Liver stiffness measured using two-dimensional shear wave elastography could predict symptomatic post-hepatectomy liver failure using the best cut-off value of 9.5 kPa.

Child–Turcotte–Pugh grade was a stronger indicator of symptomatic post-hepatectomy liver failure in minor hepatectomy, while liver stiffness was more effective in selecting candidates for major hepatectomy.

Liver stiffness could further stratify the risk of symptomatic post-hepatectomy liver failure in Child–Turcotte–Pugh grade A patients, regardless of the extent of hepatectomy (<https://doi.org/10.1245/s10434-021-10563-4>).
