The impact of residential segregation on surgical outcomes remains poorly defined. Data in the current study (<https://doi.org/10.1245/s10434-021-10034-w>) demonstrated that patients who resided in counties with a lower integration index were less likely to have an optimal textbook outcome following resection of cancer compared

with patients who resided in more integrated counties. Increased residential racial diversity and integration may be important drivers to improve patient outcomes.
