| Identification of compounds that selectively kill cancer stem cells | <p>A study in cultured cancer stem cells and mouse xenografts identified compounds that could help kill cancer stem cells that are resistant to chemotherapy. Mammary epithelial cells with cancer stem cell-like properties were generated and used to screen a 16,000-compound small molecule library. Thirty-two compounds were identified that were more toxic to breast cancer stem cells than to non-stem cell types of tumor cells. The most potent of the compounds—salinomycin, a generic veterinary antibiotic—decreased cancer stem cell levels 20-fold compared with mock treatment. In mouse xenografts, salinomycin-treated cancer stem cells had lower metastatic capacity than mock-treated controls. Next steps include developing drug-like derivatives of salinomycin or other compounds identified in the screen and conducting further xenograft experiments.</p> <p><b>SciBX 2(33); doi:10.1038/scibx.2009.1295</b><br/> <b>Published online Aug. 27, 2009</b></p> | Patent pending; available for licensing | <p>Gupta, P.B. <i>et al.
