Abstract: This study investigates the bulk density, sintering behaviour, and microwave dielectric properties of the $\text{MgO-2B}_2\text{O}_3$ series ceramics synthesised by solid-state reaction. According to the X-ray diffraction and microstructural analyses, the as-prepared $\text{MgO-2B}_2\text{O}_3$ ceramics possess a single-phase structure with a rod-like morphology. The effects of different quantities of H_3BO_3 and $\text{BaCu(B}_2\text{O}_5\text{)}$ (BCB) on the bulk density, sintering behaviour, and microwave dielectric properties of the $\text{MgO-2B}_2\text{O}_3$ ceramics were investigated. Accordingly, the optimal sintering temperature was obtained by adding 30 wt% H_3BO_3 and 8 wt% BCB. We also reduced the sintering temperature to 825 °C. Furthermore, the addition of 40 wt% H_3BO_3 and 4 wt% BCB increased the quality factor, permittivity, and temperature coefficient of resonance frequency of $\text{MgO-2B}_2\text{O}_3$ to 44,306 GHz (at 15 GHz), 5.1, and $-32 \text{ ppm/}^\circ\text{C}$, respectively. These properties make $\text{MgO-2B}_2\text{O}_3$ a viable low-temperature co-fired ceramic with broad applications in microwave dielectrics.

Keywords: low-temperature co-fired ceramics (LTCC); sintering temperature; $\text{MgO-2B}_2\text{O}_3$; H_3BO_3 ; microwave dielectrics; temperature coefficient of resonance frequency

1 Introduction

Low-temperature co-fired ceramics (LTCC) are widely used in the wireless communication and broadcasting industries as raw materials for manufacturing electronic components, owing to their low manufacturing cost, short development cycle, and potential for the miniaturisation of electronic devices [1–4]. However, most high $Q \times f$ dielectric materials are manufactured at high sintering temperatures, which hinder their incorporation with low melting-point electrodes and

polymer-based substrates and lead to excess energy consumption and evaporation of volatile components. For practical application, LTCC requires excellent microwave dielectric properties, low sintering temperature, and adequate co-fire matching between ceramics and electrodes [5–10]. Materials with low melting points are often added to LTCC to reduce the required firing temperatures. However, this approach weakens the microwave dielectric properties.

$\text{MgO-B}_2\text{O}_3$ ceramics have drawn research interest because of its potential applications in LTCC devices. Davis and Knight [11] systematically reported the chemistry of $\text{MgO-B}_2\text{O}_3$ binary systems, i.e., $\text{MgO-B}_2\text{O}_3$, $\text{MgO-1/2B}_2\text{O}_3$, and $\text{MgO-1/3B}_2\text{O}_3$. Nishizuka *et al.* [12] demonstrated that the $\text{MgO-xB}_2\text{O}_3$ ($x = 25$ and 33)

sintered at low temperatures exhibited remarkable dielectric properties with a permittivity (ϵ_r) of approximately 7 and quality factors ($Q \times f$) of 79,100–260,100 GHz ($x = 33$) and 39,600–310,000 GHz ($x = 25$). Peng *et al.*, [13,14] reported the synthesis of $0.8\text{Zn}_3\text{B}_2\text{O}_6 + 0.2\text{Mg}_3\text{B}_2\text{O}_6$ composite ceramics for LTCC applications and obtained excellent dielectric properties at 950 °C sintering with a ϵ_r of 6.47, $Q \times f$ of 89,600 GHz, and temperature coefficient of resonance frequency (τ_f) of approximately 48.6 ppm/°C.

In addition, optimized $\text{Zn}_3\text{B}_2\text{O}_6$ ceramics using Ni^{2+} instead of Zn^{2+} were reported with strong dielectric properties at 900 °C with a ϵ_r of 6.9, $Q \times f$ of 91,000 GHz, and τ_f of approximately 55.6 ppm/°C. Peng *et al.* [15] reported $\text{Li}_2(\text{Mg}_{1-x}\text{Ni}_x)\text{SiO}_4$ ceramics with the addition of 2 wt% lithium–boron–bismuth–silicon (LBBS) glass and realised excellent dielectric properties at 900 °C (sintering) and microwave dielectric properties. Fan *et al.* [16] reported optimal microwave dielectric properties at a sintering temperature as low as 1100 °C with a molecular ratio of $\text{MgO} : \text{B}_2\text{O}_3 = 1 : 1$. The resulting ceramics demonstrated strong microwave dielectric properties with a ϵ_r of 5.83, $Q \times f$ of 41,930 GHz, and τ_f of approximately 62 ppm/°C. According to Zhou *et al.* [17], $\text{MgO}-2\text{B}_2\text{O}_3-4\text{wt}\%\text{BaCu}(\text{B}_2\text{O}_5)$ ceramics possess appropriate microwave dielectric properties, showing promise in LTCC applications.

However, the microwave dielectric properties of B_2O_3 -rich ceramics in a $\text{MgO}-\text{B}_2\text{O}_3$ binary system (e.g., $\text{MgO}-2\text{B}_2\text{O}_3$ and $\text{MgO}-\text{B}_2\text{O}_3$) have not been investigated in detail. In addition, the sintering temperature of $\text{MgO}-2\text{B}_2\text{O}_3$ ceramics remains considerably high for LTCC devices [18]. Sintering additives [19–29], ultrafine powders [30–34], and low-sintering-temperature materials [35–37] can be used to reduce the sintering temperature of ceramics. However, the preparation of ultrafine powder with low intrinsic sintering temperatures is expensive, complex, and difficult to expand for commercialisation. Glass exhibits much lower $Q \times f$ value than pure microwave dielectric ceramics [38]. Therefore, when microwave ceramics are doped with glass, the quality factor decreases [1,39]. $\text{BaCu}(\text{B}_2\text{O}_5)$ (BCB) has a low melting temperature, adequate wettability, and strong microwave dielectric properties. Therefore, its addition for sintering will contribute to the densification of $\text{Mg}_3\text{B}_2\text{O}_6$ ceramics [24,40]. Furthermore, researchers effectively reduced the sintering temperature of MgO by adding the appropriate amount of sintering materials [37], such as

B_2O_3 , H_3BO_3 , and BCB. However, the microwave dielectric properties of $\text{MgO}-2\text{B}_2\text{O}_3-x\text{wt}\%\text{BCB}-y\text{wt}\%\text{H}_3\text{BO}_3$ ceramics have not been investigated systematically, which is the objective of this research.

2 Experimental

$\text{MgO}-2\text{B}_2\text{O}_3-x\text{wt}\%\text{BCB}-y\text{wt}\%\text{H}_3\text{BO}_3$ ceramics were prepared using solid-state reaction method. MgO ($\geq 98.5\%$), H_3BO_3 ($\geq 99\%$), $\text{Ba}(\text{HO})_2 \cdot 8\text{H}_2\text{O}$ ($\geq 99\%$), and CuO ($\geq 99\%$) were acquired from Guo-Yao Co., Ltd., Shanghai, China. MgO powder was pre-calcined at 800 °C for 2 h. The raw materials were weighed according to the molar ratio of $\text{MgO} : \text{B}_2\text{O}_3 = 1 : 2$. The powders were mixed thoroughly in a nylon jar before ball milling for 4 h. Then, the dried powder mixture was calcined at 800 °C for 4 h. H_3BO_3 and BCB with different mass ratios were added to the calcined powder. The mixture of H_3BO_3 , BCB, and calcined powder was re-milled for 4 h and pressed into the form of cylinder with a diameter of 10 mm and a height of 4–5 mm, under a uniaxial pressure of 100 MPa. Pellets were fired at 550 °C for 4 h to eliminate polyvinyl alcohol (PVA). Subsequently, the samples were sintered for 4 h at 750–975 °C in air.

Archimedes' principle was employed to measure the bulk density. X-ray diffractometer (X'PERT PRO, PANalytical, Almelo, the Netherlands), equipped with $\text{Cu K}\alpha$ radiation instrument ($\lambda = 0.15406$ nm), was used for the structural analysis. Scanning electron microscope (SEM; JSM-6380LV, JEOL, Tokyo, Japan) was used to observe the microstructure of the as-fired surfaces. A 300 kHz–20 GHz network analyzer (E5071C, Agilent Co., CA, USA) was used to measure the microwave dielectric properties. The τ_f values were calculated in the temperature range of 25–85 °C using the following expression:

$$\tau_f = \frac{f_T - f_{T_0}}{f_{T_0}(T - T_0)} \times 10^6 \quad (1)$$

where f_T and f_{T_0} represent the resonant frequencies at 85 °C (T) and 25 °C (T_0), respectively.

3 Results and discussion

Figure 1 illustrates the XRD profiles of $\text{MgO}-2\text{B}_2\text{O}_3-x\text{wt}\%\text{BCB}-10\text{wt}\%\text{H}_3\text{BO}_3$ ($x = 2, 4, 6$, and 8) ceramics sintered at their optimal temperatures. The XRD

Fig. 1 XRD patterns of $\text{MgO-2B}_2\text{O}_3\text{-}x\text{wt}\%\text{BCB-10wt}\%\text{H}_3\text{BO}_3$ ($x = 2, 4, 6$, and 8) ceramics sintered at their optimal temperatures: (a) $x = 2$, 950°C , (b) $x = 4$, 925°C , (c) $x = 6$, 850°C , and (d) $x = 8$, 825°C .

patterns were indexed as MgB_4O_7 (JCPDS Card No. 00-031-0787), indicating that the addition of H_3BO_3 and BCB had no effect on the phase structure of the ceramics.

Figures 2(a)–2(d) illustrate the SEM images of the $\text{MgO-2B}_2\text{O}_3\text{-}x\text{wt}\%\text{BCB-10wt}\%\text{H}_3\text{BO}_3$ ($x = 2, 4, 6$, and 8) ceramics sintered at optimal temperatures. The $\text{MgO-2B}_2\text{O}_3$ crystals possess a rod-like shape and are refined with the increase in the BCB content. As the BCB content increased to $8\text{ wt}\%$, the $\text{MgO-2B}_2\text{O}_3$ crystals exhibited a glassy phase. Moreover, the porosity increased with the increase in BCB content. When $x = 4$, two grains of the $\text{MgO-2B}_2\text{O}_3\text{-}x\text{wt}\%\text{BCB-10wt}\%\text{H}_3\text{BO}_3$ ceramics with the optimal sintering temperature of

925°C were selected for the energy dispersive X-ray spectroscopy (EDS) test. Table 1 lists the results of this test. The grains in region I consist of Mg, B, O, Cu, and Ba in the molar ratio of $\text{Mg} : \text{B} : \text{O} = 29.78 : 17.14 : 52.28$. Therefore, the compositions of the grains in regions I and II are $\text{MgB}_{0.58}\text{O}_{1.8}$ and MgB_4O_7 , respectively.

Figure 3 depicts the bulk density, ϵ_r , $Q \times f$, and τ_f of the $\text{MgO-2B}_2\text{O}_3\text{-}x\text{wt}\%\text{BCB-10wt}\%\text{H}_3\text{BO}_3$ ($x = 2, 4, 6$, and 8) ceramics sintered at different temperatures. As the sintering temperature increased, the bulk density initially increased, indicating that the samples became denser, and then decreased slightly (Fig. 3(d)). Subsequently, the increase in porosity of the samples owing to the high sintering temperature decreased the bulk density. The bulk density change remains consistent with the appearance of porosity, as shown in Figs. 2(a)–2(d).

When sintering temperature was increased from 900 to 950°C , the $Q \times f$ of the $\text{MgO-2B}_2\text{O}_3\text{-}2\text{wt}\%\text{BCB-10wt}\%\text{H}_3\text{BO}_3$ ceramics increased from $25,408$ to $33,951\text{ GHz}$, highlighting a change in porosity with a change in the sintering temperature. The minimum porosity was obtained at 900°C . However, with the further increase in the sintering temperature, the $Q \times f$ of the $\text{MgO-2B}_2\text{O}_3\text{-}2\text{wt}\%\text{BCB-10wt}\%\text{H}_3\text{BO}_3$ ceramics decreased to $32,541\text{ GHz}$ due to over-firing. The $Q \times f$ of $\text{MgO-2B}_2\text{O}_3\text{-}x\text{wt}\%\text{BCB-10wt}\%\text{H}_3\text{BO}_3$ ($x = 2, 4, 6$, and 8) ceramics first increased and then decreased with the increase in sintering temperatures.

Fig. 2 SEM images of $\text{MgO-2B}_2\text{O}_3\text{-}x\text{wt}\%\text{BCB-10wt}\%\text{H}_3\text{BO}_3$ ceramics sintered at their optimal temperatures for 4 h : (a) $x = 2$, 950°C , (b) $x = 4$, 925°C , (c) $x = 6$, 850°C , and (d) $x = 8$, 825°C .

Table 1 EDS results of MgO–2B₂O₃–4wt%BCB–10wt%H₃BO₃ ceramics

Spot	Atom element (%)				
	Mg (K)	B (K)	O (K)	Cu (K)	Ba (K)
I	29.78	17.14	52.28	0.68	0.13
II	12.28	39.62	47.74	0.21	0.15

Fig. 3 Variation in bulk density, ϵ_r , $Q \times f$, and τ_f values of MgO–2B₂O₃– x wt%BCB–10wt%H₃BO₃ ($x = 2, 4, 6$, and 8) ceramics after sintering at different temperatures.

The optimal sintering temperature decreased from 950 to 850 °C when BCB content increased from 2 to 8 wt%. The $Q \times f$ reached a maximum of 40,076 GHz at 4 wt% BCB, indicating that the addition of the appropriate amount of BCB reduced the sintering temperature and improved the $Q \times f$ of the MgO–2B₂O₃–10wt%H₃BO₃ ceramics.

Figure 3(b) illustrates the change in ϵ_r of the MgO–2B₂O₃– x wt%BCB–10wt%H₃BO₃ ($x = 2, 4, 6$, and 8) ceramics at different temperatures. The ϵ_r of ceramics with 6 and 8 wt% BCB increased with the increase in the sintering temperature, whereas that of ceramics with 2 and 4 wt% BCB decreased, indicating that the addition of BCB had a significant effect on the ϵ_r of the MgO–2B₂O₃ ceramics.

Figure 3(c) presents τ_f at different sintering temperatures, which exhibits a trend similar to that of $Q \times f$. The τ_f of the MgO–2B₂O₃–2wt%BCB–10wt%H₃BO₃ ceramic was –40 ppm/°C at a sintering temperature of 925 °C. It initially increased with the increase in the sintering temperature and then decreased marginally. Therefore, τ_f is affected by the chemical additives and composition of the ceramic

[37,41]. Notably, the τ_f of the MgO–2B₂O₃– x wt%BCB–10wt%H₃BO₃ ceramics demonstrated an overall decreasing trend with increasing BCB content. Additionally, the sintering temperature decreased with the increase in the BCB content, demonstrating its ability as a sintering aid. The optimal ceramic properties with a bulk density of 2.409 g/cm³, $Q \times f$ of 40,076 GHz, and ϵ_r of –40 ppm/°C were obtained at 4 wt% BCB and a sintering temperature of 925 °C.

Figure 4 presents the room-temperature XRD profiles of the MgO–2B₂O₃–4wt%BCB– y wt%H₃BO₃ ($10 \leq y \leq 40$) ceramics sintered at their optimal temperatures. The results showed that the MgO–2B₂O₃–4wt%BCB– y wt%H₃BO₃ ($10 \leq y \leq 40$) ceramics were crystallised in the orthorhombic space group *Pbca* without impurity phases, indicating that the addition of H₃BO₃ had no negative effect on the phase structure of the ceramics.

Figure 5 presents the SEM images of the MgO–2B₂O₃–4wt%BCB– y wt%H₃BO₃ ($10 \leq y \leq 40$) ceramics sintered at their optimal temperatures. A distinct microstructure was observed for the ceramics with different H₃BO₃ contents. With the increase in the H₃BO₃ content, the MgO–2B₂O₃–4wt%BCB– y wt%H₃BO₃ ceramics achieved denser, more homogeneous microstructures. However, at 40 wt% H₃BO₃, a mild over-burning was observed owing to the presence of excessive sintering aid, resulting in an abnormal grain growth, as shown in Fig. 5(d). The EDS test of MgO–2B₂O₃–4wt%BCB– y wt%H₃BO₃ ceramic as $y = 40$ sintered at 900 °C was carried out to identify the

Fig. 4 XRD patterns of the MgO–2B₂O₃–4wt%BCB– y wt%H₃BO₃ ($10 \leq y \leq 40$) ceramics sintered at different temperature: (a) $y = 10$, 925 °C, (b) $y = 20$, 900 °C, (c) $y = 30$, 900 °C, and (d) $y = 40$, 900 °C.

Fig. 5 SEM images of MgO–2B₂O₃–4wt%BCB–*y*wt%H₃BO₃ (*y* = 10, 20, 30, and 40) ceramics sintered at their optimal temperatures: (a) *y* = 10, 925 °C, (b) *y* = 20, 900 °C, (c) *y* = 30, 900 °C, and (d) *y* = 40, 900 °C.

composition, as shown in Table 2. Owing to the low instrumental precision, the Mg : B : O molar ratios of regions III, IV, and V were 10.85 : 41.05 : 47.75, 15.71 : 33.81 : 50.28, and 15.87 : 30.43 : 53.62, respectively. In addition, as the molar ratio of Cu and Ba in region III was approximately 1 : 1, the grain composition of this region contains MgB₄O₇ and BCB. The grains in regions IV and V can be considered as MgB_{2.2}O_{3.2} and MgB_{1.9}O_{3.2}, respectively. This confirms the results of the MgB₄O₇ phase formation.

Figure 6 illustrates the bulk density, ϵ_r , $Q \times f$, and τ_r of the MgO–2B₂O₃–4wt%BCB–*y*wt%H₃BO₃ ceramics at different sintering temperatures. The bulk density of the ceramics initially increased and then slightly decreased with the increase in the H₃BO₃ content, except for those with 10 wt% H₃BO₃. The maximum bulk density of MgO–2B₂O₃–4wt%BCB–*y*wt%H₃BO₃ with 10 wt% H₃BO₃ was obtained at a sintering temperature of 925 °C. However, when H₃BO₃ increased to 20–40 wt%, the maximum bulk density was obtained at 900 °C, indicating that the addition of H₃BO₃ as a sintering aid reduced the sintering temperature of the ceramics.

Table 2 EDS results of MgO–2B₂O₃–4wt%BCB–40wt%H₃BO₃ ceramics

Spot	Atom element (%)				
	Mg (K)	B (K)	O (K)	Cu (K)	Ba (K)
III	10.85	41.05	47.75	0.16	0.18
IV	15.71	33.81	50.28	0.19	0.01
V	15.87	30.43	53.62	0.07	0.02

In general, the $Q \times f$ of microwave dielectric ceramics is related to the grain size, porosity, densification, and secondary phases [42–44]. The $Q \times f$ of the MgO–2B₂O₃–4wt%BCB–*y*wt%H₃BO₃ ceramics first increased as the sintering temperature increased up to 900 °C and then decreased, demonstrating excellent consistency with varying bulk density. Because there was no secondary phase in the MgO–2B₂O₃–4wt%BCB–*y*wt%H₃BO₃ ceramics, the $Q \times f$ was primarily affected by the sintering temperature and H₃BO₃ content, which altered the density and grain size. At a sintering temperature of 850 °C, the MgO–2B₂O₃–4wt%BCB–10wt%H₃BO₃ ceramics showed a significant proportion of pores between grains, resulting in a lower $Q \times f$. At 900 °C, a denser

Fig. 6 Bulk density, relative permittivity, $Q \times f$, and τ_r values of the MgO–2B₂O₃–4wt%BCB–*y*wt%H₃BO₃ ceramics (*y* = 10–40) at different sintering temperatures.

microstructure of $\text{MgO-2B}_2\text{O}_3\text{-4wt\%BCB-40wt\%H}_3\text{BO}_3$ resulted in a maximum $Q \times f$ of 44,306 GHz, a relative ε_r of 5.1, and τ_f of -32 ppm/ $^\circ\text{C}$.

The dielectric properties depend on relative density, crystal structure, and other phase contents [45,46]. The relative ε_r of the $\text{MgO-2B}_2\text{O}_3\text{-4wt\%BCB-}y\text{wt\%H}_3\text{BO}_3$ ceramics was consistent with the change in bulk density. The maximum ε_r was found to be 4.81 at 10 wt% H_3BO_3 . Furthermore, an overall increase in the relative ε_r of the H_3BO_3 -containing ceramics was observed when the H_3BO_3 content was increased to 20, 30, and 40 wt%. Hence, the variations in the H_3BO_3 content, sintering temperature, and bulk density influenced ε_r .

Notably, the variations in ρ , ε_r , $Q \times f$, and τ_f values for $\text{MgO-2B}_2\text{O}_3\text{-4wt\%BCB-}y\text{wt\%H}_3\text{BO}_3$ ($y = 10, 20, 30$, and 40) were consistent with the changes in the H_3BO_3 content. As mentioned earlier, as the optimal sintering temperature of the $\text{MgO-2B}_2\text{O}_3\text{-4wt\%BCB-}y\text{wt\%H}_3\text{BO}_3$ ceramics decreased from 925 to 900 $^\circ\text{C}$, the $Q \times f$, relative ε_r , τ_f , and bulk density increased from 40,076 to 44,306 GHz, from 4.81 to 5.11, from -40 to -32 ppm/ $^\circ\text{C}$, and from 2.460 to 2.463 g/cm³,

respectively. The increase in the H_3BO_3 content both lowered the sintering temperature and improved the microwave dielectric properties of the $\text{MgO-2B}_2\text{O}_3\text{-4wt\%BCB-}y\text{wt\%H}_3\text{BO}_3$ ceramics.

Table 3 tabulates the sintering temperatures and microwave dielectric properties of the $\text{MgO-2B}_2\text{O}_3\text{-}x\text{wt\%BCB-}y\text{wt\%H}_3\text{BO}_3$ ceramics at different BCB and H_3BO_3 contents. When the BCB content was constant, the decrease in the sintering temperature was negligible as the H_3BO_3 content increased. τ_f remained stable at approximately -62 to -32 ppm/ $^\circ\text{C}$. When the H_3BO_3 content was constant, the BCB content increased, gradually decreasing the required sintering temperature. The $Q \times f$ increased initially and then decreased at a higher BCB content. In summary, the addition of BCB and H_3BO_3 reduced the sintering temperature and increased the $Q \times f$ of the $\text{MgO-2B}_2\text{O}_3\text{-}x\text{wt\%BCB-}y\text{wt\%H}_3\text{BO}_3$ ceramics. This can be attributed to the growth of the $\text{MgO-2B}_2\text{O}_3$ grains. The optimal sintering temperature of the produced ceramics reduced to 825 $^\circ\text{C}$, indicating that it can be used as an alternative material in LTCC devices.

Table 3 Microwave dielectric properties and optimal sintering temperatures of $\text{MgO-2B}_2\text{O}_3\text{-}x\text{wt\%BCB-}y\text{wt\%H}_3\text{BO}_3$ ceramics

Note: S.T. means sintering temperature.

4 Conclusions

In summary, $\text{MgO-2B}_2\text{O}_3\text{-}x\text{wt}\%\text{BCB-}y\text{wt}\%\text{H}_3\text{BO}_3$ ($x = 2, 4, 6$, and 8 ; $y = 10, 20, 30$, and 40) ceramics were prepared using solid-state reaction; the influence of the H_3BO_3 and BCB contents on the bulk density, sintering behaviour, and microwave dielectric properties were systematically investigated. The $\text{MgO-2B}_2\text{O}_3\text{-}x\text{wt}\%\text{BCB-}10\text{wt}\%\text{H}_3\text{BO}_3$ ($x = 2, 4, 6$, and 8) ceramics consisted of a single-phase $\text{MgO-2B}_2\text{O}_3$ with the orthorhombic space group *Pbca*. The $Q \times f$ of the $\text{MgO-2B}_2\text{O}_3\text{-}x\text{wt}\%\text{BCB-}10\text{wt}\%\text{H}_3\text{BO}_3$ ($x = 2, 4, 6$, and 8) ceramics increased initially and then decreased gently as the BCB content increased. The optimal properties of the resulting $\text{MgO-2B}_2\text{O}_3\text{-}4\text{wt}\%\text{BCB-}10\text{wt}\%\text{H}_3\text{BO}_3$ ceramic were $\rho = 2.409 \text{ g/cm}^3$, $Q \times f = 40,076 \text{ GHz}$, $\varepsilon_r = 5$, and $\tau_f = -45 \text{ ppm/}^\circ\text{C}$. In addition, the microwave dielectric properties and sintering temperature of the $\text{MgO-2B}_2\text{O}_3\text{-}4\text{wt}\%\text{BCB-}y\text{wt}\%\text{H}_3\text{BO}_3$ ceramics ($y = 10, 20, 30$, and 40) improved as the H_3BO_3 content increased at $4 \text{ wt}\%$ BCB. The resulting $\text{MgO-2B}_2\text{O}_3\text{-}4\text{wt}\%\text{BCB-}40\text{wt}\%\text{H}_3\text{BO}_3$ demonstrated excellent microwave dielectric properties, with ε_r , $Q \times f$, and τ_f of 5.1 , $44,306 \text{ GHz}$ (at 15 GHz), and $-32 \text{ ppm/}^\circ\text{C}$, respectively. This study presented a novel approach to modify the τ_f of $\text{MgO-B}_2\text{O}_3$ ceramics, which is an important parameter that governs the stability and performance of microwave equipment and devices.
