T-cell transcriptomics from peripheral blood highlights differences between polymyositis and dermatomyositis patients

Miranda Houtman^{1*} , Louise Ekholm¹, Espen Hesselberg¹, Karine Chemin¹, Vivianne Malmström¹, Ann M. Reed², Ingrid E. Lundberg¹ and Leonid Padyukov¹

Abstract

Background: Polymyositis (PM) and dermatomyositis (DM) are two distinct subgroups of idiopathic inflammatory myopathies, a chronic inflammatory disorder clinically characterized by muscle weakness and inflammatory cell infiltrates in muscle tissue. In PM, a major component of inflammatory cell infiltrates is CD8+ T cells, whereas in DM, CD4+ T cells, plasmacytoid dendritic cells, and B cells predominate. In this study, with the aim to differentiate involvement of CD4+ and CD8+ T-cell subpopulations in myositis subgroups, we investigated transcriptomic profiles of T cells from peripheral blood of patients with myositis.

Methods: Total RNA was extracted from CD4+ T cells (PM = 8 and DM = 7) and CD8+ T cells (PM = 4 and DM = 5) that were isolated from peripheral blood mononuclear cells via positive selection using microbeads. Sequencing libraries were generated using the Illumina TruSeq Stranded Total RNA Kit and sequenced on an Illumina HiSeq 2500 platform, yielding about 50 million paired-end reads per sample. Differential gene expression analyses were conducted using DESeq2.

Results: In CD4+ T cells, only two genes, *ANKRD55* and *S100B*, were expressed significantly higher in patients with PM than in patients with DM (false discovery rate [FDR] < 0.05, model adjusted for age, sex, *HLA-DRB1*03* status, and RNA integrity number [RIN]). On the contrary, in CD8+ T cells, 176 genes were differentially expressed in patients with PM compared with patients with DM. Of these, 44 genes were expressed significantly higher in CD8+ T cells from patients with PM, and 132 genes were expressed significantly higher in CD8+ T cells from patients with DM (FDR < 0.05, model adjusted for age, sex, and RIN). Gene Ontology analysis showed that genes differentially expressed in CD8+ T cells are involved in lymphocyte migration and regulation of T-cell differentiation.

Conclusions: Our data strongly suggest that CD8+ T cells represent a major divergence between PM and DM patients compared with CD4+ T cells. These alterations in the gene expression in T cells from PM and DM patients might advocate for distinct immune mechanisms in these subphenotypes of myositis.

Background

Polymyositis (PM) and dermatomyositis (DM) are chronic inflammatory disorders clinically characterized by skeletal muscle weakness and muscle inflammation [1]. Other organs, such as the skin, joints, and lungs, are frequently involved in these disorders. Although the etiology of PM and DM is unknown, certain environmental and genetic factors are important. The major risk factor for these disorders in Caucasian populations is *HLA-DRB1*03:01* [2–4]. In addition, autoantibodies are found in more than 80% of the PM and DM patients, supporting a role for the adaptive immune system in the pathogenesis of these disorders [5].

In both PM and DM patients, inflammatory cell infiltrates are commonly found in the affected tissues [6, 7]. In PM, the cellular infiltrates are located mainly in the endomysium surrounding muscle fibers and typically dominated by CD8+ T cells [8, 9]. In contrast, in patients with DM, the inflammatory cell infiltrates are located mainly in the perimysium and in perivascular areas, and the infiltrates are predominated by CD4+ T cells with occasional plasmacytoid dendritic cells and B cells [6]. Further phenotyping of T cells in muscle tissue has led to the observation that the muscle-infiltrating T cells in both PM and DM are predominantly of the CD8+CD28^{null} and CD4+CD28^{null} phenotypes, which both have cytotoxic properties [10, 11]. Interestingly, these subpopulations of T cells can also be detected in peripheral blood of patients with myositis [10, 12]. Still, the differences in the tissue location of inflammatory cell infiltrates suggest that the underlying immune mechanisms may vary between PM and DM.

In this study, we aimed to investigate whole-genome transcriptomes of CD4+ and CD8+ T cells from peripheral blood in different subsets of patients with idiopathic inflammatory myopathies (IIMs). We used RNA sequencing to identify differentially expressed genes between PM and DM, as well as in patients with both types of IIM, considering *HLA-DRB1*03* alleles.

Methods

Patient recruitment

Initially, 33 consecutive adult individuals with PM or DM (not drug-free) from the Karolinska Hospital Rheumatology Clinic were selected for the study on the basis of diagnosis (PM and DM) and *HLA-DRB1*03* status (positive and negative). Patients with myositis visited the clinic between January 21 and April 23, 2014, and were fully validated according to the new European League Against Rheumatism/American College of Rheumatology classification criteria [13]. Thirty-one of the 33 patients also satisfied the Bohan and Peter criteria [14, 15]. Extensive clinical data, including disease phenotypes and treatment regimen, were collected from clinical records by experienced rheumatologists. All patients gave written consent for their participation in the

study. The study was approved by the Stockholm regional ethics board.

Autoantibody detection

Patient sera were analyzed by RNA and protein immunoprecipitation for the presence of autoantibodies against Jo1, PL12, PL7, OJ, EJ, KS, Mi-2, MDA5, TIF-1 γ , SRP, PM-Scl, Ro52, Ro60, U1RNP, and Ku. Sera collected after 2013 were screened using a validated line immunoassay system (EUROLINE myositis panel 4; EUROIMMUN AG, Lübeck, Germany) according to the manufacturer's instructions or by enzyme-linked immunosorbent assays for the presence of myositis-specific autoantibodies or myositis-associated autoantibodies.

HLA typing

HLA typing was performed by sequence-specific primer PCR (*HLA-DR* low-resolution kit; Olerup SSP, Stockholm, Sweden) and analyzed by agarose gel electrophoresis [16]. An interpretation table was used to determine the specific genotype according to the manufacturer's instructions.

Blood sampling and cell sorting

Patients' blood was collected in heparin tubes (40–50 ml in total), and peripheral blood mononuclear cells (PBMCs) were isolated by density gradient centrifugation using Ficoll density gradient medium (GE Healthcare Bio-Sciences AB, Uppsala, Sweden). CD4+ cells and CD8+ cells were isolated from the PBMCs via positive selection using CD4 or CD8 MicroBeads on an autoMACS[®] Pro Separator (Miltenyi Biotec Norden AB, Lund, Sweden). Flow cytometry was used to determine the purity of some of the sorted T-cell samples, and over 90% of CD45+ cells expressed CD4 ($n = 5$) or CD8 ($n = 5$). The following antibodies were used: CD45 (HI30; BioLegend, San Diego, CA, USA), CD4 (OKT4; BioLegend), and CD8 (SK1; BD Biosciences, Stockholm, Sweden).

RNA sequencing

Total RNA was extracted with the RNeasy Mini Kit (Qiagen AB, Sollentuna, Sweden) according to the manufacturer's instructions. Samples were treated with DNase (Qiagen) for 20 minutes at room temperature to avoid contamination with genomic DNA. The quality of each RNA sample was characterized using a RNA 6000 Nano Chip (Agilent Technologies Sweden AB, Kista, Sweden) on the Agilent Bioanalyzer 2100. Fifteen CD4+ T-cell samples and nine CD8+ T-cell samples met the RNA quality criteria (RNA integrity number [RIN] > 4) and were sequenced. The RNA was fragmented and prepared into sequencing libraries using the TruSeq Stranded Total RNA Sample Preparation Kit (Illumina, San Diego, CA, USA) with ribosomal depletion using Ribo-Zero (2 × 125 bp; Illumina) and analyzed on an

Illumina HiSeq 2500 sequencer (SNP&SEQ Technology Platform, Uppsala, Sweden). On average, 50 million reads were produced per sample. Raw read quality was evaluated using FastQC. Prefiltering on quality of reads using cutadapt (version 1.9.1) was applied (-q 30 -a AGATCGG AAGAGCACACGTCTGAACTCCAGTCAC -A AGATC GGAAGAGCGTCGTGTAGGGAAAGAGTGTAGATCT CGGTGGTCGCCGTATCATT -m 40). Filtered reads were aligned to the hg38 assembly and quantified using STAR (version 2.5.1b) [17] with default settings.

Cell-type enrichment analysis

The xCell tool [18] was used to identify cellular heterogeneity in the CD4+ and CD8+ T-cell subsets from gene expression data. xCell uses the expression levels ranking (transcripts per million), and these were obtained using Salmon (version 0.8.2) [19].

Differential gene expression analysis

Raw expression counts were adjusted for library size using the R package DESeq2 (version 1.16.1) [20]. Prefiltering of low-count genes was performed to keep only genes that have at least 50 reads in total. Principal component analysis (PCA) was used to identify outliers. For each sample, the first five principal components (PCs) were extracted and correlated with available clinical and

technical data. For the CD4+ T-cell subset, age group (< 60 and ≥ 60 years), sex, *HLA-DRB1*03* status (positive and negative), and RIN value were used as covariates in the analyses. The formula used for defining the model was the following:

$$\text{Geneexpression} \sim \text{agegroup} + \text{sex} \\ + \text{HLA-DRB1} * 03\text{status} \\ + \text{RINvalue} + \text{diagnosis}$$

For the CD8+ T-cell subset, sex, age group (< 60 and ≥ 60 years), and RIN value were used as covariates in the analyses. The formula used for defining the model was the following:

$$\text{Geneexpression} \sim \text{agegroup} + \text{sex} + \text{RINvalue} \\ + \text{diagnosis}$$

Owing to possible contamination of samples with other cell types, differential gene expression analyses were performed in two stages. The analyses were performed first on all samples and second on a subset of samples excluding potential outliers. The differentially expressed genes that overlapped between the two analyses were taken as robust evidence for significant findings in order to exclude false-positive findings due to heterogeneity in the CD4+ and CD8+ T-cell subsets.

Demographic and clinical characteristics of patients with myositis in the CD4+ ($n = 15$) and CD8+ T-cell subsets ($n = 9$) at time of blood sampling. The patients were classified according to the new European League Against Rheumatism/American College of Rheumatology classification criteria [13]

The default DESeq2 options were used, including log fold change shrinkage. We considered differentially expressed genes when the Benjamini-Hochberg adjusted p value (false discovery rate [FDR]) was < 0.05 .

Functional enrichment analysis

To further understand the biological relevance and associated pathways of the differentially expressed genes, functional enrichment analysis was performed using the Gene Ontology (GO) database (released on 2 February 2018). Fisher's exact test with FDR correction (< 0.05) was used to determine significantly enriched GO biological processes.

Results

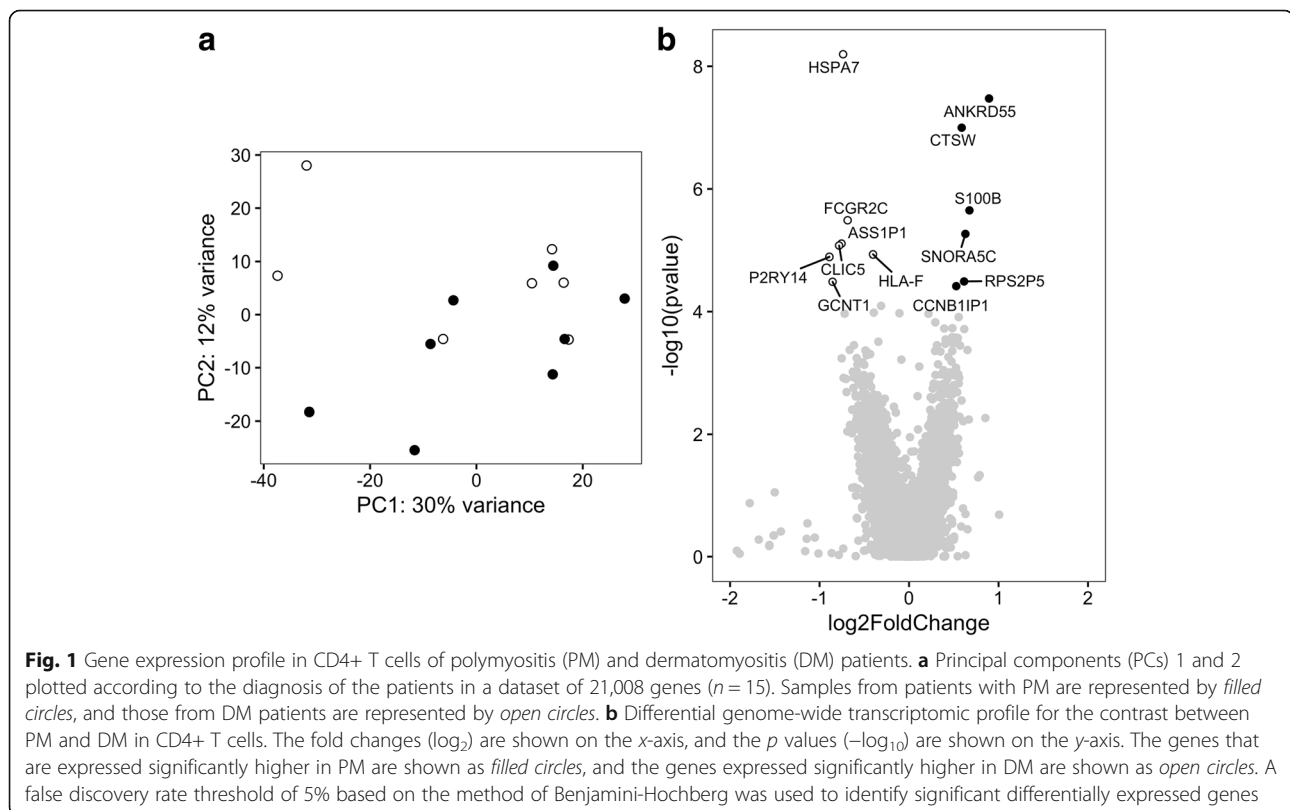

Differential gene expression in CD4+ T cells of PM and DM patients

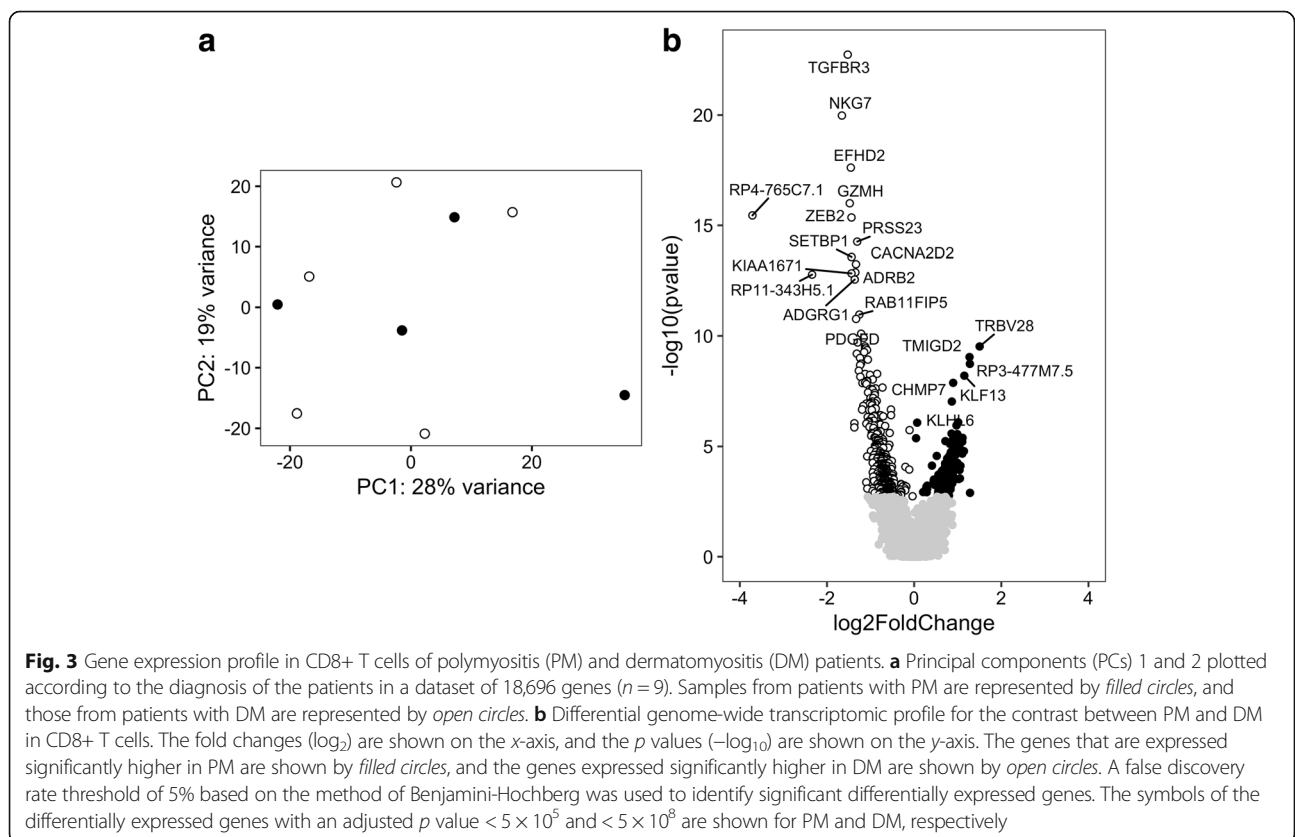

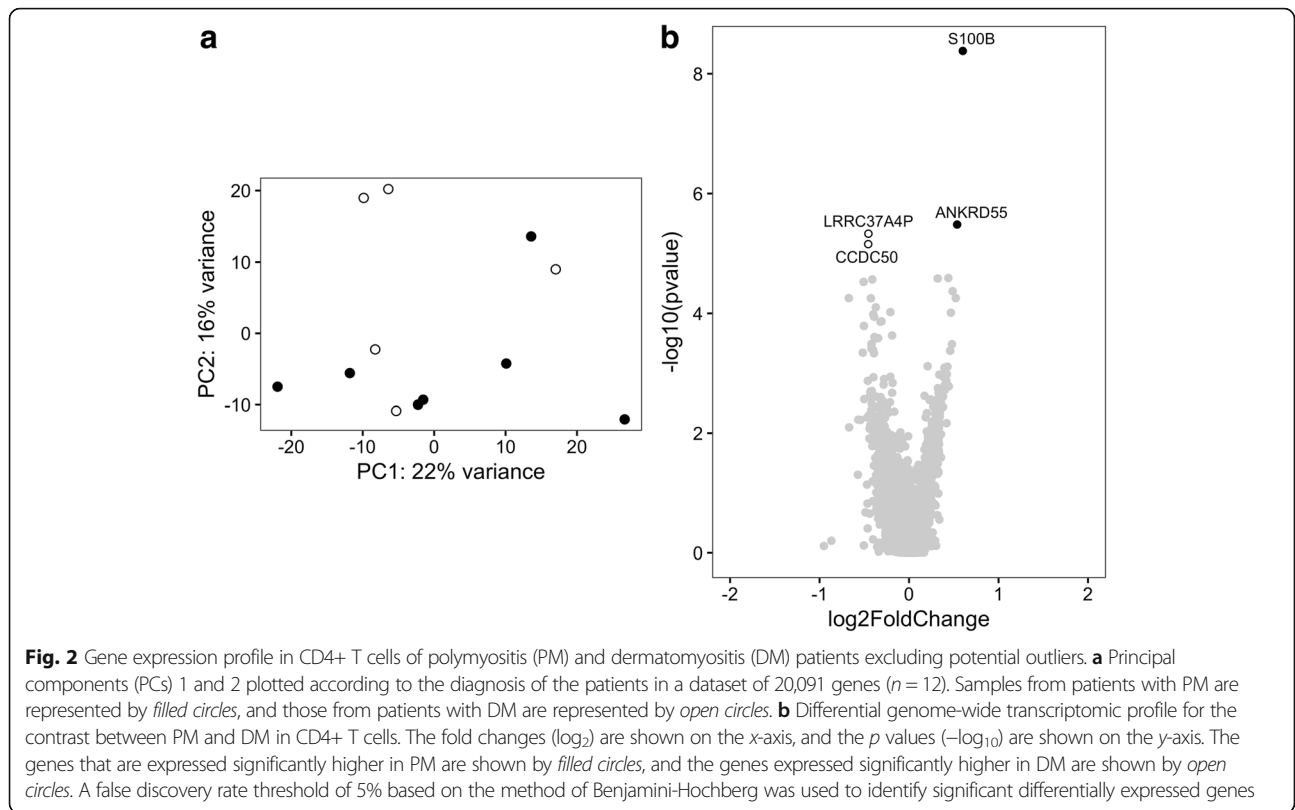

The clinical characteristics of patients with myositis in the CD4+ T-cell subset are summarized in Table 1. No significant differences were found in patients with PM compared with patients with DM regarding disease activity measures and laboratory data (Additional file 1: Table S1 and S2).

Because PM and DM represent two similar but clinically distinct diseases, we searched for differentially expressed genes in CD4+ T cells in PM versus DM

patients. First, the whole-genome expression pattern in CD4+ T cells of PM and DM patients was examined by PCA. The first two PCs did not significantly separate between PM and DM (Fig. 1a), suggesting that, in general, the overall gene expression in CD4+ T cells from patients with PM or DM is similar. At the first analytical stage, we performed differential gene expression analysis using DESeq2 with sex, age group, *HLA-DRB1*03* status, and RIN value as covariates. Based on the cutoff criteria of Benjamini-Hochberg based FDR correction of < 0.05 , 13 genes were found to be differentially expressed. Among these genes, six were expressed higher in PM patients and seven were expressed higher in DM patients (Fig. 1b and Additional file 2: Table S6).

The PCA plot shown in Fig. 1a indicates three potential outliers with a PC1 score lower than -20 . These three samples represent higher gene expression levels related to monocytes according to the xCell tool (Additional file 3: Figure S1). To exclude the possibility that the differentially expressed genes were obtained because of a difference in cell composition, at the second analytical stage, we removed the three potential outliers from the analysis. This did not affect clustering of PM and DM samples in PCA (Fig. 2a). Using the same covariates as above, four genes were found to be differentially expressed in CD4+ T cells comparing PM patients with

DM patients by applying an FDR correction cutoff of < 0.05 . Two genes had a higher expression in CD4+ T cells of patients with PM compared with patients with DM, and two genes had a higher expression in CD4+ T cells of patients with DM compared with patients with PM (Fig. 2b and Additional file 2: Table S7). Thus, after accounting for possible contamination of the CD4+ T-cell population with monocytes, we considered only the genes that were found to be differentially expressed at both analytical stages. These analyses indicate that in CD4+ T cells, *ANKRD55* and *S100B* had a higher expression in CD4+ T cells of patients with PM compared with patients with DM.

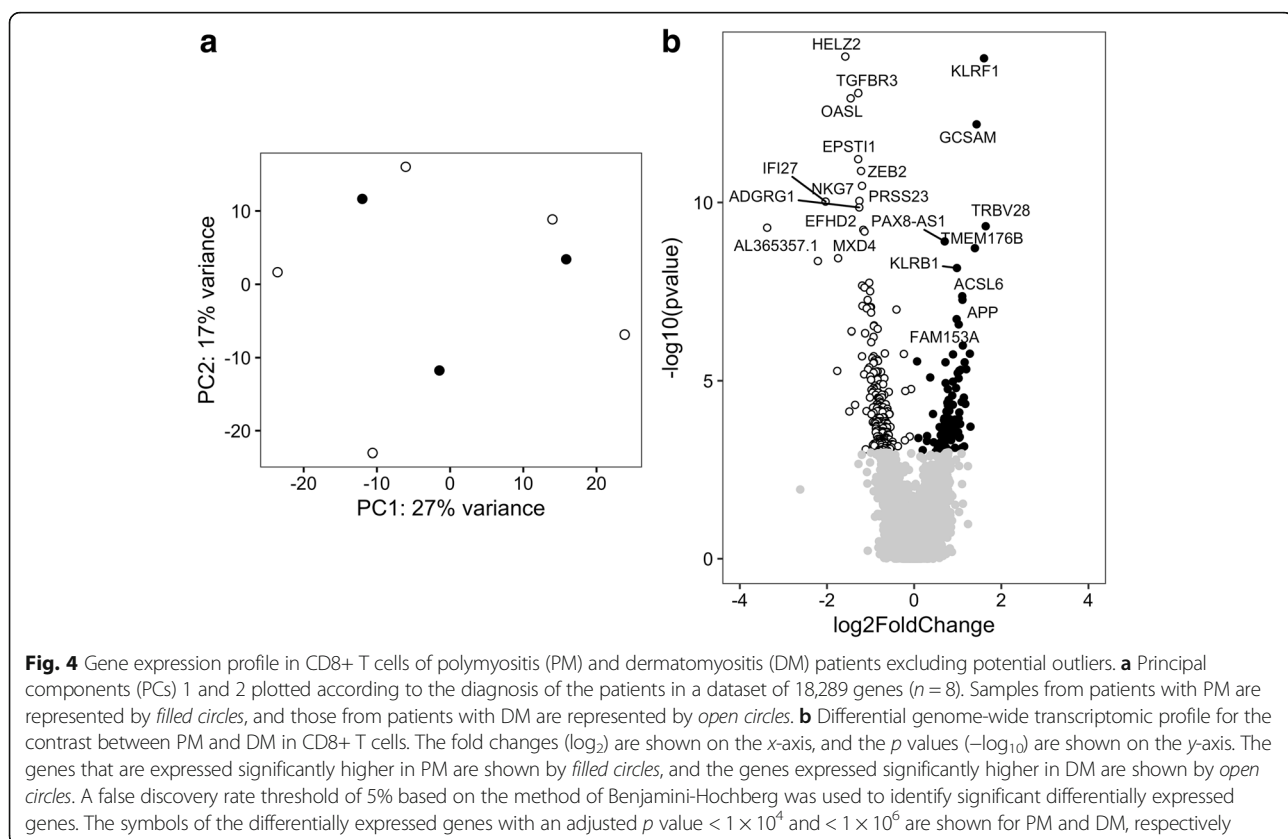

Differential gene expression in CD8+ T cells of PM and DM patients

The clinical characteristics of patients with myositis in the CD8+ T-cell subset are summarized in Table 1. No significant differences were found in patients with PM compared with patients with DM regarding disease activity measures and laboratory data (Additional file 1: Table S1 and S3).

Another cell type that is commonly found in affected tissues of patients with myositis are CD8+ T cells.

Therefore, we also searched for differentially expressed genes between PM and DM in CD8+ T cells. First, the gene expression pattern in PM and DM was examined by PCA. PCA showed no clustering of PM and DM (Fig. 3a), which suggests that the overall gene expression in PM and DM is similar in CD8+ T cells. To identify genes that are differentially expressed between PM and DM, DESeq2 was used with sex, age group, and RIN value as covariates at the first analytical stage. Upon applying Benjamini-Hochberg-based FDR correction of < 0.05 , we found that 588 genes were differentially expressed between PM and DM. Among these genes, 182 had a higher expression in CD8+ T cells of patients with PM patients compared with DM patients, and 406 had a higher expression in CD8+ T cells of patients with DM compared with patients with PM (Fig. 3b and Additional file 4: Table S8).

The PCA plot shown in Fig. 3a indicates one potential outlier with a PC1 score > 20 . This sample clustered together with the CD4+ T-cell samples (data not shown) and was removed from the analysis at the second analytical stage. After removing this sample from the analysis, the PCA showed that the overall gene expression remained similar in PM and DM (Fig. 4a). Based on the cutoff criteria of $FDR < 0.05$, 308 genes were found to be

differentially expressed in CD8+ T cells comparing PM patients with DM patients. Among these genes, 107 genes had a higher expression in CD8+ T cells of PM patients compared with patients with DM, and 201 genes had a higher expression in CD8+ T cells of DM patients compared with PM patients (Fig. 4b and Additional file 4: Table S9).

Thus, after accounting for heterogeneity in the CD8+ T-cell subset, we considered only the genes that were found to be differentially expressed at both analytical stages. Together, a total of 44 genes were commonly expressed higher in CD8+ T cells of patients with PM compared with patients with DM (Table 2), and 132 genes were commonly expressed higher in CD8+ T cells of patients with DM compared with patients with PM (Table 3).

To identify enriched biological processes and pathways for the 176 genes that were differentially expressed between PM and DM, the GO database was used. Using Fisher's exact test with FDR correction (<0.05), the enriched GO biological processes included lymphocyte migration and regulation of T-cell differentiation (Table 4 and Additional file 5: Table S10).

Differential gene expression in CD4+ T cells of *HLA-DRB1*03*-positive and -negative myositis patients

*HLA-DRB1*03* haplotype is the major genetic risk factor for myositis. Therefore, we searched for differentially expressed genes between *HLA-DRB1*03*-positive and -negative myositis patients in CD4+ T cells. No significant differences were found in patients with *HLA-DRB1*03*-positive and -negative myositis regarding disease activity measures and laboratory data (Table 1 and Additional file 1: Tables S4 and S5). The gene expression pattern in *HLA-DRB1*03*-positive and -negative myositis was examined by PCA, but the first PCs did not separate *HLA-DRB1*03*-positive from *HLA-DRB1*03*-negative myositis patients (Fig. 5a), suggesting that these patients are similar on a high genomic level. At the first analytical stage, we performed differential expression analysis using DESeq2 with sex, age group, diagnosis, and RIN value as covariates. This resulted in eight genes that were differentially expressed between *HLA-DRB1*03*-positive and -negative myositis (FDR <0.05). Of these genes, one had a higher expression in *HLA-DRB1*03*-positive patients with myositis, and seven had a higher expression in *HLA-DRB1*03*-negative patients with myositis (Fig. 5b and Additional file 6: Table S11).

Excluding the potential outliers, which represent higher gene expression levels linked to monocytes, did not affect the PCA (Fig. 6a). At the second analytical stage, we found that although *HLA-DRB1*03*-positive and -negative myositis are not separated by the first

PCs, 12 genes were differentially expressed in CD4+ T cells in comparison of myositis patients with different genotypes. Among these, five genes had a higher expression in CD4+ T cells from *HLA-DRB1*03*-positive patients with myositis, and eight genes had a higher expression in CD4+ T cells from *HLA-DRB1*03*-negative patients with myositis (Fig. 6b and Additional file 6: Table S12). Finally, we considered only the genes that were found to be differentially expressed at both analytical stages. *PI4KAP1* was found to have a higher expression in CD4+ T cells of *HLA-DRB1*03*-positive patients with myositis, and *TRGC2*, *CTSW*, *HPCAL4*, *ZNF683*, and *GOLGA8B* were found to have a higher expression in CD4+ T cells of *HLA-DRB1*03*-negative patients with myositis.

Discussion

In our study, we observed significantly more differentially expressed genes in the CD8+ T-cell subset than in the CD4+ T-cell subset when comparing PM and DM patients. In CD8+ T cells, we identified 176 genes that were differentially expressed between PM and DM. In contrast, in CD4+ T cells, only two genes, *ANKRD55* and *S100B*, were found to be differentially expressed between PM and DM. To our knowledge, this is the first study comparing transcriptomic profiles of CD4+ and CD8+ T cells between DM and PM patients. Our data align with the understanding that PM and DM have many common features but differ in genetic architecture and immunohistopathological characteristics. Our findings, together with previous observations, suggest that immune mechanisms related to subpopulations of T cells may significantly vary between these subphenotypes of myositis and also emphasize CD8+ T cells as being of interest both in patients with PM and in those with DM [10, 21, 22].

PM and DM have been modeled as subgroups of myositis in which muscle tissues are infiltrated by T cells, mainly CD8+ T cells in PM and CD4+ T cells in DM [6–9]. More recently, we have demonstrated an overlapping phenotype among the muscle-infiltrating T cells, regardless of their CD4 or CD8 lineage, in that they both display a cytotoxic signature in combination with the absence of the costimulatory CD28 receptor [10, 11]. Such differentiated T cells can also be detected in peripheral blood of patients with PM and DM, reflecting the systemic course of autoimmune disorders [10, 12].

In CD8+ T cells of PM and DM patients, 176 genes were differentially expressed. Interestingly, we noted relatively high expression of *GZMH* and *GZMB* in CD8+ T cells of DM patients compared with CD8+ T cells of PM patients. The protein encoded by *GZMB* is granzyme B and its secretion by CD28^{null} T cells may cause

The table demonstrates the genes that overlap between the two analytical stages and have a significantly higher expression in CD8+ T cells of patients with polymyositis than in those with dermatomyositis. A false discovery rate threshold of 5% based on the method of Benjamini-Hochberg was used to identify significantly differentially expressed genes

muscle cell damage [11]. Furthermore, granzyme B cleavage sites have been identified in autoantigens, such as FHL1 and HisRS, targeted in autoimmune disorders, including myositis [23, 24]. Moreover, two T-cell receptor (TCR) beta variable genes, *TRBV28* and *TRBV30*, had a higher expression in CD8+ T cells of patients with PM than in patients with DM. *TRBV28* has been found to be one of the most common TCR variable segments in muscle tissue of myositis patients carrying the *HLA-DRB1*03* allele [25]. This aligns well with the fact that in our analysis of the CD8+ T-cell subset, all PM patients are *HLA-DRB1*03*-positive and all DM patients are *HLA-DRB1*03*-negative (Table 1). The TCR beta variable genes are probably differentially expressed due to the HLA status of these patients and might reflect the expansion of pathogenic T-cell clones in this subset of patients. In addition, *TGFB1*, *ZEB2*, and *SMAD7* had a higher expression in CD8+ T cells of patients with DM than in those with PM. This may suggest that transforming growth factor- β signaling [26–29] is upregulated in CD8+ T cells of DM patients compared with PM patients.

In CD4+ T cells, two genes, *ANKRD55* and *S100B*, had a higher expression in PM than in DM. *ANKRD55* encodes ankyrin repeat domain-containing protein 55, which mediates protein-protein interactions [30]. Interestingly, single-nucleotide polymorphisms in this gene have previously been associated with several autoimmune disorders, including rheumatoid arthritis [31–33], Crohn's disease [34], and multiple sclerosis [35]. A study to reveal the function of this gene in the context of immune function is pending. *S100B* encodes a member of the S100 protein family and is involved in the calcium-dependent regulation of a variety of intracellular activities [36]. *S100B* is

<i>TOGARAM2</i>	TOG array regulator of axonemal microtubules 2
<i>FRMPD3</i>	FERM and PDZ domain containing 3
<i>TBX21</i>	T-box 21
<i>SESN2</i>	Sestrin 2
<i>PAX5</i>	Paired box 5
<i>MIDN</i>	Midnolin

Table 3 Genes expressed significantly higher in CD8+ T cells of patients with dermatomyositis than in those with polymyositis (Continued)

Gene symbol	Gene name
<i>CCL5</i>	C-C motif chemokine ligand 5
<i>SYTL3</i>	Synaptotagmin like 3
<i>GAB3</i>	GRB2 associated binding protein 3
<i>TTC38</i>	Tetratricopeptide repeat domain 38
<i>LDLR</i>	Low density lipoprotein receptor
<i>CCL4</i>	C-C motif chemokine ligand 4
<i>DMWD</i>	DM1 locus, WD repeat containing
<i>CASZ1</i>	Castor zinc finger 1
<i>LAG3</i>	Lymphocyte activating 3
<i>DYRK1B</i>	Dual specificity tyrosine phosphorylation regulated kinase 1B
<i>GPR153</i>	G protein-coupled receptor 153
<i>MATK</i>	Megakaryocyte-associated tyrosine kinase
<i>SH2D2A</i>	SH2 domain containing 2A
<i>RHBDF2</i>	Rhomoid 5 homolog 2
<i>ADGRG5</i>	Adhesion G protein-coupled receptor G5
<i>UBE2Q2P1</i>	Ubiquitin conjugating enzyme E2 Q2 pseudogene 1
<i>GALNT3</i>	Polypeptide N-acetylgalactosaminyltransferase 3
<i>RUNX3</i>	Runt related transcription factor 3
<i>PLA2G16</i>	Phospholipase A2 group XVI
<i>SLC15A4</i>	Solute carrier family 15 member 4
<i>PPP2R2B</i>	Protein phosphatase 2 regulatory subunit beta
<i>RGS9</i>	Regulator of G protein signaling 9
<i>PATL2</i>	PAT1 homolog 2
<i>C1orf21</i>	Chromosome 1 open reading frame 21
<i>S1PR5</i>	Sphingosine-1-phosphate receptor 5
<i>TMCC3</i>	Transmembrane and coiled-coil domain family 3
<i>TLR3</i>	Toll like receptor 3
<i>GLB1L2</i>	Galactosidase beta 1 like 2
<i>PRELID2</i>	PRELI domain containing 2
<i>ADAP1</i>	ArfGAP with dual PH domains 1
<i>TRGJ2</i>	T cell receptor gamma joining 2
<i>DENND3</i>	DENN domain containing 3
<i>SOX13</i>	SRY-box 13
<i>GZMB</i>	Granzyme B
<i>FGFBP2</i>	Fibroblast growth factor binding protein 2
<i>RAP2A</i>	RAP2A, member of RAS oncogene family
<i>FCRL6</i>	Fc receptor like 6
<i>ITGAL</i>	Integrin subunit alpha L
<i>ABHD17A</i>	Abhydrolase domain containing 17A
<i>CHST12</i>	Carbohydrate sulfotransferase 12
<i>NBEAL2</i>	Neurobeachin like 2

Table 3 Genes expressed significantly higher in CD8+ T cells of patients with dermatomyositis than in those with polymyositis (Continued)

Gene symbol	Gene name
<i>ADAM8</i>	ADAM metallopeptidase domain 8
<i>SLC1A7</i>	Solute carrier family 1 member 7
<i>LTBP4</i>	Latent transforming growth factor beta binding protein 4
<i>CRIP1</i>	Cysteine rich protein 1
<i>RNF166</i>	Ring finger protein 166
<i>MXD4</i>	MAX dimerization protein 4
<i>TNFSF9</i>	TNF superfamily member 9
<i>ZNF683</i>	Zinc finger protein 683
<i>CTD-2377D24.8</i>	
<i>HNRNPLL</i>	Heterogeneous nuclear ribonucleoprotein L like
<i>MPST</i>	mercaptopyruvate sulfurtransferase
<i>ATP1A3</i>	ATPase Na ⁺ /K ⁺ transporting subunit alpha 3
<i>IFNLR1</i>	Interferon lambda receptor 1
<i>PTMS</i>	Parathymsin
<i>SLC20A1</i>	Solute carrier family 20 member 1
<i>MVD</i>	Mevalonate diphosphate decarboxylase
<i>SH3RF2</i>	SH3 domain containing ring finger 2
<i>RAPGEF1</i>	Rap guanine nucleotide exchange factor 1
<i>TGFB1</i>	Transforming growth factor beta 1
<i>AL928654.3</i>	
<i>BHLHE40</i>	Basic helix-loop-helix family member e40
<i>MAPKAPK2</i>	Mitogen-activated protein kinase-activated protein kinase 2
<i>PTPRJ</i>	Protein tyrosine phosphatase, receptor type J
<i>DGKQ</i>	Diacylglycerol kinase theta
<i>MYO3B</i>	Myosin IIIB
<i>DUSP8</i>	Dual specificity phosphatase 8
<i>FLNA</i>	Filamin A
<i>NOP14-AS1</i>	NOP14 antisense RNA 1
<i>ITGB2</i>	Integrin subunit beta 2
<i>GNG2</i>	G protein subunit gamma 2
<i>MSC</i>	Musculin
<i>ARHGAP10</i>	Rho GTPase activating protein 10
<i>DNMBP</i>	Dynamin binding protein
<i>MYO1G</i>	Myosin IG
<i>DDN-AS1</i>	DDN and PRKAG1 antisense RNA 1
<i>SIPA1</i>	Signal-induced proliferation-associated 1
<i>AC093616.1</i>	Anaphase-promoting complex subunit 1-like
<i>CTSW</i>	Cathepsin W
<i>PXN</i>	Paxillin
<i>SSBP3</i>	Single-stranded DNA binding protein 3
<i>SLC2A1</i>	Solute carrier family 2 member 1

Table 3 Genes expressed significantly higher in CD8+ T cells of patients with dermatomyositis than in those with polymyositis (Continued)

Gene symbol	Gene name
<i>MCOLN2</i>	Mucolipin 2
<i>NAA50</i>	N(alpha)-acetyltransferase 50, NatE catalytic subunit
<i>RDH10</i>	Retinol dehydrogenase 10
<i>NFATC2</i>	Nuclear factor of activated T cells 2
<i>KDM4B</i>	Lysine demethylase 4B
<i>GALNT10</i>	Polypeptide N-acetylgalactosaminyltransferase 10
<i>DPY19L1P1</i>	DPY19L1 pseudogene 1
<i>INSIG1</i>	Insulin induced gene 1
<i>PLEKHA2</i>	Pleckstrin homology domain containing A2
<i>PROK2</i>	Prokineticin 2
<i>PTP4A2</i>	Protein tyrosine phosphatase type IVA, member 2
<i>GPR27</i>	G protein-coupled receptor 27
<i>LINC00355</i>	Long intergenic non-protein coding RNA 355

The table demonstrates the genes that overlap between the two analytical stages and have a significantly higher expression in CD8+ T cells of patients with dermatomyositis than in those with polymyositis. A false discovery rate threshold of 5% based on the method of Benjamini-Hochberg was used to identify significant differentially expressed genes

detected in CD8+ T cells and natural killer (NK) cells, but not in CD4+ T cells [37]. This, together with low levels of *S100B* observed in CD4+ T cells in our study, may suggest either that *S100B* expression is evidence of contamination by other cell types or that this expression is characteristic of CD4+ T cells in PM. In any scenario, these data will need replication in an independent group of patients.

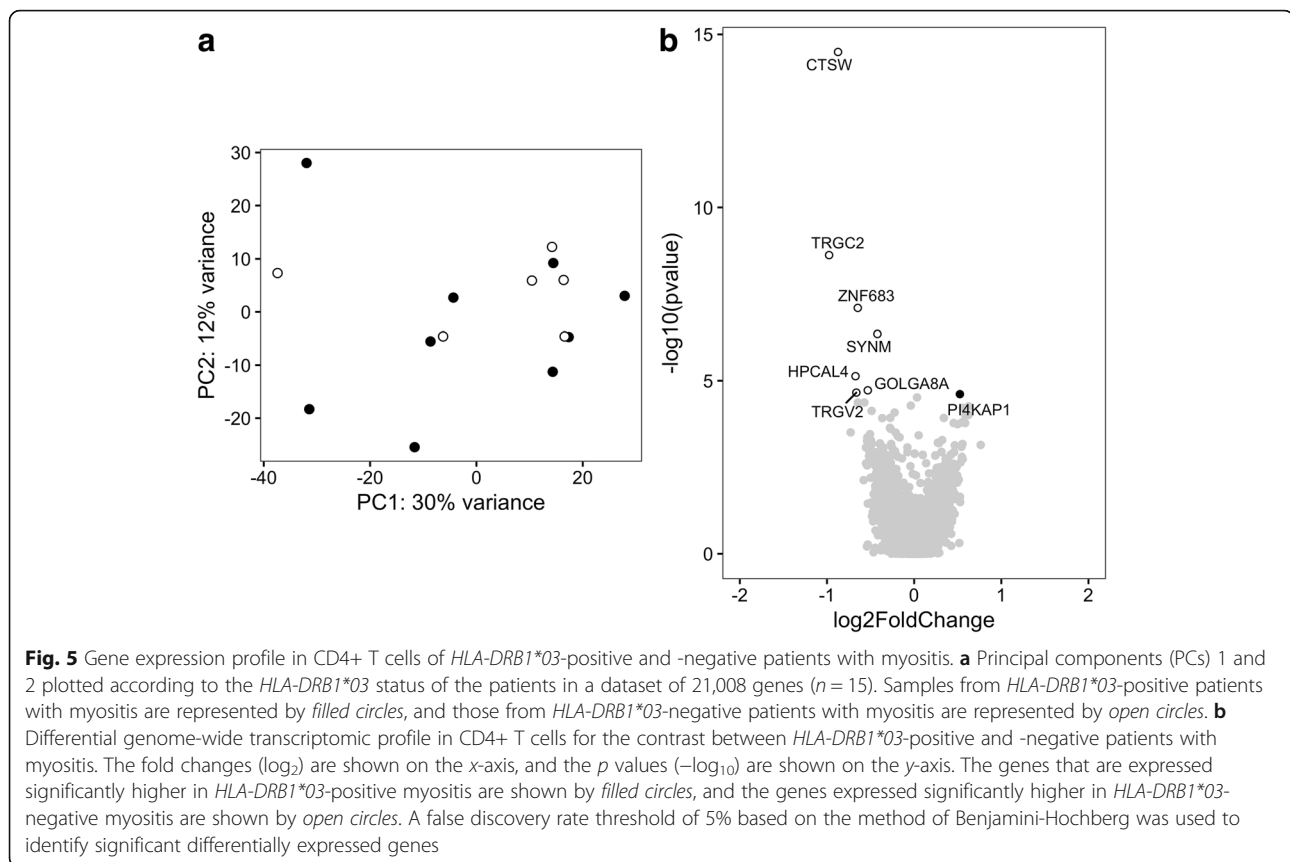

The *HLA-DRB1*03* haplotype is strongly associated with IIM, especially with PM [2, 38]. We made an effort to investigate how IIM patients with and without this genetic risk factor are different in their transcriptomic profiles in CD4+ T cells. Six genes were differentially expressed in CD4+ T cells of *HLA-DRB1*03*-positive compared with *HLA-DRB1*03*-negative myositis patients. We found that *PI4KAP1* had a higher expression in CD4+ T cells of *HLA-DRB1*03*-positive myositis and that *TRGC2*, *CTSW*, *HPCAL4*, *ZNF683*, and *GOLGA8B* had a higher expression in CD4+ T cells of *HLA-DRB1*03*-negative myositis patients. Interestingly, we found that *ZNF683* also had a higher expression in CD8+ T cells of *HLA-DRB1*03*-negative myositis patients when comparing PM and DM, suggesting that the expression of *ZNF683* is common for both subpopulations of T cells. *ZNF683* is upregulated in T cells with cytotoxic characteristics [39] and is involved in the transcriptional regulation of effector functions, such as production of interferon- γ and granzyme B [40, 41]. *CTSW* encodes a protein of the cathepsin family,

Table 4 Significant Gene Ontology (GO) biological processes in CD8+ T cells of polymyositis and dermatomyositis patients

GO biological process complete	Fold enrichment	p value	FDR
Lymphocyte migration (GO:0072676)	11.50	1.05E-04	4.19E-02

GO Gene ontology

Significant GO biological processes for the differentially expressed genes in CD8+ T cells of patients with dermatomyositis and patients with polymyositis. Fisher's exact test with false discovery rate correction (< 0.05) was used to determine significant biological processes. The genes mapped to each GO can be found in Additional file 5: Table S10

cathepsin W. Cathepsins are found in antigen-presenting cells and are involved in antigen processing [42]. Cathepsin W has been found to be exclusively expressed in CD8+ T cells and NK cells [43]. However, this does not exclude the possibility of differential expression of the transcript in other cell types.

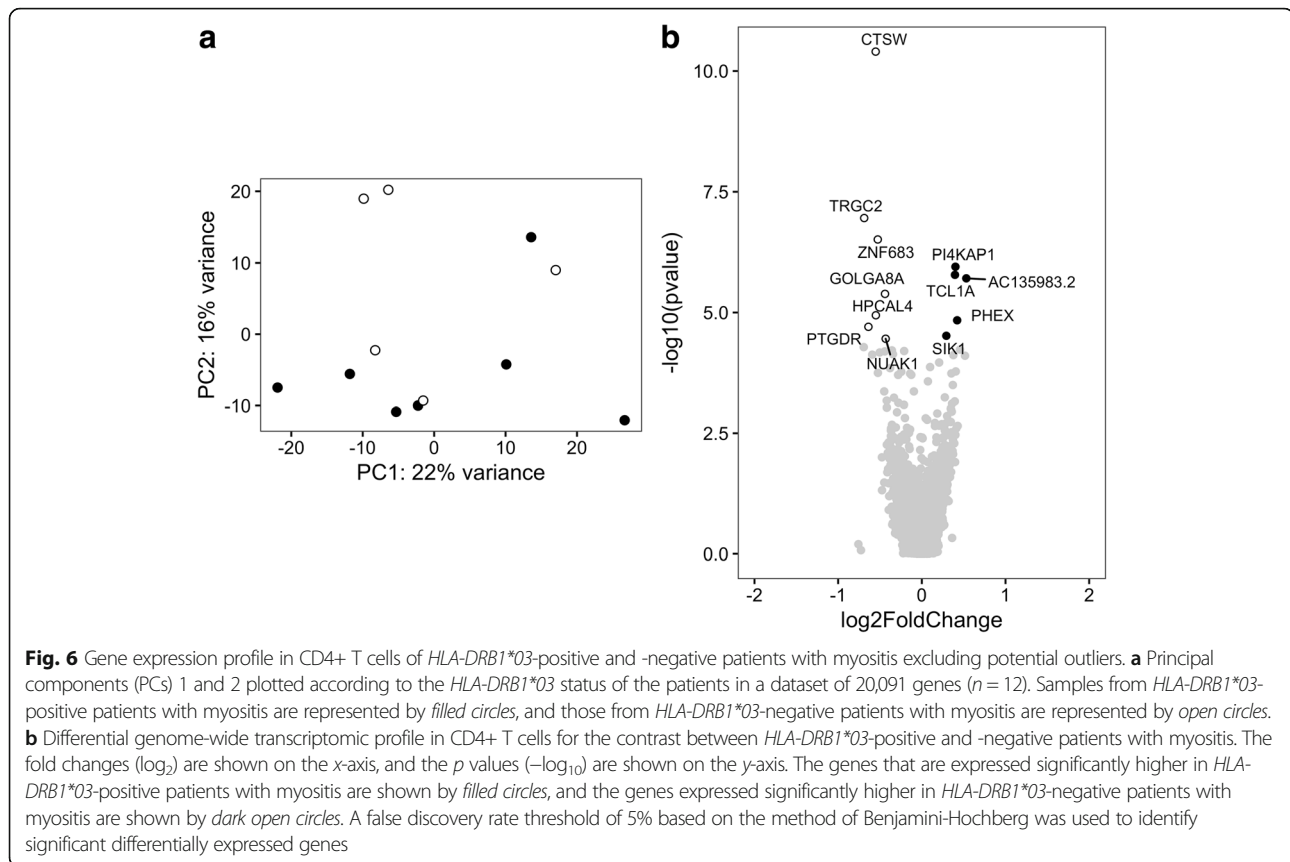

Evidence of differentially expressed genes in whole blood and muscle tissue between various subphenotypes of myositis has been reported previously [22, 44]. These prior investigators found that several type 1 interferon-induced transcripts and proteins were expressed relatively higher in DM patients than in healthy individuals and PM patients. In our study, we did not find type 1 interferon-inducible transcripts to be differentially expressed between PM and DM patients. However, we measured gene expression levels in CD4+ and CD8+ T cells and not in interferon-producing plasmacytoid dendritic cells. In addition, most of the patients in our study were receiving prednisone and additional immunosuppressive drugs that may significantly suppress the type 1 interferon-inducible signature [45].

The limited number of patients with PM and DM, which is the major weakness of our study, did not allow

us to consider contribution of autoantibody positivity in the statistical model. The majority of patients in our study had autoantibodies of different specificities (Table 1). It has been shown that anti-MDA5 antibodies are associated with DM complicated by rapidly progressive interstitial lung disease (ILD) [46]. In addition, anti-TIF1- γ antibodies have been associated with cancer-associated DM [47]. Furthermore, anti-Jo-1 antibodies are strongly associated with a clinical phenotype named anti-synthetase syndrome, characterized by ILD, arthritis, mechanic's hands, and myositis [48]. Further studies with a high number of myositis patients are needed to address correlations between transcriptomic profile and autoantibodies. Moreover, the differences in gene expression levels need to be confirmed at the protein level and in further functional studies.

Conclusions

In the current study, we analyzed, for the first time to our knowledge, the transcriptomic profiles of different subpopulations of T cells in patients with PM or DM and could demonstrate that these two clinical phenotypes differ regarding T-cell phenotypes related to gene

expression. It is evident that these differences are more profound for CD8+ T cells when comparing PM patients with DM patients. Although the differentially expressed genes will need to be confirmed in a larger group of patients, these alterations in the transcriptomes of PM and DM patients suggest different immune mechanisms involved in different subphenotypes of IIM.

Additional files

Additional file 1: Additional clinical characteristics of patients included in this study. Tables S1–S3 provide additional clinical characteristics of patients included in this study regarding PM and DM. Table S1 includes all patients, whereas, Tables S2 and S3 contain the data for the CD4+ and CD8+ T-cell subsets, respectively. Tables S4 and S5 provide additional clinical characteristics of patients included in this study regarding *HLA-DRB1*03* status. Table S4 includes all patients, whereas Table S5 contains the data for the CD4+ T-cell subset. (DOCX 24 kb)

Additional file 2: Differentially expressed genes for CD4+ T cells of PM and DM patients. Table S6 and S7 provide differentially expressed genes for CD4+ T cells of PM and DM patients at analytical stage 1 (including potential outliers) and analytical stage 2 (excluding potential outliers), respectively. (DOCX 18 kb)

Additional file 3: Clustering heat map showing cellular heterogeneity in CD4+ and CD8+ T-cell subsets. Figure S1 shows a clustering heat map indicating cellular heterogeneity in CD4+ and CD8+ T-cell subsets, which indicates minor contamination of other cell types in these subsets. (DOCX 290 kb)

Additional file 4: Differentially expressed genes for CD8+ T cells of PM and DM patients. Tables S8 and S9 provide differentially expressed genes for CD8+ T cells of PM and DM patients at analytical stage 1 (including potential outliers) and analytical stage 2 (excluding potential outliers), respectively. (DOCX 106 kb)

Additional file 5: Gene Ontology biological processes for the differentially expressed genes in CD8+ T cells of PM and DM patients. Table S10 shows the genes mapped to the enriched GO biological processes for the differentially expressed genes in CD8+ T cells of PM and DM patients. (DOCX 17 kb)

Additional file 6: Differentially expressed genes in CD4+ T cells of *HLA-DRB1*03*-positive and -negative myositis patients. Table S11 and S12 provide differentially expressed genes for CD4+ T cells of *HLA-DRB1*03*-positive and -negative myositis patients at analytical stage 1 (including potential outliers) and analytical stage 2 (excluding potential outliers), respectively. (DOCX 16 kb)

Abbreviations

DM: Dermatomyositis; FDR: False discovery rate; GO: Gene Ontology; IIM: Idiopathic inflammatory myopathy; ILD: Interstitial lung disease; NK: Natural killer; PBMC: Peripheral blood mononuclear cell; PC: Principal component; PCA: Principal component analysis; PM: Polymyositis; RIN: RNA integrity number; SNP: Single-nucleotide polymorphism; TCR: T-cell receptor; TGF: Transforming growth factor

Acknowledgements

We are very thankful to Dr. Yvonne Sundström, Dr. Danika Schepis, and Dr. Louise Berg for running flow cytometry on sorted cell populations. We thank Dr. Z. E. Betteridge (RNA and protein immunoprecipitation) and Prof. J. Rönnelid (line immunoassay) for their collaboration in autoantibody detection. Transcriptomic profiling was performed by the SNP&SEQ Technology Platform in Uppsala. This facility is part of the National Genomics

Infrastructure (NGI) Sweden and Science for Life Laboratory. The SNP&SEQ Technology Platform is also supported by the Swedish Research Council and the Knut and Alice Wallenberg Foundation. The computations were performed on resources provided by SNIC through Uppsala Multidisciplinary Center for Advanced Computational Science (UPPMAX), supported by NGI Sweden.

Funding

This study was supported by a collaborative grant between the Mayo Clinic and Karolinska Institutet, the Swedish Research Council, the Swedish Rheumatism Association, King Gustaf V's 80-year foundation, and the regional agreement on medical training and clinical research (ALF) between Stockholm County Council and Karolinska Institutet.

Availability of data and materials

Raw data from RNA sequencing are available from the authors (LP) upon request. Clinical data are not available currently, owing to protection regulations for personal information.

Authors' contributions

MH, LE, AMR, IEL, and LP were involved with the conception and design of the present study. LE and IEL provided clinical data. MH and EH performed the experiments. MH analyzed and interpreted the data. LE, KC, VM, IEL, and LP contributed to the interpretation of the results. MH and LP drafted the manuscript. All authors reviewed and edited the manuscript. All authors read and approved the final manuscript.

Ethics approval and consent to participate

Ethics approval was provided by permission from the Stockholm Regional Ethics Board and by written consent from the patients.

Consent for publication

Not applicable.

Competing interests

The authors declare that they have no competing interests.

Publisher's Note

Ready to submit your research? Choose BMC and benefit from:

- fast, convenient online submission
- thorough peer review by experienced researchers in your field
- rapid publication on acceptance
- support for research data, including large and complex data types
- gold Open Access which fosters wider collaboration and increased citations
- maximum visibility for your research: over 100M website views per year

At BMC, research is always in progress.
