CASE REPORT

Successful Treatment of Disseminated Granuloma Annulare with Upadacitinib

ABSTRACT

Disseminated granuloma annulare (DGA) is an inflammatory skin disorder characterized by more than 10 erythematous, raised, ring-shaped plaques. Its treatment remains challenging, with conventional therapies showing variable efficacy. We report the case of a woman in her 50s with a 2-year history of DGA refractory to multiple treatments. Given the recent evidence of the role of the Janus kinase-signal transducer and activator of transcription (JAK-STAT) pathway in the granuloma annulare pathophysiology, treatment with upadacitinib 30 mg per day was started with rapid effectiveness and good tolerance. This case underscores the potential of JAK inhibitors as promising therapeutic options for recalcitrant granuloma annulare.

Key Summary Points

The role of the Janus kinase-signal transducer and activator of transcription (JAK-STAT) pathway in the pathophysiology of granulomatous skin diseases pathophysiology has recently been reported.

Treatment with upadacitinib 30 mg per day was rapidly effective and well tolerated in a female patient in her 50s, with recalcitrant disseminated granuloma annulare.

Safety profile was reassuring; induced lipid changes were easily managed.

Keywords: Granuloma annulare; JAK inhibitor; Upadacitinib; Effectiveness; Tolerance

INTRODUCTION

Granuloma annulare (GA) is an inflammatory skin disease characterized by erythematous, raised, ring-shaped plaques, which may be localized or disseminated (DGA) when defined by at least 10 plaques [1]. Association with diseases such as diabetes, hyperlipidemia, autoimmune thyroiditis, or hepatitis C remain uncertain [2]. Genetic predisposition (e.g., HLA-B35) has been observed in rare cases of familial

occurrences of GA [3]. Treatment can be difficult and challenging, particularly in diffuse and generalized forms. Various conventional treatments (systemic corticosteroids, phototherapy, antimalarials, dapsone, etc.) have been proposed on the basis of case reports or clinical experience, with variable effectiveness [4]. However, to date, there is no evidence-based treatment. The potential effect of biological agents on DGA is still unclear; remission and induction of GA have been reported with tumor necrosis factor alpha (TNFα) inhibitors or anti-interleukin (IL)-17 [5].

CASE

We report the case of a woman in her 50s who presented to our dermatology consultation with a 2-year history of DGA. The patient was otherwise healthy, her past medical history included livedoid vasculopathy (currently in remission). Initial diagnosis of DGA had been confirmed by skin biopsy and previous treatments—including topical corticosteroids, hydroxychloroquine (200–400 mg/day for 1.5 years), doxycycline (200 mg/day for 2 months), methotrexate (12.5 mg/week for 2 months), and vitamin E—had all yielded poor response. The patient reported no systemic symptoms. Clinical examination revealed numerous large and extended ring-shaped plaques on both legs, upper limbs, hands, and feet (Fig. 1). Laboratory workup (including C-reactive protein, complete blood count, renal and hepatic functions, lactate dehydrogenase, fasting plasma glucose, hepatitis, and HIV serologies) was normal. Given the recalcitrant and extensive nature of the lesions, and the recent evidence of the role of the Janus kinase-signal transducer and activator of transcription (JAK-STAT) pathway in the GA pathophysiology [6], treatment with upadacitinib 30 mg per day was started (the patient provided written informed consent after discussion of the risk–benefit balance and possible adverse effects). At follow-up visit 2 months later, lesions had almost all disappeared (Fig. 2A, B) and complete remission was achieved after 6 months (Fig. 2C, D). Upadacitinib was well tolerated; an increase of total cholesterol (233 mg/dL; normal value < 190 mg/dL) and LDL-cholesterol (135 mg/dL; normal value < 115 mg/dL) was controlled with atorvastatin 20 mg daily. Treatment was stopped after a total of 10 months, with no disease recurrence at the 2-month follow-up visit.

DISCUSSION

Evidence of the involvement of T helper (Th)1/Th2 cytokines and innate immunity (IL-1β, IL-6, TNFα) in the activation of the JAK-STAT pathway and thereby, in GA pathogenesis, has opened the way to new therapeutic options, especially for recalcitrant cases [6, 7]. Few cases of patients with DGA treated orally with tofacitinib (oral JAK1/3 inhibitor) [8], baricitinib (oral JAK1/2 inhibitor) [9, 10], and only two patients with upadacitinib (oral JAK1 inhibitor) have been reported [11, 12]. In the last two cases, a 15 mg daily dosage of upadacitinib led to an almost complete regression of the disease respectively after 1 month [11] and 4 months [12]. No information about safety/tolerance was provided. Despite having treated our patient with a higher dosage of 30 mg daily, the treatment was well tolerated inducing only easily controlled lipid changes. Although our clinical observation is limited to a single clinical case, it contributes to the growing literature in this area. The close therapeutic responses between our case and the two previous reported cases suggest that the use of the 15 mg dose could be just as effective, with fewer risks of side effects.

CONCLUSION

This observation, in line with other rare cases reported in the literature, is very encouraging for the rapid effectiveness and good tolerance of JAK inhibitors, and in particular upadacitinib, in the treatment of recalcitrant DGA. Larger cohort studies or clinical trials are warranted to confirm these findings.

ACKNOWLEDGEMENTS

We thank the patient for participating in this study.

Medical Writing/Editorial Assistance. We thank Dr. Mariana Andrade, M.D., (Andrade-Evrard SRL) who provided editorial assistance. Fees were funded by the authors.

Author Contributions. Axel De Greef: Conceptualization, Methodology, Validation, Formal analysis, Investigation, Resources, Data Curation, Writing—Original Draft, Visualization; Ghita Benjelloun; Conceptualization, Methodology, Validation, Formal analysis, Investigation, Resources, Data Curation, Writing—Original Draft, Visualization; Evelyne Harkemanne: Conceptualization, Investigation; Marie Baeck: Conceptualization, Methodology, Validation, Formal analysis, Investigation, Resources, Data Curation, Writing—Review & Editing, Supervision.

Funding. No funding or sponsorship was received for this case report or publication of this article. The Rapid Service Fee was funded by the authors.

Data Availability. The datasets generated during and/or analysed during the current study are available from the corresponding author on reasonable request.

Declarations

Conflict of Interest. Marie Baeck discloses her past participation on the upadacitinib advisory boards organized by AbbVie. Axel De Greef and Marie Baeck have previously participated as speakers in events sponsored by AbbVie. Ghita Benjelloun and Evelyne Harkemanne disclose no conflict of interest. All the authors declare that the current study was conducted in an independent manner.

Ethics Approval. This case report and data collection were conducted with the approval of the hospital and faculty institutional review board (Commission d'Ethique Biomédicale Hospitalo-Facultaire) of Université catholique de Louvain (UCLouvain), Belgium. All procedures in this study were in accordance with the 1964 Helsinki declaration (and its amendments). The patient in this manuscript has given written informed consent to participate and for publication of her case details.
