Abstract We report on double-differential inclusive cross-sections of the production of secondary protons, charged pions, and deuterons, in the interactions with a 5% λ_{abs} thick stationary copper target, of proton and pion beams with momentum from ± 3 GeV/ c to ± 15 GeV/ c . Results are given for secondary particles with production angles $20^\circ < \theta < 125^\circ$. The inclusive pion production cross-sections are compared to those on beryllium and tantalum, published by us recently.

1 Introduction

The HARP experiment arose from the realization that the inclusive differential cross-sections of hadron production in the interactions of few GeV/ c protons with nuclei were known only within a factor of two to three, while more precise cross-sections are in demand for several reasons. Pion production data on a variety of nuclei are required for (i) the understanding of the underlying physics and the modeling of Monte Carlo generators of hadron–nucleus collisions, (ii) the optimization of the design parameters of the proton

driver of a neutrino factory, (iii) flux predictions for conventional neutrino beams, and (iv) the calculation of the atmospheric neutrino flux.

Consequently, the HARP detector was designed to carry out a programme of systematic and precise (i.e., at the few per cent level) measurements of hadron production by protons and pions with momenta from 1.5 to 15 GeV/ c .

The detector combined a forward spectrometer with a large-angle spectrometer. The latter comprised a cylindrical Time Projection Chamber (TPC) around the target and an array of Resistive Plate Chambers (RPCs) that surrounded the TPC. The purpose of the TPC was track reconstruction and particle identification by dE/dx . The purpose of the RPCs was to complement the particle identification by time of flight.

The HARP experiment was performed at the CERN Proton Synchrotron in 2001 and 2002 with a set of stationary targets ranging from hydrogen to lead.

Here, we report on the large-angle production (polar angle θ in the range $20^\circ < \theta < 125^\circ$) of secondary protons and charged pions, and of deuterons, in the interactions with a 5% λ_{abs} Cu target of protons and pions with beam momenta of ± 3.0 , ± 5.0 , ± 8.0 , ± 12.0 , and ± 15.0 GeV/ c .

This is the fourth of a series of cross-section papers with results from the HARP experiment. In the first paper, [1], we described the detector characteristics and our analysis algorithms, on the example of $+8.9$ GeV/ c and -8.0 GeV/ c beams impinging on a 5% λ_{abs} Be target. The second paper [2] presented results for all beam momenta from this Be target, and the third paper [3] results from the interactions with a 5% λ_{abs} Ta target.

^cOn leave of absence at Ecole Polytechnique Fédérale, Lausanne, Switzerland.

Our work involves only the HARP large-angle spectrometer, the characteristics of which are described in detail in [4] and [5].

2 The T9 proton and pion beams, and the target

The protons and pions were delivered by the T9 beam line in the East Hall of CERN's Proton Synchrotron. This beam line supports beam momenta between 1.5 GeV/c and 15 GeV/c, with a momentum bite $\Delta p/p \sim 1\%$.

Beam particle identification was provided for by two threshold Cherenkov counters, BCA and BCB, filled with nitrogen, and by time of flight over a flight path of 24.3 m. Table 1 lists the beam instrumentation that was used at different beam momenta for p/π^+ and for π/e separation.

The pion beam had a contamination by muons from pion decays. It also had a contamination by electrons from converted photons from π^0 decays. Only for the beam momenta of 3 and 5 GeV/c were electrons identified by a beam Cherenkov counter and rejected.

The fractions of muon and electron contaminations of the pion beam were experimentally determined [6, 7] and are listed in Table 2 for all beam momenta. For the determination of interaction cross-sections of pions, the muon and electron contaminations must be subtracted from the incoming flux of pion-like particles (except electrons at the beam momenta of 3 and 5 GeV/c).

There is also a kaon contamination of a few per cent in the proton and pion beams. Kaons are suppressed by the

beam instrumentation, except at 5 GeV/c beam momentum where they are indistinguishable from pions. Because the kaon interaction cross-sections are close to the pion interaction cross-sections, this kaon contamination is ignored.

The beam trajectory was determined by a set of three multiwire proportional chambers (MWPCs), located upstream of the target, several meters apart. The transverse error of the impact point on the target was 0.5 mm from the resolution of the MWPCs, plus a contribution from multiple scattering of the beam particles in various materials in the beam line. Excluding the target itself, the latter contribution is 0.2 mm for a 8 GeV/c beam particle.

We select 'good' beam particles by requiring the unambiguous reconstruction of the particle trajectory with good χ^2 . In addition we require that the particle type is unambiguously identified. We select 'good' accelerator spills by requiring a minimal beam intensity and a 'smooth' variation of beam intensity across the 400 ms long spill.¹

The target was a disc made of high-purity (99.99%) copper, with a density of 8.91 g/cm³, a radius of 15.1 mm, and a thickness of 7.52 ± 0.05 mm (5% λ_{abs}).

The finite thickness of the target leads to a small attenuation of the number of incident beam particles. The attenuation factor is $f_{\text{att}} = 0.975$.

The size of the beam spot at the position of the target was several millimeters in diameter, determined by the setting of the beam optics and by multiple scattering. The nominal beam position² was at $x_{\text{beam}} = y_{\text{beam}} = 0$, however, excursions by several millimeters could occur.³ A loose fiducial cut $\sqrt{x_{\text{beam}}^2 + y_{\text{beam}}^2} < 12$ mm ensured full beam acceptance. The muon and electron contaminations of the pion beam, stated above, refer to this acceptance cut.

Table 1 Beam instrumentation for p/π^+ and π/e separation

Beam momentum (GeV/c)	p/π^+ separation	π/e separation
± 3.0	TOF	BCB (1.05 bar)
± 5.0	TOF	BCA (0.60 bar)
± 8.0	BCA (1.25 bar) BCB (1.50 bar)	
± 12.0 and ± 15.0	BCA (3.50 bar) BCB (3.50 bar)	

Table 2 Contaminations of the pion beams by muons and electrons

Beam momentum (GeV/c)	Muon fraction	Electron fraction
± 3.0	$(4.1 \pm 0.4)\%$	Rejected
± 5.0	$(5.1 \pm 0.4)\%$	Rejected
± 8.0	$(1.9 \pm 0.5)\%$	$(1.2 \pm 0.5)\%$
± 12	$(0.6 \pm 0.6)\%$	$(0.5 \pm 0.5)\%$
± 15	$(0.0 \pm 0.5)\%$	$(0.0 \pm 0.5)\%$

3 Performance of the HARP large-angle detectors

Our calibration work on the HARP TPC and RPCs is described in detail in [4] and [5], and in references cited therein. In particular, we recall that static and dynamic TPC track distortions up to 10 mm have been corrected to better than 300 μm . Therefore, TPC track distortions do not affect the precision of our cross-section measurements.

¹A smooth variation of beam intensity eases corrections for dynamic TPC track distortions.

²A right-handed Cartesian and/or spherical polar coordinate system is employed; the z axis coincides with the beam line, with $+z$ pointing downstream; the coordinate origin is at the upstream end of the copper target, 500 mm downstream of the TPC's pad plane; looking downstream, the $+x$ coordinate points to the left and the $+y$ coordinate points up; the polar angle θ is the angle with respect to the $+z$ axis.

³The only relevant issue is that the trajectory of each individual beam particle is known, whether shifted or not, and therefore the amount of matter to be traversed by the secondary hadrons.

The resolution $\sigma(1/p_T)$ is typically $0.2 \text{ (GeV}/c)^{-1}$ and worsens towards small relative particle velocity β and small polar angle θ .

The absolute momentum scale is determined to be correct to better than 2%, both for positively and negatively charged particles.

The polar angle θ is measured in the TPC with a resolution of $\sim 9 \text{ mrad}$, for a representative angle of $\theta = 60^\circ$. To this a multiple scattering error has to be added which is on the average $\sim 7 \text{ mrad}$ for a proton with $p_T = 500 \text{ MeV}/c$ in the TPC gas and $\theta = 60^\circ$, and $\sim 4 \text{ mrad}$ for a pion with the same characteristics. The polar-angle scale is correct to better than 2 mrad.

The TPC measures dE/dx with a resolution of 16% for a track length of 300 mm.

The intrinsic efficiency of the RPCs that surround the TPC is better than 98%.

The intrinsic time resolution of the RPCs is 127 ps and the system time-of-flight resolution (that includes the jitter of the arrival time of the beam particle at the target) is 175 ps.

To separate measured particles into species, we assign on the basis of dE/dx and β to each particle a probability of being a proton, a pion (muon), or an electron, respectively. The probabilities add up to unity, so that the number of particles is conserved. These probabilities are used for weighting when entering tracks into plots or tables.

4 Monte Carlo simulation

We used the Geant4 tool kit [8, 9] for the simulation of the HARP large-angle spectrometer.

Geant4's QGSP_BIC physics list provided us with reasonably realistic spectra of secondaries from incoming beam protons with momentum less than $12 \text{ GeV}/c$. For the secondaries from beam protons at 12 and $15 \text{ GeV}/c$ momentum, and from beam pions at all momenta, we found the standard physics lists of Geant4 unsuitable [10].

To overcome this problem, we built the HARP_CDP physics list for the production of secondaries from incoming beam pions. It starts from Geant4's standard QBBC physics list, but the Quark–Gluon String Model is replaced by the FRITIOF string fragmentation model for kinetic energy $E > 6 \text{ GeV}$; for $E < 6 \text{ GeV}$, the Bertini Cascade is used for pions, and the Binary Cascade for protons; elastic and quasi-elastic scattering is disabled. Examples of the good performance of the HARP_CDP physics list are given in [10].

For the simulation of the interactions of protons at 12 and $15 \text{ GeV}/c$ momentum, we used the HARP_CDP physics list for incoming pions, with the abundances of secondary

pions weighted such as to reproduce the observed abundances for incoming protons. The reason for this procedure is that, at these energies, all physics lists failed to produce high-momentum pion secondaries by incoming proton beams.

5 Systematic errors

The systematic uncertainty of our inclusive cross-sections is at the few-per-cent level, from errors in the normalization, in the momentum measurement, in particle identification, and in the corrections applied to the data.

The systematic error of the absolute flux normalization is taken as 2%. This error arises from uncertainties in the target thickness, in the contribution of large-angle scattering of beam particles, in the attenuation of beam particles in the target, and in the subtraction of the muon and electron contaminations of the beam. Another contribution comes from the removal of events with an abnormally large number of TPC hits.⁴

The systematic error of the track finding efficiency is taken as 1% which reflects differences between results from different persons who conducted eyeball scans. We also take the statistical errors of the parameters of a fit to scan results as systematic error into account [1]. The systematic error of the correction for losses from the requirement of at least 10 TPC clusters per track is taken as 20% of the correction which itself is in the range of 5 to 30%. This estimate arose from differences between the four TPC sectors that were used in our analysis, and from the observed variations with time.

The systematic error of the p_T scale is taken as 2% as discussed in [4]. For the data from the $+15 \text{ GeV}/c$ beams, this error was doubled to account for a larger than usual uncertainty of the correction for dynamic TPC track distortions.⁵

The systematic errors of the proton, pion, and electron abundances are taken as 10%. We stress that errors on abundances only lead to cross-section errors in case of a strong overlap of the resolution functions of both identification variables, dE/dx and β . The systematic error of the correction for migration, absorption of secondary protons and pions in materials, and for pion decay into muons, is taken as 20% of the correction, or 1% of the cross-section, whichever

⁴In less than 0.5% of the number of good events, because of apparatus malfunction, the number of TPC hits was much larger than possible for a physics event. Such events were considered unphysical and eliminated.

⁵The precision of the dynamic distortion corrections across the full TPC volume is a function of the number of secondary pions available for its evaluation. The data set of the $+15 \text{ GeV}/c$ beam on the Cu target has particularly poor statistics.

is larger. These estimates reflect our experience with remanent differences between data and Monte Carlo simulations after weighting Monte Carlo events with smooth functions with a view to reproducing the data simultaneously in several variables in the best possible way.

All systematic errors are propagated into the momentum spectra of secondaries and then added in quadrature.

6 Cross-section results

In Tables 4–48, in the Appendix of this paper, we give the double-differential inclusive cross-sections $d^2\sigma/dp d\Omega$ for various combinations of incoming beam particle and secondary particle, including statistical and systematic errors. In each bin, the average momentum at the vertex and the average polar angle are also given.

The data of Tables 4–48 are available in ASCII format in [11].

Some bins in the tables are empty. Cross-sections are only given if the total error is not larger than the cross-section itself. Since our track reconstruction algorithm is optimized for tracks with p_T above ~ 70 MeV/c in the TPC volume, we do not give cross-sections from tracks with p_T below this value. Because of the absorption of slow protons in the material between the vertex and the TPC gas, and with a view to keeping the correction for absorption losses below 30%, cross-sections from protons are limited to $p > 450$ MeV/c at the interaction vertex. Proton cross-sections are also not given if a 10% error on the proton energy loss in materials between the interaction vertex and the TPC volume leads to a momentum change larger than 2%. Since the proton energy loss is large in the copper target, particularly at polar angles close to 90 degrees, the latter condition imposes significant restrictions. Pion cross-sections are not given if pions are separated from protons by less than twice the time-of-flight resolution.

The large errors and/or absence of results from the +15 GeV/c pion beams are caused by scarce statistics because the beam composition was dominated by protons.

We present in Figs. 1 to 7 what we consider salient features of our cross-sections.

Figure 1 shows the inclusive cross-sections of the production of protons, π^+ 's, and π^- 's, from incoming protons between 3 GeV/c and 15 GeV/c momentum, as a function of their charge-signed p_T . The data refer to the polar-angle range $20^\circ < \theta < 30^\circ$. Figures 2 and 3 show the same for incoming π^+ 's and π^- 's.

Figure 4 shows the inclusive cross-sections of the production of protons, π^+ 's, and π^- 's, from incoming protons between 3 GeV/c and 15 GeV/c momentum, this time as a function of their charge-signed polar angle θ . The data refer to the p_T range $0.24 < p_T < 0.30$ GeV/c. In this p_T

range pions populate nearly all polar angles, whereas protons are absorbed at large polar angle and thus escape measurement. Figures 5 and 6 show the same for incoming π^+ 's and π^- 's.

In Fig. 7, we present the inclusive cross-sections of the production of secondary π^+ 's and π^- 's, integrated over the momentum range $0.2 < p < 1.0$ GeV/c and the polar-angle range $30^\circ < \theta < 90^\circ$ in the forward hemisphere, as a function of the beam momentum.

7 Deuteron production

Besides pions and protons, also deuterons are produced in sizeable quantities on copper nuclei. Up to momenta of about 1 GeV/c, deuterons are easily separated from protons by dE/dx .

Table 3 gives the ratio of deuteron to proton production as a function of the momentum at the vertex, for 8 GeV/c beam protons, π^+ 's, and π^- 's.⁶ Cross-section ratios are not given if the data are scarce and the statistical error becomes comparable with the ratio itself—which is the case for deuterons at the high-momentum end of the spectrum.

The measured deuteron to proton production ratios are illustrated in Fig. 8, and compared with the predictions of Geant4's FRITIOF model. FRITIOF's predictions are shown for the same beam particles for which measured values are plotted. There is virtually no difference between its predictions for incoming protons, π^+ 's and π^- 's. FRITIOF underestimates deuteron production.

8 Comparison of charged-pion production on beryllium, copper, and tantalum

Figure 9 presents a comparison between the inclusive cross-sections of π^+ and π^- production, integrated over the secondaries' momentum range $0.2 < p < 1.0$ GeV/c and polar-angle range $30^\circ < \theta < 90^\circ$, in the interactions of protons, π^+ and π^- , with beryllium ($A = 9.01$), copper ($A = 63.55$), and tantalum ($A = 181.0$) nuclei.⁷ The comparison employs the scaling variable $A^{2/3}$ where A is the atomic number of the respective nucleus. We note the approximately linear dependence on this scaling variable. At low beam momentum, the slope exhibits a strong dependence on beam particle type, which tends to disappear with higher beam momentum.

⁶We observe no appreciable dependence of the deuteron to proton ratio on beam momentum.

⁷The beryllium data with +8.9 GeV/c beam momentum [1, 2] have been scaled, by interpolation, to a beam momentum of 8.0 GeV/c.

Fig. 1 Inclusive cross-sections of the production of secondary protons, π^+ 's, and π^- 's, by protons on copper nuclei, in the polar-angle range $20^\circ < \theta < 30^\circ$, for different proton beam momenta, as a function of the charge-signed p_T of the secondaries; the shown errors are total errors

Fig. 2 Inclusive cross-sections of the production of secondary protons, π^+ 's, and π^- 's, by π^+ 's on copper nuclei, in the polar-angle range $20^\circ < \theta < 30^\circ$, for different π^+ beam momenta, as a function of the charge-signed p_T of the secondaries; the shown errors are total errors

Fig. 3 Inclusive cross-sections of the production of secondary protons, π^+ 's, and π^- 's, by π^- 's on copper nuclei, in the polar-angle range $20^\circ < \theta < 30^\circ$, for different π^- beam momenta, as a function of the charge-signed p_T of the secondaries; the shown errors are total errors

Fig. 4 Inclusive cross-sections of the production of secondary protons, π^+ 's, and π^- 's, with p_T in the range 0.24–0.30 GeV/c, by protons on copper nuclei, for different proton beam momenta, as a function of the

charge-signed polar angle θ of the secondaries; the shown errors are total errors

9 Comparison of our results with results from other experiments

9.1 Comparison with E802 results

Experiment E802 [12] at Brookhaven National Laboratory (BNL) measured secondary π^+ 's in the polar-angle range

Fig. 8 Deuteron to proton ratio for 8 GeV/c beam particles on copper nuclei, as a function of the momentum at the vertex, for four polar-angle regions; open squares denote beam protons, open circles beam π^+ 's, and full circles beam π^- 's; the errors shown are total errors; the full and broken lines denote predictions of Geant4's FRITIOF model for the three different beam particles

$5^\circ < \theta < 58^\circ$ from the interactions of +14.6 GeV/c protons with copper nuclei.

Figure 10 shows their published Lorentz-invariant cross-section of π^+ and π^- production by +14.6 GeV/c protons, in the rapidity range $1.2 < y < 1.4$, as a function of $m_T - m_\pi$, where m_T denotes the pion transverse mass. Their data are compared with our cross-sections from the interactions of +15.0 GeV/c protons with copper nuclei, expressed in the same unit as used by E802. Since E802 quoted only statistical errors, our data in Fig. 10 are also shown with their statistical errors.

The E802 $\pi^\pm$ cross-sections are in good agreement with our cross-sections measured nearly at the same proton beam momentum, taking into account the normalization uncertainty of (10–15)% quoted by E802. We draw attention to the good agreement of the slopes of the cross-sections over two orders of magnitude.

9.2 Comparison with E910 results

BNL experiment E910 [13] measured secondary charged pions in the momentum range 0.1–6 GeV/c from the interactions of +12.3 GeV/c protons with copper nuclei. This experiment used a TPC for the measurement of secondaries, with a comfortably large track length of ~ 1.5 m. This feature, together with a magnetic field strength of 0.5 T, is of

Fig. 9 Inclusive cross-sections of π^+ and π^- production by protons (open squares), π^+ 's (open circles), and π^- 's (black circles), as a function of $A^{2/3}$ for, from left to right, beryllium, copper, and tanta-

lum nuclei; the cross-sections are integrated over the momentum range $0.2 < p < 1.0$ GeV/c and the polar-angle range $30^\circ < \theta < 90^\circ$; the shown errors are total errors and often smaller than the symbol size

Fig. 10 Comparison of our cross-sections (*black circles*) of $\pi^\pm$ production by +15.0 GeV/c protons off copper nuclei, with the cross-sections on copper nuclei published by the E802 Collaboration for the proton beam momentum of +14.6 GeV/c (*open circles*); all errors are statistical only

Fig. 11 Comparison of our cross-sections (*black circles*) of $\pi^\pm$ production by +12.0 GeV/c protons off copper nuclei, with the cross-sections published by the E910 Collaboration for the proton beam momentum of +12.3 GeV/c (*open circles*); all errors are statistical only

particular significance, since it permits considerably better charge identification and proton–pion separation by dE/dx than is possible in the HARP detector. Figure 11 shows their published cross-section $d^2\sigma/dp d\Omega$ of $\pi^\pm$ production by +12.3 GeV/c protons, in the polar-angle range $0.8 < \cos \theta < 0.9$. Since E910 quoted only statistical errors, our data in Fig. 11 from the interactions of +12.0 GeV/c protons with copper are also shown with their statistical errors. The normalization uncertainty that is quoted by E910 is $\leq 5\%$.

Fig. 12 (a) Comparison of our cross-sections (*black circles*) of $\pi^\pm$ production by +12.0 GeV/c protons off copper nuclei with the cross-sections published by the HARP Collaboration (*open circles*); (b) Comparison of our ratio π^+/π^- at +12.0 GeV/c beam momentum as a function of the polar angle θ with the ratios published by the HARP Collaboration; also shown are the ratios π^+/π^- published by the E910 Collaboration for a +12.3 GeV/c beam momentum; in (a) total errors are shown; in (b) for the HARP Collaboration total errors are shown (only those are published), for E910 statistical errors (only those are published), and for our group also statistical errors (for the cancellation of most systematic errors in the ratio π^+/π^-)

Also here, the E910 data are shown as published, and our data are expressed in the same unit as used by E910. We draw attention to the good agreement in the π^+/π^- ratio between the cross-sections from E910 and our cross-sections, see also Fig. 12(b).

9.3 Comparison with results from the HARP Collaboration

Figure 12(a) shows the comparison of our cross-sections of pion production by +12.0 GeV/c protons off copper nuclei

with the ones published by the HARP Collaboration [14], in the polar-angle range $0.35 < \theta < 0.55$ rad. The latter cross-sections are plotted as published, while we expressed our cross-sections in the unit used by the HARP Collaboration. Figure 12(b) shows our ratio π^+/π^- as a function of the polar angle θ in comparison with the ratios published by the E910 Collaboration (at the slightly different proton beam momentum of $+12.3$ GeV/ c) and by the HARP Collaboration. We follow E910 and give statistical errors only; for the data of the HARP Collaboration total errors are shown (only those are published). Nevertheless, the data points can be directly compared. In our data points the systematic errors largely cancel in the π^+/π^- ratios and their inclusion would be hardly visible in the plot.

The discrepancy between our results and those published by the HARP Collaboration is evident. We note the difference especially of the π^+ cross-section, and the difference in the reported momentum range. The discrepancy is even more serious as the same data set has been analysed by both groups.

We hold that the discrepancy is caused by problems in the HARP Collaboration's data analysis. They result primarily, but not exclusively, from a lack of understanding TPC track distortions and RPC timing signals. These problems, together with others that affect the HARP Collaboration's

data analysis, are discussed in great detail in [15–17] and summarized in the Appendix of [1].

10 Summary

From the analysis of data from the HARP large-angle spectrometer (polar angle θ in the range $20^\circ < \theta < 125^\circ$), double-differential cross-sections $d^2\sigma/dp d\Omega$ of the production of secondary protons, π^+ 's, and π^- 's, and of deuterons, have been obtained. The incoming beam particles were protons and pions with momenta from ± 3 to ± 15 GeV/ c , impinging on a 5% λ_{abs} thick stationary copper target. Our cross-sections for π^+ and π^- production agree with results from BNL experiments E802 and E910 but disagree with the results of the HARP Collaboration that were obtained from the same raw data.

Acknowledgements We are greatly indebted to many technical collaborators whose diligent and hard work made the HARP detector a well-functioning instrument. We thank all HARP colleagues who devoted time and effort to the design and construction of the detector, to data taking, and to setting up the computing and software infrastructure. We express our sincere gratitude to HARP's funding agencies for their support.

Appendix: Cross-section tables

Table 4 Double-differential inclusive cross-section $d^2\sigma/dp d\Omega$ [mb/(GeV/ c sr)] of the production of protons in $p + \text{Cu} \rightarrow p + X$ interactions with $+3.0$ GeV/ c beam momentum; the first error is statistical, the second systematic; p_T in GeV/ c , polar angle θ in degrees
