Androgen receptor mutations that convey resistance to second-generation anti-androgen receptor compounds	<p>Studies in cell culture and in patient samples identified drug resistance mutations that could help guide prostate cancer treatment. In cells, chronic exposure to the anti-androgen receptor compounds Xtandi enzalutamide or ARN-509 resulted in the acquisition of the F876L androgen receptor mutation. In cells with the F976L mutation, the drugs acted as agonists, whereas in wild-type cells the drugs acted as antagonists and inhibited cell proliferation. In circulating tumor DNA obtained from patients' plasma, the mutation was identified after treatment with ARN-509. Next steps include determining the frequency of the mutation in patients receiving second-generation anti-androgen receptor compounds.</p> <p>Xtandi enzalutamide is marketed by Astellas Pharma Inc. and Medivation Inc. for castration-resistant prostate cancer. ARN-509 from Aragon Pharmaceuticals Inc. is in Phase II testing.</p> <p>SciBX 6(29); doi:10.1038/scibx.2013.776 Published online Aug. 1, 2013</p>	Patent application filed; licensing status undisclosed	<p>Joseph, J.D. <i>et al.
