Coastal sand dune ecosystem services in metropolitan suburbs: effects on the sake brewery environment induced by changing social conditions

Korehisa Kaneko^{1*} and Hajime Matsushima²

Abstract

Chiba Prefecture, Japan, lies very near Tokyo, the capital city of Japan. It borders the sea on three sides and is banded by coastal dunes. Several sake breweries are located near these dunes. Although there are records of sake brewing along the coast of Tokyo Bay since 1925, sake breweries have completely disappeared in several areas. We believe that sake brewing in these areas benefited from the ecosystem services afforded them by their proximity to the coastal ecosystem. We investigated potential environmental factors (e.g., landscape, soil, and groundwater), as well as conditions that could have driven sake brewers away from the coastal area. Many of the sake breweries that no longer exist were located on coastal dunes (i.e., sand, sandbanks, and natural levees) and obtained their water from a freshwater layer located 3–10 m below the surface. We speculate that these sake breweries benefited from using natural ingredients found in the coastal zone. We also investigated the following factors that may have negatively impacted the breweries, driving them out of business: (1) bankruptcies and reconstruction difficulties that followed the destructive 1923 Great Kanto earthquake, (2) industrial wartime adjustments during World War II (1939–1945), (3) development of coastal industries during the period from 1960 to 1975, and (4) increasing choices for other alcoholic drinks (e.g., beer, wine, and whiskey) from the 1960s to the present.

Keywords: Ecosystem service, Coastal dune system, Land use change, Japanese sake, Brewing, Soil and groundwater

Introduction

Japanese sake is brewed from rice and water, which are the central ingredients of the food culture of Japan. Sake is produced by a singular fermentation technology that applies the power of microorganisms. The beverage has attracted attention worldwide. In addition, sake is an alcoholic drink specific to Japan and a component of a traditional food culture that has continued for approximately 2000 years (Food and Beverage Specialist Organization NPO 2009). Japan's traditional food culture, known as "Washoku," was given UNESCO intangible cultural heritage status on December 4, 2013. The sake industry, however, is in decline. There were over 4000 licensed sake breweries in 1955, but their number

had dropped to about 1600 in 2016, and consumption of sake has decreased, as of 2015, by two thirds since 1974 (National Tax Agency HP: <http://www.nta.go.jp/kohyo/tokei/kokuzeicho/jikeiretsu/01.htm>).

The diverse natural environment in which sake is brewed includes coastal sand dunes, river plains, hills, and mountains. The natural characteristics of these environments (e.g., soil, groundwater quality, and climate) substantially affect the taste of the finished product. Water has a significant impact on the taste of sake. In sake brewed in coastal dune systems, the freshwater layer that lies 5–10 m below the ground surface provides mineral-rich, hard water in that is high in calcium and magnesium. These nutrients actively promote the proliferation of *Aspergillus oryzae* and yeast, the predominant microorganisms used in sake brewing. The taste of Japanese sake from such coastal areas is dry and full-bodied (Kaneko et al. 2012, 2013).

Full list of author information is available at the end of the article

As detailed by the records of Chiba Prefecture, Japan, the number of sake breweries in the coastal areas around Tokyo Bay during Japan's Taisho era (1912–1926) was 5–10 times higher than at present (Suzuki 1997). A freshwater layer forms under coastal sand dunes, and it is this water that is used in sake brewing. Chiba Prefecture's Tokyo Bayside, near the Japanese capitol, is formed on coastal sand dunes. This area flourished in ship transportation in the Edo era (1603–1868), and there were many sake breweries there. The sake brewing conducted there used the water from the freshwater layer in its brewing processes, making use of an ecosystem service. The term “ecosystem service” means the benefits that human beings receive from the bounty of nature. Sake breweries have been supporting this region for a few hundred years, and brewing has received the natural benefits of the coastal sand dunes (terrain, soil, water quality, etc.). However, because these areas faced Tokyo, there has been extensive infrastructure maintenance and coastal development since the high economic growth period of the 1960s. The coastal sand dunes of Tokyo Bayside have been affected by urban development, and most of the sake breweries have closed.

In this study, we investigate sake brewing in these areas, which benefitted from the natural environment, and factors that have led to its decline, based on a survey of the social changes such as land development that have occurred in the coastal area, modifying those features that promoted sake brewery during the Taisho era (1912–1926).

Methods/Experimental

Study site

Chiba Prefecture is located east of Tokyo and is bordered on three sides by the sea (Fig. 1). In several parts of Chiba, there is a band-shaped coastal dune system (Fig. 2). The number of sake breweries concentrated in the coastal regions known as Uchibo (inner) and Sotobo (outer) has dropped substantially in the last century. Figure 3 shows the number of sake breweries by municipality in 1925 and the locations of breweries operating in 2012, grouped topographically.

Although there is only one sake brewery currently operating in the coastal area of Tokyo Bay, records show that in 1925, there were sake breweries in many parts of what is now Chiba City, including Makuhari Town (present-day Hanamigawa Ward), Kemigawa Town (Inage Ward), and Shiina Village (Midori Ward). In addition, there were breweries in Goi Town (present-day Ichihara City), Kaneda Village and Kisarazu Town (present-day Kisarazu City), and Funagata Town, Nako Town, Hojo Town, and Tateyama Town (present-day Tateyama City) (Fig. 4).

Locations and soil and groundwater environments of sake breweries

For information regarding historical and current sake breweries, we relied on Suzuki (1997) and Kaneko et al. (2012, 2013). In our research, we investigated the environment, including soil, topography, groundwater, and land use around sake breweries recorded in 1925. We investigated the soil and topography using subsurface geological maps, topographic maps, and soil maps created based on borings and well surveys (Ministry of Land, Infrastructure, Transport and Tourism, National Land Information). Groundwater conditions are described using groundwater quality data collected by Chiba Prefecture. Groundwater sampling and analysis were conducted in 1953, 1963, 1965, and 1966, during the development of coastal area in Chiba Prefecture. Since that time, very little further development has occurred in that area. We assumed that the study sites enjoyed a natural coastal environment in the 1950s and 1960s. Groundwater hardness was based on the American scale (soft 0–60 ppm, medium hard 60–120 ppm, hard 120–180 ppm, very hard 180 ppm or more), which is the reference standard of the World Health Organization (2011). The land use investigation used blank maps for 1925, 1930, 2004, and 2009 from the Geospatial Information Authority of Japan. To investigate extinction factors for sake brewing, we conducted an oral survey with individuals who were engaged in local sake brewing in 1925.

We calculated sake production rates in Chiba Prefecture as an indicator of how many people in Chiba Prefecture are economically dependent on sake, based on the volume of sake produced in Chiba Prefecture and sake imported from other prefectures:

$$Y = A/(A + B) \quad (1)$$

where Y is the sake production rate, A is the volume produced in Chiba Prefecture, and B is the volume transferred from outside the prefecture.

Results and discussion

Change in the number of sake breweries in Chiba Prefecture

In the 1880s, there were more than 1100 sake breweries in Chiba Prefecture. However, according to an official announcement that prohibited home-brewed sake in 1899, this number decreased to 383 by 1896. Later, many brewing companies suspended operations because of the Industrial Adjustment Act issued during World War II (1939–1945), and the number of sake breweries had decreased to 68 in 1946. During the high economic growth period of the 1960s and afterward, the number of sake breweries continued to decrease, reaching 39 in 2012 (Fig. 5).

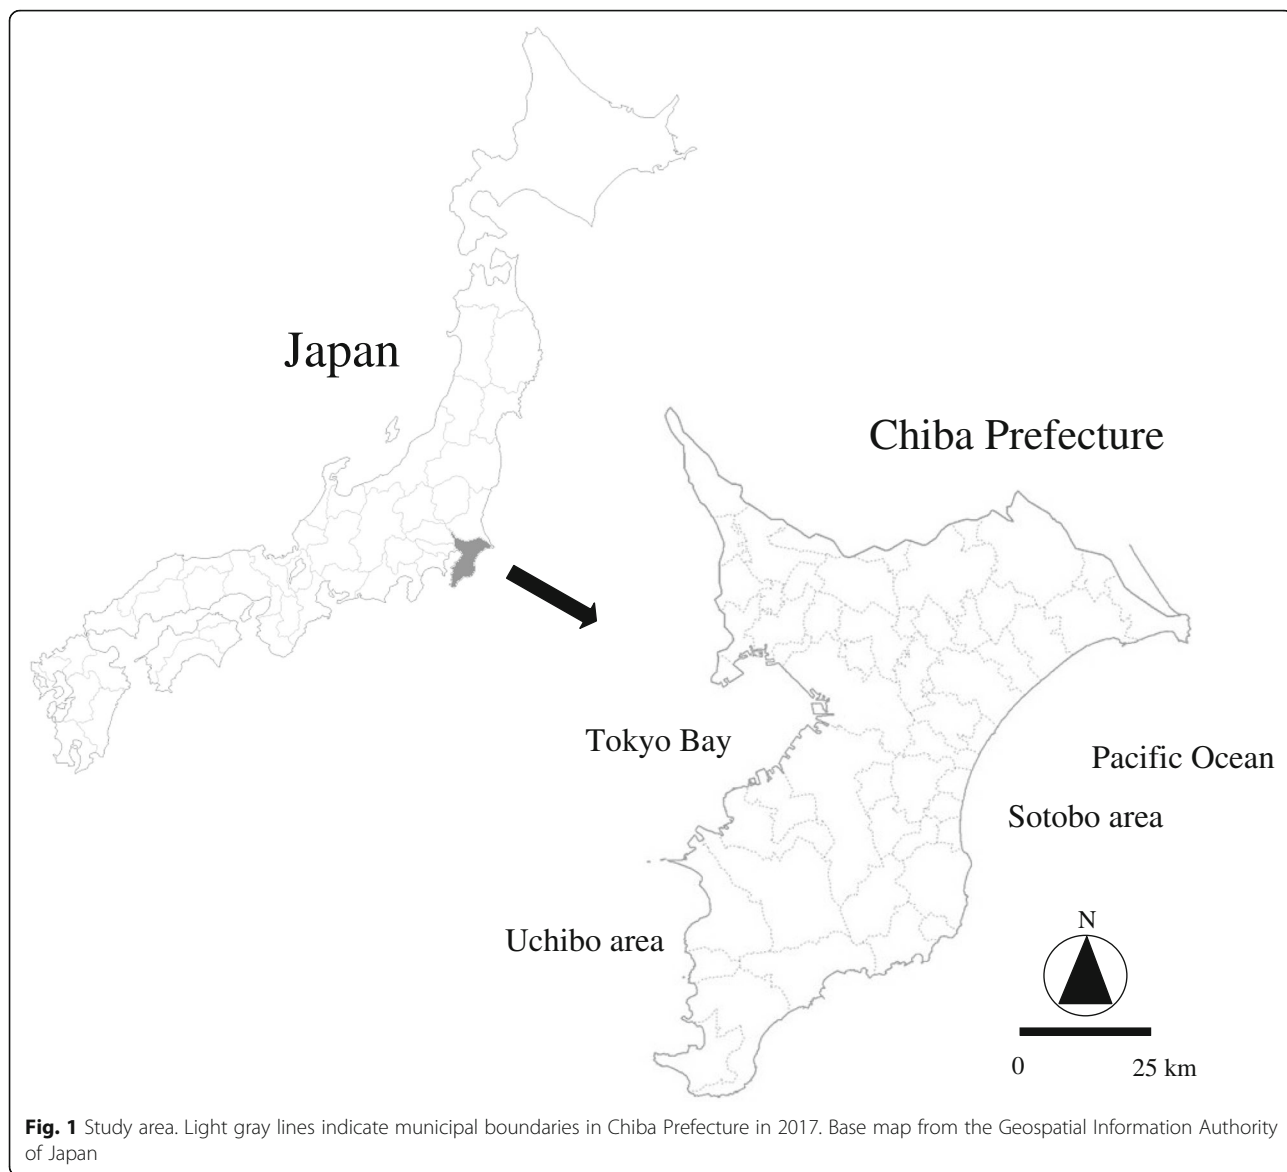

Fig. 1 Study area. Light gray lines indicate municipal boundaries in Chiba Prefecture in 2017. Base map from the Geospatial Information Authority of Japan

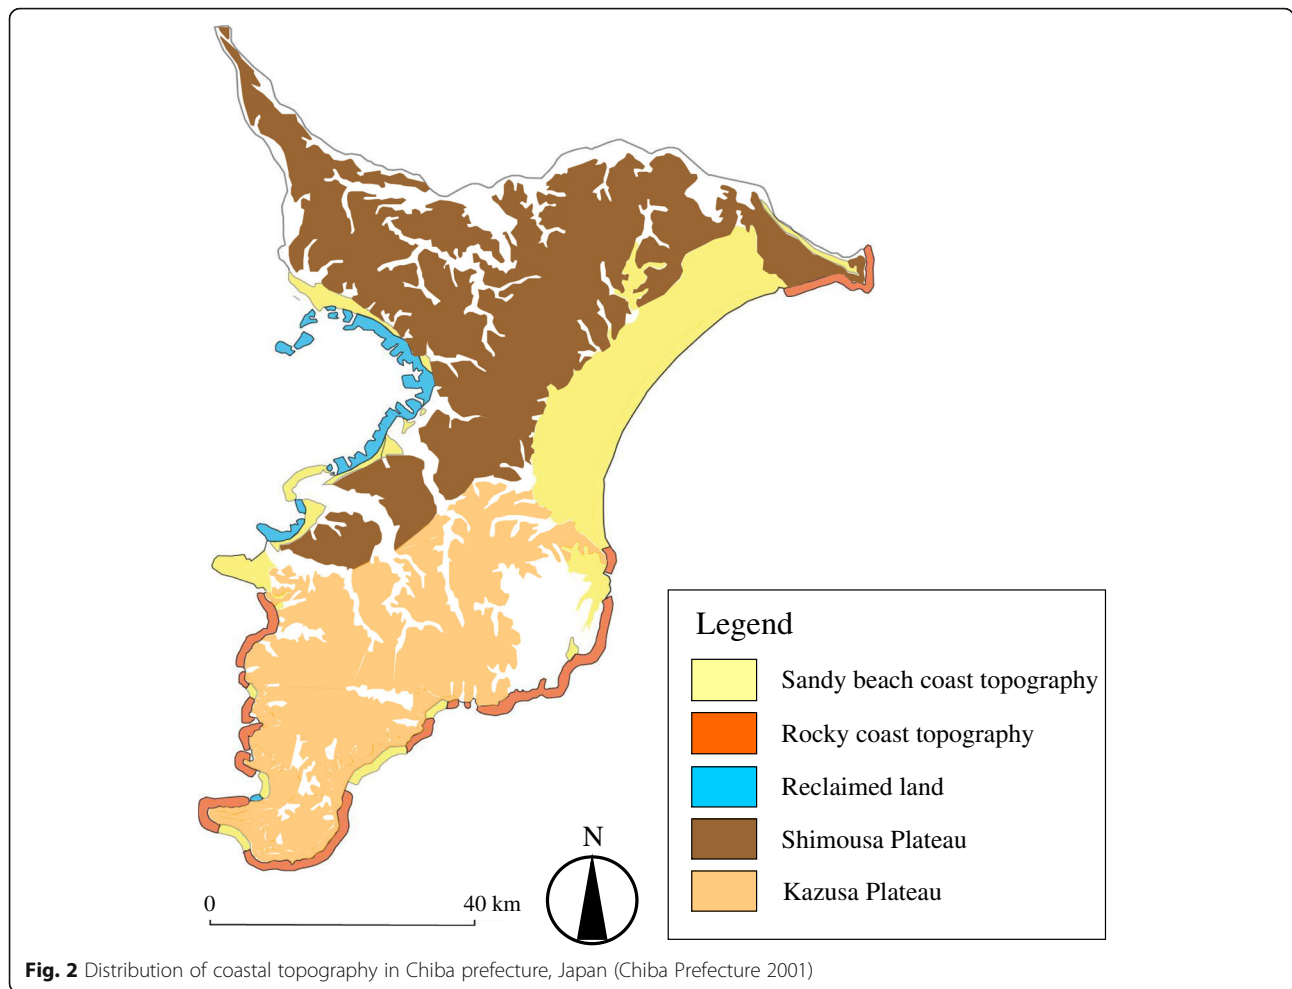

As Fig. 5 shows, there were 168 sake breweries in Chiba Prefecture in 1925 (Chiba Prefecture Brewing Association 1925), four times the number that existed in 2012.

In 1925, there were 56 sake breweries in the coastal vicinity. In 2012, there were 10. The number of sake breweries along the coast has thus decreased to one fifth of the 1925 number (Fig. 6).

Land use change

We investigated land use changes by comparing base maps created by the Geospatial Information Authority of Japan. Land use changes in the coastal dune system have been remarkable in Makuhari Town, Kemigawa Town, Shiina Village, Goi Town, Hojo Town, and Tateyama Town (Fig. 7). In 1925 (Fig. 7a; left), Makuhari Town was a fishing village with a foreshore tidal flat spread in front

of the town. By 2009 (Fig. 7a; right), this 5–6 km tidal flat had been substantially changed by development of residential and industrial areas. In 1920 (Fig. 7b; left), Kemigawa Town had a foreshore tidal flat that spread 3 km toward the sea. By 2009 (Fig. 7b; right), this area had been transformed into a coastal industrial zone. In 1920 (Fig. 7c; left), Shiina Village was an agricultural village on sand approximately 2 km inland from the sea. A sake brewery was located on the sand, and the expansive coastal area around the sake brewery included rice paddies. However, by 2004 (Fig. 7c; right), the 3 km foreshore seaward tidal flat had been developed into an industrial zone. In 1925 (Fig. 7d; left), Goi Town was a fishing and agricultural town with a predominantly natural coastline. The expanse of sand and wetlands that existed in 1925 was developed into a coastal industrial zone by

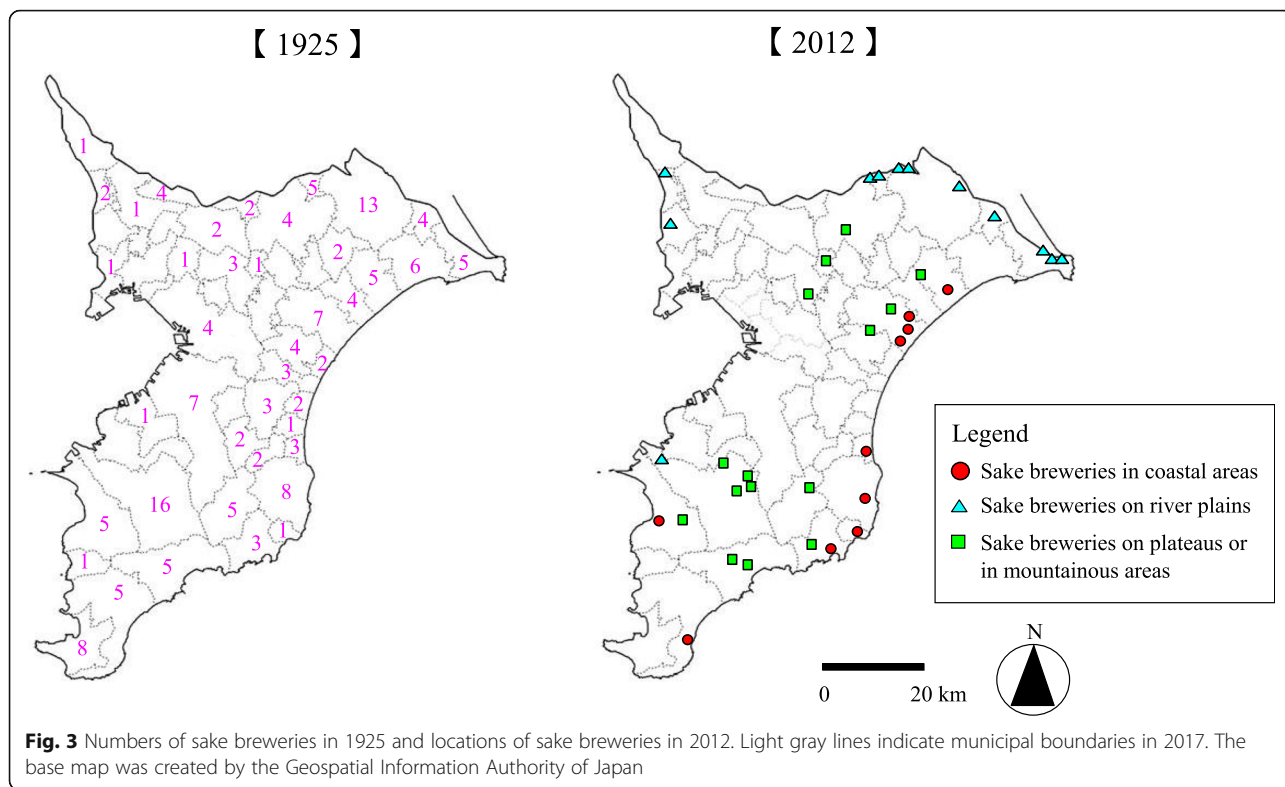

2004 (Fig. 7d; right). Hojo and Tateyama Towns were fishing and sightseeing towns on a predominantly natural sandy coastline. Although these towns were near the coast in 1930 (Fig. 7e; left), by 2004 (Fig. 7e; right), the town area had expanded because of residential-area growth and the construction of the Ground Self-Defense Force’s Tateyama Airport. The character of what were the central parts of these towns in 1925 has changed substantially because of the progressive development of residential areas, roads, and industrial land. Notably, the sake breweries operating in 1925 were located along what was then the main street.

Soil and topography

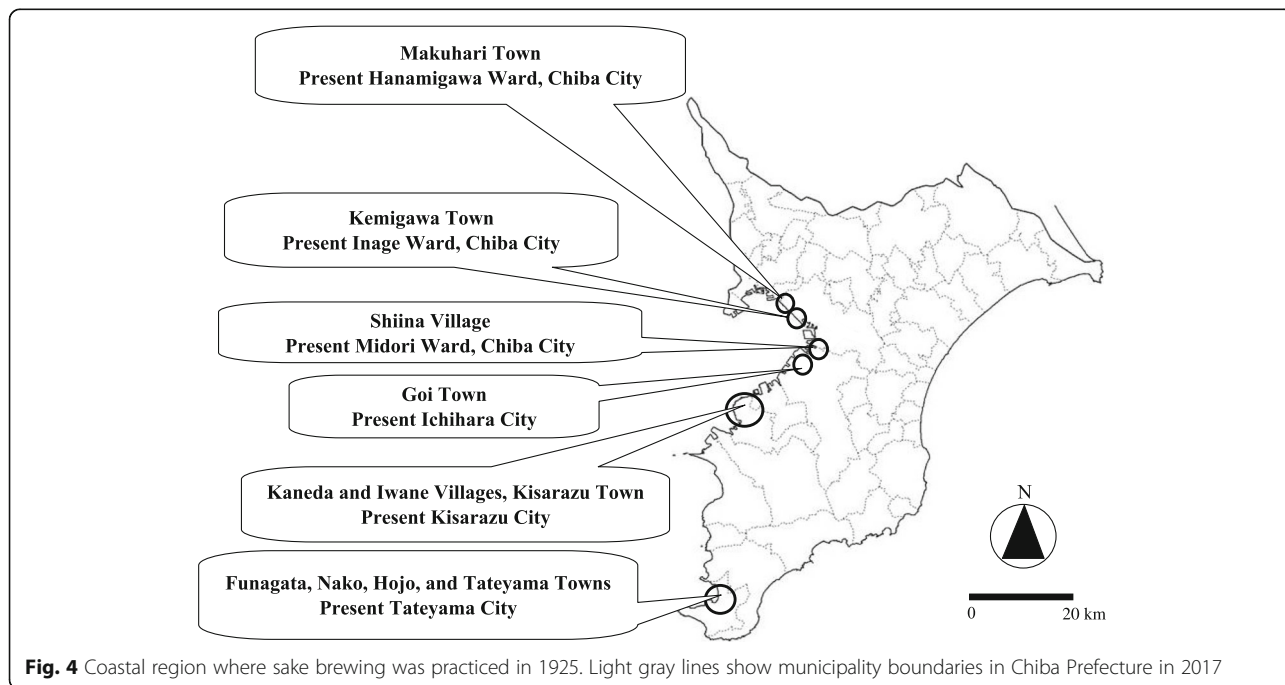

The surface geology consists of sand-rich sediments (in which the sand and sandbanks in the coastal region consist of fine-to-medium grain sand) and sand 1, which is a stratum of fine-to-medium grain and coarse sand sandwiching a layer of gravel and clay. Mud-rich sediments are distributed along the tributaries that traverse the valley lowlands of the river, plateaus, and coastal lowlands that face Tokyo Bay in a stratum approximately 10–20 m thick.

The coastal area of the study site is primarily occupied by sand-rich sediments. Its land classification is dominated by sandbanks, natural levees, sand bars, and covering dunes (i.e., a sandbar–sandbank beach ridge that consists of sand formed by waves and coastal currents in the coastal vicinity) (Table 1). According to a survey-based soil and land classification of Makuhari Town from the sea to the terrestrial area, its land is classified as sandbanks, natural levees, a valley plain, and middle gravel terraces in the terrestrial area (Fig. 8a; left). The surface geology moving inland is sand-rich sediment, loam formations, mud-rich sediment, sand, and then loam formations, with the strata formed by the weathering of volcanic ash deposits in the terrestrial area (Fig. 8a; right). In Kemigawa Town, Shiina Village, and Goi Town, the land is classified as having alternating repeated sandbanks, natural levees, valley plains, coastal plains, and delta plains, with middle gravel terraces in the terrestrial area (Fig. 8b–d; left). The surface geology has alternately repeating mud-rich sediment and a stratum of sand 1 approximately 10–20 m thick, with loam formations in the terrestrial area (Fig. 8b–d; right). In Tateyama Town, the

land is classified as alternately repeated sandbars, inter-bar lowlands, and naked dunes and includes river terraces and dissected hills in the terrestrial area (Fig. 8e; left). The surface geology shows alternately repeated mud-rich and sand-rich sediments and with sandstone and mudstone in

the terrestrial area (Fig. 8e; right). The postulated natural environment had alternately repeating sand and wetlands from the sea to the terrestrial area and included middle gravel terraces, coastal terraces, or dissected hills. We investigated the soil environment of each sake brewery that

Fig. 5 Numbers of sake-brewery licensed in Chiba Prefecture (Chiba Prefecture 2012). Black bars indicate pre-home-brewing prohibition values

was operating in these regions in 1925, including the altitude and distance from the sea. Sake breweries were frequently located on sandbanks, natural levees and sandbars, or in surface geology terms, on sand-rich sediments (Fig. 9). They were most often located within 1.0 km from the sea, at altitudes of 11.0 m or less. Even sake breweries located over 2.0 km from the sea were at relatively low altitudes of 5.0 m or less (Fig. 10).

Groundwater quality

The wells in Makuhari and Kemigawa Towns were 2.0–3.5 and 2.0–5.5 m deep, respectively. In Goi, Kisarazu, and Nako Towns, they were 3.6, 10 or less, and 3.0 m deep, respectively. The groundwater in all these locations was very hard (Chiba Prefecture 1966). Hojo Town had hard water at depths of 4.0 m, Kaneda Village had medium hard water at depths of 5–10 m, and Tateyama Town had medium hard water at 4.0 m (Chiba Prefecture 1954 and 1963; Institute for Health in Chiba Prefecture 1983). We were unable to confirm the figures for Makuhari, Kemigawa, and Funagata Towns and Shiina and Iwane Villages (Table 2). Additionally, groundwater data for individual sake breweries were unavailable.

Study site environment

As noted above, the sake breweries operating in the coastal area along Tokyo Bay in 1925 were often situated at an altitude of approximately 10 m, approximately 1.0 km from the sea (Figs. 8 and 9). The surface geology in their locations consisted of exceedingly soft sand-rich sediments, including sand, and the land is classified as sandbanks, natural levees, and sandbars (Table 1, Fig. 8). The topography inland from the coast in these regions is characterized by a coastal dune system in which sand and wetlands alternate, and there are hills and terraces (Fig. 7). Groundwater depths are 3–10 m, and the water is variably hard, from medium hard to very hard (Table 2).

The groundwater under the sand dunes contains nutrients that originate in the remains of seaweed and animals deposited on the dunes and the salt spray carried by the wind. Nutrient concentrations are also high where sand-dune vegetation is abundant (Brown and McLachlan 1990). In the marine sandy alluvial soil in Chiba Prefecture, potassium, phosphoric acid, calcium, and magnesium concentrations are high. The calcium concentration of the groundwater that flows through the aquifer that contains the shell layer has been influenced by the dissolution of splintered shells (Kaneko 1994; Kaneko et al. 1994). These nutrients actively promote the proliferation of *Aspergillus oryzae* and yeast, which are the predominant microorganisms used in sake brewing. Japanese sake that is brewed using hard water tends to be full-bodied, deep, and dry. Sake brewed using soft water tends to be mellow and slightly sweet (Inoue 2009). According to Kaneko et al. (2012, 2013), sake breweries that were on the sand dunes used groundwater depths of 5–10 m, which placed it deep within a freshwater layer in the sand dunes. Therefore, we believe that the Japanese sake brewed in the study area made use of this freshwater layer that was formed due to the coastal dune system. If such water was used to brew sake, it would have a dry, full-bodied taste.

The study cites all lie on alluvium. The alluvium forms an unpressurized aquifer based on the sand-rich

Nako Town		Sand bar (covered sand dune)	Sand-rich sediment ^a	Unclassifiable
Hojo Town		Sand bar	Sand-rich sediment ^a	Unclassifiable
Tateyama Town		Sand bar	Sand-rich sediment ^a	Unclassifiable

^aSand-rich sediments: composed of sand and sand banks in the coastal area and composed of fine- medium sand

^bSand 1: consists of fine-to-medium grain sand, coarse sand, sandwiching a gravel clay. The thickness of the stratum is approximately 10–20 m

^cSand bar-sand bank: beach ridge composed of sand forced near the coast by waves and coastal currents

^dMud-rich sediments: distributed along the tributary valleys to cut the lowlands of the rivers and plateaus as well as the coastal lowland facing Tokyo Bay; composed of silt and clay

sediment. However, the topography and geology are quite different, and the groundwater flow is different in the northern and southern parts of Chiba Prefecture. In the northern part, the aquifer tends to flow to an alluvial lowland on the coast of Tokyo Bay from the Shimousa Plateau, where the recharge area that provides water resources is rich in groundwater. However, in the Tateyama district in southern Chiba, there is little freshwater in the basement of the surrounding plateaus. However, in the alluvium along the coast and in the alluvial plain, where the study area is located, the unpressurized aquifer in the sand layer is used as for shallow wells (Institute for Health in Chiba Prefecture 1983).

Therefore, we conclude that because in 1925 development that would affect the groundwater supply had not yet occurred, the coastal dune system was in a relatively natural condition. Thus, water suitable for brewing could be taken from the groundwater of the coastal sand dunes along Tokyo Bay (Chiba Prefecture side), and sake brewing was feasible.

Factors leading to sake brewery decline

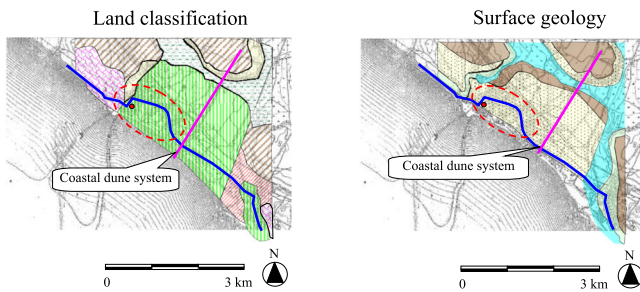

According to our survey results and other research, the following items caused the decline in sake brewing, compared to that practiced in the coastal area in 1925: (1) bankruptcies and reconstruction difficulties that followed the destructive 1923 Great Kanto earthquake (7 breweries); (2) the wartime Industrial Adjustment Act (6 breweries), which required the nation to adapt,

integrate, or close non-military-related industrial facilities to support military-related industry during World War II (1939–1945); (3) the increased difficulty of sake brewing as a result of the large quantities of groundwater used by coastal industry during the 1960s and 1970s (1 brewery); and (4) altered transportation methods resulting from the development of distribution based on infrastructure improvements since the 1960s (e.g., changing from ships to railroad and road transport) (3 breweries), whereby (a) Japanese sake from other regions and imported alcoholic beverages such as beer, wine, and other alcohol could be obtained at cheaper prices, (b) changes in the availability of luxury goods occurred, and (c) it was no longer possible to sell sake brewed in the region.

The Great Kanto earthquake disaster

In Nako Town, there was a sake brewery until the Taisho era (1912–1926) (Nako District Union Neighborhood Association 2007). Other sake breweries known from records to exist in 1925 are as follows: 3 in Goi Town, 2 in Hojo Town, 1 in Tateyama Town, 1 in Funagata Town, 1 in Kaneda Village, 1 in Iwane Village, and 1 in Kisarazu Town (Chiba Prefecture Brewing Association 1885, Chiba Prefecture Brewing Association 1925). However, several sake breweries were not visible in a bird’s-eye view of Chiba City (Matsui 1929). According to an interview with a descendant of a sake-brewing family that engaged in the brewing industry in Tateyama Town in 1925, the family

business ceased operation after the brewery building was destroyed by the 1923 Great Kanto earthquake. In addition, according to earthquake disaster records, Tateyama, Hojo, Nako, and Funagata Towns were destroyed by the earthquake, where 97–98% of the buildings were gutted by fire, and the brewing industry was devastated (Awa Country Office in Chiba

Prefecture 1925). We surmise that for small-scale sake breweries, reconstruction was financially difficult.

Industrial adjustment in wartime

Sake brewery closings because of the wartime industrial adjustment occurred in Goi Town and Iwane, Kaneda, and Shiina Villages in 1939–40. Although a sake brewery in Makuhari Town was depicted in a bird’s-eye view of Makuhari Town from 1929 (Matsui 1929), the brewery was not included in the Chiba Prefecture brewery list of 1962 (Chiba Prefecture Brewing Association 1962). Therefore, it is likely that this brewery closed because of the wartime industrial adjustment.

Coastal industrial development

Reclamation was performed in the coastal zone of Tokyo Bay in Chiba Prefecture, from 1955 to 1975 to create land for the Keiyo coastal industrial zone (Chiba Enterprise Department Coastal Division 1976). In the Goi and Ichihara districts, development occurred from 1957 to 1963 (Chiba Prefecture Development Department 1961a). Because the quantity of groundwater pumped for industrial uses in the coastal area increased rapidly, the groundwater level decreased. This practice influenced private wells, and ground subsidence occurred (Chiba Prefecture Development Department 1961b). According to an interview with a descendant of a sake-brewing family from Shiina Village (present-day Midori Ward), although the vicinity of the sake brewery was rich in spring water (with an artesian spring water height of up to 20–30 cm throughout the area before coastal industrial development occurred), after the coastal industrial zones were created, artesian spring water was no longer seen. In addition, according to interviews with individuals who were engaged in the brewing industry until 1969 in Goi Town, after the reclamation of the coastal area for industrialization, the brewing industry

^dChiba Prefecture(1963) Annual reports of Industrial Res. Inst. of Chiba Prefecture

ceased operation because the well water had become polluted. The pollution was confirmed by color tone, organic matter at concentrations greater than 1000 ppm, and the detection of ammonia. Thus, high-quality groundwater was no longer available (Chiba Prefecture 1963). Although spring water occurred in many artesian wells in Chiba Prefecture, the pumping increased because of continuing urbanization and the development of industry and agriculture. Therefore, the groundwater level decreased, as did the number of artesian wells. In particular, artesian wells distributed in the center of Goi Town, dug using the *Kazusa-bori* technique (a representative construction method in which wells are dug using bamboo), subsided for several years and then disappeared after the pumping of industrial water for the Keiyo industrial complex on Tokyo Bay commenced (Chiba Prefecture 2002). Therefore, we can conclude that the sake breweries located near the developed area could no longer be assured of an adequate supply of water because of the large quantity of groundwater used by industry and because of industrial pollution of the groundwater. Thus, the breweries in the district could no longer brew sake.

Increased availability of luxury goods due to distribution system development

Viewing the history of sake in Chiba Prefecture and the surrounding areas, the Japanese sake brewing industry of the Kanto area, which is located in the eastern part of Japan, was done on a small scale, was relatively undeveloped, and was of inferior quality compared to that of the Kansai area located in midwest Japan. The Kansai sake industry has been continuously producing for the Edo (now Tokyo) market since the

beginning of the seventeenth century. Therefore, Japanese sake made in the Kanto area was deemed to be inferior local sake and was neglected by both Samurai and commoners in Edo. The Edo feudal government aimed to improve the quality and increase the volume produced by representative sake breweries and tried to restrict the volume of Japanese sake in Kansai. As a result, the Edo feudal government could not restrict the imported volume of sake from the Kansai area to Edo, and Japanese sake from Kansai was more popular than that from Kanto. However, this policy later led to improvements in the brewing technology of Kanto (Yoshida 1997a). The volume of kudari-zake shipped to Edo in 1856 was 72 million liters, whereas there were only 7.2 million liters of jimawari-zake, sake made in the Kanto area. Because of this, residents in Edo drank kudari-zake overwhelmingly. Sawara Village (now Katori City in Chiba Prefecture) produced jimawari-zake that was shipped to Edo. In 1789, it shipped 37,800 l of sake to Edo in 1789 (Yoshida 1997b). Moreover, although sake breweries in the various parts of Chiba Prefecture shipped to neighboring areas, there was no connection with Edo (Yoshida 1997a; 1997b; Takahashi, 2012). In the fishing villages of Chiba Prefecture in the Edo period, there was one sake brewery per village. People engaged in the heavy labor of fishing exerted a large demand for sake, so sake brewing developed (Chiba Prefecture 2009). We expect that people in Chiba Prefecture drank local sake during the Edo period.

According to an interview with a descendant of a sake-brewing family from Hojo Town, this region had a custom of drinking sake from other regions. Therefore, we researched the shares of alcohol consumption in

Chiba Prefecture. The consumption of Japanese sake has indeed decreased, whereas beer consumption increased until 1994, and consumption of other alcoholic beverages have increased since the 2000s (Fig. 11). The reason for this change is that other alcoholic beverages are cheaper and easier to drink than beer. Moreover, consumption of Japanese sake produced in Chiba Prefecture has decreased, moving toward consumption of sake produced outside of Chiba Prefecture, as PR advertising has become more effective and transport has undergone remarkable improvement. Japanese sake was originally transported by land and sea before World War II, and demand within the prefecture was satisfied in those days. Nearly two thirds of the Japanese sake consumed in Chiba Prefecture came from outside the prefecture (Chiba Prefecture Brewing Association 1970a, b). The production of local sake in Chiba Prefecture decreased from 30.6% in 1979 to 25.4% in 2015, down to about one fourth of the prefecture’s consumption (Fig. 12). Thus, even 40 years ago, people in Chiba preferred drinking sake brewed in other prefectures in Japan over local sake (National Tax Agency HP: <http://www.nta.go.jp/kohyo/tokei/kokuzeicho/jikeiretsu/01.htm>).

It is clear that recent developments in the distribution system, thanks to improved highway infrastructure, have increased the availability of Japanese sake brewed in other regions and imported alcoholic beverages, such as beer and wine. The increased availability of such luxury goods had a significant detrimental impact on Chiba’s

sake breweries. There were three sake breweries in Tateyama Town in a list compiled by the Chiba Prefecture Brewing Association (1977), and according to information from our survey, the brewing industry operated until the 1980s or 1990s. All of these sake breweries have gone out of business because of the combination of reasons presented above.

Conclusions

In this study, we investigated potential environmental factors (e.g., landscape, soil, and ground water) and societal factors that were favorable for sake brewing in the coastal area in the 1920s. We clarified how sake brewing in these areas benefited from their proximity to the coast (the ecosystem service).

The breweries operating in the coastal area along Tokyo Bay in 1925 were often located below 10 m in altitude and within 1 km of the sea (Fig. 10). The surface geology consisted of exceedingly soft sand-rich sediments, including sand. The groundwater, ranging from medium hard to very hard, lay 3–10 m below the surface (Tables 2 and 3). The topography from the coast to the plateau in these regions is a coastal dune system in which sand and wetlands alternate, rising to a plateau (Fig. 8).

The groundwater under the sand dunes contains nutrients that originate in the remains of seaweed and animals deposited on the dunes and the salt spray carried by the wind. Nutrient concentrations are also high where

sand-dune vegetation is abundant (Brown and Mclachlan 1990). The study sites all lay on alluvium, which forms an unpressurized aquifer in the sand-rich sediment. The groundwater in the northern part of the prefecture tends to flow to an alluvial lowland on the coast of Tokyo Bay from the Shimousa Plateau, which has an abundance of groundwater (Fig. 2). However, in the Tateyama district in the south, there is little freshwater in the basements of the surrounding plateaus. The unpressurized aquifer in the sand layer is used for shallow wells (Institute for Health in Chiba Prefecture 1983).

In the sandy marine alluvial soil in Chiba Prefecture, potassium, phosphoric acid, calcium, and magnesium concentrations are high. The calcium concentration of the groundwater in the aquifer containing the shell layer has been raised by the dissolution of splintered shells (Kaneko 1994; Kaneko et al. 1994).

Table 3 Water hardness classification

Hardness classification	USA hardness (ppm)
Soft water	0–60 less than ^a
Medium hard water	60–120 less than ^a
Hard water	120–180 less than ^a
Very hard water	180 or more ^a

^aWorld Health Organization (2011)

Most of the sake brewery wells on the coast in Chiba Prefecture were approximately 5–10 m underground, providing a mineral-rich, hard water, high in calcium and magnesium (Kaneko et al. 2012, 2013). Much of the sake brewed in the study area used water from a freshwater layer formed by the coastal dune system.

We also clarified the following as factors that caused the decline of sake brewing as practiced in the coastal area in 1925: (1) bankruptcies and reconstruction difficulties that followed the destructive 1923 Great Kanto earthquake; (2) the wartime Industrial Adjustment Act, under which the nation was required to adapt, integrate, or close non-military-related industrial facilities to support military-related industries during World War II (1939–1945); (3) increased difficulty of sake brewing due to large quantities of groundwater being used by coastal industries during the 1960s and 1970s; and (4) altered transportation and distribution systems resulting from infrastructure improvements (e.g., changing from ship transport to railroads and roads), whereby Japanese sake from other regions and imported alcoholic beverages (e.g., beer and wine) could be obtained at cheaper prices. This brought on changes in the availability of luxury goods, and it was no longer possible to sell locally brewed sake.

Originally, we hypothesized that the fate of Chiba's sake breweries was linked to the natural endowments of the local area. However, the situation is more complex than that, and many sake breweries went out of business because of changes in social circumstances.

Acknowledgements

We wish to express our sincere gratitude to the individuals engaged in sake brewing in Chiba Prefecture, Japan, Chiba Prefectural Library, and Chiba Prefectural Archives that provided Japanese sake information for their support of this research.

Funding

Not applicable.

Authors' contributions

Both authors carried out the ecosystem services studies, participated in the sake breweries investigation and drafted the manuscript. KK participated in the design of the study and performed the statistical analysis. HM participated in its design and coordination. Both authors read and approved in the final manuscript.

Competing interests

The authors declare that they have no competing interests.

Publisher's Note

Springer Nature remains neutral with regard to jurisdictional claims in published maps and institutional affiliations.
