

NRF2-driven miR-125B1 and miR-29B1 transcriptional regulation controls a novel anti-apoptotic miRNA regulatory network for AML survival

NM Shah^{1,2}, L Zaitseva¹, KM Bowles^{1,3}, DJ MacEwan^{2,4} and SA Rushworth^{*,1,4}

Transcription factor NRF2 is an important regulator of oxidative stress. It is involved in cancer progression, and has abnormal constitutive expression in acute myeloid leukaemia (AML). Posttranscriptional regulation by microRNAs (miRNAs) can affect the malignant phenotype of AML cells. In this study, we identified and characterised NRF2-regulated miRNAs in AML. An miRNA array identified miRNA expression level changes in response to NRF2 knockdown in AML cells. Further analysis of miRNAs concomitantly regulated by knockdown of the NRF2 inhibitor KEAP1 revealed the major candidate NRF2-mediated miRNAs in AML. We identified miR-125B to be upregulated and miR-29B to be downregulated by NRF2 in AML. Subsequent bioinformatic analysis identified putative NRF2 binding sites upstream of the miR-125B1 coding region and downstream of the miR-29B1 coding region. Chromatin immunoprecipitation analyses showed that NRF2 binds to these antioxidant response elements (AREs) located in the 5' untranslated regions of miR-125B and miR-29B. Finally, primary AML samples transfected with anti-miR-125B antagomiR or miR-29B mimic showed increased cell death responsiveness either alone or co-treated with standard AML chemotherapy. In summary, we find that NRF2 regulation of miR-125B and miR-29B acts to promote leukaemic cell survival, and their manipulation enhances AML responsiveness towards cytotoxic chemotherapeutics.

Cell Death and Differentiation (2015) 22, 654–664; doi:10.1038/cdd.2014.152; published online 17 October 2014

Acute myeloid leukaemia (AML) is a biologically heterogeneous disorder that occurs as a consequence of a wide variety of genetic abnormalities in haematopoietic progenitors that are derived from the bone marrow.¹ However, it is likely that AML share various survival pathways downstream of the driver mutations, making the existence of common survival pathways and therapeutic targets likely.²

Nuclear factor (erythroid-derived 2)-like 2 (NRF2) is a member of the Cap 'n' Collar basic leucine zipper transcription factor family that protects cells from reactive oxygen species through the regulation of a number of cytoprotective genes including heme oxygenase-1 (HO-1) and NAD(P)H dehydrogenase quinone 1 (NQO1).^{3–5} In cancer, NRF2 activation is pro-tumoural in a spectrum of malignancies through mutations in NRF2 or its cytosolic inhibitor KEAP1.^{6–9} However, we have previously shown that in human AML constitutive activation of the NRF2 signalling pathway is not through somatic mutations of NRF2/Keap1 but as a consequence of upstream constitutive activation by NF- κ B.^{10,11} In addition to contributing to the malignant phenotype of AML, we also found that NRF2 contributes to intrinsic leukaemia cell resistance to standard front-line chemotherapy agents.^{12,10}

microRNAs (miRNAs) are short non-coding RNA molecules, approximately 20–30 nucleotides in length, that can

posttranscriptionally regulate gene expression by binding to the 3' UTR of their target mRNA, thereby repressing gene transcription.¹³ miRNA expression has shown to be dysregulated in a range of cancers, and can act as tumour suppressor miRNAs (by downregulating oncogenes) or oncomiRNAs (by targeting tumour suppressors).¹⁴ miRNAs are being increasingly studied with the expectation that modulation of their expression can be harnessed to improve cancer therapy. A recent study using chromatin immunoprecipitation sequencing (ChIP-Seq) identified high-confidence ChIP-Seq peaks for NRF2 binding in the vicinity of several miRNAs, suggesting they could be regulated by NRF2.¹⁵

In the present study, we look to identify whether NRF2 regulates miRNA in human AML. Furthermore, we evaluate whether NRF2-regulated miRNAs have functional importance not only on the biology of the disease but also in the leukaemia cell death to chemotherapy treatment.

Results

Lentiviral NRF2 knockdown alters miRNA expression.

NRF2 can regulate drug resistance in AML via the induction of cytoprotective and detoxification genes.^{10,12} To assess whether NRF2 regulates miRNA expression in AML, we used

a commercially available OncomiR Cancer miRNA qRT-PCR Array on THP-1 cells infected with an NRF2 lentiviral knockdown (NRF2-KD) and a negative control knockdown (NEG-KD). Figure 1a shows the change in expression of miRNA in response to NRF2-KD compared with the control infected with NEG-KD. We then treated THP-1 cells with the NRF2 activator sulforaphane for 6 h for comparison. Supplementary Table 1 shows the fold increase of miRNA in response to both NRF-KD and sulforaphane treatment. From these experiments, we identified miR-125B, miR-222, miR-221 and miR-223 as potential miRNAs upregulated by NRF2 and miR-29B and miR-154 as potential miRNAs downregulated by NRF2. Figure 1c shows western blot analysis of NRF2 and KEAP1 protein expression in THP-1 cells in response to NRF2-KD, KEAP1-KD and NEG-KD.

Increased NRF2 activity increases miR-125B and decreases miR-29B expression in AML. We used a qRT-PCR approach to validate the data from the lentiviral array experiments.¹⁰ NRF2-KD results in THP-1 cells showing a consistent decrease in miR-125B expression and increasing miR-29B expression as well as smaller but not significant fluctuations in miR-221, miR-222, miR-223 and miR-154 expression (Figure 1b). To further assess the role of NRF2 in regulating miRNA, we increased the activity of NRF2 in THP-1 cells by knockdown of the NRF2 inhibitor KEAP1.¹⁶ THP-1 were infected with KEAP1 lentiviral knockdown (KEAP1-KD). QRT-PCR confirmed the downregulation of KEAP1 and as a positive control, we showed that KEAP-KD upregulated the NRF2 target gene HO-1. Moreover, miR-125B expression showed a similar increase to HO-1 and miR-29B showed a significant decrease in response to KEAP1-KD (Figure 1b). The expression of miR-221, miR-222, miR-223 and miR-154 were not significantly changed in response in NRF2-KD or KEAP1-KD to warrant its inclusion in further experiments.

NRF2 regulates homologues miR-125B1 and miR-29B1 and miR-29A in human AML. Both miR-125B and miR-29B exist as two homologues (Figure 2a). miR-125B1 (located on chromosome 11) and miR-125B2 (located on chromosome 21), both contain identical seed sequences. Both homologues lie in the region of regulatory miRNA clusters, miR-100-let-7-a-2 and LINC00478, respectively. miR-29B also exists as two homologues, miR-29B1 (located on chromosome 7) and miR-29B2 (located on chromosome 1) (Figure 2a).

The sequence of the miRNA seed region of both miR-125B1 and 2 is identical. Similarly, the seed sequence of miR-29B1 is identical to that of miR-29B2. Therefore, we used primers designed specifically for the immature miRNA sequences (which does differ between the miRNA homologues) to identify which miR-125B and miR-29B homologues were being regulated by NRF2. QRT-PCR on lentiviral NRF2-KD THP-1 cells identified reduced expression of the immature miR-125B1 and increased expression of the immature miR-29B1, but no change in the expression of immature miR-125B2 and miR-29B2 sequence (Figures 2b and c). This suggests that miR-125B1 and miR-29B1, but not miR-125B2 or miR-29B2, are regulated by NRF2.

To determine whether NRF2 specifically regulated miR-125B1 and miR-29B1 or had a more general regulatory effect on their clusters, we looked for a differential expression on other miRNAs in each of the homologue regions in response to NRF2-KD. Following NRF2 knockdown, however, there was no difference in the expression of miR-100 and let-7a-2 (miR-125B1 cluster; chromosome 11) or miR-99a and let7c (miR-125B2 cluster; chromosome 21) (Figure 2b). This implies that NRF2 does not regulate these clusters to control miR-125B expression but instead binds to a miR-125B1-specific regulatory region. Conversely, knockdown of NRF2 elevated miR-29B1 and miR-29A but had no effect on miR-29B2 and miR-29C (Figure 2c). NRF2 therefore regulates

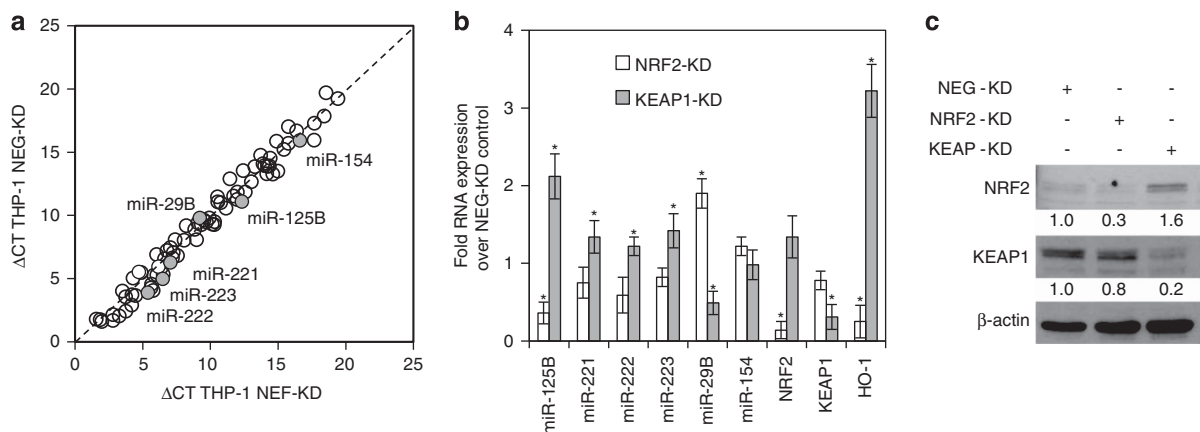

Figure 1 miRNA profiling of AML cells in response lentiviral NRF2 knockdown. (a) THP-1 cells were transduced with NEG (NEG-KD)- and NRF2 (NRF2-KD)-targeted miRNA lentiviral constructs. QRT-PCR analysis of 92 cancer-associated miRNAs in NRF2-KD THP-1 cells. Values represent change in qRT-PCR cycle threshold normalised to RNU6B (Δ CT). Dashed line indicates no change in expression. A red circle indicates miR-125B, miR221, miR-223, miR222, miR29B and miR154. (b) QRT-PCR of miR-125B, miR221, miR-223, miR222, miR29B, miR154, NRF2, KEAP1 and HO1 in THP-1 cells transduced with NEG-KD, NRF2-KD or KEAP1-KD. Values represent fold change in RNA expression over NEG-KD control. (c) THP-1 were transduced with NEG-KD, NRF2-KD or KEAP1-KD before cells were analysed for NRF2 and KEAP1 using western blotting. Blots were reprobred for β -actin to show sample loading. The numbers under the blots indicate densitometry analysis of the blots using Image J software, and the results are expressed as fold change relative to the NEG-KD control

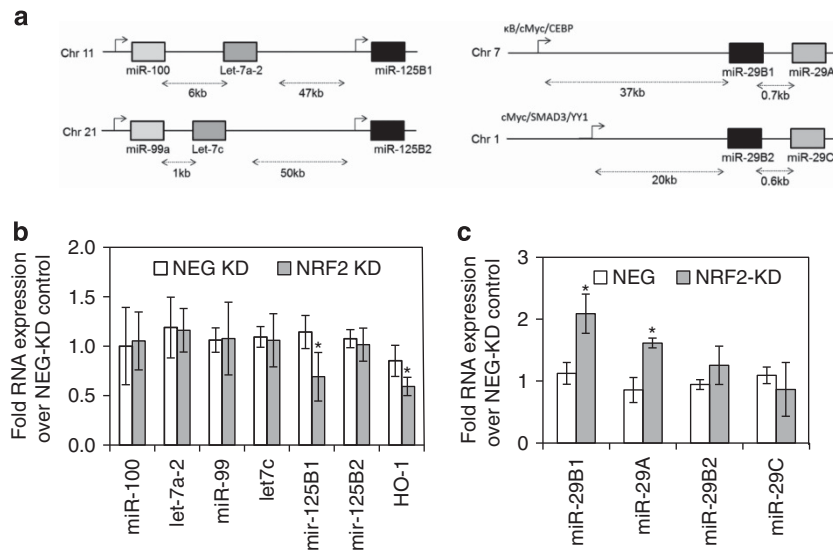

Figure 2 NRF2 regulates homologues miR-125B1 and miR-29B1 and miR-29A in human AML. (a) Schematic representation of the miRNA chromosomal positioning of miR-125B (1 and 2) and miR-29B (1 and 2). (b) Total RNA was extracted from THP-1 transduced with NEG-KD and NRF2-KD and examined for miRNA expression including immature miR-125B1, miR-125B2 RNA and HO-1 mRNA expression. (c) Total RNA was extracted from THP-1 transduced with NEG-KD and NRF2-KD and examined for miR-29A and miR-29C expression including immature miR-29B1, miR-29B2 RNA and HO-1 mRNA expression

a defined pattern of expression of the miR-125B1 and miR-29B1 cluster in human AML. Moreover, results from Figure 1b and Figures 2b and c show that changes in total levels of miR-125B and miR-29B are similar to changes in miR-125B1 and miR-29B1. The main reason for this similarity is that constitutive levels of miR-125B2 and miR-29B2 are much lower in AML than that of their homologue, thus changes observed in total miR-125B and miR-29B reflect changes observed in miR-125B1 and miR-29B1 levels.

NRF2 binds to ARE sites in the promoters of miR-125B1 and miR-29B1. NRF2 acts as a transcription factor by binding to the antioxidant response element (ARE) region in the promoter regions of its target genes.¹⁷ To analyse the 5' miR-125B1 and miR-29B1 promoter sequence, we used transcription factor analysis programmes (<http://www.gene-regulation.com/cgi-bin/pub/programs/pmatch/bin/p-match.cgi> and www.genomatix.de/matinspector.html). These analyses identified three potential ARE sites within the miR-125B1 promoter and two in the miR-29B1 promoter (Figure 3a).

To confirm whether NRF2 bound to ARE binding sites in the miR-29B1 or the miR-125B1 promoter, a ChIP assay was undertaken. Figure 3b shows the analysis using antibodies for NRF2 and quantified against control IgG with specific primers for ARE1-3 (promoter region of miR-125B1; chromosome 11) and ARE4 and ARE5 (promoter region of miR-29B1; chromosome 7). Recruitment of NRF2 was markedly enhanced to ARE5 in the miR-29B1 promoter and ARE3 in the miR-125B1 promoter. Next, we evaluated the recruitment of NRF2 to ARE1-5 sites in THP-1 cells transfected with KEAP1 siRNA. Figure 3c shows that there was increased recruitment of NRF2 to the ARE3 and ARE5 site, but not the other potential ARE sites in THP-1 cells transfected with KEAP1 siRNA over control siRNA. These observations confirmed that NRF2 specifically binds the miR-29B1 ARE5 site and the miR-125B1 ARE3 site.

To establish whether NRF2 functionally controls miR-125B1 expression, the miR-125B1 promoter was cloned into a PGL4 luciferase plasmid and the putative ARE3 site was mutated (Figure 3d). AML is a disease characterised by constitutive activation of NRF2, therefore the luciferase vector PGL4 and PGL4/p125B were transfected into THP-1 cells without prior treatment of an NRF2 activator or repressor. We observed an approximate eightfold increase in luciferase activity in the PGL4/p125B plasmid in comparison with the control (Figure 3e). Site-directed mutagenesis of the ARE3 site in the miR-125B1 promoter corresponded with a significant decrease in miR-125B1 promoter activity (Figure 3e). Moreover, when we co-transfected KEAP1 and NRF2 siRNA with the p125B and p125BNRF2Mut plasmids, KEAP1 siRNA induced significant increase in p125B promoter activity and NRF2 siRNA inhibited p125B promoter activity. KEAP1 siRNA and NRF2 siRNA had no effect on p125BNRF2Mut promoter activity (Figure 3f). Similar experiments on the miR-29B1 promoter were technically not possible as the construct was too big and would not clone into a luciferase reporter vector. These results demonstrate that the ARE3 site in the promoter of miR-125B1 is regulated by NRF2.

NRF2 regulates the expression of miR-125B1 and miR-29B1 in primary human AML. As we have established in AML that high NRF2 mRNA expression causes an increase in NRF2 activity,¹⁰ and that miR-125B1 and miR-29B1 are regulated by NRF2 in AML cell lines, we next examined the expression of NRF2, miR-125B1 and miR-29B1 in primary human AML cells. NRF2 and miR-125B1 is increased in AML compared with normal CD34+ haematopoietic stem cells (HSC), whereas miR-29B1 is decreased in AML compared with normal CD34+ HSC (Figure 4a). As total levels of miR-125B and miR-29B most likely determine their biological function, we analysed total levels of miR-125B and

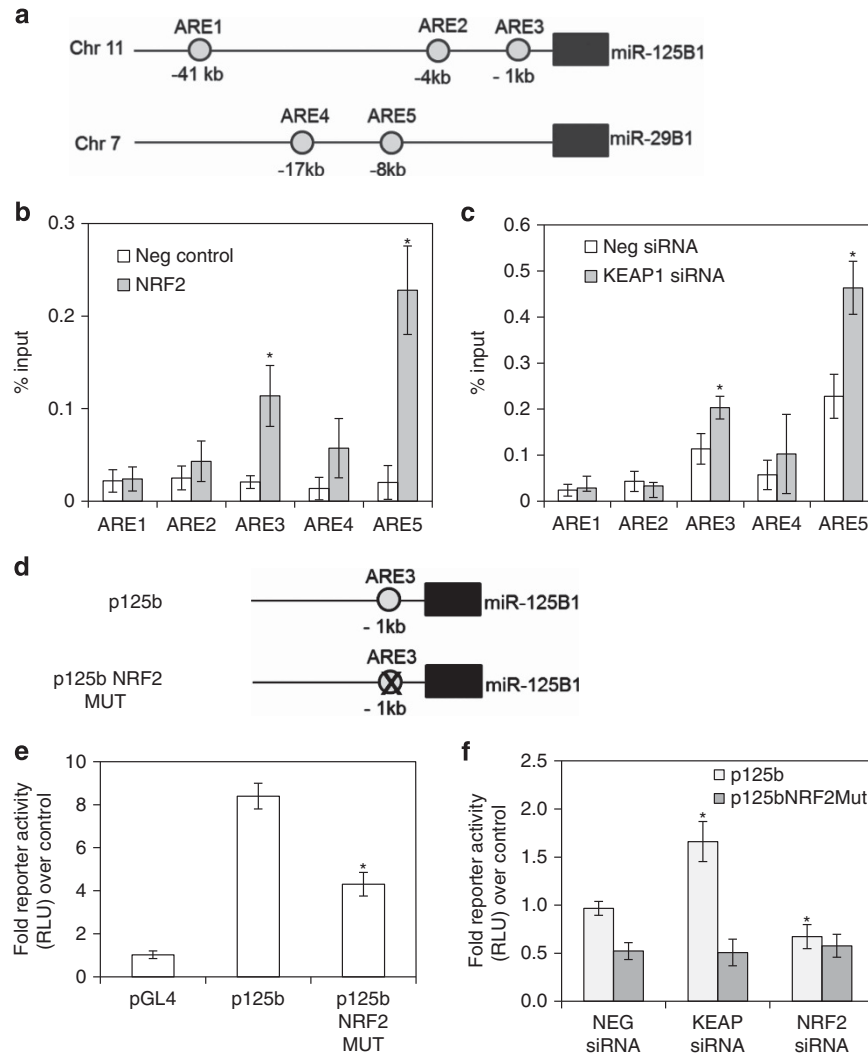

Figure 3 NRF2 binds to ARE sites in the promoters of miR-125B1 and miR-29B1. (a) Schematic presentation of ARE binding sequences in the 5' region of miR-29B1 on chromosome 7 and miR-125B1 on chromosome 11. (b) Chromatin immunoprecipitation (ChIP) analysis of the miR-29B1 and miR-125B1 promoter using antibodies against NRF2 and normal rabbit IgG was used as a control. QRT-PCR was performed in triplicate on immunoprecipitated DNA and input DNA. Data presented as percent of input. * indicates $P < 0.05$ between the different treatment groups. (c) THP-1 cells were transfected with control siRNA and KEAP1 siRNA for 24 h and ChIP was performed. Real-time PCR was performed in triplicate on immunoprecipitated DNA and input DNA. Data presented as percent of input. * indicates $P < 0.05$ between the different treatment groups. (d) Schematic representation of mutated miR-125B promoter sequence. (e) THP-1 cells were transiently transfected with 0.5 μ g of each promoter construct including control plasmid and pRL-TK for normalisation of transfection efficiency. Cell extracts were harvested and luciferase assays were performed. Values are the means \pm S.D., $n = 4$. * indicates $P < 0.01$ of deleted ARE against PGL4 control. (f) Control, KEAP1 and NRF2 siRNA were transfected at the same time as p125b and p125bNRF2 MUT and incubated for 48 h. Cell extracts were harvested and luciferase assays were performed. Values are the means \pm S.D., $n = 4$. * indicates $P < 0.01$ of KEAP1 siRNA and NRF2 siRNA against NEG siRNA control

miR-29B in AML. Supplementary Figure 2 shows that total miR-125B is increased in AML compared with normal CD34+ HSC, whereas miR-29B is decreased in AML compared with normal CD34+ HSC. Furthermore, there is a positive correlation between NRF2 RNA expression and miR-125B1 RNA expression, with an inverse correlation between NRF2 RNA expression and miR-29B1 RNA expression in primary AML cells (Figure 4b). To confirm that NRF2 regulates miR-125B1 and miR-29B1 expression in primary human AML cells, we used NRF2 siRNA to silence NRF2 RNA expression in eight AML patient samples. NRF2 mRNA is significantly knocked down in seven out of the eight AML samples of

which the majority also had significantly lower miR-125B1 expression (Figure 4c). Moreover, NRF2 siRNA in the AML samples increased miR-29B1 expression (Figure 4c). Together, these results show that knockdown of NRF2 regulates the expression of miR-125B1 and miR-29B1 in primary human AML.

miR-125B antagomiR and miR-29B mimic increases AML apoptosis and sensitivity to frontline chemotherapy agents. Previous studies in AML have suggested that the overexpression of miR-125B plays an oncogenic role by repressing apoptosis and the reduction of miR-29B increases

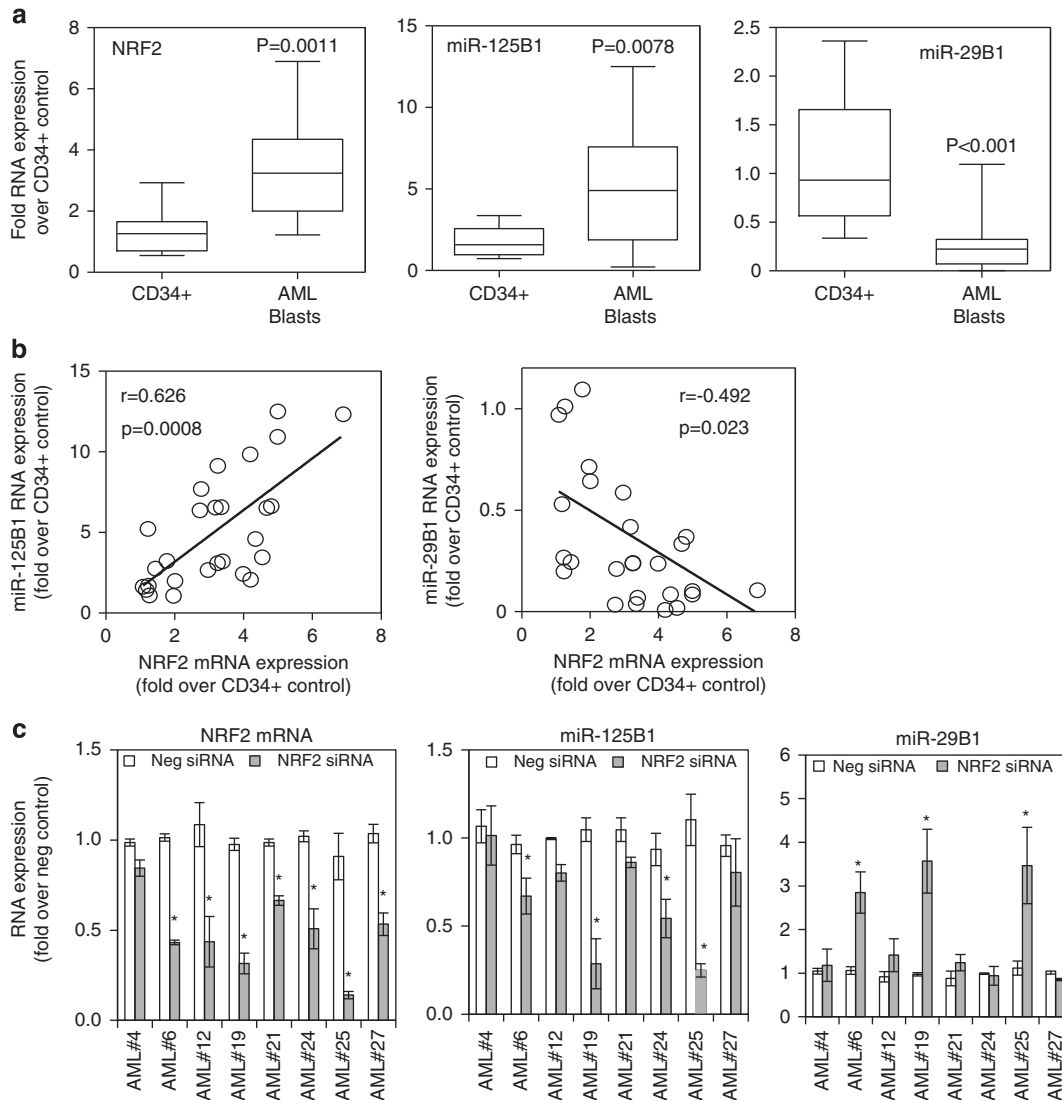

Figure 4 NRF2 regulates miR-29B1 and miR-125B1 in primary AML. (a) Total RNA was extracted from patient AML blasts ($n=18$) and CD34+ HSC ($n=8$). NRF2, miR-29B1 and miR-125B1 RNA expression levels were measured using QRT-PCR. (b) Pearson's correlation analysis between miR-125B1 or miR-29B1 and NRF2 mRNA expression in human primary AML cells. (c) Control and NRF2 siRNA were transfected into primary blasts ($n=7$) for 48 h and RNA extracted. RNA was analysed for NRF2, miR-125B1 and miR-29B RNA expression. Values are the means \pm S.D., $n=3$

proliferation and represses apoptosis.^{18,19} To determine the functional role of inhibiting miR-125B and overexpressing miR-29B both alone and in-combination, we transfected miR-125B antagomiR and miR-29B mimic into THP-1 cells and analysed cells for apoptosis by annexin V/PI staining. However, before we did this, we showed that the concentrations of transfected miR-125B antagomiR and miR-29B mimic used manipulated the miRNA levels comparable with that observed in the NRF2-KD and KEAP1-KD THP-1 cells (Supplementary Figure 1). THP-1 cells transfected with the miR-125B antagomiR or miR-29B mimic showed a small but significant increase in annexin V/PI staining in comparison with the control transfection (Figure 5a). Moreover, when we co-transfected miR-125B antagomiR and miR-29B mimic, we observed a synergistic increase in annexin V/PI staining in comparison with the control (Figure 5a). Transfection of

miR-125B antagomiR and miR29B mimic into THP-1 and Kasumi-1 cells potentiated the cytotoxic effect of the frontline AML chemotherapy agent daunorubicin (Supplementary Table 2).

Next, we examined the effects of inhibiting miR-125B and increasing miR-29B expression in primary AML cells in comparison with non-malignant primary CD34+ HSC. In six primary AML patient samples, inhibition of miR-125B or increasing miR-29B showed a significant decrease in cell viability (Figure 5b). Finally, we compared the viability of primary AML patient cells that had normal NRF2 expression (and thus normal miR-125B and miR-29B expression) with an AML patient sample that had high NRF2 expression (and thus high miR-125B and low miR-29B expression) after treatment with daunorubicin (Figure 5c and Table 1 and Supplementary Table 2). AML with normal NRF2 and normal miR-125B and

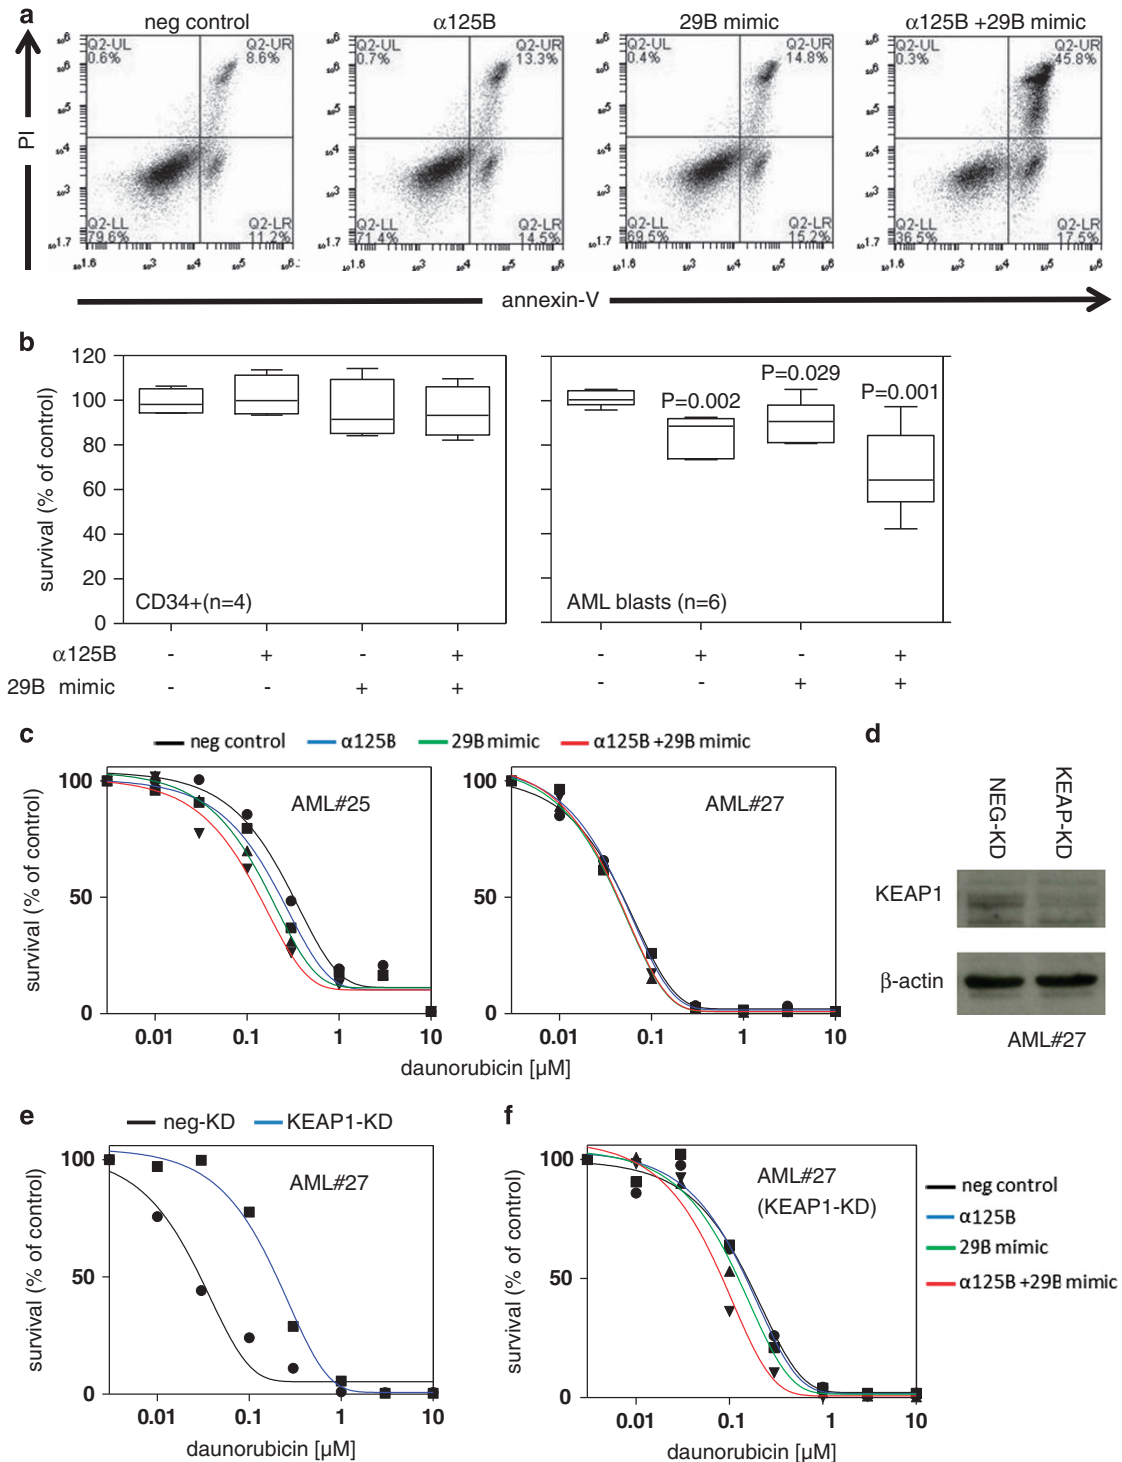

Figure 5 miR-125B antagonomiR and miR-29B mimic induce apoptosis of AML cells and increases there sensitivity to AML chemotherapy. (a) THP-1 were transfected with control miRNA, miR-125B antagonomiR ($\alpha 125B$), miR-29B mimic (29B mimic) and miR-125B antagonomiR in combination with miR-29B mimic for 48 h before cells were analysed for apoptosis by PI/Annexin V staining. (b) AML blasts ($n=6$) and CD34+ ($n=4$) were transfected with control miRNA, miR-125B antagonomiR and miR-29B mimic and miR-125B antagonomiR in combination with miR-29B mimic for 24 h and then assessed for cell viability by Cell Titer-GLO. (c) AML blasts and CD34+ cells were transfected with control miRNA (miR-mimic negative control and the anti-miR miRNA inhibitor negative control for single experiments and combined miR-mimic negative control and the anti-miR miRNA inhibitor negative control in combined experiments), miR-125B antagonomiR, miR-29B mimic and miR-125B antagonomiR in combination with miR-29B mimic for 24 h before the addition of increasing doses of daunorubicin for 48 h. Cells assessed for viability by Cell Titer-GLO. (d) AML#27 was transduced with NEG-KD and KEAP1-KD for 48 h before cells before the addition of increasing doses of daunorubicin for 48 h before cells were analysed for KEAP1 using western blotting. Blots were reprobred for β -actin to show sample loading. (e) AML#27 was transduced with NEG-KD and KEAP1-KD for 48 h before the addition of increasing doses of daunorubicin for 48 h. Cells were assessed for viability by Cell Titer-GLO. (f) AML#27 was transduced with KEAP1-KD for 48 h before cells were transfected with control miRNA, miR-125B antagonomiR, miR-29B mimic and miR-125B antagonomiR in combination with miR-29B mimic for 24 h followed by the addition of increasing doses of daunorubicin for 48 h. Cells were assessed for viability by Cell Titer-GLO

This table defines the nature of the AML disease including WHO diagnosis and cytogenetics. NRF2, miR125B1 and miR-29B1 RNA expression levels over CD34+ control cells

miR-29B expression were much more sensitive to daunorubicin than AML patient samples that had high NRF2 expression and thus high miR-125B and low miR-29B expression. Moreover, when we transfected the primary AML that had high NRF2 and high miR-125B and low miR-29B with miR-125B antagomiR together with miR-29B mimic, the result was that sensitivity of these AML cells to daunorubicin was increased to a level comparable with AML with normal NRF2 expression. Because AML#27 has low NRF2 expression over normal CD34+ HSC (Table 1), which is more sensitive to daunorubicin (Figure 5c), and miR-125B antagomiR together with miR-29B mimic had no effect on resistance to daunorubicin (Figure 5c), we examined the effect of KEAP1-KD on AML#27 to determine if we could increase the activity of NRF2 and increase the chemoresistance of this sample. Figure 5d shows KEAP1-KD in AML#27. Figure 5e shows that KEAP1-KD AML#27 is more resistant to daunorubicin compared with NEG-KD. However, when we transfected AML#27 KEAP1-KD cells with control miRNA, miR-125B antagomiR, miR-29B mimic and miR-125B antagomiR in combination with miR-29B mimic, only the combination decreased resistance to daunorubicin (Figure 5f). These results demonstrate that inhibiting miR-125B and overexpressing miR-29B in combination increases apoptosis of primary AML and also increases sensitivity of AML cells to current frontline chemotherapy.

miR-29B and miR-125B gene targets in human AML. Studies have shown that a number of different targets exist

for both miR-29B and miR-125B in AML (Supplementary Table 3).^{18,20–28} Here we examine the expression of genes listed in Supplementary Table 3 for their response to transfection of control miRNA, miR-125B antagomiR, miR-29B mimic and miR-125B antagomiR in combination with miR-29B mimic. Figure 6a shows that MYBL2, AKT2, CDK4 and SP1 are inhibited by miR-29B mimic in THP-1 cells; we also observe that AKT2 and CDK4 are further inhibited by the addition of miR-125B antagomiR. From the miR-125B targets, Figure 6a shows that MAPK14, STAT3 and BAK1 show an increase in mRNA in response to miR-125B antagomiR. Next, we examined the protein expression of AKT2, STAT3 and BAK1. Figure 6b shows a reduction in AKT2 protein expression in response to miR-29B mimic and miR-125B antagomiR in combination with miR-29B mimic. STAT3 showed a slight increase in response to miR-29B mimic and miR-125B antagomiR in combination with miR-29B mimic. BAK1 showed an increase in response to miR-125B antagomiR and miR-125B antagomiR in combination with miR-29B mimic.

Finally, we wanted to determine whether NRF2 deregulation in AML affects miRNA levels to such an extent that expression of their target genes is changed as a consequence. Figure 6c shows a change in expression of AKT2, STAT3 and BAK1 but not MCL1 mRNA in response to NRF2-KD or KEAP1-KD compared with NEG-KD. Figure 6d shows changes in AKT2 and BAK1 protein expression in response to NRF2-KD and an increase in response to KEAP1-KD. Together, these results link the two major observations of this study; first, that NRF2

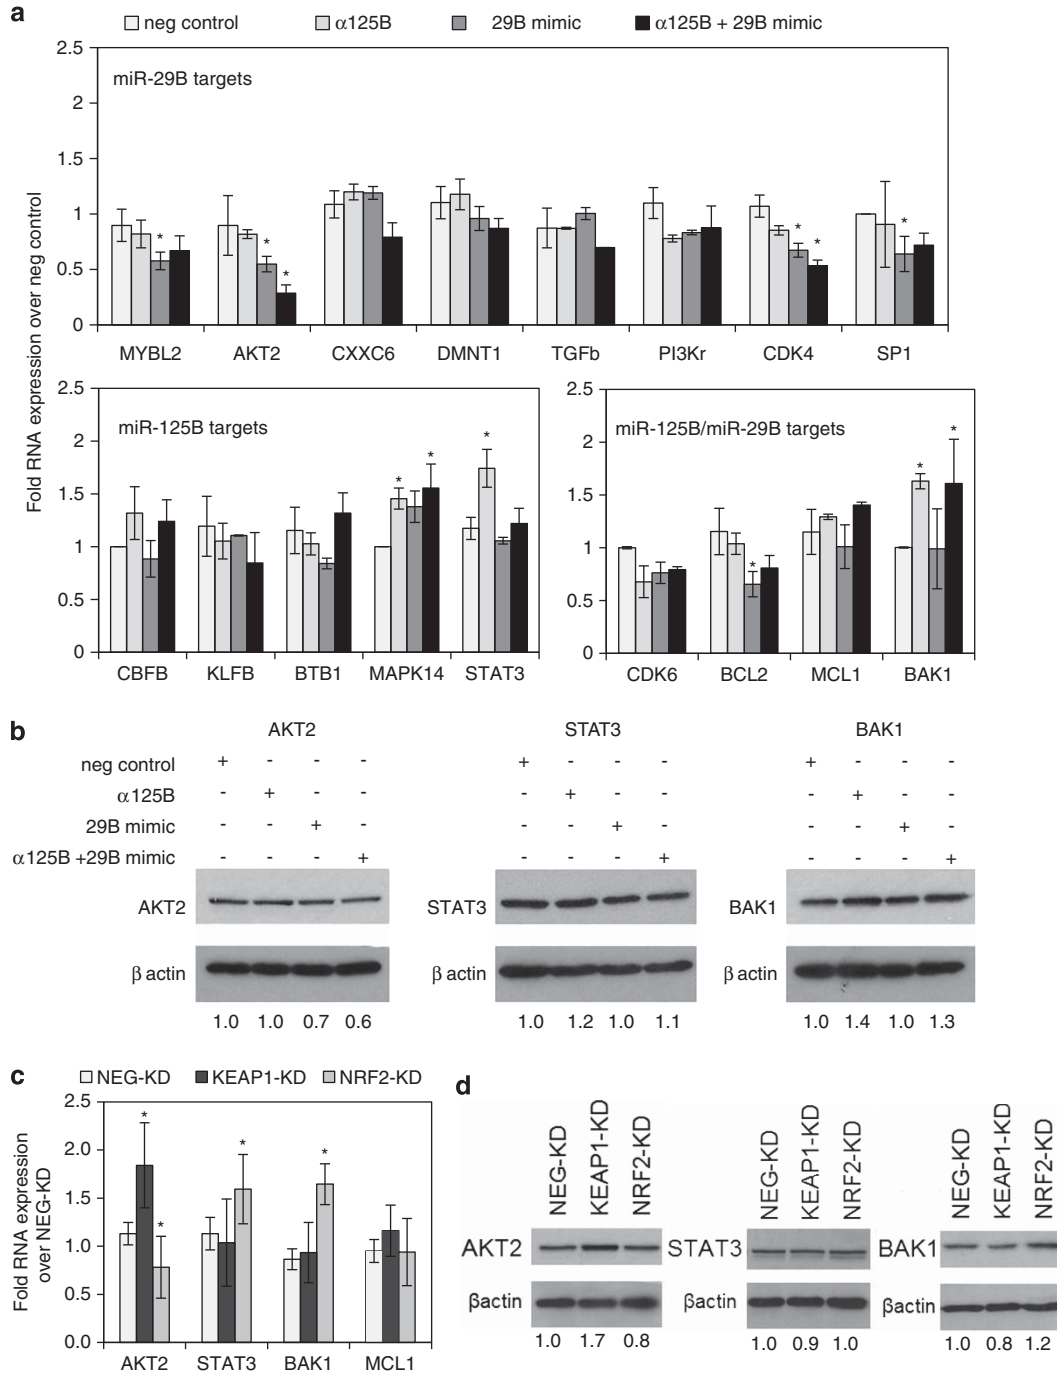

Figure 6 miR-125B antagoniR and miR-29B mimic gene targets in AML cells. (a) THP-1 were transfected with control miRNA, miR-125B antagoniR (α 125B), miR-29B mimic (29B mimic) and miR-125B antagoniR in combination with miR-29B mimic for 48 h before cells were analysed for target gene expression using QRT-PCR. (b) THP-1 cells were transfected with control miRNA, miR-125B antagoniR (α 125B), miR-29B mimic (29B mimic) and miR-125B antagoniR in combination with miR-29B mimic for 48 h before cells were analysed for AKT2, STAT3 and BAK1 using western blotting. Blots were reprobed for β -actin to show sample loading. (c) QRT-PCR of mRNA for AKT2, STAT3, BAK1 and MCL1 in THP-1 cells transfected with NEG-KD, NRF2-KD or KEAP1-KD. Values represent fold change in RNA expression over NEG-KD control. (d) THP-1 cells were transfected with NEG-KD, NRF2-KD or KEAP1-KD before cells were analysed for AKT2, STAT3 and BAK1 protein expression using western blotting. Blots were reprobed for β -actin to show sample loading. The numbers under the blots indicate densitometry analysis of the blots using Image J software, and the results are expressed as fold change relative to the negative control

directly regulates miR-125B and miR-29B expression. Second, that miR-125B and miR-29B synergistically influence AML survival and chemoresistance, possibly via deregulation of target genes such as AKT2, STAT3 or BAK1.

Discussion

Our understanding of the role of non-coding RNA molecules in diseases such as cancer is presently in its infancy. To date, miRNAs have been shown to have a significant role in cancer

biology through the regulation of both tumour suppressors and oncogenes. Less is known, however, about the upstream control of miRNA expression in cancer and the biological processes that control miRNA expression. In AML, the differential expression of a number of miRNAs has been reported to be associated with the malignant phenotype but as yet the upstream mechanisms by which this is controlled are yet to be described.^{29–32} As we have previously identified NRF2 as an important regulator of cell survival in AML, the aim of the present study was to investigate the ability of NRF2 to affect miRNA expression and furthermore define the function of these miRNAs in human AML both in a resting state and in response to front-line chemotherapeutic agents.

Through gene expression data and multiple transcription factor binding assays, we found that NRF2 upregulates miR-125B1 and downregulates miR-29B1 through binding to specific ARE sites in the miR-125B1 and miR-29B1 regulatory regions. Furthermore, we observed that by decreasing the expression of miR-125B and increasing the expression of miR-29B, the cells become more sensitive to apoptotic stimuli. These findings are in keeping with previous observations that miR-29B and miR-125B regulate the expression of multiple survival pathways in AML. The global repression of miR-125B targets and elevation of miR-29B targets genes would aid the uncontrolled proliferative phenotype of AML. Therefore, in Figures 6a and b, we analyse the targets of miR-29B and miR-125B in AML cells transfected with corresponding mimic and antagomir, both alone and in combination. We observe changes in a number of genes including AKT2, CDK4, MAPK14, STAT3, BCL2 and BAK1. Interestingly, AKT2 and CDK4 are targets of miR-29B only; however, when we co-transfect miR-125B antagomir and miR-29B mimic, we do observe a further reduction over miR-29B mimic only. There are no miR-125B sites within these two genes suggesting that the combined observations are due to off-target effects. Together, the cumulative repression of miR-29B and the overexpression of miR-125B significantly contribute to leukaemia cell proliferation within the bone marrow niche.

Transcription factors are generally structured in context of networks. In AML, miR-29B downregulation has been found to be associated with high C-MYC levels as well as high SP1 and NF- κ B.^{33,34} Furthermore, NF- κ B, JUN and C-MYC have been linked to increased NRF2 activity in human cancer (including AML)^{10,35} and NRF2 has been shown to transcriptionally regulate miR-125B in kidney epithelia cells in response to cisplatin-induced toxicity.³⁶ Taken together, it is likely that NRF2 has a central role in the complex network regulating miR-29B and miR-125B in human AML.

We also highlight that other miRNAs may be regulated by NRF2. The array data shown as Supplementary Table 1 show that some miRNAs are downregulated in response to NRF2-KD and increased in response to sulforaphane. This list includes miR-222, miR221, miR-223, miR-23a, miR-195 and miR-196a. Of particular interest from this group is miR-222, miR-221 and miR223, which have been shown to be highly expressed in AML compared with other leukaemias.³⁷ Moreover, we also noted that high NRF2 activity caused a decrease in the expression of miRNAs, which includes miR-154, miR146a and miR-181B. All these miRNAs have been shown to be of interest in AML with miR-146a being shown to have low expression in AML, which

correlates with high expression of its target gene CXCR4,³⁸ which in a separate study has been shown to be regulated by NRF2 in human HSC.³⁹ Consequently in human AML, NRF2 not only regulates key genes involved in the reaction to oxidative stress but also regulates miRNAs that appear to have a broader impact on gene expression and regulation.

In summary, here we report the first description of upstream miRNA regulation by NRF2 in a human cancer and its downstream cyto-protective consequences. In doing so, we not only provide novel mechanistic insight into the pro-tumoural consequences of the constitutive NRF2 expression in AML, but we also propose that targeting the NRF2 regulation of these miRNA (or the miRNA directly) would be a biologically plausible therapeutic strategy to increase the effectiveness of chemotherapy in human AML.

Materials and Methods

Materials. The AML-derived cell lines were obtained from the European Collection of Cell Cultures where they are authenticated by DNA fingerprinting. In the laboratory, they are used at low passage number for a maximum of 6 months post-resuscitation, testing regularly for Mycoplasma infection. All primers were purchased from Invitrogen (Paisley, UK). AKT2, STAT3 and BAK1 antibodies were purchased from Cell Signalling Technology (Cambridge, MA, USA). NRF2 and KEAP1 antibodies were purchased from Santa Cruz Biotechnology (Santa Cruz, CA, USA). All other reagents were obtained from Sigma-Aldrich (St. Louis, MO, USA), unless indicated. To assess whether NRF2 regulates miRNA expression in AML, we used commercially available OncomiR collection Cancer miRNA qRT-PCR Array (SBI, Mountain View, CA, USA).

Primary AML cell culture. AML cells were obtained from patients' bone marrow or blood following informed consent and under approval from the UK National Research Ethics Service (LRECre07/H0310/146). For primary cell isolation, heparinised blood was collected from volunteers and human peripheral blood mononuclear cells isolated by Histopaque (Sigma-Aldrich, Dorset, UK) density gradient centrifugation. AML samples that were less than 80% blasts were purified using the CD34-positive selection kit (Miltenyi Biotec, Auburn, CA, USA) (denoted by * in Table 1). Cell type was confirmed by microscopy and flow cytometry. We obtained haematopoietic CD34+ cells from two sources, Stem Cell Technologies (Manchester, UK) and volunteers. Positive selection of CD34+ cells were isolated from peripheral blood mononuclear cells using a CD34-positive selection kit (Miltenyi Biotec). For all CD34+ experiments, at least three different donors were used to obtain the results presented in this paper. Cell type was confirmed by microscopy and flow cytometry.

RNA extraction and real time PCR (RT-PCR). Total mRNA extraction was carried out using mirVana miRNA isolation kit (Ambion, Paisley, UK) and reverse transcribed using the miRscript II RT kit (Qiagen, Manchester, UK). All mature miRNA were normalised to RNU6B and immature miRNA and mRNA were normalised to GAPDH for qRT-PCR as described previously.⁴⁰ qRT-PCR was carried out using SYBR green technology (Qiagen). The samples were preamplified at 95 °C for 2 min, after which was amplified for 45 cycles at 95 °C for 15 s, 60 °C for 10 s and 72 °C for 10 s. The qRT-PCR was performed on the LightCycler480 (Roche, Burgess Hill, UK).

Virus construction and infection. Lentiviruses containing miRNA sequence miRNA-Nrf2 (5'-TTAATGAGTTCAGTCAACT-3'), miRNA-KEAP1 (5'-GTTTGGCCACTGACTGAC-3') and miR-NEG were constructed and produced as described previously.⁴¹ For transduction, THP-1 cells and AML blasts cells were plated onto 12-well plates (5 × 10⁴ cells/well) and infected with lentiviruses (multiplicity of infection of 15) with 8 μg/ml Polybrene (Sigma, Dorset, UK). Transduced cells were analyzed by flow cytometry (Accuri, BD Biosciences, Oxford, UK), real-time PCR (Roche) and western blotting.

Transfections. AML transfections were carried out with 2 × 10⁶ cells using the Amaxa Nucleofactor Kit II (Cambridge, UK). Control miR, miR-29B mimic and miR-125B antagomir, control siRNA, KEAP1 and NRF2 siRNA were purchased

from Invitrogen were transfected in at a concentration of 45 nm. For control miR, the miR-mimic negative control and the anti-miR miRNA inhibitor negative control for single experiments and combined miR-mimic negative control and the anti-miR miRNA inhibitor negative control in combined experiments were used. For all gene expression experiments, the cells were incubated for 24 h post transfection before RNA extraction. For the cell viability assays, AML cells were incubated for 48 h post transfection. For reporter assays, 0.5 μ g of PGL4 reporter and pRL-TK control constructs were co-transfected into THP-1. Transfected cells were incubated for 24 h before the indicated treatments. For reporter assay, cells were treated with Dual-Luciferase reporter assay system (Promega, Southampton, UK).

Western blotting. Sodium dodecyl sulfate-polyacrylamide gel electrophoresis and western blot analyses were performed as described previously. Briefly, whole cell lysates as well as nuclear and cytosolic were extracted and sodium dodecyl sulfate-polyacrylamide gel electrophoresis separation was performed.⁴² Protein was transferred to nitrocellulose and western blot analysis performed with the indicated antisera according to their manufacturer's guidelines.

Cloning of miR-125B promoter construct. To generate the p125B promoter construct containing ARE3, a DNA fragment containing 2.6 kb of the human 125b promoter region was amplified from genomic DNA with PCR and specific primers: 5'-TGAGAGGAGCGCAACAATG-3' reverse primer and 5'-AGAAAGGCCACCAAGATTAC-3' forward primer. The fragment was cloned into the PGL4.11 basic plasmid (Promega). To generate mutated NRF2 construct (p125B NRF2 MUT) the sense PCR primer used was 5'-GCTGTG GCTGTGTTTGTATTCTCTTTGACTAG-3'. This mutation was introduced with the QuikChange XL Site-Directed Mutagenesis Kit (Agilent, Stockport, UK).

Cell viability and apoptosis assays. THP-1, Kasumi-1, primary CD34+HSC and primary AML cells were transfected with control miR (miR-mimic negative control and the anti-miR miRNA inhibitor negative control for single experiments and combined miR-mimic negative control and the anti-miR miRNA inhibitor negative control in combined experiments), miR-29B mimic and miR-125B antagomiR and combined miR-29B mimic and miR-125B antagomiR for 24 h. THP-1 cells were analysed for apoptosis using PI/Annexin V staining. THP-1, Kasumi-1, primary CD34+ HSC and primary AML transfected cells were treated with different concentrations of chemotherapy agents and incubated for 48 h; then, viable cells were measured with Cell-Titre GLO (Promega).

Chromatin immunoprecipitation assay. THP-1 cells were transfected with control siRNA or KEAP1 siRNA 24 h before the cells were fixed with 1% formaldehyde in medium for 10 min at room temperature. The sonication conditions were optimised to determine generation of DNA fragments between 300 and 600 base pairs in length. Chromatin was immunoprecipitated with IgG, anti-NRF2 (Cell Signalling). The association of NRF2 was measured by RT-PCR on immunoprecipitated chromatin using primers spanning the ARE sites described in Figure 3a and Supplementary Table 4.

Statistical analyses. Student's *t* test was performed to assess statistical significance from controls. Results with $P < 0.05$ were considered statistically significant (*). Results represent the mean \pm S.D. of three independent experiments.

Conflict of Interest

The authors declare no conflict of interest.
