This retrospective study (<https://doi.org/10.1245/s10434-021-10706-7>) demonstrated that histological liver inflammation may be a predictor of postoperative complications, early recurrence, and poor short- and long-term prognosis in 500 patients with hepatocellular carcinoma

who underwent hepatectomy. Severe liver inflammation was associated with poor short- and long-term prognoses independent of cirrhosis. Controlling liver inflammation in the perioperative period may be essential to improving the prognosis of patients with HCC after hepatectomy.
