Fibroepithelial lesion of the breast (FEL) can pose a diagnostic challenge with a core needle biopsy (CNB) because cellular fibroadenoma is difficult to distinguish from phyllodes tumor (PT). In this 10-year single-institution experience with FEL ([https://doi.org/10.1245/s10434-](https://doi.org/10.1245/s10434-021-10931-0)

[021-10931-0](https://doi.org/10.1245/s10434-021-10931-0)), age, size of tumor, mitotic activity, and stromal overgrowth on the CNB were predictive of PT after excision, and FEL on CNB was upstaged to PT in 25.8 % of the resected cases. To rule out phyllodes tumor, FEL on CNB warrants excision.

This research was selected for a poster presentation at the 2021 Society of Surgical Oncology virtual meeting, March 18–19, 2021.
