Automatically listing senior members of departments as co-authors is highly prevalent in health sciences: meta-analysis of survey research

Reint A. Meursing Reynders^{1,2}✉, Davide Cavagnetto^{1,2}, Gerben ter Riet^{3,4}, Nicola Di Girolamo^{5,6} & Mario Malički^{7,8,9}

A systematic review with meta-analysis was conducted to assess the prevalence of automatically listing (a) senior member(s) of a department as co-author(s) on all submitted articles in health sciences and the prevalence of degrees of support on a 5-point justification scale. Survey research was searched in PubMed, Lens.org, and Dimensions.ai. until January 5 2023. We assessed the methodological quality of studies and conducted quantitative syntheses. We identified 15 eligible surveys, that provided 67 results, all of which were rated as having low quality. A pooled estimate of 20% [95% CI 16–25] (10 surveys, 3619 respondents) of researchers in various health sciences reported that a senior member of their department was automatically listed as an author on all submitted articles. Furthermore, 28% [95% CI 22–34] of researchers (10 surveys, 2180 respondents) felt that this practice was 'never', 24% [95% CI 22–27] 'rarely', 25% [95% CI 23–28] 'sometimes', 13% [95% CI 9–17] 'most of the time', and 8% [95% CI 6–9] 'always justified'. The practice of automatically assigning senior members of departments as co-authors on all submitted manuscripts may be common in the health sciences; with those admitting to this practice finding it unjustified in most cases.

Registration of the protocol The protocol was registered in Open Science Framework. Link: <https://osf.io/4eywp/>.

HA	Honorary authorship
ICMJE	International Committee of Medical Journal Editors
OSF	Open Science Framework
QRP	Questionable research practice

The practice of listing a senior member(s) of a department, who did not qualify for authorship, as a co-author on all or most submitted articles can be an efficient way to boost the scientific output of these individuals. This practice sets a poor role model, dilutes the input of those who really did the work and can also mislead other

researchers, practicing physicians, policymakers, and the public¹. This systematic review of survey research assessed the prevalence of this practice in research departments of health sciences and the prevalence of degrees of support.

Honorary authorship (HA) refers to authorship assigned to individuals that should not have been included as authors of a publication, because they made no or insufficient contributions to qualify as authors². The International Committee of Medical Journal Editors (ICMJE) has defined a series of criteria for authorship, which are commonly used in publications in health sciences³. Not fulfilling one or more of these criteria has been defined as ICMJE-based HA. The prevalence of HA is commonly measured as perceived HA or ICMJE-based HA^{3–6}. The practice of automatically listing senior members of a department as co-authors on all or most submitted articles from these departments when such members did not qualify for authorship can be considered as a form of serial honorary authorship. This practice has several consequences: (1) the mass production of honorary authors, (2) the facilitation of the publication of manuscripts, especially when the senior members are well known researchers and when editors and peer-reviewers are not blinded to the authors' identities, (3) propagation of inequality and unfairness, (4) violation of the principle that an academic author has made an important intellectual contribution to a scholarly work, (5) undermining of scientific integrity in that readers might assume that the research is more credible than it actually is, based on the reputation of honorary author(s), and (6) erosion of accountability for the work.

Although a few studies assessed this practice in specific fields^{6–8}, insight into the magnitude of this practice in the health sciences more broadly is missing. The objective of this study was to assess, in the health sciences, the prevalence of:

- (1) Researchers reporting the practice of listing (a) senior member(s) of a department, who did not qualify for authorship, as co-author(s) on all or most submitted articles by default (Review item 1).
- (2) Researchers reporting the practice of automatically listing (a) senior member(s) of a department as a co-author(s) on all submitted articles (Review item 2).
- (3) Degree of support for the practice reported under review item 2 (Review item 3).

Methods

The objectives and outcomes of the protocol differed only slightly from those of a previous protocol on honorary authorship issues². We assessed all outcomes that were originally planned in this new protocol. We registered this new protocol in Open Science Framework (OSF), <https://osf.io/4eywp/>. The Checklist of the Preferred Reporting Items for Systematic review and Meta-Analysis (PRISMA) statement^{9,10} was included with this manuscript. Additional information on our research procedures and methodological differences between the original published protocol² and the completed review are given in the Appendix.

Eligibility criteria

We included publications in health sciences which reported on survey results on a series of pre-defined items regarding the practice of listing (a) senior member(s) of a department, as (a) co-author(s) on all or most submitted articles by default. We included publications on this topic in any language, and any setting and time point. We used the same eligibility criteria as those used in our previous review on HA in health sciences². Full eligibility criteria are in the Appendix (Additional item C, page 5).

Information sources and search strategy

We searched PubMed, Lens.org, and Dimensions from inception till January 5 2023 with no language or data filters. We chose these databases as they are freely available to all researchers and their coverage has been shown to be greater than that of proprietary databases^{11–13}. Only for Lens.org and Dimensions.ai we applied health sciences filters. To avoid missing eligible studies we also manually searched all references of the included surveys for additional eligible surveys. The complete strategy is presented in the Appendix (Additional item D, page 6). For the development of our search strategy, we consulted both previous systematic reviews on our research topic as well as an information specialist to help design our initial strategies. These strategies were subsequently piloted and fine-tuned and were then peer-reviewed and approved in our published protocol.

Survey selection process and data collection

Survey selection and data collection was conducted by RMR and DC, independently. Disagreements were resolved through discussions, information provided by the contacted authors of the surveys, or through arbitration by a third reviewer (GTR). Rayyan¹⁴ was used first to remove duplicates and then for the initial screening of titles and abstracts. Full texts of potentially eligible manuscripts were subsequently retrieved and assessed. References of included surveys were also assessed for eligibility. We implemented Cochrane's strategies¹⁵ to identify multiple reports from the same study and checked eligible surveys for retractions, possible scientific misconduct, or for published corrections, errata or comments. Excluded full-text articles and the rationale for their exclusion are given in the Appendix (Additional item K, pages 30–33). All data items to extract were defined in our data extraction forms (Appendix, Additional item E, pages 7–12).

Study risk of bias assessment

We used a critical appraisal tool tailored to our review to assess how the non-implementation of specific quality safeguards could have affected each eligible result of each survey. This tool consists of a 14 items pilot-tested checklist². Congruent with the AMSTAR-2 tool¹⁶, 7 of the 14 items were labeled as 'critical'. We adopted the

AMSTAR-2 ratings high, 'moderate', 'low', and 'critically low' to rate the overall confidence in each result of each eligible survey. These ratings were reported in tables together with the prevalence of yes, no, and unclear answers to each question of our critical appraisal tool. All assessments and ratings were conducted by RMR and DC, independently. In the case of disagreements, we implemented the same strategies as reported for the study selection and data collection procedures. The 14-item checklist of our quality assessment tool with user's instructions is given in the protocol² and in the Appendix (Additional item F, pages 13–17).

Occurrence measures and synthesis methods

The prevalence was the occurrence measure used both in the presentation of single outcomes as well as in the quantitative syntheses. These proportions are reported with their exact (Wilson) 95% confidence intervals. All outcomes for the three review items were defined in the Appendix (Additional item G, page 18) with the pertinent numerators and denominators. We also reported the various response rates measured.

A narrative systematic synthesis was first conducted for all outcomes. Based on the criteria delineated in the Appendix (Additional item G, page 19) and in our established protocol, we refrained from conducting certain meta-analyses². When conducting quantitative syntheses, proportions are presented in forest plots with 95% confidence intervals. The meta-analyses were done using metaprop command in Stata 18¹⁷. Random-effects models were used, because we expected between-survey variance. To address unit-of-analysis issues we checked whether the same surveyees participated more than once in the same survey. To address missing data issues, we contacted either the corresponding authors or those involved in the statistical analysis by email and sent them reminders after one and two weeks. The data were labelled as missing when after 2 weeks no data were received.

Investigation of heterogeneity and sensitivity analyses

The presence and extent of heterogeneity was inspected visually by assessing the overlap of the confidence intervals in the forest plot, by conducting the test of homogeneity (χ^2), and by calculating tau² i.e., the estimate of between study variance, and by calculating I^2 to assess the inconsistency in the results of the surveys¹⁸. We explored heterogeneity through meta-regression and subgroup analyses of a series of survey- and methodology-related explanatory variables defined in our protocol². Additional information on our methods to explore possible causes of heterogeneity among study results and sensitivity analyses to assess the robustness of pooled results are reported in the Appendix (Additional item G, pages 18–20).

(Non)-reporting bias assessment

We used the term non-reporting bias which is the preferred term suggested by Cochrane¹⁹ and adopted the various strategies according to Cochrane to address these biases (Appendix, Additional item H, page 21). Tests for funnel plot asymmetry were not conducted, because there is no evidence that proportions adequately adjust for these tests²⁰.

Certainty assessment

The GRADE approach was implemented to assess the overall certainty of the body of evidence²¹. Four levels of certainty were assigned according to GRADE, i.e., 'high', 'moderate', 'low', and 'very low certainty'²¹. For each outcome these ratings were presented in summary of findings tables together with the rationale for these ratings. The Appendix (Additional item I, pages 22–23) reports further guidance for grading the overall certainty of evidence.

Results

Study selection and study characteristics

Of the 1952 records identified, 1584 remained after deduplication (Fig. 1)^{9,10}. After screening 69 articles were selected for full-text assessments of which 12 were finally included in the review. Three additional articles were identified during the screening of references. This added up to a total of 15 included surveys with 15 questions on researchers reporting the practice of automatically listing a senior member(s) of a department as co-author(s) on submitted articles and 12 questions on the various justifications of this practice. These latter questions could be addressed with the following 5 justifications i.e., 'never justified', 'rarely justified', 'sometimes justified', 'most of the time justified', and 'always justified'. A total of 67 results were obtained. All full text reports that were excluded are listed in the Appendix (Additional item K, pages 30–33) with the rationale for their non-eligibility. The questionnaires for all included surveys were either identified in the manuscripts or through contacting of authors.

Across 11 surveys that reported gender of respondents, 76.3% of respondents were male (IQR 76.3 to 80.4) (Table 1)²². Across 10 surveys that reported academic positions, 48.8% of respondents were associate professor or full professor (IQR 32.1 to 51.7) (Table 1). We could not reliably extract the prevalences of the continents of the respondents' origins, because these characteristics were often not assessed or were unclear. Additional characteristics of all 15 included surveys and their characteristics are reported in the Appendix (Additional item J, pages 24–29).

Assessment of methodological quality

The overall confidence in the 67 results in the 15 eligible surveys was rated as either 'low' (n = 31) or 'critically low' (n = 36). These ratings were based on the 7 'critical items of the 14-item quality checklist. The prevalence of the critical and non-critical ratings are in Table 2³³. The characteristics of the respondents (item 6), and the review items (Item 7) were defined in all surveys. However, whether the characteristics of the respondents were representative for the target population (item 7) was unclear, often caused by partial or poor reporting

PRISMA 2020 flow diagram for new systematic reviews which included searches of databases, registers and other sources

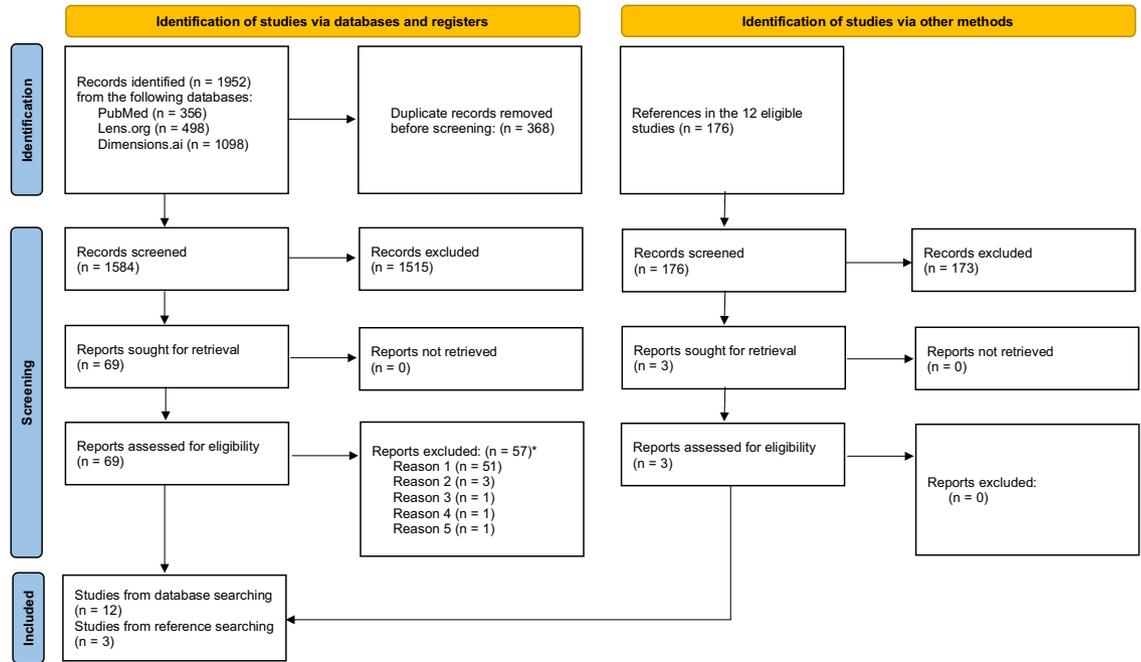

Figure 1. PRISMA flow diagram. *Reason for exclusion: reason 1: did not assess honorary authorship issues as defined in our protocol; reason 2: could not obtain the survey questionnaire through contacting of the authors; reason 3: non-eligible participants; reason 4: not a survey; reason 5: duplicate.

on socio-demographics and non-reporting on the characteristics of non-responders. The low-quality ratings were predominantly the result of shortcomings in the survey methods (31% (21/67), low response rates (99% (66/67), and inadequate sample sizes (46% (31/67). The overall confidence in the results of each survey question of each eligible survey together with the ratings for the 7 critical items of the quality checklist are presented in the Appendix (Additional item L, pages.

Results of individual studies and of syntheses

All results to individual survey questions are reported in Tables 3 and 4 and are further explained in the Appendix (Additional item M, pages 38–54). When identical questions were used in more than one study, we conducted meta-analyses. This applied to review items 2a, 2b, and 3a. When a specific question was used by one single survey only, we reported the prevalence with the 95% confidence intervals. This applied to review items 2c, 2d, 3b, and 3d.

Researchers reporting the practice of listing a senior member(s) of a department, who did not qualify for authorship, as co-author(s) on all or most submitted articles by default (Review item 1).
No surveys addressed this review item.

Researchers reporting the practice of automatically listing (a) senior member(s) of their department (including section chief or department head) as an author on all submitted articles (Review item 2a) and the justification for this practice (Review item 3a).

Different questions were used to assess the prevalence of researchers reporting the practice of automatically listing a senior member(s) of their department as an author on all submitted articles (Review item 2) and the justification for this practice (Review item 3). These review items were therefore divided in Review item 2a and 2b and Review item 3a and 3b (Tables 3 and 4).

A pooled average of 20% [95% CI 16–25] of researchers (based on data from 10 surveys, and a total of 3619 respondents) reported that a senior member of their department (including section chief or department head) was automatically listed as an author on all submitted articles (Review item 2a) (Table 3) (Fig. 2). Results were heterogeneous ($\text{Chi}^2 = 95.84$ (df = 9) $P < 0.001$; $I^2 = 90.61\%$). 2180 respondents (10 surveys) reported on how they justified this practice. A pooled weighted average of 28% [95% CI 22–34] felt it was ‘never justified’, 24% [95% CI 22–27] ‘rarely justified’, 25% [95% CI 23–28] ‘sometimes justified’, 13% [95% CI 9–17] ‘most of the time justified’, and 8% [95% CI 6–9] felt it was ‘always justified’, respectively. Corresponding forest plots are reported in the Appendix (Additional item M, pages 46–43).

Researchers reporting the practice of automatically listing their section or department head as an author on all submitted articles (Review Item 2b) and the justification for this practice (Review item 3b).

Review item 2b (Table 3) did not refer to senior members in general, but specifically to section or department heads and when pooled this led to an average of 25% [95% CI 22–27] of researchers (based on data from 3 surveys, and a total of 1020 respondents). The corresponding forest plot is in the Appendix (Additional item M, pages 52–53). All three surveys were conducted in the field of radiology by the same research group^{4,24,25}. Results were homogeneous ($\text{Chi}^2 = 0.29$ (df = 2) $P = 0.87$; $I^2 = 0.00\%$). Exploration of this homogeneity was not possible,

Study/year	Response rate (%) [*]	Target field	Target population	Characteristics of the responding surveyees reported	Characteristics of the non-responding surveyees reported	Males among responding surveyees (%) ^{**}	Females among responding surveyees (%) ^{**}	Associate professor and higher among responding surveyees (%)

Table 1. Characteristics of the 15 included studies. *N1: Number of emails with questionnaires sent, N2: Number of emails with questionnaires not bounced, N3: Number of questionnaires for which the surveyee was available. **None of the included surveys gave complete gender/sex breakdowns for all considered categories and only the terms ‘males’ and ‘females’ were used²².

because the contacted corresponding author reported that individual survey data of all 3 surveys were not available anymore. All 3 surveys assessed the justification of this practice, but only 1 of these surveys²⁴ published the results, i.e., 35.4% (34/96) of respondents felt that this practice was justified in all cases (Review item 3b) (Table 4).

Researchers reporting the practice of automatically listing (a) senior member(s) of their department, including their section chief or department head, as a co-author on a manuscript without fulfilling the ICMJE criteria for authorship (Review Item 2c).

Review item 2c (Table 3) was addressed in one survey²⁸ only and showed that 6.8% [95% CI 5–8.9] of 666 researchers reported that a senior member of their department, including their section chief or department head was automatically listed as a coauthor in a Cochrane review without fulfilling the ICMJE criteria for authorship³. The justification of this practice was not assessed (Table 4). The question for this review item differed from the previous questions in that it did not refer to automatically listing of a co-author to all submitted manuscripts, but to a specific manuscript submitted by the surveyee. Further, this question referred to co-authorship without fulfilling the ICMJE criteria for authorship in Cochrane reviews (Appendix, Additional item M, page 54).

Researchers reporting the practice of automatically listing (a) senior member(s) of their department, including their section chief or department head, as a co-author(s) on all articles submitted by these researchers (Review item 2d) and the justification of this practice (Review item 3d).

Contrary to the previous review items, review item 2d referred specifically to all manuscripts submitted by the surveyee. This review item was assessed in 1 survey³² (Table 3), which showed that 27.2% [95% CI 24.3–30.2] of 908 researchers reported that a senior member of their department including their section chief or department head was automatically listed as a coauthor on all manuscripts submitted by the surveyee. This practice was considered ‘always justified’ by 67.7% of 31 respondents (Review item 3d) (Table 4).

Response rates

Response rate of each individual survey questions are reported in the Appendix (Additional item M, pages 38–45). Response rates were meta-analyzed when surveys had used the same denominators, e.g., number of

Quality checklist item and number	Unclear*	Yes	No
(Item 1) Were there no potential conflict of interests or funding issues that could have affected the outcome of the review item?	10% (7/67)	90% (60/67)	0% (0/67)
(Item 2) Was there no risk of selective (non-) reporting bias regarding the review item?	100% (67/67)	0% (0/67)	0% (0/67)
(Item 3) Were the target population, field, and context for the survey on the review item defined?	0% (0/67)	100% (67/67)	0% (0/67)
(Item 4) Did each individual in the target population have an equal chance for being selected for the survey on the review item?	27	40	0% (0/67)
(Item 5) Were there no survey methods that could have introduced bias, i.e., systematic error in the outcomes of the survey on the review item?	69% (46/67)	0% (0/67)	31% (21/67)
(Item 6) Were the characteristics of the responding surveyees on the review item defined?	0% (0/67)	100% (67/67)	0% (0/67)
(Item 7) Were the characteristics of the responding surveyees on the review item representative of the target population?	100% (67/67)	0% (0/67)	0% (0/67)
(Item 8) Was the review item defined?	0% (0/67)	100% (67/67)	0% (0/67)
(Item 9) Did the survey (or any additional file) report the survey question to assess the review item?	0% (0/67)	100% (67/67)	0% (0/67)
(Item 10) Was the question to assess the review item validated (tested) a priori e.g., through pilot testing or used in previous surveys?	0% (0/67)	100% (67/67)	0% (0/67)
(Item 11) Was the initial sample size and the number of questionnaires that answered the question on the review item reported?	0% (0/67)	61	6
(Item 12) Did the magnitude of the response rate on the review item or the way the response rate (in the case of a low response rate) was managed provide certainty in the validity of the results on the review item?	0% (0/67)	1% (1/67)	99% (66/67)
(Item 13) Was the sample size adequate for the prevalence statistic of the review item?***	0% (0/67)	54% (36/67)	46% (31/67)
(Item 14) Were the complete outcome measures given for the review item, i.e., were the numerators and denominators reported?	0% (0/67)	61	6

Table 2. Prevalence of answers to quality checklist questions (the 7 critical items are shaded grey). *Unclear* was assigned when too few details were reported in the manuscript or additional files to make a judgment of assigning 'Yes' or 'No'. **The required sample size was calculated with EpiTools epidemiological calculators and was based on the identified prevalence and the total sample size³³. The estimated prevalence was calculated with a 0.95 confidence level (desired precision of estimate 0.05).

emails with questionnaires sent (Tables 3 and 4)^{4,24,25,28,32}. It was not always clear which denominators were used to calculate the response rates for the justification of the practice of automatically listing a senior member of a department as an author on all submitted articles (Review item 3). To avoid possible overestimation of these rates, we used the same denominators for review item 3 as those used for review item 2, i.e., researchers reporting the practice of automatically listing a senior member of their department as an author on all submitted articles. Overall, response rates for review item 3 were lower than those for review item 2 (Tables 3 and 4).

Investigation of heterogeneity and sensitivity analyses

Meta-regression and subgroup analyses identified significant associations ($p < 0.05$) with several explanatory variables, but these associations were all based on small numbers of observations ($n = 10$). Further, for all tested associations only 1 of the survey characteristics differed from the other 9 surveys, which could further jeopardize the drawing of sound conclusions. We did not conduct sensitivity analyses, because the sources in which the eligible surveys were identified and the survey design and quality of the included surveys were found to be similar. All results of the meta-regression and subgroup analyses are given in the Appendix (Additional item N, pages 55–61).

Non-reporting biases in syntheses

An overall judgement about risk of bias due to missing results in a synthesis (non-reporting biases) was ‘moderate’ for the results of questions 2a, 2b, and 3a¹⁹. The methods, results, and rationale for these judgments were reported in the Appendix (Additional item O, pages 62–64).

Certainty of evidence

Table 5 summarizes the findings of this systematic review and assigns certainty of evidence grades (GRADE)²¹ to each outcome. These grades were either low or very low (Table 5). The rationales for assigning these grades are further explained in the Appendix (Additional item P, pages 65–66).

Discussion

Principal findings

Pooling results from 10 surveys, we found that 20% of researchers across health sciences reported the practice of automatically listing (a) senior member(s) of their department (including section chief or department head) as (a) co-author(s) on all submitted articles. Heterogeneity and inconsistency of results were explored through subgroup analyses and meta-regression, but the small number of included studies (n = 10) prevented us from obtaining robust results (Appendix, Additional item N, pages 55–61). In those same 10 surveys, researchers were also asked on how they judged the practice of automatic authorship and 52% of researchers felt it is ‘never or rarely justified’.

Comparison with other studies

In a recent systematic review and meta-analysis we found high prevalences for a series of honorary authorship issues in the health sciences³⁴. In particular, more than a quarter of researchers perceived at least one of their co-authors as honorary authors on their manuscript, not referring to specific criteria for authorship and more than half when assessed against ICMJE criteria for authorship. This systematic review³⁴ as well as another systematic review³⁵ addressed different honorary authorship issues than were the focus of our current review. Other reviews on honorary authorship were narrative^{36–38} or integrative³⁹.

Limitations

The main limitation of our study we see is pooling data from surveys of low quality with high likelihood of biases, whose direction is hard to judge. This hinders generalizability and drawing strong conclusions. Nevertheless, surveys based on self-report remain the main approach for quantifying the prevalence of honorary authorship. Also, as our study only covered health sciences, it does not shed light on the prevalence of this practice in other disciplines. Further, it is difficult to interpret the meaning of the statement: “Automatic authorship, defined as

automatically listing the senior on all manuscripts is ‘sometimes justified.’” Since, how can something be justified part of the time when the phenomenon itself is happening always, without exceptions?

Why this study is important and what is next

If automatic listing of senior department members as authors on all submitted articles were as common as the 20% estimate from this meta-analysis suggests, it is worrisome. The finding that in half of these cases such listings were considered ‘unjustified’ is even more problematic. First, automatic authorship disconnects, at least partly, the accountability for the work from those listed as authors. Second, when automatic authors are authorities in their field, the practice may influence the acceptance probabilities of submitted manuscripts. Third, automatic authorship unjustly inflates the publication output of senior researchers, further benefiting their careers in a competitive research environment in which long publication lists are still seen as the crucial element of academic performance. Fourth, automatic authorship may deflate the work done by those who actually merit authorship, although in our courses on research integrity we do encounter, even junior, researchers who actively welcome

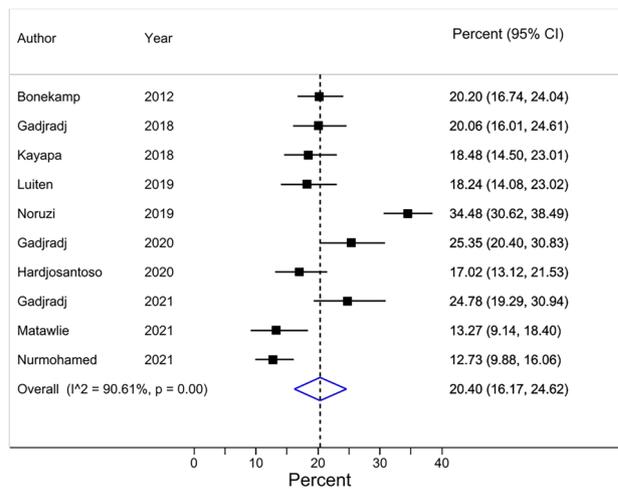

Figure 2. Forest plot for ‘Researchers reporting the practice of automatically listing (a) senior member(s) of their department (including section chief or department head) as an author on all submitted articles.’* Effect Size (ES) 20% [95% CI 16–25]. Heterogeneity $\chi^2 = 95.84$ [df=9]; $P < 0.001$. Variation in ES attributable to heterogeneity: $I^2 = 90.61\%$. Between-study variance estimate $\tau^2 = 0.00$. Test of ES=0: $z = 9.47$; $P < 0.001$. *The results of each individual survey were based on the answers to the same question regarding a specific publication by the surveyee.

addition of authoritative names on their papers. In other cases it seems that senior researchers make deals about authorships without asking consent of juniors listed as first authors. We believe that the practice of automatic authorship may be hard to eradicate unless the academic recognition and reward system is overhauled and will pay more attention to for example clarifying authorship contributions at the start of research projects, responsible mentoring, peer review, quality over quantity and the transparency associated with open science work styles^{40–43}. Courses on ICMJE and CRediT principles^{3,44} may play a minor role, but are currently mostly directed at junior researchers, possibly creating more frustration than when they had been unaware of the rules around authorship. In our view, a minor role could be played by better protection of whistleblowers and potential funding or legal repercussions for those engaging in automatic authorship. Research institutions play a key role in drawing up rules and monitoring compliance.

Conclusions

The practice of automatically assigning senior members of departments as co-authors on all submitted manuscripts may be common in the health sciences, with those admitting to this practice finding it unjustified in most cases. These findings, when replicated in high quality surveys, are worrisome and require an effective response, most likely in the realm of the academic reward system.

Surveyee: Any author on the author list of a scientific publication, e.g., first, last, corresponding author, that was invited to participate in a survey on at least one of our review items. Settings: Any. Intervention: Surveys based on questionnaires for self-completion			
Survey items	Prevalence (95% CI)	# of respondents and surveys	Certainty of the evidence (GRADE)*
<i>Review Item 2a (Question 2a)</i> . Researchers reporting the practice of automatically listing a senior member(s) of their department (including section chief or department head) as an author on all submitted articles	20% [95% CI 16–25]	3619 respondents in 10 surveys	⊕⊕⊕⊖ Very low Due to risk of bias, inconsistency, imprecision, and moderate risk of non-reporting biases
<i>Review Item 2b (Question 2b)</i> . Researchers reporting the practice of automatically listing their section or department head as an author on all submitted articles	25% [95% CI 22–27]	1020 respondents in 3 surveys	⊕⊕⊕⊖ Low Due to risk of bias, and moderate risk of non-reporting biases
<i>Review Item 2c (Question 2c)</i> . Researchers reporting the practice of automatically listing a senior member(s) of their department, including their section chief or department head, as a co-author on a manuscript without fulfilling the ICMJE criteria for authorship	6.8% (45/666) [95% CI 5–8.9]	666 respondents in 1 survey ²⁸	⊕⊕⊕⊖ Low Due to risk of bias, imprecision, and moderate risk of non-reporting biases
<i>Review Item 2d (Question 2d)</i> . Researchers reporting the practice of automatically listing a senior member(s) of their department, including their section chief or department head, as a co-author(s) on all articles submitted by these researchers	12.6% (31/247) [95% CI 8.7–17.4]	247 respondents in 1 survey ³²	⊕⊕⊕⊖ Very low Due to risk of bias, imprecision, and moderate risk of non-reporting biases
<i>Review item 3a (Question 3a)</i> . Justification ‘Never justified’ for review item 2a, i.e., researchers reporting the practice of automatically listing a senior member(s) of their department (including section chief or department head) as an author on all submitted articles	28% [95% CI 22–34]	2180 respondents in 10 surveys	⊕⊕⊕⊖ Very low Due to risk of bias, inconsistency, imprecision, and moderate risk of non-reporting biases
<i>Review item 3a (Question 3a)</i> . Justification ‘Rarely justified’ for review item 2a, i.e., researchers reporting the practice of automatically listing a senior member(s) of their department (including section chief or department head) as an author on all submitted articles	24% [95% CI 22–27]	2180 respondents in 10 surveys	⊕⊕⊕⊖ Low Due to risk of bias and moderate risk of non-reporting biases
<i>Review item 3a (Question 3a)</i> . Justification ‘Sometimes justified’ for review item 2a, i.e., researchers reporting the practice of automatically listing a senior member(s) of their department (including section chief or department head) as an author on all submitted articles	25% [95% CI 23–28]	2180 respondents in 10 surveys	⊕⊕⊕⊖ Low Due to risk of bias and moderate risk of non-reporting biases
<i>Review item 3a (Question 3a)</i> . Justification ‘Most of the time justified’ for review item 2a, i.e., researchers reporting the practice of automatically listing a senior member(s) of their department (including section chief or department head) as an author on all submitted articles	13% [95% CI 9–17]	2180 respondents in 10 surveys	⊕⊕⊕⊖ Very low Due to risk of bias, inconsistency, imprecision, and moderate risk of non-reporting biases
<i>Review item 3a (Question 3a)</i> . Justification ‘Always justified’ for review item 2a, i.e., researchers reporting the practice of automatically listing a senior member(s) of their department (including section chief or department head) as an author on all submitted articles	8% [95% CI 6–9]	2180 respondents in 10 surveys	⊕⊕⊕⊖ Very low Due to risk of bias, inconsistency, imprecision, and moderate risk of non-reporting biases
<i>Review item 3b (Question 3b)</i> . Justification ‘Justified in all cases’ for review item 2b, i.e., Researchers reporting the practice of automatically listing their section or department head as an author on all submitted articles	35.4% (34/96) [95% CI 25.9–45.8]	96 respondents in 1 survey ²⁴	⊕⊕⊕⊖ Very low Due to risk of bias, imprecision, and high risk of non-reporting biases
<i>Review item 3d. (Question 3d)</i> Justification ‘Justified in all cases’ for review item 2d, i.e., Researchers reporting the practice of automatically listing a senior member(s) of their department, including their section chief or department head, as a co-author(s) on all articles submitted by these researchers	67.7% (21/31) [95% CI 48.6–83.3]	31 respondents in 1 survey ³²	⊕⊕⊕⊖ Very low Due to risk of bias, imprecision, and non-reporting biases

Table 5. Summary of findings. Prevalence of issues regarding the practice of automatically listing senior members as co-authors on submitted articles. *The rationales for the certainty grades (GRADE) are further explained in the Appendix (Additional item P, pages 65–66).

Data availability

All raw and analyzed data of this systematic review are reported in the manuscript and Appendix or were deposited in OSF Storage <https://osf.io/4eywp/>. We will respond rapidly to requests for additional clarifications on our data. Requests can be made to the corresponding author (RMR) at reyndersmail@gmail.com.

Protocol registration and publication: The protocol for this systematic review was registered in Open Science Framework. Link: <https://osf.io/4eywp/>. This protocol was based on our previous published protocol² for a systematic review on honorary authorship issues. Link: <https://systematicreviewsjournal.biomedcentral.com/articles/https://doi.org/10.1186/s13643-022-01928-1>.

Author contributions

All 5 authors, i.e., R.A.M.R., D.C., G.T.R., N.D.G., and M.M., participated substantially in all research steps outlined as the 4 criteria for authorship recommended by the ICMJE: Substantial contributions to the conception or design of the work; or the acquisition, analysis, or interpretation of data for the work; AND. Drafting the work or revising it critically for important intellectual content; AND. Final approval of the version to be published; AND. Agreement to be accountable for all aspects of the work in ensuring that questions related to the accuracy or integrity of any part of the work are appropriately investigated and resolved. All 5 authors had full access to all of the data (including statistical reports and tables) in the study and can take responsibility for the integrity of the data and the accuracy of the data analysis. R.A.M.R. is the guarantor. The corresponding author (R.A.M.R.) attests that all listed authors meet authorship criteria and that no others meeting the criteria have been omitted. R.A.M.R.: Conceptualization, Methodology, Formal analysis, Investigation, Data curation, Writing—original draft, Writing—review & editing, Supervision, Project administration. D.C.: Conceptualization, Methodology, Formal analysis, Investigation, Writing—original draft, Writing—review & editing. G.T.R.: Conceptualization, Methodology, Investigation, Supervision, Writing—review & editing. N.D.G.: Conceptualization, Methodology, Investigation, Writing—review & editing. M.M.: Conceptualization, Methodology, Investigation, Supervision, Writing—review & editing.
