient continuity among third-year residents following open access scheduling using the usual provider method may reflect patients' improved access to timely care with available providers when resident providers are unavailable. Next steps include investigating the specific drivers behind these changes in continuity, which may allow the design of a resident clinical experience that optimizes resident-patient continuity.

THE INTENSIVE OUTPATIENT CLINIC: TARGETING SUPER-UTILIZERS AT DENVER HEALTH Holly A. Batal; Vishnu Kulasekaran; Jeremy Long; Michael J. Durfee; Rachel Everhart; Daniel Brewer; Mary vander Heijde; Deborah Rinehart; Carlos Irwin Oronce; Kathy Thompson; Diana Botton; Tracy L. Johnson. Denver Health, Denver, CO. (Tracking ID #2193905)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): High risk patients, or super-utilizers, utilize a disproportionately large amount of health care resources and cost and represents an important area of focus for optimal resource allocation.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Improve population health by 5 % 2. Improve between-visit patient satisfaction by 5 % 3. Decrease total cost of care by 2.5 % relative to trend

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): In 2012, Denver Health received a Center for Medicare and Medicaid Innovation grant to implement a "21st Century Care" program, aimed at reducing costs and improving patient outcomes. This multifaceted program involves numerous components of system and care re-design to address the utilization of high-risk patients, among other interventions. One primary intervention targeting adult "very high-risk" patients, or super-utilizers, is the Intensive Outpatient Clinic (IOC). The IOC is a primary care clinic based within an integrated health system, Denver Health. It is modeled as an ambulatory ICU to draw on super-utilizing patients who suffer from no source of primary care or who are beyond the reach of typical primary care scope within Denver Health's community health center system. The clinic offers longer appointments, a robustly-staffed interdisciplinary team, easy access, and interfaces with mental health systems, hospital medicine teams, and primary care. The clinic benefits from longer appointment times for patients and the ability to provide higher intensity and more care for patients suffering from the overlay of chronic disease, substance abuse, mental health disorders, chronic pain, and homelessness.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): The IOC is guided by a strong analytical team who guides evaluation efforts and supports the clinic as it gains a database of experience in caring for super-utilizers. This team is focused on numerous outcomes for high risk patients across the Denver Health system. Financial metrics, such as cost aversion and total charges, have been tracked to determine program impact. A historical cohort model will offer the opportunity to compare high risk populations before and after interventions occurred within the context of the 21st Century Care grant.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Under the tiering strategy used to identify high risk adult patients, a cohort of 300+ patients has been enrolled in the IOC. Another 400+ patients have been excluded according to pre-determined criteria. The utilization of all high-risk adult patients at Denver Health has been examined. An actuarial analysis confirmed that baseline Medicaid per member per month (PMPM) costs increase by risk strata: Tier 1 (\$343.71 PMPM); Tier 2 (\$814.05 PMPM); Tier 3 (\$2887.07 PMPM); Tier 4 (\$7741.93 PMPM). Preliminary actuarial findings based on the first 11 months of program data estimated a 2.7 % overall reduction in Medicaid spending—driven primarily by a 6.1 % reduction in Tier 4 spending—relative to the prior (baseline) year's spending, adjusted for inflation.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): The IOC was developed based upon criteria determined by the 21st Century Care team and available resources within Denver Health. It would not function in nearly the same capacity without the guidance and support of this team, which offers analytical, programmatic, and policy support. An integrated health system, with substantial inpatient and outpatient services, lends itself to creation of an ambulatory ICU model for delivering care to super-utilizers. This model is different in theory and practice from alternative models which "HotSpot" patients and focus more on identification and direction of patients than on re-designing their care model. Financial impact can be demonstrated according to measures that offer the ability to examine current patients with regard to a historical cohort.

THE MOBILE INSULIN TITRATION INTERVENTION (MITI) STUDY: INNOVATIVE CHRONIC DISEASE MANAGEMENT OF DIABETES Natalie K. Levy¹; Victoria Moynihan⁸; Annielyn Nilo⁶; Karyn Singer⁴; Mary-Ann Etiebet⁵; Lidia Bernik⁷; James H. Cho¹; Yixin Fang²; Sundar Natarajan³. ¹NYU School of Medicine, Bellevue Hospital, New York, NY; ²New York University, New York, NY; ³VA New York Harbor Healthcare System, New York City, NY; ⁴Urban Health Plan, New York, NY; ⁵HHC, New York, NY; ⁶Bellevue Hospital, New York, NY; ⁷Mount Sinai Health System, New York, NY; ⁸NYU School of Medicine, New York, NY. (Tracking ID #2180410)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Can a 12 week program using text messaging and phone calls be used to adjust Lantus doses for type 2 insulin dependent diabetic patients of the Bellevue medical clinic?

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): In addition to evaluating the % of patients that reach their optimal Lantus dose in each arm, the MITI Study evaluates: 1. The feasibility of this type of study in a public hospital's outpatient medical clinic 2. If the intervention saves time and money 3. Patient satisfaction

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Remote Lantus insulin adjustment is appealing at a busy outpatient medicine clinic where appointment access can be limited and appealing to the low-income patients served by our hospital who often have to miss hours of work, make arrangements for the children in their care, and arrange transportation in order to come for an in-person clinic appointment. English or Spanish speaking patients in Bellevue's outpatient medical clinic who need their Lantus dose adjusted are randomized to two arms- the MITI intervention and usual care. MITI patients are enrolled in a secure web platform that texts them each weekday morning asking them to text back their fasting blood glucose. The MITI diabetes nurse reviews these numbers for alarm values daily. Each Thursday, the MITI diabetes nurse consults the (pre specified, MITI physician created) adjustment algorithms and calls patients advising them on Lantus dose titration. (When the diabetes nurse was unavailable on any given day of the study, the PI or co-investigator reviewed for alarm values or made titration phone calls.) This process continues until the patients reach their optimal Lantus dose (defined as the Lantus dose that achieves one fasting blood glucose value less than or equal to 130, or the maximal dose of Lantus that can be safely given). Patients in the usual care group continue to come to in-person titration visits in the manner specified by their primary medical doctor.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Our study measures four main areas 1) Clinical Effectiveness: The number of patients in each arm (MITI vs. usual care) that reach their optimal Lantus dose in 12 weeks. 2) Feasibility: The % of text message responses, the ability of the MITI nurse to reach patients via phone calls, and the volume of time spent by the MITI nurse. 3) Cost savings: The time saved by patients in the MITI arm is measured by the usual travel time to and from clinic, the time spent in the waiting room prior to each appointment, and the co-pays that accompany in person visits. 4) Satisfaction: Patient satisfaction is measured using the validated Diabetes Treatment Satisfaction Questionnaire at baseline and at 12 weeks.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): We had a pilot grant for 2013 and again for 2014. Each pilot grant allowed about 6 months of the active intervention which allowed us to enroll patients and follow them for 12 weeks. In 2013, 27 eligible patients enrolled in the MITI Study, 13 in the MITI arm and 14 in usual care: Clinical outcome: All 13 MITI patients reached their optimal Lantus dose within 12 weeks, while only 5 usual care patients reached their optimal Lantus dose (100 vs. 35.7 %, $p<0.001$). Feasibility outcome: 82.7 % of our text messages were returned by patients. The nurse was able to reach patients with a single phone call 54 % of the time, spent an average of <5 min a day checking for alarm values, and spent an average of only 15 min on titration phone calls on Thursdays. Cost savings: Patients saved an average of 45 min of transportation time to and from the clinic, saved a \$15 co-pay for

each visit, and the duration of the titration interaction was much shorter in the MITI arm (6 vs. 30 min for in-person visit). The waiting room time was not measured in 2013 but is being measured in 2014. There was no increased utilization of Bellevue ER, walk-in, or med refill visits for the MITI arm patients. **Satisfaction:** The 12 week Diabetes Treatment Satisfaction Questionnaire showed that MITI patients reported higher satisfaction ($p = 0.03$) **Other:** There were 8 cases of mild hypoglycemia (5 MITI, 3 in Usual Care, BG 60–79). There was no increased use of Bellevue Hospital services in the MITI arm. The analysis of the 2014 data is ongoing. Enrollment ended 12/12/14 and 12 week data collection for these 2014 patients will end in March 2015. [Thus far we can report that 14 of 15 2014 MITI patients reached their optimal Lantus dose (within the 12 weeks of the trial). The 15th patient is still within her 12 weeks. Feasibility, Cost saving, and Satisfaction data will follow]

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Remote Lantus adjustment is effective, feasible, cost saving and satisfactory. Lantus can be adjusted remotely using basic cell phone technology and a low cost web platform in the medical clinic of a large public hospital. This intervention helps ease the burden on demand for access in a busy clinic, and provides patient centered care for low-income diabetic patients who have challenges coming to in-person appointments.

TOWARDS THE DEVELOPMENT OF PATIENT-CENTERED DISCHARGE SUMMARIES Karen Okrainec; Shoshana Hahn-Goldberg; Tai Huynh; Nina Zahar; Howard Abrams. University Health Network, Toronto, ON, Canada. (Tracking ID #2200041)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Despite discharge from hospital being a vulnerable transition for patients, many health-care institutions do not use patient-centered discharge summaries which are written in a way that is easy for patients to understand or act on.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): To design a discharge summary for inpatients which can complement the current discharge process with information most relevant and actionable for patients, presented in an easily understandable and usable form.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Our group at OpenLab, along with the Toronto Central Local Health Integration Network, set out to engage patients, caregivers and providers to understand the patient experience at discharge and to redesign the way in which information is communicated into a Patient Oriented Discharge Summary (PODS). Our group worked with over 56 patients and caregivers, 30 health-care personnel, 7 patient education professionals and 8 designers in Toronto, Ontario to design a PODS based on best practices in information design, graphic design and patient education. Our mixed-methods involved patients and caregivers throughout the project, mostly on the Internal Medicine inpatient ward, including observations, interviews, surveys, focus groups, cultural probes, process and experience mapping. While no specific inclusion or exclusion criteria were used, deliberate efforts were made to engage harder to reach patients such as those with limited health literacy and language barriers and those with mental health issues.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Early pilot data to test usability and feasibility of the PODS included 1) using focus groups with Cantonese speaking patients and patients with mental health issues, 2) an online discussion with a virtual patient and caregiver panel, and 3) a usability test of a paper-based version of the PODS across 3 different hospital sites. Questions of usability and feasibility centered around: staff time needed to fill out and administer the PODS, usefulness, ease of reading and understanding of the information presented, and open-ended qualitative questions on favorite things about the summary, missing information they would like, and anything they would change. Currently, the newly updated PODS is being adopted and implemented across 8 health-care institutions across the city. Measures of success will include usability and feasibility, patient experience (patient satisfaction and patient understanding and adherence to discharge instructions using Transitional Care Model 3 validated questions) and secondary health outcomes (30 day unscheduled ER visits and readmissions). The primary outcome will be the demonstration of feasibility of adapting PODS into the discharge process of institutions with differing discharge workflows as measured by 75 % of pilot sites utilizing the PODS at 12 months.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Essential elements to communicate at discharge were: (1) Medication instructions, (2) How I can expect to feel, danger signals, and what to do, (3) When to resume activities and other lifestyle changes, (4) Follow up appointments including phone numbers, (5) Resources and pointers to information. The prototype PODS reflects these essential elements. White space is included on the margin for patients to jot down their

own notes, which has been found to improve information retention and recall. The results of the pilot data showed that patients would benefit from using the PODS. 94.8 % of patients and 75 % of providers said that the PODS would be helpful to have when discharged from hospital. Patients rated a sample PODS as either “good” or “very good” in terms of both the accessibility of the PODS and how easy the PODS was to read and understand. Suggestions for improvement included recommendations for changes to visual elements and language used in the PODS. Usability scores from providers were reasonably high, with an average value of 78 % for the paper prototype. The biggest recommendation from providers was to create an electronic version. Providers noted that the PODS was most useful for patients with multiple comorbidities, new diagnoses, a lot of required follow up, and limited health literacy.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Current discharge summaries are designed for the provider, not for patients, and are not well suited for use as tools to support communication. Given the amount of research and feedback incorporated in the design of PODS, we recommend that hospitals use the PODS and refine it over time. For hospitals that would like to create their own, they are encouraged to not start from scratch, but to learn from what this project has already uncovered. We have taken these lessons and packaged them into a set of guidelines for the content that should be included in a PODS, the design of PODS to make it accessible and usable for patients, and the process of delivering the PODS to the patient. These guidelines have been summarized in a single tip sheet.

TRANSITION FROM PEDIATRIC TO ADULT HEALTH CARE BASED ON THE ACP/AAFP/AAP HEALTH CARE TRANSITION CLINICAL REPORT AND THE SIX CORE ELEMENTS OF TRANSITION Patience H. White²; April Barbour¹. ¹George Washington University, Washington, DC; ²George Washington University, Bethesda, MD. (Tracking ID #2197651)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): An estimated 18 million adolescents ages 18–21, about 1/4 of whom have chronic conditions, will need to change from pediatric to adult approach to care and although much has been written about effective approaches for transition from hospital to home, little has been published about effective quality improvement interventions from pediatric to adult health care.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): To examine improvements in transition from pediatric to adult health care involving pediatric and adult primary care practices using the “Six Core Elements of Health Care Transition,” a quality improvement intervention modeled after the American Academy of Pediatrics/American Academy of Family Physicians/American College of Physicians Clinical Report on Transition.⁽¹⁾ 1. American Academy of Pediatrics, American Academy of Family Physicians, and American College of Physicians, Transitions Clinical Report Authoring Group. Supporting the health care transition from adolescence to adulthood in the medical home. Pediatrics 2011;128:182e200.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): A time-series comparative study of changes in 5 large academic primary care outpatient pediatric and adult practice teams of internists, family medicine and pediatricians that also included nurses, family navigators, social workers, and youth in the District of Columbia participating in a 2-year transition learning collaborative. The Learning collaborative methodology utilized was developed by NICHQ and pioneered by the Institute for Healthcare Improvement.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): The Health Care Transition Index, modeled after the Medical Home Index developed by Center for Medical Home Improvement, was used to assess progress in implementing the Six Core Elements of Transition, which include development of an office transition policy, provider knowledge and skills related to transition, identification of transitioning young adults, transition Readiness/orientation to adult practice, transition planning/integration into adult practice, and transfer of care/initial adult provider visit.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): There were improvements in all of the transition quality indicators in the pediatric and adult practices that participated in a health care transition learning collaborative. All sites established a practice-wide policy on transition and utilized an organized clinical process for documenting the youth's progress through the transition to an adult provider. Pediatric sites performed transition readiness assessments with 88 % of eligible youth, and 29 % prepared transition plans. Adult sites conducted transition readiness assessments with 73 % of eligible young adults, and 33 % had care plans developed. A total of 50 were transferred in a systematic way to adult primary care practices over the project period, the majority in the last 6 months of the learning collaborative, after the QI processes were in place at the pediatric and adult sites.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Quality improvement approach utilizing the Six Core Elements of Health Care Transition resulted in the development of a systematic clinical transition process in pediatric and adult academic primary care practices. The practices found the ready made customizable tools easy to use, improved the transition process and were sustainable. Involvement of all stakeholders including key leadership from the beginning along with consumers was essential. Internal medicine physicians developed appreciation for and developed ways to incorporate young adults into their practice as a special population. Improvements in the 6 core elements were suggested and completed. Electronic health record customization and financial incentive are hurdles that need further work.

UNDERSTANDING IMPORTANCE THROUGH PAPERWORK Heidi Vrolijk¹; Julie L. Mitchell². ¹Medical College of Wisconsin, Wauwatosa, WI; ²Medical College of Wisconsin, Milwaukee, WI. (Tracking ID #2199295)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Patient- or agency-initiated forms, hereafter referred to as paperwork, occupy staff time, often frustrate providers, and dissatisfy patients when not completed in a timely fashion.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Describe patient, provider, and clinic staff expectations about paperwork. 2. Compare the data between what patients want and what physicians and staff think patients want. 3. Develop a process to meet the goal turn-around-time for paperwork

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): We surveyed primary care patients, physicians, and staff about clinic paperwork anonymously using a convenience sample ($N=65$). Survey domains included preferred turn-around-time and importance of timely completion regarding paperwork for durable medical equipment (DME) orders, home health plans of care (POC), and medication prior authorizations (PA). We created a value-stream map of our current process for paperwork using Lean systems engineering principles. We eliminated inefficient and ineffective steps and reformulated the process so that each step was handled by a staff member working at the top of his or her license.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Paperwork turn-around-time (TAT)

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): On average, patients expect the following turn-around-times: 7.6 days for DME, 6.8 days for POC, and 5.7 days for PA. They rated all three as "somewhat important." Physicians and staff expect the following turn-around-times: 6.2 days for DME, 7.9 days for POC, and 4.3 days for PA. They rated DME and POC as "somewhat important" and PA as "very important." Physicians and staff expected patients to desire a 3.2 day TAT for DME, a 3.9 day TAT for POC, and a 1.9 day TAT for PA. They also expected patients to rate all the forms as "very important." The clinic's paperwork process went from 29 to 15 steps and went from hitting the goal TAT 50 % of the time to hitting it 97 % of the time.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Patients' understanding of processing paperwork requests is limited. Physicians and staff were unable to predict patient expectations possibly biased by negative anecdotal experiences with patients' concerns. Patients who had experienced delays in their paperwork being processed were dissatisfied at the time of the event, yet set low expectations for paperwork TAT when surveyed. Our original paperwork process was clumsy and ineffective, primarily because it was a job no one wanted to do: staff found it tedious, not rewarding (little direct patient contact), and an "add-on" to their usual work based in the EHR. Systems engineering principles helped us improve efficiencies and staff input was key. Our next steps include patient education to set realistic expectations and continuing to lower our turn-around-time.

USE OF A DATA DRIVEN MULTIDISCIPLINARY TEAM TO REDUCE READMISSIONS FOR HIGH RISK MEDICAID PATIENTS IN AN ACADEMIC MEDICAL PRACTICE Jennifer Verbsky²; Janet R. Zolli²; Daniel J. Coletti⁶; JoAnne Gottridge¹; Joseph Conigliaro⁴; Maansi D. Amin³. ¹Hofstra North Shore LIJ School of Medicine, Great Neck, NY; ²Hofstra-NS/LIJ School of Medicine, North Shore University Hospital, Great Neck, NY; ³North Shore LIJ Health System, Dix Hills, NY; ⁴North Shore LIJ Health System, New Hyde Park, NY; ⁵North Shore LIJ Health System, Great Neck, NY; ⁶The Zucker Hillside Hospital, Glen Oaks, NY. (Tracking ID #2196739)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): A small subset of Medicaid-insured patients cared for by the faculty and residents of the Division of General Internal Medicine of the North Shore Long Island Jewish Health System were

responsible for the majority of hospital readmissions and we sought to determine if a multimodal team approach could decrease hospitalizations for these high-risk utilizers.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): The main objective of our innovation was to decrease the re-hospitalization rate for our Medicaid patient population. Additionally, we sought to build a multidisciplinary team to improve the efficient and effective use of available resources for the most medically and psychosocially complex patients in our practice. Finally, we wanted to educate our internal medicine resident physicians about transitions of care procedures and PCMH principles.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): We developed a Hospital to Medical Home Project at the North Shore University General Internal Medicine Clinic, a large ambulatory medicine resident and faculty practice with 15 full-time faculty and 75 resident physicians. Both practices combined accommodate 32,000 visits each year from an ethnically and socioeconomically diverse urban/suburban patient population. Prior to the initiation of our project, we developed four major innovations that were all integral components of the project. First, we formed a multidisciplinary Hospital Medical Home Project Team comprised of medical providers, behavioral health specialists, patient educators, case managers, and secretarial staff. Each team member had a well-defined role and brought their individual expertise and experience to the team. Second, we developed a multifaceted communication infrastructure where communication among team members occurred both formally and informally, on daily, weekly, and monthly schedules, encouraging all members of the team to work together as a cohesive unit. Third, we implemented several IT enhancements including electronic notification of patient hospitalizations or emergency room visits, and note templates in the electronic medical record that standardized post-discharge documentation and provided decision support. Fourth, we conducted multiple PDSA (Plan, Do, Study, Act) cycles with continuous data collection, analysis, reflection, and subsequent change to improve the process. Project implementation began with the creation of a structured process for enrolling patients in the project after a hospital discharge, and a stratification system to define "high-risk" Medicaid patients based on number of hospital encounters, medical and psychiatric conditions. Administrative staff reviewed daily electronic notifications of patient hospitalizations and developed a patient hospitalization registry. The registry was then reviewed to identify patients who met "high-risk" criteria for entry into the program. Each "high-risk" patient was contacted within 48 h of discharge to set up a post-discharge office visit with a nurse practitioner and a nurse care manager. After the initial post-discharge office visit, patients were presented at a weekly interdisciplinary Team Meeting and assessed using a sub-stratification protocol to identify and prioritize patient needs, facilitate staff resource allocation, and formulate individualized care plans. Subsequent patient visits occurred with the nurse practitioner as well as other team members to review and simplify medication regimens, address behavioral issues and medication compliance, provide patient education, and discuss goals of care. Biomarkers of patient health status, patterns of adherence to treatment, and healthcare utilization (including re-hospitalizations) were tracked continuously. After "high-risk" patients were deemed stable, they were transitioned back to the resident physician to assume the role of primary care provider. Residents were educated on the project mission, available resources, and participated in weekly interdisciplinary meetings.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Hospitalization rates and 30-day readmission rates are used to measure project success. We also plan to use qualitative data from surveys and focus groups to assess resident education.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): The unadjusted all-cause 30-day readmission rates for all Medicaid-insured patients in our practice dropped from 35 % in 2012 (baseline) to 16 % in 2013 and to 13 % by the third quarter of 2014. As of November 1st, 39 of the 121 (32.2 %) patients enrolled in the project had been managed without re-hospitalization for over 12 months, 69 (57 %) remained out of the hospital for at least 6 months, and 85 (70.2 %) for at least 3 months. All cause 30-day re-hospitalization rates for the patients enrolled in the project declined from a rate of 3.19/1000 patient days to 0.94/1000 patient days during the third quarter of 2014.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Hospital readmissions can be successfully reduced with the use of an ambulatory multidisciplinary care team that provides enhanced outpatient resources for high-risk hospital utilizers. Data analysis plays an integral role by stimulating continued improvements.

USING GROUP MEDICAL VISITS AND A NOVEL WEBSITE TO HELP DIVERSE OLDER ADULTS ENGAGE IN ADVANCE CARE PLANNING IN PRIMARY CARE Emily Wistar¹; Carly S. Benner²; Claire K. Horton¹; Rebecca L. Sudore¹. ¹University of California at San Francisco, San Francisco, CA; ²University of California, San Francisco, San Francisco, CA. (Tracking ID #2198644)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): With the aging United States population facing increasingly complex medical decisions, advance care planning (ACP) is becoming ever more important for patients and their families; however, primary care providers in busy office practices often do not have the time or resources to discuss ACP, especially for diverse older adults with low health literacy and multiple chronic conditions.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): Group medical visits (GMV) have shown promise as a means to efficiently provide health education to patients for a variety of conditions, such as diabetes. However, little is known about the feasibility of using GMV for ACP in the primary care setting. In addition, although preliminary studies show that the ACP website called PREPARE (prepareforyourcare.org) helps diverse older adults engage in ACP, it has not yet been studied in GMV. Therefore, the goal of this residency based quality improvement (QI) program was to determine the feasibility of GMV for ACP that utilize the PREPARE website.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): We conducted a pre-post pilot QI GMV program among English-speaking primary care patients who were ≥ 55 years of age and had ≥ 2 chronic medical conditions. Participants were recruited from two primary care clinics in an urban safety net setting in Northern California through study fliers and recruitment phone calls. Participants attended two 90-min GMV, during which they were shown informational videos from the PREPARE website about choosing a medical decision maker, deciding what matters most in life, choosing flexibility for a surrogate decision maker, telling others about their wishes, and asking doctors appropriate questions. Participants were also given booklets corresponding to the video content, and an easy-to-read advance directive. We targeted 5–10 participants per group.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): We assessed pre-to-post ACP knowledge (percent answered correctly) and whether participants designated a surrogate decision maker or completed an advance directive using Fisher's exact tests. We also assessed ease-of-use of program materials (1–10 point scale).

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): We conducted two GMVs with 8 and 9 participants, respectively. The mean age of participants was 62 years (± 8.5). Forty-four percent were women, 67 % were non-white, 55 % had less than a high school education, 44 % rated their health as fair-to-poor, and 33 % had limited health literacy. Preliminary findings show that the group visits improved patient knowledge about ACP. Specifically, knowledge about designating a surrogate decision maker improved from 44.4 % correct pre GMV to 85.7 % post GMV (p -value 0.09) and knowledge about how to inform others of their decisions also improved significantly (55.6 vs 100 %, p -value 0.04). The percentage of participants who identified a surrogate decision maker increased pre to post GMV (44 vs. 86 %, $p=0.09$), as did the percentage that had plans to complete an advance directive in the next 30 days (11 vs. 29 %, $P=0.37$). Participants rated the GMV and PREPARE materials a mean of 8 (± 3.1) on a 10 point ease-of-use scale.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): It is feasible to conduct GMV for ACP using the PREPARE website. GMV and PREPARE were rated highly, improved ACP knowledge, and may be efficient ACP tools in the primary care setting.

USING PATIENT NARRATIVES TO IDENTIFY CLINICAL AND SOCIAL DRIVERS OF HIGH EMERGENCY DEPARTMENT (ED) UTILIZATION AMONG COMPLEX, HIGH-RISK PATIENTS Sonia Panigrahy²; Winnie Wang³; Carly Hudelson⁴; Yamini Saravanan¹. ¹Cambridge Health Alliance, Cambridge, MA; ²Sonia Panigrahy Consulting, New York, NY; ³Harvard School of Public Health, Boston, MA; ⁴Harvard Medical School, Boston, MA. (Tracking ID #2200103)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Five percent of the population account for approximately 50 % of total healthcare costs. The healthcare industry is responding to this disproportionate utilization, concentrated among patients with multiple conditions and social needs, by moving towards team-based chronic care management models, such as Complex Care Management (CCM). There is a paucity of work to engage high utilizing patients to identify their own needs, collaborate with providers to design care plans that integrate clinical problems with social determinants, and consequently develop aligned care goals for better health outcomes. This small pilot uses narrative methodology to understand the healthcare and social needs of this very complex, and misunderstood population so to design patient-centered care.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): This innovation uses a narrative methodology to collect patient stories from complex care patients to : (1) understand these patients in a more humanistic manner; (2) understand the reasons for high ED utilization and (3) identify the healthcare needs of this vulnerable patient population.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The Cambridge Health Alliance (CHA) is the only public health system in Massachusetts and is a safety-net academic health center for vulnerable populations. Approximately 25 CHA patients, covered under a Medicaid subsidy, were identified as over-utilizers. The project team was able to outreach 12 of these patients, and using narrative methodology interviewed them for 70–90 min. The interviews were semi-structured with 8 standard open-ended questions that were audio-recorded, transcribed, coded, and analyzed in Dedoose. These transcripts are written up as patient stories and will be shared with both the patient, and their PCPs.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): This pilot process aims to standardize a method for collecting a patient-centered assessment of health and social needs to provide the care team humanizing contextual clues that drive patients' behavior.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Preliminary analysis show that a majority of these patients report unstable childhoods, current financial stressors, social isolation, and a personal history of sexual trauma. All patients described healthier periods in their lives as times when they were more financially stable, felt safe, and had more of a social community. With respect to ED use, the main theme is a self-perceived sense of urgency of chronic symptoms exacerbated by social isolation. All 12 patients also felt very stigmatized for their ED use.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): This small pilot adds evidence that health is determined by social drivers, and any healthcare intervention to decrease utilization and improve health outcomes will also have to influence social drivers. A first step is to standardize a process by which the healthcare team can fully understand the patient as a person. We propose that using a narrative patient story will be both humanizing and therapeutic. This exploratory process could lay the groundwork for the creation of a streamlined process within chronic care management (CCM) to co-design care with their other high-risk patients. Utilizing narrative methodology can increase the success of CCM as determined by systems outcomes (i.e. health, utilization, and cost) by first improving upon patient-determined outcomes based on the understanding of the needs of this population.

WORKING TO REDUCE ADVERSE EVENTS IN PATIENTS THAT ARE "HANDED OFF" Natasha Cuk²; Sun Yoo²; Rachel Brook³; Neveen S. El-Farra²; Neil Wenger³; Nimesh Patel³; Teryl Nuckols¹. ¹Cedars-Sinai, Los Angeles, CA; ²David Geffen School of Medicine at UCLA, Los Angeles, CA; ³University of California, Los Angeles, Los Angeles, CA. (Tracking ID #2199788)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Handoffs have been shown to result in a substantial number of adverse patient care events (i.e. medical errors leading to patient injury and care delay) especially among trainees; although standardized signout protocols have been demonstrated to decrease handoff errors, there has been limited literature on the effectiveness of these interventions due to the increased transitions of care created by the 16 h work day duty hour restrictions, particularly those of night admitting teams to primary accepting teams.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): At Ronald Reagan UCLA Medical Center (RRUCLA), close to 50 % of admissions are handled by a housestaff night admitting team and then "handed off" to accepting primary medicine teams in the morning. Currently, the night admitting team admits all patients between 7 PM and 7 AM, which are then distributed to the various "on call" medicine teams the following day. Some of these admissions (depending on the time they are admitted) may involve double signouts. The objective of this study was to examine and compare the adverse event rates among handoff patients to those that are directly admitted by the primary team (de-novo admissions) Our hypothesis was that handoff patients will have a higher incidence of adverse events than patients admitted directly by the primary team. An additional objective was to examine the adverse event rate in the current admissions system in order to compare it to the rate of adverse events after an intervention.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): We collected daily data from all residents on General Medicine Inpatient Wards from 11/13/14 to 12/12/14 at RRUCLA. Each ward

resident received an email on their post-call days with an individualized survey for all admissions using REDCap software. Residents were prompted to identify the type of admission (e.g. handoff or de novo), followed by any adverse events that may have occurred. If an adverse event was observed, residents were further asked to categorize the event and also write a brief narrative, in order to identify any contributing factors or potential areas for intervention. Finally, residents were asked to rate the harm associated with the event (a Likert Scale). Residents were given up to 2 weeks after the conclusion of a 4-week period on inpatient wards to complete the surveys. Residents who completed at least 80 % of the surveys received a 50 dollar gift certificate. The acquisition of this data is the first step in a larger plan to develop and implement interventions for safer transitions of care. RRUCLA's enrollment and randomization into a 30-h call schedule as part of the iCOMPARE trial, taking effect July of 2015, provides a natural interruption to the current admissions system. We plan to survey adverse events in the new system and compare their frequency to our findings from the current study involving 16 h work days.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): A difference in adverse events observed between de novo admissions and handoff patients or between admissions experiencing single signout vs double signout was sought. A reduction in adverse events after a new admissions system is implemented will serve to evaluate the intervention.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): During the study period, there were 354 admissions to the inpatient medicine teaching service, with surveys reflecting all of these admissions sent to 17

residents. One hundred ninety-seven surveys on these admissions were completed, with a total response rate of 56 %. Of those surveys completed, 105 (53 %) were de novo admissions (either direct admissions or transfers from another service) and 92 (47 %) were handoffs. Overall, 13 (6.5 %) adverse events were observed. 7/105 (7 %) events were observed in the de novo group and 6/92 (7 %) were seen in the handoff group. Among the latter, there were 2/70 (2.9 %) events in the holdover admission group, with 3/9 (33.3 %) in the double signout group. Because of the small number of events, the confidence intervals for the differences between the proportions are wide; for example, for holdover vs. the double signout group it is 30.5 %; 95 % CI (-.5 %, 62 %). 5/7 (71 %) de novo adverse events were due to poor documentation (either by an outside hospital or transferring service). In contrast, 4/6 (67 %) handoff admissions experienced medical management errors. All three of the adverse events arising from admissions involving double signout (100 %) had true medical management problems.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Although adverse event rates were similar in the de novo admissions and handoff groups, medical management errors were more predominate in the handoff group, implying that those admissions are more likely to result in near misses and patient injury (similar to how night coverage has been shown to affect patient care). Importantly, medical management errors encompassed all of the adverse events in the double signout group. The large proportion of errors attributed to documentation (both in the de novo and handoff admissions) highlights the fact that transitions of care in general are an important risk factor for adverse events, making them an area for intervention.
