

Normative multitrial recall performance, metacognitive judgments, and retrieval latencies for Lithuanian–English paired associates

PHILLIP J. GRIMALDI, MARY A. PYC, AND KATHERINE A. RAWSON
Kent State University, Kent, Ohio

Memory researchers using paired associates have benefited greatly from the Swahili–English norms reported by Nelson and Dunlosky (1994). Given recent increases in the amount and kinds of research using paired associates, however, researchers would now benefit from an expanded set of normative measures for foreign language vocabulary words. We report data for 120 Lithuanian–English word pairs collected from 236 undergraduates. Participants completed three study–test trials and were asked to make metacognitive judgments for each item. We report normative recall performance, recall latencies, and error types for each item across trials, as well as the perceived difficulty of each item on the basis of metacognitive judgments.

Paired associates have long been a favorite tool of researchers in the field of human memory. The most common example of paired associates is concrete English noun pairs. In a typical experiment, participants study a list of paired associates and later take a memory test in which they are asked to recall the second word of a paired associate (i.e., the target) when they are prompted with the first word (i.e., the cue). These noun paired associates are often used under the assumption that results found with this type of paired associate (i.e., concrete nouns) will generalize to other types of paired associates, such as foreign language paired associates (i.e., translation equivalents from two different languages). One reason results should generalize in such a case is that both types contain a cue and an associated target word. However, with many foreign languages, such as French or Spanish, it is not uncommon for participants to have exposure to the language (and potentially some paired associates that would be used from that language) prior to the experiment. The issue of prior exposure can be avoided by choosing arbitrary noun paired associates. However, subjects learn foreign language words differently than they do English word pairs, because foreign language pairs rely heavily on phonological encoding, whereas English pairs rely more on semantic encoding (Papagno, Valentine, & Baddeley, 1991). Nelson and Dunlosky (1994) argued that because of this finding, arbitrary noun paired associates do not necessarily generalize to foreign language vocabulary. At the time, no normative data existed for a foreign language vocabulary set suitable to serve as a substitute for arbitrary noun paired associates. To fill this gap, Nelson and Dunlosky provided normative data on Swahili–English translations.

These Swahili–English paired associates have been used frequently by memory researchers (e.g., Dunlosky &

Thiede, 1998; Jang & Nelson, 2005; Kelemen & Creeley, 2001; Kelemen, Frost, & Weaver, 2000; Kelemen, Winingham, & Weaver, 2007; Richards & Nelson, 2004; Scheck, Meeter, & Nelson, 2004; Scheck & Nelson, 2005; Thiede, 1999; Toppino & Cohen, 2009; Van Overschelde & Nelson, 2006) and have become increasingly popular in certain areas of research, such as research on testing effects (e.g., Bahrick & Hall, 2005; Carpenter, Pashler, Wixted, & Vul, 2008; Karpicke, 2009; Karpicke & Roediger, 2008; Kornell & Bjork, 2008; Kornell & Metcalfe, 2006; Pyc & Rawson, 2007, 2009, *in press*). However, the normative measures reported by Nelson and Dunlosky (1994) focus almost exclusively on retrieval accuracy. Although the Swahili–English norms have served memory researchers well, the field would benefit from an additional set of foreign language paired associates, not only to facilitate establishing the generalizability of key findings but also to provide measures beyond those originally reported by Nelson and Dunlosky. For example, given recent interest in the impact of retrieval difficulty on learning (see, e.g., Karpicke & Roediger, 2007; Pyc & Rawson, 2009), a researcher might want to consider the retrieval latency of a particular item. Metamemory researchers would be interested in the perceived difficulty of a particular item from ease-of-learning judgments (EOLs) and judgments of learning (JOLs). Both memory and metamemory researchers alike may be interested in the types of errors common to a particular item (e.g., commission vs. omission errors).

Of practical concern, it is also reasonable to assume that researchers frequently use Swahili–English paired associates across multiple experiments. Utilizing these items across multiple experiments has the unfortunate consequence of automatically excluding individuals from participating in more than one experiment that includes Swahili–English

P. J. Grimaldi, pgrimald@purdue.edu

paired associates. Researchers can increase the functional size of their available subject pool by having an additional language set available for paired-associate learning studies. Additionally, utilizing multiple language sets has the added benefit of establishing the generalizability of results across foreign language paired-associate studies.

Accordingly, the purpose of the present study was to provide an expanded set of normative measures for a different foreign language vocabulary set, which will provide researchers with more options when choosing paired associates for experiments. Specifically, we examined retrieval accuracy, recall latency, perceived item difficulty, and error patterns for a set of Lithuanian words and their English translations. Lithuanian was chosen primarily on the basis of Nelson and Dunlosky's (1994) rationale for the use of Swahili. Like Swahili, Lithuanian is a relatively uncommon language, ensuring low rates of prior exposure among participants. Because Lithuanian is a Baltic language, it is dissimilar to Romance languages familiar to most people through schooling, which also minimizes the occurrence of cognates. Additionally, Lithuanian uses the standard English alphabet, avoiding issues of transliteration that would necessarily occur with languages that use other alphabets. For practical purposes, Nelson and Dunlosky avoided the use of letter modifiers such as accents. A portion of the Lithuanian items in our material set contains modifiers (42 of 120 items) permitting researchers to vary the orthographic variability of their item set as they see fit.

METHOD

Participants

Participants included 240 Kent State University undergraduates who volunteered to participate in exchange for \$10 compensation. Data from 4 participants were not included because of a programming error that rendered their data unusable. As a motivator for performance, each participant was entered into a drawing for a \$100 prize; prior to beginning the task, participants were informed that the top third of performers would be entered into the drawing three times, and that the middle third of performers would be entered two times.

Materials

The item list included 125 Lithuanian–English paired associates. Each paired associate consisted of a Lithuanian word and its English translation. All English words were concrete nouns with concreteness ratings in the range of 500–700 (Coltheart, 1981). Additionally, each word was greater than three characters in length, each word was not a hyphenated or compound word, and the two words of any given paired associate were not cognates. Five items were used as primacy buffer items at the beginning of each study trial, and they were not presented during test trials.

Procedure

Each participant was presented with 40 target Lithuanian–English items via computer. Participants learned a subset of 40 items to manage total task time, minimize boredom and fatigue, and keep the to-be-learned item list at a reasonable length. We used a random yoking procedure to ensure that each item was presented an equal number of times across participants. The yoking procedure was as follows: The list of 120 items was first randomized and split into thirds. The first 40 items were assigned to the first participant, the second 40 items were assigned to the second participant, and the third 40 items were assigned to the third participant. The list of 120

items was then randomized anew, split into thirds, and assigned to the next 3 participants. This procedure continued until each item was assigned to 80 participants.

Each participant completed three alternating study–test trials for each of his or her assigned items. During the study phase of each trial, participants were first presented with the 5 primacy buffer items in random order, followed by the 40 target items in random order. Items were presented for study at a rate of 10 sec per item. Participants then completed the test phase. The first 20 items presented in the study phase were randomized anew and presented one at a time for a test trial. The remaining 20 items from the study phase were then randomized anew and presented for a test trial. This method ensured at least a 20-item lag between studying a given item and being tested on that item. During test trials, the Lithuanian cue word of a paired associate was presented (e.g., “bulvė = ??”), and the participant had 12 sec to type the corresponding English target translation into a response field before being moved on to the next item. Items were computer scored by comparing the first three letters of the target answer and the cue.¹ Recall latencies were recorded for each response as the time (in seconds) between the onset of a Lithuanian word and the first keypress of the participant's response.

Following the third test phase, the 40 target items were randomized anew and were presented for judgment trials. During judgment trials, items were serially presented on the screen, and participants made two judgments for each item using a slider on a continuous scale. Participants were first prompted to make an EOL, in which they were asked to rate how difficult it was for them to learn the given item. The left side of the scale was labeled “very hard,” and the right side was labeled “very easy.” For the JOL, participants were asked to rate the likelihood of being able to recall the English word of a given item were they to be tested on that item in 1 week. The left side of the scale was presented as “0% likely to recall,” and the right side was presented as “100% likely to recall.” Each judgment was recorded as a number between 0 and 100 depending on the position of the slider on the scale.

RESULTS

Recall Performance

Mean recall performance for each item is reported in Table A1 in the Appendix. Mean recall performance was .22 for Trial 1 ($SD = .13$), .50 for Trial 2 ($SD = .16$), and .66 for Trial 3 ($SD = .13$). These data indicate performance off the floor in the initial trial, substantial positive gains in recall performance with each additional trial, and performance off the ceiling after the third trial. Additionally, these data indicate a wide range of recall performance throughout the item set on each trial, giving researchers an ample range of performance to consider across practice trials when selecting items for experiments.

Similar to the Nelson and Dunlosky (1994) norms, performance for an individual item on any given trial was highly predictive of performance on subsequent trials. Recall performance on Trial 1 was highly correlated with performance on Trial 2 ($r = .88, p < .001$). Likewise, recall performance on Trial 2 was highly correlated with performance on Trial 3 ($r = .93, p < .001$). These results indicate that items retained their relative difficulty across trials.

Metacognitive Judgments

Mean EOL and JOL for each item are reported in Table A1. The two judgments were highly correlated ($r = .99, p < .001$), suggesting that both judgments were relatively equivalent for gauging the perceived difficulty of a given item. Both judgments were also highly correlated

with recall performance for each of the three trials. The correlations between EOL judgments and recall performance were $r = .91$, $.97$, and $.93$ for Trials 1, 2, and 3, respectively. The correlations between JOLs and recall performance were $r = .89$, $.95$, and $.93$ for Trials 1, 2, and 3, respectively (all $p < .001$). EOL judgments ranged from 19.6 to 88.6 (median = 45.8, $SD = 13.2$), and JOLs ranged from 20.6 to 83.8 (median = 45.69, $SD = 12.14$).

Frequency of Occurrence

To parallel statistics reported by Nelson and Dunlosky (1994), the Thorndike and Lorge (1944) frequency-of-occurrence norms for the English words are presented in Table A1. To examine any possible effects that familiarity of an English word might have had for establishing an association with the Lithuanian translation, we computed Pearson correlations between word frequency and the proportion correct on Trial 1. The correlation was significant ($r = .25$, $p = .006$) and consistent with the magnitude of the correlation reported by Nelson and Dunlosky with Swahili–English pairs ($r = .25$). Although the size of the correlation was only moderate, this repeated finding indicates that preexperimental familiarity was a predictive factor for successful recall. The extent to which this effect was due to improved target memory and/or a stronger associative link between the cue and target is a question for future research.

Recall Latency

Mean recall latencies for each item are reported in Table A2 in the Appendix. Recall latency was computed as the time in seconds between the onset of a Lithuanian word and the first keypress of the participant's response. Only latency data from trials on which the response was scored as correct are included in Table A2. The data are ordered from shortest to longest recall latency on Trial 1. Table A2 is partitioned vertically by the first occurrence of a correct response. The first partition reports the latency data across trials for items that were correctly recalled in Trial 1 first, the second partition reports the latency data across trials for items correctly recalled in Trial 2 first, and the third partition reports the latency data across trials for items correctly recalled in Trial 3 first. Within any given partition, a participant's response to an item was included only if that item was also correctly recalled in the preceding trials. For example, a participant who correctly responded to an item in Trial 1 and Trial 3 but not in Trial 2 would have latency data included in the Trial 1 means but not the Trial 2 or Trial 3 means. By arranging the data in this manner, a researcher can assess the expected retrieval latency of an item at any given trial of recall on the basis of the number of times the item has been correctly recalled.

Types of Error

The error frequencies across trials for each item are reported in Table A3 in the Appendix, as are the rates of commission. The rates of commission are reported as the ratio of commission errors to total errors for an item. To conserve space, errors of omission are not reported; however, these can be calculated easily from the reported data.

Although the majority of errors for items are represented by errors of omission, researchers are still left with a good range of commission rates to choose from. Commission rates ranged from .12 to .63 (median = .28, $SD = .11$).

SUMMARY

Swahili–English word pairs have seen an upsurge in popularity, especially in testing-effect research. The present set of norms provides a number of measures not reported in the Nelson and Dunlosky (1994) Swahili–English set, and this provides greater utility to researchers. In addition to recall accuracy, we provide recall latency, error patterns, and metacognitive measures. Each of these measures will be useful for a variety of interests in memory research. For example, the recall latency data are useful for research examining the effects of retrieval fluency on memory, and the error analysis is useful for research examining the perseverance of errors across learning trials. It should be noted that use of these measures should be limited to experimental designs using the Lithuanian word to cue retrieval of the English word. Caution should be exercised when using the English word to cue the Lithuanian word, since the measures reported here do not necessarily generalize to this reversed procedure. Overall, the present data provide a good range across all measures, in which values are off the floor and ceiling, thereby providing a large set of new foreign language paired associates for researchers.

AUTHOR NOTE

P.J.G. is now at the Department of Psychological Sciences, Purdue University. The research reported here was supported by the Institute of Education Sciences, U.S. Department of Education, through Grant R305H050038 to Kent State University. The opinions expressed are those of the authors and do not represent views of the Institute or the U.S. Department of Education. Thanks to Michael Appleman, Rochelle O'Neil, and Tonya Hardway for assistance with data collection. A special thanks also to Amanda Pyc and Arnas Gasparonis for assistance with compiling the list of Lithuanian–English translations. Correspondence concerning this article should be addressed to P. J. Grimaldi, Department of Psychological Sciences, Purdue University, West Lafayette, IN 47907-1364 (e-mail: pgrimald@purdue.edu).
