Colonoscopy-assisted laparoscopic wedge resection (CAL-WR) is the first available local resection technique for deep invasive pT1 colon cancer (>15 mm) showing high R0-resection rates. It therefore fills the gap between

endoscopic local treatment and major surgical resection, providing more patients with organ-preserving treatment option (<https://doi.org/10.1245/s10434-022-12973-4>).
