Idelalisib addition has neutral to beneficial effects on quality of life in bendamustine/rituximab-treated patients: results of a phase 3, randomized, controlled trial

Marco Montillo^{1*}, Árpád Illés², Tadeusz Robak³, Alexander S. Pristupa⁴, Malgorzata Wach⁵, Miklós Egyed⁶, Julio Delgado⁷, Wojciech Jurczak⁸, Franck Morschhauser⁹, Anna Schuh¹⁰, Herbert Eradat¹¹, Sanatan Shrey¹², Jacqueline C. Barrientos¹³ and Andrew D. Zelenetz¹⁴

Abstract

Background: In a phase 3 randomized, double-blind, placebo-controlled trial, treatment with idelalisib, a phosphoinositol-3 kinase δ inhibitor, + bendamustine/rituximab improved progression-free survival (PFS) and overall survival (OS) in adult patients with relapsed/refractory chronic lymphocytic leukemia (R/R CLL). Here we report the results of health-related quality of life (HRQL) analyses from this study.

Methods: From June 15, 2012 to August 21, 2014, 416 patients with R/R CLL were enrolled; 207 patients were randomized to the idelalisib arm and 209 to the placebo arm. In the 416 patients randomized to receive bendamustine/rituximab and either oral idelalisib 150 mg twice-daily or placebo, HRQL was assessed at baseline and throughout the blinded part of the study using the Functional Assessment of Cancer Therapy–Leukemia (FACT-Leu) and EuroQoL Five-Dimension (EQ-5D) visual analogue scale (VAS) questionnaires. The assessments were performed at scheduled patient visits; every 4 weeks for the first 6 months from the initiation of treatment, then every 8 weeks for the next 6 months, and every 12 weeks thereafter until end of study. Least-squares mean changes from baseline were estimated using a mixed-effects model by including treatment, time, and treatment-by-time interaction, and stratification factors as fixed effects. Time to first symptom improvement was assessed by Kaplan-Meier analysis.

Results: In mixed-effects model analysis, idelalisib + bendamustine/rituximab treatment led to clinically meaningful improvements from baseline in leukemia-associated symptoms. Moreover, per Kaplan-Meier analysis, the proportion of patients with symptom improvement was higher and time to improvement was shorter among patients in the idelalisib-containing arm compared with those who did not receive idelalisib. The physical and social/family FACT-Leu subscale scores, along with the self-rated health assessed by EQ-VAS, showed improvement with idelalisib over placebo, but the difference did not reach statistical significance. The functional and emotional FACT-Leu subscale scores remained similar to placebo.

Conclusions: Addition of idelalisib to bendamustine/rituximab, apart from improving PFS and OS, had a neutral to beneficial impact on HRQL in patients with R/R CLL, particularly by reducing leukemia-specific disease symptoms.

Trial registration: Clinicaltrials.gov [NCT01569295](https://clinicaltrials.gov/ct2/show/study/NCT01569295). Registered April 3, 2012.

Background

In 2018, chronic lymphocytic leukemia (CLL)—the most common chronic leukemia—represented an estimated 1.2% of all newly diagnosed cancers in the US, with an estimated 20,940 new CLL cases and 4510 deaths [1]. The age-adjusted rate of CLL incidence is 4.7 per 100,000 persons per year. Owing to the introduction of new, improved treatment regimens, the 5-year relative survival rate increased from 65.5% in 1975 to 84.2% in 2014 [1]. Despite this improvement, CLL remains incurable, and the majority of patients experience disease relapse [2]. The risk of relapse is increased in patients with CLL-associated genomic aberrations [3–6], patients ≥ 65 years with comorbid conditions [7–10], and refractory disease [11]. It is not uncommon for these patients to experience low treatment satisfaction and greatly reduced health-related quality of life (HRQL), mostly due to disease-related symptoms, toxicity of therapies, and anxiety associated with relapsing disease [12–14]. Despite recommendations to include prospective analyses of patient-reported outcomes (PROs) as additional endpoints in oncology clinical trials [15–17], PRO-based reports on HRQL in CLL are sparse. Patient-reported outcomes data can provide important information on the impact of new treatment regimens, including their efficacy and toxicity, as seen from the patient's perspective [16], and improvement in HRQL often reflects the efficacy of the new treatment under evaluation [18–21].

Idelalisib, in combination with rituximab, was approved for the treatment of patients with relapsed CLL for whom rituximab alone would be considered an appropriate therapy due to other comorbidities [22]. To examine the usefulness of idelalisib in additional clinical scenarios, we conducted a pivotal phase 3, randomized, multicenter, double-blind, placebo-controlled trial of idelalisib, a phosphoinositol-3 kinase δ (PI3K δ) inhibitor, in combination with bendamustine and rituximab, in patients with relapsed/refractory CLL (R/R CLL). The efficacy of the idelalisib/bendamustine/rituximab combination in this trial was superior to placebo/bendamustine/rituximab, and substantially improved the primary endpoint of progression-free survival (PFS) as well as the key secondary endpoint of overall survival (OS) [23].

Prespecified exploratory endpoints in this study included assessment of HRQL using the Functional Assessment of Cancer Therapy – Leukemia (FACT-Leu) validated questionnaire [24–28]. The FACT-Leu was developed as a disease-specific HRQL questionnaire for patients with leukemia [27, 28], and is composed of subscales scoring the patient's physical, functional, social/family, and emotional well-being, as well as leukemia-specific disease symptoms [27, 28]. Another prespecified exploratory endpoint was global health status and self-rated health assessed using the EuroQoL Five-Dimension

(EQ-5D) visual analogue scale (VAS) questionnaires [29, 30]. We present the results of these prospectively defined analyses comparing the impact of treatment with idelalisib combined with bendamustine/rituximab with that of bendamustine/rituximab/placebo, on patients' HRQL.

Methods

Study design and participants

This was a phase 3, randomized, multicenter, double-blind, placebo-controlled study (NCT01569295) in adult patients who were diagnosed with CLL requiring treatment according to International Workshop on Chronic Lymphocytic Leukemia criteria [17]. Eligible patients had measurable lymphadenopathy by computed tomography or magnetic resonance imaging, received prior therapy containing a purine analog or bendamustine and an anti-CD20 monoclonal antibody, experienced CLL progression within < 36 months since completion of the last prior therapy, were eligible to receive cytotoxic therapy, and had a Karnofsky Performance Status score of ≥ 60 . Study design and detailed eligibility criteria were published previously [23].

Ethics, consent, and permissions

The study protocols were approved by the Institutional Review Boards at each study site. The trial was conducted according to the principles of Good Clinical Practice and the Declaration of Helsinki. All patients provided written informed consent.

Treatments and endpoints

Patients received oral idelalisib 150 mg or matching placebo twice daily. Bendamustine 70 mg/m² was administered intravenously on days 1 and 2 for six 28-day cycles in both arms. Rituximab was administered intravenously with each cycle of bendamustine at 375 mg/m² on day 1 of cycle 1, and 500 mg/m² on day 1 of cycles 2 to 6. Idelalisib/placebo was given continuously, until disease progression, death, or intolerable toxicity. Bendamustine and rituximab were administered for up to a maximum of 12 and 6 infusions, respectively [23].

The details on primary and secondary endpoints have been reported [23]. Briefly, the primary endpoint was PFS; OS, overall response rate, and safety were among the key secondary endpoints. The prespecified HRQL-related exploratory endpoints were change from baseline in HRQL domain and symptom scores based on the FACT-Leu, and change from baseline in overall health and single-item dimension scores from the EQ-5D and EQ-VAS questionnaires. Key time points were the end of the randomized, double-blind initial period of combination therapy with bendamustine/rituximab at week 24 and the end of the preplanned continuing therapy period with idelalisib or placebo alone at week 48.

HRQL assessments

Patient well-being was assessed using the FACT-Leu questionnaire composed of 44 items measuring physical well-being (PWB, 7 items), functional well-being (FWB, 7 items), social/family well-being (S/FWB, 7 items), emotional well-being (EWB, 6 items), and leukemia-specific concerns (LeuS, 17 items) [28], scored based on the Functional Assessment of Chronic Illness Therapy-3 scoring guideline and user manual [31]. The subscale scores represent the sums of each individual item score. The composite scores include FACT-Leu total score (range 0–176), which is the sum of all subscales, and the Trial Outcome Index (TOI, range 0–124), which is the sum of the PWB, FWB, and LeuS subscales. Higher scores are associated with better self-reported HRQL.

The EQ-5D questionnaire contains 5 dimensions: mobility, self-care, usual activities, pain/discomfort, and anxiety/depression. Each dimension has 3 levels: no problems, some problems, and extreme problems [32]. The EQ-5D is converted into a single utility index, designed as an international, standardized questionnaire for evaluation of HRQL [29, 30], by applying the US preference-weighted index [33]. The EQ-VAS is used to assess patient’s self-rated health on a 100-mm scale ranging from “Worst imaginable health state” to “Best imaginable health state.” The EQ-5D utility and EQ-VAS scores are considered reliable and valid for assessing HRQL in cancer patients [34]. Positive changes from baseline indicate improvement in HRQL.

The surveys were administered every 4 weeks for the first 6 months from the initiation of treatment, then every 8 weeks for the next 6 months, and every 12 weeks thereafter until the end of study or until the patient was no longer receiving blinded study drug for any reason.

HRQL statistical analyses

The FACT Leu and EQ-5D questionnaire was scored and processed according to the user manual [32]. The HRQL questionnaire compliance was defined as a patient having answered at least 1 question at an assessment time point. The compliance rates for each study arm and at each time point were calculated as the number of patients who completed at least 1 question divided by the total number of patients available at that assessment time point. The frequency and proportion of reported problems for each of the five EQ-5D dimensions were summarized at each scheduled assessment. For the FACT-Leu, EQ-VAS questionnaires, and EQ-5D utility index, least-squares mean changes from baseline were estimated using a mixed-effects model, by including treatment, time, and treatment-by-time interaction, and stratification factors as fixed effects. Mixed-effects model used all available data up to week 84, as < 10% of placebo patients have data available beyond week 84. The least-squares means of change from baseline over time were plotted. The minimally important difference (MID) ranges were defined for the different subscales and are summarized in Additional file 1: Table S1. The lower bound of the MID range was utilized when defining symptom improvement; an increase of at least 3 points from baseline for PWB, S/FWB, FWB, and EWB, and 5 points for LeuS (reaching MID). Time to first symptom improvement was analyzed by the Kaplan-Meier (KM) method. The hazard ratios with 95% confidence intervals (CIs) were estimated from a Cox proportional hazards model without any adjustment and *P*-value from log-rank test was reported to examine the difference between the 2 treatment arms.

The HRQL analyses were based on the intent-to-treat analysis set, which included all patients randomized

Results

Key patient characteristics

From June 15, 2012, to August 21, 2014, 416 patients with R/R CLL were enrolled; 207 patients were randomized to the idelalisib arm and 209 to the placebo arm. Based on the results of the formal interim analysis performed in June 2015, the Independent Data Monitoring Committee recommended study unblinding. Although the study is still ongoing, the HRQL data presented herein reflect a data cutoff date of October 7, 2015, at the time of study unblinding. At the time of this analysis, 141 (34%) of 416 patients were continuing in the study; 95 (46%) of 207 in the idelalisib group and 46 (22%) of 209 in the placebo group.

Patient disposition and demographic and baseline characteristics were published previously [23]. The patients received a median (quartile [Q1, Q3]) of 6 (4, 6) cycles of treatment with bendamustine and 6 (5, 6) with rituximab; the median (Q1, Q3) exposure to

idelalisib and placebo was 14.8 (5.9, 18.9) months and 11.1 (5.8, 15.3) months, respectively. Generally, demographic and baseline disease characteristics were balanced across the treatment groups [23].

Summary of the efficacy and safety results

The detailed efficacy and safety results were previously reported at the data cutoff of October 7, 2015 [23], the same as the present analysis. The addition of idelalisib to bendamustine/rituximab led to a substantial improvement in the efficacy of the treatment, compared with bendamustine/rituximab alone [23]. The most common all-grade adverse events (AEs) were neutropenia and pyrexia in the idelalisib arm and neutropenia and nausea in the placebo arm [23].

Patient-reported FACT-Leu and EQ-5D outcomes

Among patients randomized to idelalisib and placebo arms, similar numbers of patients were available for HRQL analyses at baseline (Table 1). Mean baseline scores for the FACT-Leu and EQ-5D questionnaires were also comparable between the treatment arms (Table 1).

Assessments of compliance for the FACT-Leu and EQ-5D questionnaires were conducted over the initial

144 weeks of study. Compliance rates for both FACT-Leu and EQ-5D were high and exceeded 80% during the first 120 weeks of study in both treatment arms (Additional file 1: Tables S2 and S3).

FACT-Leu

The addition of idelalisib to bendamustine/rituximab had no significant impact on FWB, EWB, and PWB compared with placebo/bendamustine/rituximab (Fig. 1a, b, c). In contrast, idelalisib increased the S/FWB and

LeuS subscale scores, as well as composites TOI and FACT Leu total score, compared with the placebo arm, indicating an improvement in HRQL in idelalisib-treated patients (Fig. 1d, e, f, g). In a mixed-effects model including treatment arm (idelalisib vs placebo) and duration, treatment arm had no significant fixed effect on any FACT-Leu score. The effect of treatment duration was significant for FACT-Leu total score ($P = 0.0076$), TOI score ($P = 0.0103$), PWB ($P = 0.0017$), EWB ($P = 0.0142$), and LeuS ($P = 0.0023$); there was no significant

 EQ-5D EuroQoL Five-Dimension, ITT intent-to-treat

interaction between treatment arm and duration for any FACT-Leu score. The treatment difference for idelalisib vs placebo was statistically significant for the LeuS subscale at week 60 ($P = 0.0192$), and for S/FWB and FACT-Leu total score at week 4 ($P = 0.0525$ and $P = 0.0343$, respectively) (Fig. 1, Additional file 1: Table S4). The least squares mean changes from baseline in the LeuS subscale scores were within the MID range of 4 to 7 during the period between week 48 and week 60 in the idelalisib arm, while the values in the placebo arm did not reach the MID at any time points (Fig. 1e).

The KM analysis of symptom improvement suggests that an increased number of patients with the MID improvement, as well as shorter time to symptom improvement, were reported for the 5 FACT-Leu subscales in the idelalisib-containing arm compared with the placebo arm, but none of the differences reached statistical significance (Table 2). A higher proportion of patients treated with idelalisib achieved improvement in PWB, S/FWB and LeuS subscale scores, but not EWB and FWB scores, compared with patients treated with placebo (Fig. 2a–e). Overall, addition of idelalisib to bendamustine/rituximab had a neutral to numerically favorable

effect on change from baseline in FACT-Leu scores of patients with R/R CLL.

EQ-5D

Proportions of patients reporting level 1 or 2 EQ-5D health scores at weeks 24 and 48 were generally similar between the idelalisib and placebo treatment arms. Slightly fewer idelalisib-treated patients reported extreme problems (level 3) with anxiety/depression and pain/discomfort at baseline and after 24 and 48 weeks of treatment compared with patients who received placebo (Table 3). The EQ-5D utility index and EQ-VAS showed trends toward improvement with idelalisib relative to placebo treatment, but these did not reach significance (Table 4, Fig. 3). In a mixed-effects model including treatment (idelalisib vs placebo) and treatment duration, treatment duration had a significant fixed effect for EQ-5D utility index ($P = 0.0169$) and EQ-VAS ($P = 0.0061$); treatment had no significant fixed effect on either score, but there was a significant fixed effect of the interaction between treatment and treatment duration on EQ-5D utility index ($P = 0.0395$). Combination therapy with idelalisib vs placebo did not worsen patient-reported

health—and resulted in favorable trends in some measures—in patients with R/R CLL treated with bendamustine/rituximab.

Discussion

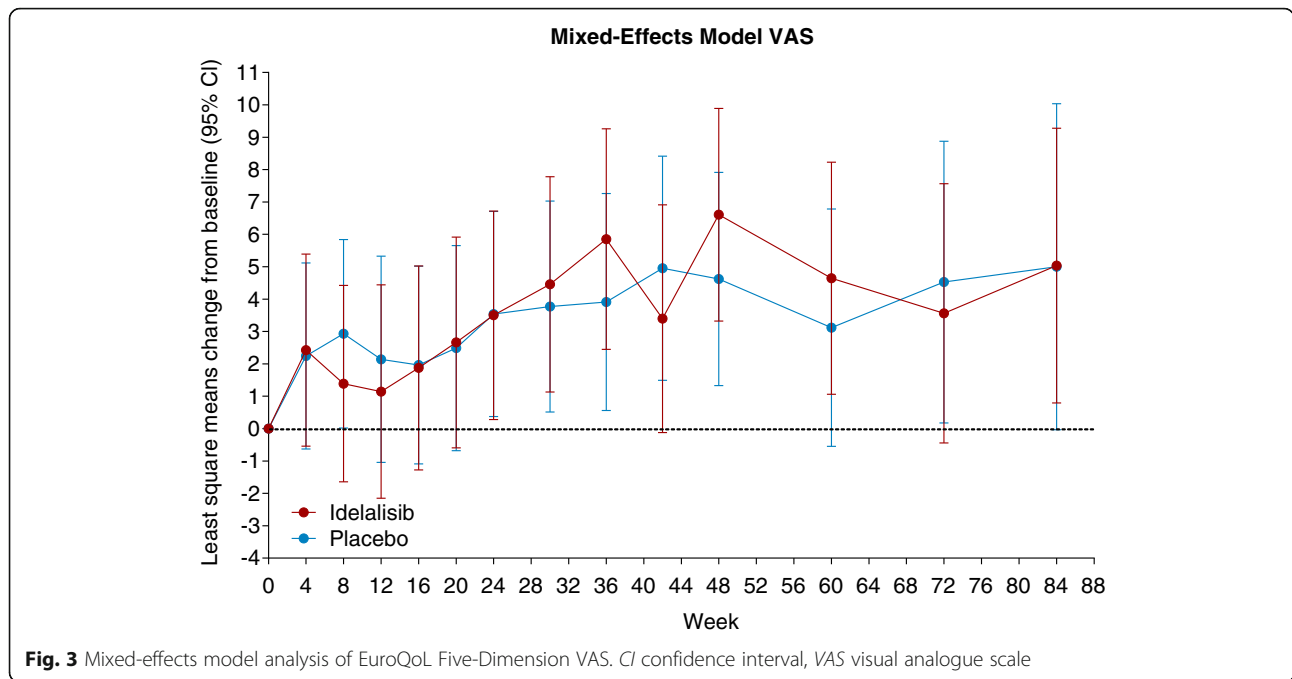

In the primary analysis, the addition of idelalisib to bendamustine/rituximab resulted in superior PFS and OS compared with bendamustine and rituximab alone, thus providing a substantial clinical benefit to R/R CLL patients—a patient population that is difficult to treat [23]. Apart from treatment goals, a more holistic understanding of the impact of treatment including patients' quality of life is also important, and HRQL data constitutes an important part of treatment evaluation. Because patients in both the idelalisib and placebo arms received concurrent chemo-immunotherapy with associated side effects, idelalisib could not be expected to substantially

improve quality of life (QoL) compared with placebo. However, there was potential concern that addition of idelalisib to bendamustine/rituximab would adversely affect change in QoL relative to treatment with bendamustine/rituximab alone.

These prospectively defined HRQL analyses indicate that idelalisib in combination with bendamustine/rituximab treatment had a neutral impact on several HRQL domains in patients with R/R CLL compared with bendamustine/rituximab alone. Per mixed-effects model analyses, the addition of idelalisib to bendamustine/rituximab did not affect the FWB and EWB subscale scores, but provided minor improvements in the PWB, S/FWB, and LeuS subscale scores as well as the FACT-Leu composite measures TOI and FACT-Leu total score. Increased LeuS subscale scores in the idelalisib arm were within the MID range at weeks 48 and 60 and reached statistical significance at week 60. The KM analysis of the symptom improvement showed that among idelalisib-treated patients, time to symptom improvement was shortened by approximately 4 to 12 weeks for the LeuS, PWB, and S/FWB subscales, compared with the placebo arm, and a higher proportion of patients had clinically meaningful improvements in these HRQL domains.

Idelalisib treatment led to small numerical improvements in HRQL in the global health status, as evidenced by the EQ-5D results, particularly reduction of the number of patients who perceived themselves to experience “extreme problems” within the anxiety/depression and pain/discomfort dimensions. The mean changes from baseline in self-rated health, as assessed by EQ-VAS, was also improved, and reached statistical significance vs placebo at week 36 when patients had stopped concurrent chemo-immunotherapy. The rather small differences in overall quality of life observed between the 2 treatment arms may be due to side effects from the concurrent chemo-immunotherapy exerting a dominant effect on quality of life measurements. However, even the slight QoL improvement in patients treated with idelalisib vs placebo in addition to bendamustine/rituximab is valuable information considering the AEs recorded in previous clinical trials of idelalisib [23, 35, 36].

Recently published analyses of PROs assessed in phase 3 randomized trials in patients with relapsed CLL reported that ibrutinib in combination with bendamustine/rituximab vs bendamustine/rituximab alone neither improved nor adversely impacted HRQL [37], and small positive improvements were noted with the addition of ofatumumab to chlorambucil [38] or to fludarabine and cyclophosphamide [21]. However, apart from the fact that comparisons of the results across different studies have several limitations, even indirect comparison of these findings with the results from our study is difficult because of different tools used for PRO evaluations (The Functional

Assessment of Chronic Illness Therapy - Fatigue scale and European Organisation for Research and Treatment of Cancer Quality of Life Questionnaire, in the ibrutinib and ofatumumab studies, and FACT-Leu in this study).

Conclusion

In summary, in patients with incurable diseases such as CLL, treatment efficacy needs to be balanced with safety and HRQL. In this study, we found that adding idelalisib to bendamustine/rituximab—even for those patients already treated with a prior bendamustine-containing regimen—improved treatment efficacy with, importantly, a neutral or beneficial impact on patients’ HRQL. These HRQL findings provide additional information to balance the improved efficacy of the combination regimen with possible safety concerns reported with idelalisib use [23]. Overall, these results further support the existing body of evidence indicating that idelalisib treatment benefits patients with R/R CLL.

AE: Adverse event; CI: Confidence interval; CLL: Chronic lymphocytic leukemia; EQ-5D: EuroQoL Five-Dimension; EWB: Emotional well-being; FACT-

Leu: Functional assessment of cancer therapy – leukemia; FWB: Functional well-being; HR: Hazard ratio; HRQL: Health-related quality of life; KM: Kaplan-Meier; LeuS: Leukemia-specific concerns; MID: Minimally important difference; OS: Overall survival; PFS: Progression-free survival; PI3Kδ: Phosphoinositol-3 kinase δ; PRO: Patient-reported outcomes; PWB: Physical well-being; Q: Quartile; QoL: Quality of life; R/R: Relapsed/refractory; S/FWB: Social/family well-being; TOI: Trial outcome index; VAS: Visual analog scale

Acknowledgements

This study was sponsored by Gilead Sciences, Inc. (Foster City, CA; and Seattle, WA). The authors would like to thank Henry Adewoye and Yeonhee Kim, former employees of Gilead Sciences, Inc., for their invaluable input on the early drafts of this manuscript. Medical writing and editorial support were provided by Ewa Wandzioch, PhD; and Meryl Gersh, PhD, of AlphaBioCom, LLC, King of Prussia, PA, and was funded by Gilead Sciences, Inc.

Authors’ contributions

All authors made substantial contributions to the acquisition, analysis, and/or interpretation of the data, provided critical feedback on manuscript content, provided final approval for submission of the manuscript to this journal, and have agreed to be accountable for all aspects of the work.

Funding

This study was funded by Gilead Sciences, Inc.

Availability of data and materials

The data that support the findings of this study are available from Gilead Sciences, Inc., but restrictions apply to the availability of these data, which were used under license for the current study, and so are not publicly available. Data are however available from the authors upon reasonable request and with permission of Gilead Sciences, Inc.

Ethics approval and consent to participate

The study protocols were approved by the Institutional Review Boards at each study site. The trial was conducted according to the principles of Good Clinical Practice and the Declaration of Helsinki. All patients provided written informed consent.

Consent for publication

Not applicable.
