## ABSTRACT

**Introduction:** Apremilast is approved for the treatment of psoriasis and psoriatic arthritis. However, data on the efficacy and safety of apremilast in clinical practice are limited. We assessed the real-world use and effectiveness of apremilast in patients with moderate to severe plaque psoriasis visiting dermatologist practices

in Belgium, from the perspectives of the patient and the physician.

**Methods:** This prospective observational study enrolled adults aged 18 years or more initiating apremilast between 6 April 2017 and 30 June 2018, per Belgian reimbursement criteria. Primary outcome was the Patient Benefit Index for Skin Diseases (PBI-S). Secondary outcomes included the Patient Global Assessment (PtGA), Dermatology Life Quality Index (DLQI), Psoriasis Area and Severity Index (PASI), and body surface area (BSA). Patients were followed up for up to 18 months.

**Results:** Overall, 122 enrolled patients received at least one dose of apremilast, of which 89 received treatment for more than 150 days and were included in the reference population. Treatment goals most frequently identified (at least 70% of patients) as “very important” in the PBI-S were related to physical impairments. After 6 months of apremilast treatment, 61–78% of patients reported they had achieved these goals; only 12.5% assessed their disease as severe (PtGA, 53.6% at apremilast initiation) and over half reported a DLQI score of 5 or less, indicating improved quality of life. As assessed by the physician, 68.4% and 35.1% of patients achieved at least a 50% and 75% reduction in PASI, respectively, at month 6. Apremilast was well tolerated with no new safety signals identified.

**Conclusions:** Our real-world data indicate that apremilast fulfils the expectations of Belgian

patients with moderate to severe psoriasis, and from the perspectives of both the patient and physician, apremilast has a positive impact on their disease.

**Trial Registration:** ClinicalTrials.gov Identifier NCT03097003.

**Keywords:** Apremilast; Patient Benefit Index; Patient-reported outcomes; Psoriasis; Quality of life

### Key Summary Points

#### *Why carry out this study?*

Data on the real-world effectiveness and tolerability of apremilast for treatment of plaque psoriasis are limited.

This prospective observational study assessed the effectiveness and safety of apremilast for the treatment of moderate to severe psoriasis in Belgian clinical practice, from the perspectives of the patient and the physician.

#### *What was learned from the study?*

Using the Patient Benefit Index for Skin Diseases, patients identified treatment goals relating to physical impairment as most important and the majority of patients achieved these treatment goals following 6 months of apremilast treatment.

Apremilast improved patient-reported outcomes, including quality of life, psoriasis severity and treatment satisfaction, and was well tolerated with no new safety signals identified.

Our real-world data indicate that apremilast fulfils the expectations of Belgian patients with moderate to severe psoriasis, and from the perspectives of both the patient and physician, has a positive impact on their disease.

## INTRODUCTION

Psoriasis is an immune-mediated, progressive, proliferative and potentially debilitating inflammatory disease of the skin. In 2016, the World Health Organization reported that the prevalence of psoriasis worldwide ranges between 0.09% and 11.43% with more than 100 million individuals affected, making it a serious global issue [1]. In Europe, psoriasis affects 1–3% of the general population [1–4]. Plaque psoriasis is the most common type of psoriasis, and almost a third of patients with chronic disease have associated psoriatic arthritis [5]. While there are no validated diagnostic criteria, the clinical manifestation of psoriasis is characterised by sharply demarcated skin lesions that are typically covered with white or silvery scales and can cause itching, stinging and pain. Consequently, the impact of psoriasis on the quality of life (QoL) is significant, with substantial physical, emotional and social burden [6].

The aetiology of psoriasis is not fully understood despite evidence for genetic predisposition [7, 8]. Notably, the role of the immune system has received significant research interest in recent years, allowing development of treatments which target specific immunological aspects of the disease. One such treatment is apremilast, an orally administered systemic drug, which is approved in Europe for the treatment of immune-mediated inflammatory conditions: psoriasis, psoriatic arthritis and Behçet disease [9].

In psoriasis, apremilast is approved for the treatment of moderate to severe chronic plaque psoriasis in adult patients (at least 18 years of age) who fail to respond to, or have a contraindication for, or are intolerant to other systemic therapies including cyclosporine, methotrexate, or psoralen and ultraviolet A (PUVA) light. The recommended dose is 30 mg twice daily following an initial up-titration phase of 5 days administered orally, independent of meals [10].

The efficacy and safety of apremilast in treating patients with psoriasis was demonstrated in the phase III ESTEEM clinical trials [11, 12]. However, data on the use of apremilast in clinical practice are limited. The OTELO study was designed to describe the real-world use of apremilast for the treatment of moderate to severe plaque psoriasis in patients visiting dermatologist practices in Belgium, and to assess treatment effectiveness from the perspectives of both the patient and treating dermatologist.

## METHODS

### Patients

The OTELO study (NCT03097003) included patients aged 18 years or older, diagnosed with moderate to severe chronic plaque psoriasis (defined by a body surface area [BSA] > 10% or a Psoriasis Area and Severity Index [PASI] > 10) who had initiated apremilast treatment between 6 April 2017 and 30 June 2018 according to Belgian reimbursement criteria [13]. As per local reimbursement criteria, efficacy was assessed after 6 months; if the patient had achieved a reduction in PASI score of at least 50% (PASI 50), the treatment could be continued for another 12 months. Otherwise, the treatment was to be interrupted.

Patients allergic to apremilast or its excipients, those treated with apremilast for more than 4 weeks prior to enrolment, pregnant women, breastfeeding women or women not under adequate contraception were excluded. Written informed consent was obtained from all patients before enrolment into the study. The study protocol was approved by the medical ethics committee of UZ Leuven and was conducted in accordance with the International Council for Harmonisation of Technical Requirements for Pharmaceuticals for Human Use Guideline for Good Clinical Practice, the guiding principles of the Declaration of Helsinki and other applicable guidelines for non-interventional studies.

### Study Design

OTELO was a multicentre, prospective, observational study with data collected at routine (3-monthly) clinical visits; there were no mandatory study visits. Patient follow-up was between 6 and 18 months (i.e. at 6, 9, 12, 15 and 18 months after apremilast initiation).

### Study Objectives and Outcomes

The primary objective was to assess patient-reported treatment success 6 months after apremilast initiation using the validated Patient Benefit Index for Skin Diseases (PBI-S, standard version). Secondary objectives were to assess the effect of apremilast on patient's QoL using the Dermatology Life Quality Index (DLQI); assess the improvement in disease symptoms from the perspective of the patient, using the Patient Global Assessment (PtGA), and the physician, using the PASI and BSA; and to assess patient treatment satisfaction using the 9-item Treatment Satisfaction Questionnaire for Medication (TSQM-9).

The PBI-S questionnaire evaluates patient-defined benefits of dermatological therapies and consists of two parts [14–16]. The first part, the Patient Needs Questionnaire (PNQ), contains a list of 25 treatment goals and is completed by patients before treatment initiation. A five-step Likert scale (0 = “not important at all” to 4 = “very important”) records the relevance of each treatment goal to the patient. In the second part, the Patient Benefit Questionnaire (PBQ), patients evaluate the benefit of their treatment. The PBQ comprises the same items as the PNQ and patients evaluate the extent to which treatment needs have been fulfilled by the treatment (scaled from 0 = “treatment did not help at all” to 4 = “treatment helped a lot”). A preference-weighted global benefit score is then calculated for all items of the PNQ and PBQ, which can have a value from 0 = “no benefit” to 4 = “maximal benefit” [14, 17].

The DLQI is a validated questionnaire that measures the QoL across several health dimensions: symptoms and feelings (two items), daily activities (two items), leisure (two items), work

and school (one item), personal relationships (two items) and treatment (one item). Each item is graded on a Likert scale of 0 to 3, giving an overall score from 0 to 30, where lower scores indicate better QoL [18, 19].

The TSQM-9 questionnaire is a validated self-administered questionnaire that comprises nine items evaluating the patient's overall satisfaction with treatment. These nine items make up two specific scales (effectiveness, convenience) and one global satisfaction scale. Scale scores are transformed into scores from 0 to 100 with higher scores representing higher satisfaction in that domain [20, 21].

The PtGA asks patients to rate the severity of aspects of their disease on a scale from 0 (clear/no psoriasis) to 4 (severe) [22, 23].

PASI is a composite score grading the severity of psoriasis in four body regions according to erythema, scaling and thickness as well as the total area of skin affected. The final composite score ranges from 0 to 72, with a higher score indicating a greater severity of psoriasis [24, 25]. BSA measures the extent of body coverage by psoriasis [24]. Safety and tolerability of apremilast were assessed using the incidence of treatment-emergent adverse events (TEAEs), defined as adverse events that started or worsened within 6 days before the first dose of apremilast and up to 30 days after the last dose.

### Statistical Analysis

As a result of the observational design of the study, a formal sample size calculation was not performed. Enrolment was planned for approximately 250 patients, which was considered a meaningful cohort relative to the prescribed use of apremilast in Belgium. All analyses were descriptive. The safety analysis set (SAF) included all enrolled patients who had received at least one dose of apremilast and was used to analyse TEAEs. The reference analysis set (REF) included patients receiving at least 150 days of apremilast treatment and was used to analyse all other outcomes. Quantitative variables were described using mean, standard deviation (SD) and 95% confidence interval (where appropriate). Qualitative variables were

presented in terms of absolute frequency and percentage.

Measurements that were not performed or recorded were treated as missing data. For PBI-S, a treatment goal was regarded missing if the patient had not responded to the corresponding item in the PNQ and/or PBQ. If less than 25% of the treatment goals were missing for an individual, the global PBI score was calculated using the non-missing data. If more than 25% of the treatment goals were missing for an individual patient, the global PBI score was not calculated. Missing data were excluded from the summary of quantitative and qualitative variables. TEAEs were coded using the Medical Dictionary for Regulatory Activities (MedDRA) version 21.0.

## RESULTS

### Patient Characteristics

Overall, 124 patients were enrolled between 6 April 2017 and 20 December 2018. Of these, 122 had received at least one dose of apremilast and were included in the SAF; 89 had received apremilast for more than 150 days and were included in the REF. Mean (SD) follow-up was 8.7 (4.7) months; 5 (4.1%) patients had less than 6 months' follow-up (due to termination of the study). At month 6, over half (73/122 [59.8%]) of all patients in the SAF continued with apremilast therapy and one-third (44/122 [36.1%]) discontinued apremilast (insufficient effectiveness, 26/44 [59.1%]; TEAEs, 12/44 [27.3%]; intolerance, 3/44 [6.8%]); sufficient disease control, 1/44 [2.3%]; other, 2/44 [4.6%]).

Patient characteristics are summarised in Table 1. In general, patients included in the SAF and the REF were similar. Mean age was 53–54 years and mean body mass index was 28 kg/m<sup>2</sup>. Mean time since initial psoriasis diagnosis was 20 years with scalp psoriasis the most frequent disease manifestation (approximately 70% of patients), followed by nail psoriasis (39–42%) and palmoplantar psoriasis (approximately 25%). In the SAF, the most common comorbidities were hypercholesterolemia (38/122 [31.1%] patients),

cardiovascular disease (31/122 [25.4%]), with the majority suffering from hypertension) and depression (20/122 [16.4%]).

Most patients (120/122 [98.4%]) had received at least one prior treatment for psoriasis, most commonly systemic (106/122 [86.8%]), light (90/122 [73.8%]) and topical (69/122 [56.6%]) therapies. Few patients (15/122 [12.3%]) had received prior biologic therapy. Among patients with prior therapy, most patients were receiving systemics immediately prior to apremilast initiation (74/120 [61.7%]) and switched to apremilast because of insufficient effectiveness or intolerance (56/120 [46.7%; Fig. 1]).

## Patient Benefit Index for Skin Diseases

PBI-S scores are summarised in Fig. 2. The treatment goals most frequently identified in the PNQ as “very important” were related to physical impairments. Regaining control of the disease, being healed from all defects, getting better skin quickly, and being free of itching were identified as “very important” by more than 70% of patients. Confidence in therapy, finding a clear diagnosis and therapy, leading an everyday normal life, no longer having a burning sensation, and not fearing the disease will become worse were identified as “very important” by more than half of all patients; 47.6% of patients identified spending less time for daily treatment as “very important”. After 6 months of apremilast treatment, more than half of all patients with available data reported a positive response (“very”, “quite” or “moderate”) in the PBQ regarding achievement of the treatment goals which they had identified as “very important” (Fig. 2). The majority of patients with available data achieved an overall PBI-S  $\geq 1$  at months 3 and 6 [83.7% (36/43) and 92.3% (36/39), respectively], indicating a “minimum clinically relevant benefit” from apremilast.

## Dermatology Life Quality Index

DLQI scores are summarised in Fig. 3. Mean (SD) global DLQI score decreased from 11.2 (6.3) at apremilast initiation to 7.4 (6.2) and 5.8 (5.4) at months 3 and 6, respectively. The percentage of patients with a DLQI score of 5 or less increased from 18.8% (16/85) at apremilast initiation to 49.3% (35/71) and 58.5% (38/65) at months 3 and 6. Similarly, the percentage of patients with a DLQI score of 0 or 1 increased from 3.5% (3/85) to 16.9% (12/71) and 27.7% (18/65), respectively.

## Treatment Satisfaction Questionnaire for Medication

Among patients with data at month 6 (*n* = 64), mean (SD) TSQM-9 scores were 56.8 (25.4) for

**Fig. 1** Last psoriasis treatment before apremilast initiation and reasons for discontinuation (safety analysis set). PsO psoriasis

effectiveness, 75.9 (21.0) for convenience, and 54.7 (29.0) for global satisfaction.

**Patient Global Assessment**

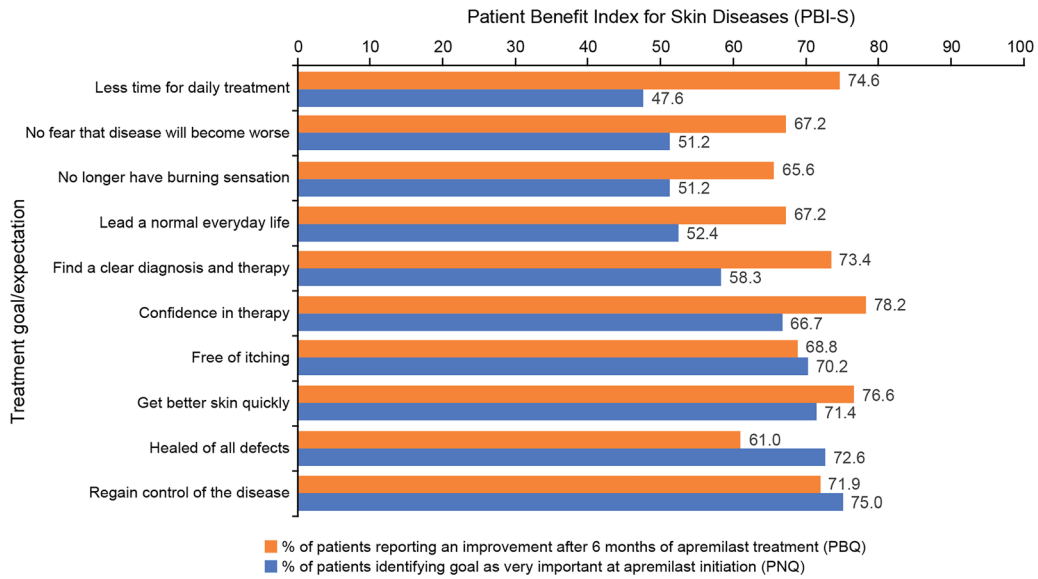

At apremilast initiation, over half of all patients with available data assessed their disease as “severe” (45/84 [53.6%]). At month 6, the majority of patients assessed their disease as “very mild” or “mild” (15/64 [23.4%] and 19/64 [29.7%]), and only 12.5% (8/64) assessed their disease as “severe” (Fig. 4).

**Disease Activity Scores**

PASI scores are summarised in Table 2. At apremilast initiation, mean (SD) PASI was 13.6

(6.8) and only one patient had a PASI score of 3 or less. Among patients with data at months 3 and 6, mean (SD) scores were 6.4 (6.5) and 6.8 (7.3), respectively, and 34.8% and 37.1% had a PASI score of 3 or less, respectively (Table 2). Most patients achieved a reduction of at least 50% (PASI 50) at months 3 and 6 (71.9% and 68.4%, respectively); 29.7% and 35.1% achieved at least a 75% reduction (PASI 75) at months 3 and 6, respectively.

BSA scores are summarised in Table 3. Mean (SD) BSA scores decreased from 14.5% (9.2) at apremilast initiation to 8.6% (10.7) and 8.7% (10.7) at months 3 and 6, respectively. The percentage of patients with a BSA score of at least 10% decreased from 84.9% at baseline to 27.3% and 32.1% at months 3 and 6, respectively.

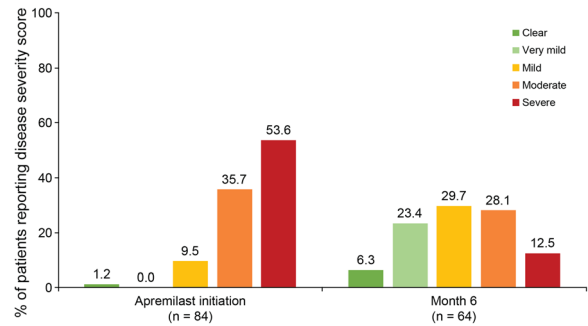

**Fig. 2** Patient Benefit Index for Skin Diseases (REF): the 10 treatment goals most commonly identified as “very important” at apremilast initiation (PNQ) and the percentage of patients reporting benefit on these goals at

month 6 (PBQ). Data are expressed as percentages. PBQ Patient Benefit Questionnaire, PNQ Patient Needs Questionnaire, REF reference analysis set

**Fig. 4** PtGA scores at apremilast initiation and months 3 and 6 (REF). PtGA Patient Global Assessment, REF reference analysis set

**Safety**

A total of 51 (41.8%) patients in the SAF (N = 122) reported at least one treatment-related TEAE, the most frequently reported being gastrointestinal disorders (36/122 [29.5%] patients; specifically, diarrhoea, 26 [21.3%], nausea 11 [9.0%]), followed by nervous system disorders (11 [9.0%] patients), psychiatric disorders (10 [8.2%] patients), general disorders and administrative site conditions (9 [7.4%])

tissue disorders (3 [2.5%] patients; Table 4). The majority of the treatment-related events of diarrhoea and headache occurred in the 6 days before or 1 week after apremilast initiation (diarrhoea, 13/26 [50.0%] and 9/26 [34.6%], respectively; headache, 1/9 [11.1%] and 5/9 [55.6%], respectively). The majority of treatment-related TEAEs were assessed as mild or moderate, except for erythema and facial oedema (1 [0.8%] patient, each), two events of diarrhoea (2 [1.6%]), one event of gastritis and one of nausea (1 [0.8%] each) which were assessed as severe. Most of these events led to apremilast discontinuation or withdrawal; the event of gastritis led to a dose reduction and dose was not modified for one event of diarrhoea. Two psychiatric disorder events, depression and suicidal ideation (1 [0.8%] patient each), were assessed as serious and severe, and led to apremilast withdrawal.

Other serious TEAEs observed during the study but assessed as not related to apremilast were erysipelas, septic shock (resulting in death), urinary tract infection, unstable angina, head injury and diabetes mellitus (reported for 1 [0.8%] patient each).

## DISCUSSION

Data regarding the effectiveness and tolerability of apremilast for the treatment of moderate to

severe plaque psoriasis in clinical practice are limited. The OTELO study was designed to assess this from the perspectives of both the patient and the treating dermatologist.

In clinical trials, efficacy is typically assessed by the physician, using clinical scores or questionnaires, which provide a general clinical impression. PASI is the most frequently used score to assess the efficacy of psoriasis treatment over time [24–26] and is part of the eligibility criteria for apremilast reimbursement in Belgium. However, several studies on skin disease suggest the physicians' and patients' assessments of the effectiveness of treatment can differ markedly and that patients themselves are more reliable in assessing treatment benefits [27]. The PBI-S was developed to evaluate patient-defined benefits of dermatological therapies [14–17]. We used the PBI-S as the primary outcome in our study to evaluate the patient's perception of the effectiveness of apremilast after 6 months of treatment. To complement the PBI-S, we evaluated patient QoL using the DLQI questionnaire, patient treatment satisfaction using the TSQM-9 questionnaire and patient-reported disease severity using the PtGA questionnaire.

The PBI-S questionnaire identified a clear trend in patients' treatment expectations, with the majority of patients identifying items relating to physical impairments as the most important. The benefits of apremilast treatment were apparent at 6 months, with more than half of patients reporting satisfactory progress against these expectations. The DLQI, TSQM-9 and PtGA scores showed a similar trend, with patients reporting improvement in their QoL and disease severity, and satisfaction with apremilast treatment. From a patient's perspective, these results indicate that use of apremilast for the treatment of psoriasis was linked to improvement in all QoL indicators assessed in this study, with a reduction in the physical, social and psychological impacts of the disease. These findings were also reflected in the PASI and BSA scores, which assess disease symptoms from the physician's perspective. A reduction in PASI was seen after 3 months of apremilast treatment and was maintained after 6 months. Correspondingly, the number of patients

achieving PASI 50 and PASI 75 increased on apremilast treatment.

Our results for the PASI scores are consistent with those observed in the phase III ESTEEM 1 and 2 and in the phase IIIb LIBERATE studies [11, 12, 28, 29]. In these studies, the percentage of patients achieving PASI 75 at 4 months after treatment initiation was 28.8% (ESTEEM 2) and 39.8% (LIBERATE), similar to the 29.7% we observed at month 3. Furthermore, our results for PBI-S are in line with interim results from the observational APPRECIATE study [30], in which the majority of patients (76–84%, depending on the item) reported an improvement of the identified primary needs after 6 months of treatment with apremilast.

Diarrhoea, nausea, and headache were the most common treatment-related adverse events reported in our study. Most treatment-related events of diarrhoea and headache occurred in the 6 days prior to or the week after apremilast initiation. Most of these AEs were mild in severity and generally resolved within 1 month, which was in line with previous studies on apremilast [11, 12, 28]. Overall, the TEAEs observed in the OTELO study were aligned with the known safety profile of apremilast [10]; most treatment-related adverse events were mild or moderate and no new safety signals were observed.

The key strength of OTELO is that it provides insights into the impact of apremilast treatment among patients with moderate to severe psoriasis in a real-world setting. However, the following limitations should be considered while interpreting the findings of this observational study: the sample size was small, especially after month 9 as a result of study termination; the percentage of missing data increased over time (with data missing for approximately 50% of patients by month 3); the study focused on patient-reported outcomes (PBI-S, DLQI, TSQM-9 and PtGA) and few clinical outcome measures were assessed; while the patients' evaluation of their disease progression is becoming ever more significant in clinical trials, they are subjective and most likely lead to large inter-individual variability in the observed data. Therefore, the data should be interpreted with caution.

## CONCLUSIONS

Our data demonstrate the real-life effectiveness and tolerability of apremilast for the treatment of moderate to severe plaque psoriasis in Belgian clinical practice. Apremilast improved quality of life, disease activity measures, patient benefits and treatment satisfaction, and was well tolerated with no new safety signals.

## ACKNOWLEDGEMENTS

We thank all the patients who participated in the OTELO study, as well as the investigators from each study centre and their collaborators.

**Funding.** This study was funded by Celgene. Amgen acquired the worldwide rights to Otezla<sup>®</sup> (apremilast) on November 21, 2019. Amgen funded the journal's rapid service and open access fees.

**Medical Writing and Editorial Assistance.** Roberta Farina and Pavlos Alifragkis from Keyrus Life Science, funded by Amgen, provided support for data management, statistical analysis, the writing of OTELO protocol and study report and medical writing support for this manuscript. Claire Desborough, an Amgen employee, provided editorial support for this manuscript.

**Authorship.** All named authors meet the International Committee of Medical Journal Editors (ICMJE) criteria for authorship for this article, take responsibility for the integrity of the work as a whole, and have given their approval for this version to be published.

**Author Contributions.** Conceptualization: Jo Lambert, Michel de la Brassinne, Pierre-Dominique Ghislain, and Siegfried Segært. Methodology: Jo Lambert, Michel de la Brassinne, Pierre-Dominique Ghislain, and Siegfried Segært. Formal analysis and investigation: Jo Lambert, Michel de la Brassinne, Pierre-Dominique Ghislain, Pierre-Paul Roquet-Gravy, Siegfried Segært, Tom Hillary, Xuân-Lan Lam

Hoai. Writing—review and editing: Jo Lambert, Michel de la Brassinne, Pierre-Dominique Ghislain, Pierre-Paul Roquet-Gravy, Siegfried Segært, Tom Hillary, Xuān-Lan Lam Hoai.

**Disclosures.** Dr. Pierre-Dominique Ghislain has received speaker and investigator fees or grants from AbbVie, Almirall, Amgen, BMS, Eli Lilly, Flen, Galderma, Janssen, LEO Pharma, Maruho, Meda, Menarini, MSD, Novartis, PellePharm, Pfizer, Serono, UCB and Viatrix. Dr. Tom Hillary received grants or fees for consultancy, speaker fees, support for travel from AbbVie, Almirall, Amgen, Biogen, Celgene, Janssen, Leo, Eli Lilly, Novartis, Pfizer, Roche, Sandoz, Sanofi and UCB. Dr. Pierre-Paul Roquet-Gravy has been an investigator, speaker, advisory board member, and consultant for AbbVie, Bioderma, Boehringer Ingelheim, Galderma, GSK, Janssen, LEO Pharma, Merck, MSD, Novartis, Pfizer, Regeneron Pharmaceuticals and Sanofi Genzyme. Prof. Dr. Michel de la Brassinne has received lecture and/or consultation fees and/or travel reimbursement from AbbVie, Almirall, Amgen, Celgene, Eli Lilly, Galderma, Janssen, LEO Pharma, Novartis, Pfizer, UCB and Viatrix. Prof. Dr. Siegfried Segært has received speaker or consultation fees from AbbVie, Almirall, Amgen, Biogen, Boehringer Ingelheim, Celgene, Eli Lilly, Galderma, Glenmark, Janssen, LEO Pharma, Merck Serono, MSD, Novartis, Pierre Fabre, Pfizer, Roche, Sun Pharma and UCB. Prof. Dr. Jo Lambert and Dr. Xuān-Lan Lam Hoai have no conflicts to disclose.

**Compliance with Ethical Guidelines.** The study protocol was approved by the medical ethics committee of UZ Leuven and was conducted in accordance with the International Council for Harmonisation of Technical Requirements for Pharmaceuticals for Human Use Guideline for Good Clinical Practice, the guiding principles of the Declaration of Helsinki 1964, and its later amendments. Informed consent was obtained from all the subjects participating in this study.

**Data Availability.** The datasets generated during and/or analysed during the current

study are available from the corresponding author on reasonable request. Qualified researchers may request data from Amgen clinical studies. Complete details are available at the following: <https://www.amgen.com/science/clinical-trials/clinical-data-transparency-practices/clinical-trial-data-sharing-request>.
