HIGHLIGHTS

- Dimensional gradient structure of sheet–tube–dots was constructed with CoSe₂@CNTs–MXene for fast ion and electron transportation.
- Density functional theory study discloses the electrochemical difference of CoSe₂@CNTs–MXene in ether/ester electrolyte system.
- Phase transformation of CoSe₂@CNTs–MXene was analyzed by in situ XRD. The full cell based on CoSe₂@CNTs–MXene anode was also assembled.

ABSTRACT Recently, abundant resources, low-cost sodium-ion batteries are deemed to the new-generation battery in the field of large-scale energy storage. Nevertheless, poor active reaction dynamics, dissolution of intermediates and electrolyte matching problems are significant challenges that need to be solved. Herein, dimensional gradient structure of sheet–tube–dots is constructed with CoSe₂@CNTs–MXene. Gradient structure is conducive to fast migration of electrons and ions with the association of ether electrolyte. For half-cell, CoSe₂@CNTs–MXene exhibits high initial coulomb efficiency (81.7%) and excellent cycling performance (400 mAh g⁻¹ cycling for 200 times in 2 A g⁻¹). Phase transformation pathway from crystalline CoSe₂–Na₂Se with Co and then amorphous CoSe₂ in the discharge/charge process is also explored by in situ X-ray diffraction. Density functional theory study discloses the CoSe₂@CNTs–MXene in ether electrolyte system which contributes to stable sodium storage performance owing to the strong adsorption force from hierarchical structure and weak interaction between electrolyte and electrode interface. For full cell, CoSe₂@CNTs–MXene//Na₃V₂(PO₄)₃/C full battery can also afford a competitively reversible capacity of 280 mAh g⁻¹ over 50 cycles. Concisely, profiting from dimensional gradient structure and matched electrolyte of CoSe₂@CNTs–MXene hold great application potential for stable sodium storage.

1 Introduction

Recently, emerging sodium-ion batteries (SIBs) have been deemed to be the new-generation battery for large-scale energy storage applications benefitting for abundant resources, low cost and low standard hydrogen potential (-2.71 V) [1–4]. In the last ten years, researchers have developed a great variety of anode electrode materials and different kinds of cathode materials for SIBs [5, 6]. Meanwhile, advanced SIBs systems, such as Na–S, Na–metal and Na–O₂ batteries, have also achieved prominent energy density in the effort of researchers [7–9]. However, owing to its large ionic radius (1.02 Å) compared to Li ion (0.76 Å) and dense molar mass, poor reaction kinetics, bad rate performance and weak cycling performance limit the large-scale application of SIBs [10]. Therefore, constructing high specific capacity anode materials with good reaction kinetics is an effective method to build extraordinary energy density sodium-ion full cells. Meanwhile, appropriate electrolyte systems are another way to ensure long-term and high cycling performance for full batteries. So, it is necessary to develop compatible electrode materials and electrolyte system to promote the application of SIBs.

Transition metal chalcogenides (TMCs), a kind of narrow/zero bandgap materials with low cost, high electric conductivity and unique electrochemical properties, have been widely investigated as the potential active materials for alkali-ion batteries [11–14]. In most cases, pulverization caused by huge volume change and dissolution of intermediate in electrochemical processes leads to poor cycling performance. A generic strategy is encapsulating TMCs in functionalized carbon transferred from metal–organic frameworks (MOFs) [15]. MOFs can provide high surface area and controllable microstructure. After carbonization and selenylation process, the hollow functionalized carbon shell can tolerate tremendous phase change stress [16]. Meanwhile, heterogeneous element-doped carbon shell can also restrain the dissolution of sodium selenide in electrolyte [17]. Xu et al. synthesized ZnSe/N-doped hollow carbon architectures for SIBs with a revisable capacity of 250.8 mAh g⁻¹ at 1 A g⁻¹ exhibiting excellent stability [18]. CoSe₂@N-CF/CNTs can give a capacity of 428 mAh g⁻¹ at 1 A g⁻¹ after cycling for 500 times [19]. Synergistic effect in hierarchical gradient structure can greatly enhance electron/ion diffusion, as well as carbon shell encapsulation strategy can guarantee the stabilization of active materials and impede the strain

during electrochemical processes. Therefore, constructing hierarchical structure of TMCs transferring from MOFs is a potential method to acquire high-performance sodium-ion anode materials.

Electrolyte, an ion conductor, is another critical component of the rechargeable battery system [20]. Common carbonate ester-based solvents such as ethylene carbonate (EC) and propylene carbonate (PC) are widely applied in SIBs. These electrolyte systems can obtain high ionic conductivity, wide electrochemical window and stable solid electrolyte interphase (SEI) film on the surface of electrode materials [21]. However, low initial coulombic efficiency (ICE), poor cycling stability and the dissolution of reaction intermediate are severe challenges that need to be addressed. Compared with LIBs, the working voltage is usually lower than 4 V, which makes it possible for the adoption of ester electrolyte system [22]. On the other hand, the ester-based electrolyte can significantly improve ICE and rate performance of SIBs [23, 24]. Transition metal sulfides (TMDC) like ZnS showed a superior rate capability and outstanding long-term cyclability assisted by ether electrolyte [25]. Cu₂MoS₄-RGO exhibited excellent cycling stability (215 mAh g⁻¹ after 2000 cycles) and good full cell performance (75.5% after 500 cycles) [26].

Herein, we report a dimensional gradient structure building with CoSe₂@CNTs–MXene anode materials for SIBs by exploiting a NaPF₆ in a new DEGDMC electrolyte system. Cobalt (Co)–MOFs are deposited on the MXene by an easy coprecipitation method. Carbon nanotubes (CNTs) grow on the surface of MXene in the catalysis of Co particles, followed by selenylation process. MXene, acting as the flexible matrix, not just promotes the fast ion and electronic transmission by constructing a “sheet–tube–dots” hierarchical structure, but also impedes the dissolution of Na₂Se in electrochemical processes. The CoSe₂@CNTs–MXene in ether electrolyte maintains an outstanding cycling performance of 400 mAh g⁻¹ after 200 cycles at 2 A g⁻¹ with a high ICE of 81.7% and excellent rate stability of 347.5 mAh g⁻¹ at 5 A g⁻¹, which is much better than electrochemical behaviors in ester system (only 27 mAh g⁻¹ for 200 cycles). The great electrochemical contrast of CoSe₂@CNTs–MXene in disparate electrolyte systems is evidenced by DFT calculations. Meanwhile, phase transformation of CoSe₂@CNTs–MXene in the first cycle was successfully analyzed by in situ XRD and dynamic electrochemical impedance spectroscopy (EIS) analysis. Importantly, CoSe₂@CNTs–MXene

and $\text{Na}_3\text{V}_2(\text{PO}_4)_3/\text{C}$ full cell is assembled, delivering outstanding cycle performance with a capacity of 280 mAh g^{-1} after 50 cycles at 100 mA g^{-1} .

2 Experimental Section

2.1 Materials

2-Methylimidazole, $\text{Co}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$, methanol, LiF and HCl were purchased from Shanghai Aladdin Bio-Chem Technology Co., Ltd. Ti_3AlC_2 powders were purchased from Jilin 11 Technology Co. Ltd., China. All chemical reagents were used without further purification. The ultrapure water was used throughout the experiment process.

2.2 Synthesis of $\text{Ti}_3\text{C}_2\text{T}_x$ MXene Nanosheets

Firstly, 1 g LiF was dissolved in 10 mL 9 M HCl at room temperature. Then, 1 g Ti_3AlC_2 powders were added into LiF/HCl solution for 10 min to avoid overheating. The next, mixed solution was transferred into a Teflon autoclave and kept at 60°C for 24 h. After cooling to room temperature, the etching product was washed with 3 M HCl and ultrapure water successively, until the pH of solution reached 7. Finally, the black jelly was sonicated in water under the protection of argon for 2 h and centrifuged at 3500 rpm. The concentration of final obtained $\text{Ti}_3\text{C}_2\text{T}_x$ MXene nanosheets colloidal solution was about 8 mg mL^{-1} .

2.3 Synthesis of CoSe_2 @CNTs–MXene

In a popular method, 0.6 mmol $\text{Co}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ and 10 mL MXene colloidal solution were mixed in 40 mL methanol. Then, 6 mmol 2-methylimidazole in 50 mL methanol with 12 μL triethylamine was poured into the above solution followed by stirring continuously for 1 h. After washing with methanol, the ZIF-67@MXene was dried in vacuum at 80°C for 12 h. Next, ZIF-67@MXene was annealed under Ar/H_2 atmosphere at 700°C for 2 h with a heating rate for 2°C min^{-1} , the $\text{Co}@CNTs$ –MXene. At last, $\text{Co}@CNTs$ –MXene was mixed with Se powder at a weight ratio of 1:3 and heated under Ar atmosphere at 500°C for 3 h. The preparation of CoSe_2 @CNTs was synthesized by a similar method without MXene.

2.4 Materials Characterization

X-ray diffraction (XRD) was tested by Rigaku SmartLab SE with Cu $K\alpha$ radiation ($\lambda = 1.5406 \text{ \AA}$). Thermogravimetric analysis (TGA) was measured by STA 449 F5 Jupiter. Raman spectrum was obtained by LabRAM HR Evolution using 532-nm laser. The surface composition of samples was analyzed by X-ray photoelectron spectroscopy (XPS, ESCALAB250Xi). Morphology was acquired by a field emission scanning electron microscope (FESEM, ZEISS SIGMA) and a field emission transmission electron microscope (FETEM, JEOL JEM-2100F); both of them were equipped with an EDX spectrometer (Oxford Instruments). In situ XRD was represented by a special electrochemical reaction unit with a beryllium (Be) window.

2.5 Electrochemical Measurements

For half-cell, active materials (AC), Super P and PVDF were stirred with a weight ratio of 8:1:1 by a high-speed homogenizer. The slurry was coated on copper foil with a scraper, and the mass load of AC is about 1.1 mg cm^{-2} . Sodium foil and glass fiber (Whatman) were used as a counter electrode and a separator. Two different kinds of system ether (1 M NaPF_6 in DEGDM) and ester (1 M NaPF_6 in PC) were adopted as electrolyte, respectively. And the ratio of electrolyte/electrode in the half-cell is about 10 uL mg^{-1} . For full cell, $\text{Na}_3\text{V}_2(\text{PO}_4)_3/\text{C}$ was adopted as cathode materials. The capacity matching was achieved by controlling the coating thickness and promoting the anode capacity having a 5–10% surplus compared with cathode capacity. The mass loading of cathode electrode slice is about 6 mg cm^{-2} . Before assembling full cell, CoSe_2 @CNTs–MXene was activated for three cycles in advance. Cyclic voltammetry (CV) curves were obtained by CHI 660D workstation. A Neware BTS-4008 system was employed for charge/discharge and rate performance. Electrochemical impedance spectroscopy (EIS) was evaluated by using a Zahner IM6 system (0.01 – 10^5 Hz).

2.6 Computational Details

Quantum ESPRESSO v6.4.1 software packages were adopted for all density functional theory (DFT) calculation [27]. Perdew–Burke–Ernzerhof (PBE) in generalized

gradient approximation (GGA) considering van der Waals force (VDW) was employed to analyze the exchange functional [28]. The kinetic energy cutoffs for the wavefunction were 60 Ry. $5 \times 5 \times 1$ C–N surface and $3 \times 3 \times 1$ $\text{Ti}_3\text{C}_2\text{O}_2$ surface built with a 20 Å vacuum region. A $3 \times 3 \times 1$ k-point mesh of Brillouin zone was put to use. The binding energy (E_{bind}) of Na_2Se on different matrix could be calculated by $E_{\text{bind}} = E_{\text{Na}_2\text{Se-matrix}} - E_{\text{Na}_2\text{Se}} - E_{\text{matrix}}$. For all structure and adsorption models, the energy convergence accuracy was within 1×10^{-7} eV and 0.001 eV Å for force. Rietveld method was used to refine the XRD data of $\text{Na}_3\text{V}_2(\text{PO}_4)_3/\text{C}$ [29].

3 Results and Discussion

3.1 Synthesis and Characterization of CoSe_2 @CNTs–MXene

CoSe_2 @CNTs–MXene was prepared by a universal strategy followed by carbonization and selenylation processes, which

is displayed in Fig. 1a. Typically, single-layer $\text{Ti}_3\text{C}_2\text{T}_x$ was synthesized through a fluoride-based salt etchants method reported by Ghidui [30, 31]. To avoid the oxidation of $\text{Ti}_3\text{C}_2\text{T}_x$ during usage, appropriate sodium *L*-ascorbate was added in the colloidal solution [32]. XRD patterns (Fig. S1) indicate successful synthesis of $\text{Ti}_3\text{C}_2\text{T}_x$ MXene. Microstructure of single-layer $\text{Ti}_3\text{C}_2\text{T}_x$ characterized by TEM is shown in Fig. S2, and the individual $\text{Ti}_3\text{C}_2\text{T}_x$ MXene looks ultrathin and transparent, with a size range from 100 to 700 nm [33]. Selected area electron diffraction (SAED) patterns reveal excellent crystallinity and unique hexagonal structure of single-layer $\text{Ti}_3\text{C}_2\text{T}_x$ MXene [34]. Then, ZIF-67 nanocubes were prepared through a conventional co-precipitation method at ambient temperature [35]. SEM images of ZIF-67 (Fig. 1b) exhibit homogeneous octahedrons with a diameter of 150–250 nm. For ZIF-67/MXene, ZIF-67 with an average size of 25 nm covered the entire surface of MXene (Fig. 1c, d) evenly under the effect of electrostatic interaction [36]. The growth of ZIF-67 could

Fig. 1 a Synthesis scheme of CoSe_2 @CNTs–MXene. b SEM image of ZIF-67. c SEM image of ZIF-67/MXene. d TEM image of ZIF-67/MXene. e SEM image of Co/CNTs –MXene. f TEM image of CoSe_2 @CNTs–MXene. g HRTEM image of CoSe_2 @CNTs–MXene

well impede the reunion of MXene benefitting for construction the conductive network. XRD analysis in Fig. S3 also clearly shows the similarity between ZIF-67 and ZIF-67/MXene. After annealing treatment at 800 °C under Ar/H₂ atmosphere, a novel “tube-on-nanosheet” structure of Co@CNTs–MXene was obtained (Fig. 1e). CNTs with hundreds of nanometers grew neatly on the surface of MXene. Co²⁺ ions were reduced to elemental cobalt (ICPDS No.15–0806) under the effect of H₂ (Fig. S4). Pure cobalt nanoparticles constantly catalyze the growth of carbon nanotubes during the carbonization process of ZIF-67 [37]. The final product CoSe₂@CNTs–MXene was acquired after selenylation at 500 °C for 3 h, as displayed in Fig. 1f, g. CoSe₂ particles were encapsulated on the top of CNTs. Two crystal interplanar spacings, 0.253 and 0.319 nm, could be well fitted with the (221) of CoSe₂ and (103) of carbon, respectively. The elemental mapping of CoSe₂@CNTs–MXene is also displayed in Fig. S5. For comparison, CoSe₂@CNTs was also prepared without the addition of MXene (Fig. S6). The construction of a “sheet–tube–dots” hierarchical structure can significantly enhance the transport of electrons and sodium ions.

The XRD patterns of CoSe₂@CNTs and CoSe₂@CNTs–MXene are displayed in Fig. 2a. Both of them clearly show a single-phase composition of cubic CoSe₂ (ICPDS no. 65–3327, space group: Pa 3). No additional reflection appearing in the spectrogram means the high purity of products. At the same time, characteristic peaks of MXene at 5–10° could not be found in the diagram. This phenomenon indicates MXene has been evenly dispersed in CoSe₂@CNTs–MXene. Raman spectroscopy (Fig. 2b) of CoSe₂@CNTs–MXene shows two peaks at 186 and 673 cm⁻¹, respectively, owing to the A_g and A_{1g} modes for CoSe₂. Some tiny peaks near 500 cm⁻¹ can be attributable to the slight oxidation of CoSe₂ surface. D and G peaks for sp³ and sp² carbon are situated at 1345 and 1586 cm⁻¹, respectively. The I_D/I_G scale is about 1.07, indicating a good degree of graphitization, which is conducive to the transfer of electrons and sodium ions.

TGA of CoSe₂@CNTs–MXene was tested in hot air from 25 to 800 °C with a heating rate of 10 °C min⁻¹, as shown in Fig. 2c. The mass increases between 400 and 500 °C owing to the formation of SeO₂ and oxidation of MXene, respectively. The primary mass loss after 600 °C contributes to the transformation from CoSe₂ to Co₃O₄ and the sublimation of SeO₂ [19]. Based on the above TGA tests, the calculated

mass percentage of CoSe₂ in CoSe₂@CNTs–MXene is about 63%. XPS was measured to investigate chemical states of CoSe₂@CNTs–MXene, total spectrogram of CoSe₂@CNTs–MXene (Fig. 2d) is clearly observed the coexistence of Co, Se, Ti, C and N, relatively. Figure 2e–i exhibits the fine spectrogram of Co 2p, Se 3d, Ti 2p, C 1s and N 1s, respectively. The signal of Co 2p (Fig. 2e) shows two broad peaks locating at 781.1 and 797.2 eV corresponding to Co 2p_{3/2} and Co 2p_{1/2}. Peaks at 778.4 and 793.7 eV can be corresponded to the Co–O bond due to the surface oxidation of CoSe₂ [38]. Owing to the orbital between Co atoms and Se atoms, two satellite peaks also can be found in the spectrogram [35]. The Se 3d spectra (Fig. 2f) can be split into two main peaks at 54.5 and 55.4 eV for Se 3d_{5/2} and Se 3d_{3/2}, respectively. Peaks between 57 and 62 eV belong to the existence of CoSe₂ and SeO₂ [39]. In the high-resolution Ti 2p spectra (Fig. 2g), peaks at 458.55 and 464.3 eV correspond to Ti 2p_{3/2} and Ti 2p_{1/2} [40]. For C 1s in Fig. 2h, three peaks locating at 284.8, 286.6 and 287.55 eV can be assigned to sp² C, C–O and C=O, respectively. Peaks from left to right for N 1s are attributed to graphitic, pyrrolic and pyridinic nitrogen, in turn [18].

3.2 Electrochemical Performance of CoSe₂@CNTs–MXene

The unique structure of CoSe₂@CNTs–MXene makes it a promising application in energy storage fields. Electrochemical performances of CoSe₂@CNTs–MXene were investigated by assembling half-cell countering with sodium foil. Cyclic voltammetry (CV) curves of CoSe₂@CNTs–MXene (Fig. 3a) in ether electrolyte were measured in 0.1–3 V at a scan rate of 0.1 mV s⁻¹. In the first discharge, a broad cathodic peak at 1.065 V corresponds to the insertion of sodium ion into CoSe₂, leading to the formation of Na_xCoSe₂. With further discharge, Na_xCoSe₂ was eventually broken into Na₂Se and Co till to 0.1 V. Then, in the anodic process, peaks locating at 1.7–2.0 V stand for Na₂Se, which regenerated to amorphous CoSe₂ clusters [38, 41, 42]. For comparison, CV curves of CoSe₂@CNTs are also displayed in Fig. S7. In order to reveal the electrochemical reaction progress of the first cycle, in situ XRD was also tested, which is displayed in Fig. 4. When the voltage decreased from 2.0 to 1.0 V, diffraction peaks of CoSe₂ at 30.5°, 34.2° and 37.6° gradually vanished. At this

Fig. 2 **a** XRD patterns of CoSe₂@CNTs–MXene and CoSe₂@CNTs. **b** Raman spectrum of CoSe₂@CNTs–MXene. **c** TG analysis of CoSe₂@CNTs–MXene. **d** XPS survey spectrum. **e–i** Co 2p, Se 3d, Ti 2p, C 1s and N 1s of CoSe₂@CNTs–MXene

stage, sodium ion embedded into CoSe₂ and further formed Na_xCoSe₂. With the voltage down to 0.1 V, Na_xCoSe₂ was decomposed completely and peaks of Na₂Se became apparent. In the charging process, Na₂Se has sloughed the sodium ion and transformed to CoSe₂ again. Reaction processes can be described as Eqs. 1 and 2:

Due to the highly disordered structure of CoSe₂ in charge course, the characteristic peaks of CoSe₂ cannot

be discovered in the spectra. In order to illustrate this mechanism clearly, ex situ Raman was measured. After charging to 3 V, the characteristic peak of CoSe₂ is found in Fig. S8. All these pieces of evidence can prove the CoSe₂–Na₂Se–CoSe₂ conversion process.

Figure 3b exhibits the CV graphs of CoSe₂@CNTs–MXene in the ester environment, which presents a distinct electrochemical process. The cathodic peak in 0.8 V in the first cycle shifts left about 0.26 V than ether electrolyte, and a loose anodic peak exists around 2 V. However, reaction peaks could not fit commendably and disappeared gradually after the second cycle. Galvanostatic charge/discharge profiles of CoSe₂@CNTs–MXene in ether

Fig. 3 **a, b** CV curves of $\text{CoSe}_2\text{@CNTs-MXene}$ in ether/ester electrolyte at a scan rate of 0.1 mV s^{-1} in the range of 0.1–3 V. **c, d** Discharge/charge curves of $\text{CoSe}_2\text{@CNTs-MXene}$ in ether/ester electrolyte. **e** Cycle performance of $\text{CoSe}_2\text{@CNTs-MXene}$ in ether and ester electrolyte at a current of 2 A g^{-1} . **f** Rate performance of $\text{CoSe}_2\text{@CNTs-MXene}$ in ether

at a current of 2 A g^{-1} are shown in Fig. 3c. In the first cycle, the discharge/charge capacities can be evaluated to $397.5/324.6 \text{ mAh g}^{-1}$, with high coulombic efficiency (CE) about 81.7%. Irreversible capacity loss in the first cycle can be attributed to the generation of solid electrolyte interface (SEI) film. At the same time, the plateaus in discharge/charge processes can exhibit well fitness with CV curves. Reversible capacity for $\text{CoSe}_2\text{@CNTs-MXene}$ in ether retains at 315.7, 317.2, 346.6, 376.8 and 397.7 mAh g^{-1} after 2nd, 3rd, 20th, 50th and 100th cycles, with a CE of about 99.8%. Continuous capacity increase benefits from the improvement in electrode wettability and capacitance effect in electrochemical processes. On the other hand, a great deal of capacity loss was observed at $\text{CoSe}_2\text{@}$

CNTs-MXene in ester; discharge/charge capacities in the first cycle are $413/223.9 \text{ mAh g}^{-1}$ with a low CE of 54.2% (Fig. 3d). Side reactions of electrolyte and serious dissolution of selenide lead to the low coulombic efficiency in the first cycle. Reversible capacity after 2nd, 3rd, 20th, 50th and 100th cycles is only 143.5, 122.9, 56.8, 40 and 31 mAh g^{-1} , respectively. With the cycle proceeding in progress, discharge/charge plateaus disappear gradually and only matrix materials contributive capacity exists after 200 cycles. Cycle performances of $\text{CoSe}_2\text{@CNTs-MXene}$ in the different electrolyte systems at 2 A g^{-1} are displayed in Fig. 3e. $\text{CoSe}_2\text{@CNTs-MXene}$ in the ether can keep up a stable capacity at 400 mAh g^{-1} after 200 cycles, which is vastly superior to a low capacity of 27 mAh g^{-1} for the electrode in ester. For

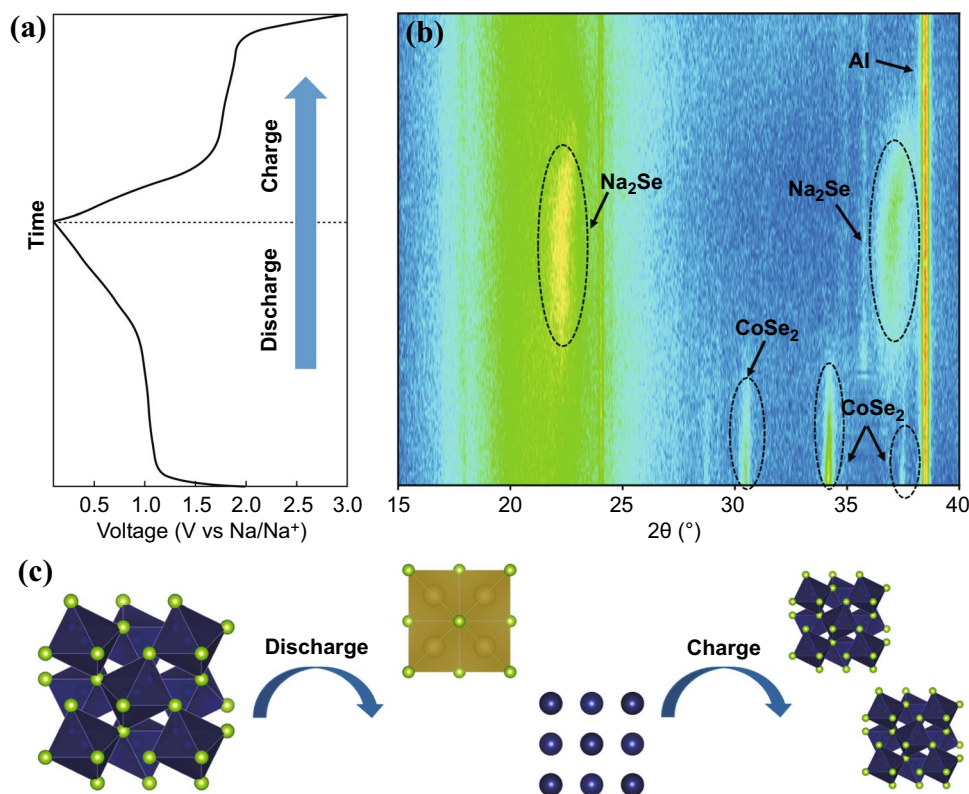

Fig. 4 **a** Discharge/charge curves of CoSe_2 in the first cycle at 100 mA g^{-1} . **b** Corresponding in situ XRD patterns of CoSe_2 in the first cycle. **c** Transformation mechanism of CoSe_2

CoSe_2 @CNTs and pure MXene, the reversible capacity is only $215.34 \text{ mAh g}^{-1}$ after 200 cycles (Figs. S9 and S10), respectively. Rate performances of CoSe_2 @CNTs–MXene in the ether (Fig. 3f) can obtain invertible capacities for 450.5, 423, 391.5, 366 and 347.5 mAh g^{-1} at a current of 1, 2, 3, 4 and 5 A g^{-1} , respectively, which is superior to some other MXene-based anodes (Table S1). All of these performance tests indicate CoSe_2 @CNTs–MXene can exhibit great electrochemical properties in ether electrolyte. In order to explain the huge electrochemical performance discrepancy of CoSe_2 @CNTs–MXene in different electrolyte systems, XPS investigation for C 1 s, O 1 s and F 1 s of anode materials (after the first cycle) is shown in Fig. S11. The SEI layer comprises sodium inorganic/organic complex, organic matter and fluoride. For ether, an obvious peak locating at 686.7 eV can be contributed to the C–F bond. Such high fluorine content guarantees prominent mechanical strength of SEI layer, which can keep the cycling stability during electrochemical processes [7]. After cycling for 100 times, separators were disassembled for XPS analysis. Spectra in Fig. S12 can also verify the dissolution of selenide. A weak

peak ranging from 58 to 60 eV can be found in the ester spectra, which belongs to selenide signals. In contrast, no signal was detected in the ether separator.

3.3 DFT Calculations

Density functional theory (DFT) was used to describe the polyselenide shuttling constraint mechanism in different electrolytes. The space group of cubic CoSe_2 (Fig. 5a) is Pa 3, which can be well fitted with XRD data. Band structure of CoSe_2 demonstrates its metallic behavior and outstanding electron conductivity. For MXene, the bandgap of $\text{Ti}_3\text{C}_2\text{O}_2$ is only 0.3 eV . In our previous research, sodium ion can migrate easily on the surface of MXene. CoSe_2 nanoparticles, carbon nanotubes and MXene nanosheets together construct a spot–line–surface system that contributes to the ultrafast kinetics for ion transport and electron conduction. The lowest unoccupied molecular orbital (LUMO) and highest occupied molecular orbital (HOMO) of propylene carbonate (PC) and bis (2-methoxy ethyl) ether (DEGDME)

Fig. 5 a–d Crystal structure and band structure of CoSe_2 and $\text{Ti}_3\text{C}_2\text{O}_2$. e–h Optimized adsorption structure of PC/ Na_2Se , DEGDME/ Na_2Se , C-N/ Na_2Se and $\text{Ti}_3\text{C}_2\text{O}_2$ / Na_2Se

are shown in Fig. S13. Energy gaps of PC and DEGDME are 6.0363 and 5.2606 eV, respectively; both of them can satisfy the requirement of SIBs. Relaxed adsorption geometries of $\text{Na}_2\text{Se}/\text{PC}$, $\text{Na}_2\text{Se}/\text{DEGDME}$, $\text{Na}_2\text{Se}/\text{C-N}$ and $\text{Na}_2\text{Se}/\text{Ti}_3\text{C}_2\text{O}_2$ are demonstrated in Fig. 5e–h. The binding energy between PC, DEGDME and Na_2Se is 0.69 and 0.6 eV. It follows that PC as the electrolyte solvent has an interaction with sodium selenide. DFT calculation further confirmed the binding strength of Na_2Se on C–N nanosheet is only 0.62 eV. So, when Na_xCoSe_2 transferred into Na_2Se and pure Co in the first discharge process, abundant Na_2Se dissolved in the electrolyte, leading to the low initial coulombic efficiency and serious capacity loss. Charge density difference of Na_2Se on $\text{Ti}_3\text{C}_2\text{O}_2$ (Fig. S14) shows an electron-loss region around selenium atoms and an electron-rich region around MXene surface. Exposed Ti atoms and O atoms on MXene could capture electrons from selenium atoms under the effect of the Lewis acidity property [43]. Ti–Se bond and Se–O bond guarantee Na_2Se can be anchored tightly (2.04 eV) on the surface of MXene [42]. The enormous binding energy

prevents the dissolution of Na_2Se in the process of electrochemical processes, which is in good agreement with experimental results.

3.4 Kinetics Analysis of CoSe_2 @CNTs–MXene

Capacitive/diffusion behavior analysis, galvanostatic intermittent titration technique (GITT) and electrochemical impedance spectroscopy (EIS) are adopted to investigate the excellent electrochemical kinetics of CoSe_2 @CNTs–MXene in detail. The cathode and anode peaks of CoSe_2 @CNTs–MXene (Fig. 6a) at different scan rates (from 0.5 to 2.5 mV s^{-1}) show no significant deviation and can be repeatable at a high scan rate. This evidence can also explain the reason for outstanding rate performances of CoSe_2 @CNTs–MXene. The plot $\log(i)$ against $\log(v)$ and the fitting line are displayed in Fig. 5b. Calculation formulas of the capacitive contribution are Eqs. S1 and S2 described detail in supporting information. Capacitive

Fig. 6 **a** CV curves of CoSe₂@CNTs–MXene at various currents from 0.5–2.5 mV s⁻¹. **b** log *i* versus log *v* plots. **c** Contribution ratio of capacitive capacity of CoSe₂@CNTs–MXene at various scan rates. **d** GITT of CoSe₂@CNTs–MXene in ether at a current of 100 mA g⁻¹. **e**, **f** Nyquist plots of CoSe₂@CNTs–MXene in ether/ester electrolyte

contribution for specific capacity is 47.6, 56.2, 61.2, 64.5 and 67%, respectively, under the scan rate of 0.5, 1.0, 1.5, 2.0 and 2.5 mV s⁻¹ (Fig. 6c). Higher contribution of capacitance at high scan rate is conducive to favorable cycle and rate properties [44, 45]. Diffusion stability of sodium ion in CoSe₂@CNTs–MXene under different electrolytes could get further insight by GITT. Figure 6d shows the discharge curve from 3.0 to 0.1 V under an identical current of 100 mA g⁻¹ for 5 min followed by a relaxation step for 30 min until the cutoff voltage. The ether battery shows evident cycling stability than ester than the good reaction kinetics of CoSe₂@CNTs–MXene in ether electrolyte.

Electrochemical impedance spectroscopy analysis of CoSe₂@CNTs–MXene in different electrolytes was also explored. Nyquist plots of CoSe₂@CNTs–MXene in ether and ester are displayed in Fig. 6e–f. EIS of CoSe₂@CNTs was also tested (Fig. S15). EIS curves can be divided into three parts, inductive reactance and semicircle related to the resistance of electrode in high-frequency region and the linear part for ion diffusion in low frequency [46]. Both curves can be well fitted with the classic equivalent circuit model as shown in Fig. S16. Charge-transfer resistance between interfaces for CoSe₂@CNTs–MXene in ether is 9.77 Ω, which is much lower than the ester system

Fig. 7 **a** XRD refinement of $\text{Na}_3\text{V}_2(\text{PO}_4)_3$, **b** First discharge-charge curves of $\text{Na}_3\text{V}_2(\text{PO}_4)_3$ half-cell at the current of 100 mA g^{-1} . **c** Model structure of $\text{Na}_3\text{V}_2(\text{PO}_4)_3/\text{CoSe}_2@\text{CNTs-MXene}$ full cell. **d** Discharge-charge curves of $\text{Na}_3\text{V}_2(\text{PO}_4)_3/\text{CoSe}_2@\text{CNTs-MXene}$ full cell at the current of 100 mA g^{-1} . **e** Cycle performance of $\text{Na}_3\text{V}_2(\text{PO}_4)_3/\text{CoSe}_2@\text{CNTs-MXene}$ full cell at 100 mA g^{-1}

(239 Ω). Other parameters are also listed in Table S2. This phenomenon also proves the favorable invasion at interface. Low resistance for the interface of electrode and electrolyte contributes to high sodium-ion diffusion rate during electrochemical processes. Dynamic EIS analysis of $\text{CoSe}_2@\text{CNTs-MXene}$ in different kinds of electrolyte at first discharge/charge cycle (Fig. S17) can also prove the excellent reaction kinetics of ether. The addition of MXene can also improve interface situations owing to the contact of the solid-liquid interface.

3.5 Full Cells Evaluation of $\text{CoSe}_2@\text{CNTs-MXene}$

To confirm the application value of $\text{CoSe}_2@\text{CNTs-MXene}$ as the anode in SIBs, $\text{Na}_3\text{V}_2(\text{PO}_4)_3/\text{C}$ cathode and $\text{CoSe}_2@\text{CNTs-MXene}$ anode full cell was assembled with NaPF_6 in DEGDME as the electrolyte (Fig. 7c). The synthesis strategy of $\text{Na}_3\text{V}_2(\text{PO}_4)_3/\text{C}$ was reported in our previous work [47]. Figure 7a displays the experimental XRD pattern and calculated data of $\text{Na}_3\text{V}_2(\text{PO}_4)_3$, with low R_{wp} (5.7%) and R_p (4.4%), indicating the high purity of

$\text{Na}_3\text{V}_2(\text{PO}_4)_3$ phase. Lattice parameters of $\text{Na}_3\text{V}_2(\text{PO}_4)_3$ are $a = 8.712798 \text{ \AA}$, $b = 8.712798 \text{ \AA}$, $c = 21.804346 \text{ \AA}$ with $\alpha = 90^\circ$, $\beta = 90^\circ$, $\lambda = 120^\circ$ (R-3c), respectively, which can greatly match with preceding literature. Capacity–voltage curve of $\text{Na}_3\text{V}_2(\text{PO}_4)_3/\text{C}$ at the first cycle (Fig. 7b) shows the voltage plateau is at 3.4 V and $\text{Na}_3\text{V}_2(\text{PO}_4)_3/\text{C}$ can provide an 80 mAh g^{-1} at 100 mA g^{-1} after 50 cycling periods (Fig. S18). For $\text{Na}_3\text{V}_2(\text{PO}_4)_3/\text{C}/\text{CoSe}_2@\text{CNTs-MXene}$ full sodium-ion batteries, the cell can provide an initial charge/discharge capacity (Fig. 7d), 401 and 331 mAh g^{-1} , under the current of 100 mA g^{-1} , respectively, from 0.5 to 3 V (based on the weight of anode). Beyond that, the full cell can obtain an invertible capacity of about 280 mAh g^{-1} after 50 cycles (Fig. 7e), indicating the good application prospect in energy storage fields.

4 Conclusions

Dimensional gradient structure of $\text{CoSe}_2@\text{CNTs-MXene}$ transferred from ZIF-67/MXene has been successfully designed. A particular “sheet–tube–dots” hierarchical structure can greatly promote the fast ion/electronic transmission and keep the stability of CoSe_2 nanoparticles. Meanwhile, electrochemical performances of $\text{CoSe}_2@\text{CNTs-MXene}$ in two-electrode systems, ether/ester electrolyte systems were systematically explored. $\text{CoSe}_2@\text{CNTs-MXene}$ in ether exhibits outstanding cycling properties which can obtain 400 mAh g^{-1} after 200 cycles at 2 A g^{-1} with a high ICE of 81.7%, and excellent rate stability of 347.5 mAh g^{-1} at 5 A g^{-1} is much better than electrochemical behaviors in ester system (only 27 mAh g^{-1} for 200 cycles). Transformation mechanisms of CoSe_2 were also explored by in situ XRD and ex situ Raman. Density functional theory study discloses that the $\text{CoSe}_2@\text{CNTs-MXene}$ in ether electrolyte system contributes to stable sodium storage performance owing to the strong adsorption force from hierarchical structure and weak interaction between electrolyte/electrode. For full cell, $\text{CoSe}_2@\text{CNTs-MXene}/\text{Na}_3\text{V}_2(\text{PO}_4)_3/\text{C}$ can also afford a reversible capacity of 280 mAh g^{-1} over 50 cycles at a current of 100 mA g^{-1} . Briefly, unique dimensional gradient structure and suitable electrolyte design promote potential application of $\text{CoSe}_2@\text{CNTs-MXene}$ in sodium storage fields.
