Preface to the Series

The extraordinary conditions in space, especially microgravity, are utilized today not only for research in the physical and materials sciences—they especially provide a unique tool for research in various areas of the life sciences. The major goal of this research is to uncover the role of gravity with regard to the origin, evolution, and future of life and to the development and orientation of organisms from single cells and protists up to humans. This research only became possible with the advent of manned spaceflight some 50 years ago. With the first experiment having been conducted onboard Apollo 16, the German Space Life Sciences Program celebrated its 40th anniversary in 2012—a fitting occasion for Springer and the DLR (German Aerospace Center) to take stock of the space life sciences achievements made so far.

The DLR is the Federal Republic of Germany's National Aeronautics and Space Research Center. Its extensive research and development activities in aeronautics, space, energy, transport, and security are integrated into national and international cooperative ventures. In addition to its own research, as Germany's space agency the DLR has been charged by the federal government with the task of planning and implementing the German space program. Within the current space program, approved by the German government in November 2010, the overall goal for the life sciences section is to gain scientific knowledge and to reveal new application potentials by means of research under space conditions, especially by utilizing the microgravity environment of the International Space Station ISS.

With regard to the program's implementation, the DLR Space Administration provides the infrastructure and flight opportunities required, contracts the German space industry for the development of innovative research facilities, and provides the necessary research funding for the scientific teams at universities and other research institutes. While so-called small flight opportunities like the drop tower in Bremen, sounding rockets, and parabolic airplane flights are made available within the national program, research on the International Space Station ISS is implemented in the framework of Germany's participation in the ESA Microgravity Program or through bilateral cooperations with other space agencies. Free flyers

such as BION or FOTON satellites are used in cooperation with Russia. The recently started utilization of Chinese spacecraft like Shenzhou has further expanded Germany's spectrum of flight opportunities, and discussions about future cooperation on the planned Chinese Space Station are currently under way.

From the very beginning in the 1970s, Germany has been the driving force for human spaceflight as well as for related research in the life and physical sciences in Europe. It was Germany that initiated the development of Spacelab as the European contribution to the American Space Shuttle System, complemented by setting up a sound national program. And today Germany continues to be the major European contributor to the ESA programs for the ISS and its scientific utilization.

For our series, we have approached leading scientists first and foremost in Germany, but also—since science and research are international and cooperative endeavors—in other countries to provide us with their views and their summaries of the accomplishments in the various fields of space life sciences research. By presenting the current SpringerBriefs on muscle and bone physiology, we start the series with an area that is currently attracting much attention—due in no small part to health problems such as muscle atrophy and osteoporosis in our modern ageing society. Overall, it is interesting to note that the psychophysiological changes that astronauts experience during their spaceflights closely resemble those of ageing people on Earth but progress at a much faster rate. Circulatory and vestibular disorders set in immediately, muscles and bones degenerate within weeks or months, and even the immune system is impaired. Thus, the ageing process as well as certain diseases can be studied at an accelerated pace, yielding valuable insights for the benefit of people on Earth as well. Luckily for the astronauts: these problems slowly disappear after their return to Earth, so that their recovery processes can also be investigated, yielding additional valuable information.

Booklets on nutrition and metabolism, on the immune system, on vestibular and neuroscience, on the cardiovascular and respiratory system, and on psychophysiological human performance will follow. This separation of human physiology and space medicine into the various research areas follows a classical division. It will certainly become evident, however, that space medicine research pursues a highly integrative approach, offering an example that should also be followed in terrestrial research. The series will eventually be rounded out by booklets on gravitational and radiation biology.

We are convinced that this series, starting with its first booklet on muscle and bone physiology in space, will find interested readers and will contribute to the goal of convincing the general public that research in space, especially in the life sciences, has been and will continue to be of concrete benefit to people on Earth.

Foreword

The cardiovascular as well as the respiratory systems of the human body are challenged—like the vestibular system—immediately after the astronauts enter into the microgravity conditions of space: several liters of fluids are shifted from the lower to the upper part of the human body leading to the well-known phenomenon of bird legs and puffy faces of astronauts. For adaptation to this new environment, a proper regulation of the cardiorespiratory system is mandatory; results from space research on this topic will, therefore, provide new insights into the functioning of this important system not only for astronauts but also for people on Earth.

“The cardiovascular system, red blood cells and oxygen transport in space” is thus the title of the fourth volume in the SpringerBriefs series on Space Life Sciences. In their short introductory chapter, the authors describe the physiological functions of the cardiorespiratory system with special emphasis on basic differences in the functioning of the circulatory and respiratory systems on Earth and in space.

In the second chapter, these changes are described in more detail differentiating between acute or immediate effects and those of long-term adaptation and the problems astronauts encounter upon return to Earth. Results from space experiments are compared with those of terrestrial studies such as bedrest and immersion studies as well as on parabolic airplane flights or in centrifuges.

Changes in red blood cells and oxygen transportation are the focus of the third chapter. It is well known that microgravity leads to significant changes in blood volume, red blood cells, and hemoglobin. The regulation of the hormone erythropoietin (EPO) plays an important role here. Results from spaceflight experiments are compared with those from terrestrial studies; the influence of exercise is also covered.

The lungs are directly affected by microgravity: their shape and the distribution of gas-filled spaces are immediately changed. This makes parabolic airplane flights a suitable tool for research in addition to experiments under real space conditions such as on the ISS (International Space Station). In fact, the authors present results from short-term microgravity on parabolic flights and from space platforms which

were available before the development of the American shuttle system and the Russian MIR station and conclude with data from the ISS. The good news: all in all, the lungs possess highly effective compensation mechanisms against the influence of microgravity.

The booklet presents in its fifth chapter an overview of countermeasures that are either already in use, under development, or discussed for the future and concludes with an outlook on existing or potential terrestrial—e.g., clinical—applications of knowledge and technologies gained from space research in this field. In this sense, it follows nicely after the conclusions of the other booklets in the series that all try to build a bridge between the accomplishments from space experiments and from terrestrial research for the benefit of people on Earth.

Acknowledgments

We wish to express our thanks to Mrs. Himmelsbach-Wegner and Mrs. Felicitas Kern for their help to prepare the manuscript. We would like to thank all subjects and the following institutions for their unremitting support: ESA, CNES, DRET, and GIP in France; DLR in Germany; ZPK and IBMP in Russia; ESTEC (the Netherlands); NASA (USA); and NBRI (USA). The studies were supported by the Bundesministerium für Wirtschaft, Raumfahrtagentur DLR (BMW, Bonn, Germany), Grant No. 50 WB 93 773, 50 QV 8726, 50 WB 92397, 50 WP 0022, and 50WP0223.

Contents

1	General Introduction	1
1.1	The Circulatory System	1
1.2	The Circulatory System on Earth	3
1.3	The Circulatory System in Space	6
1.4	The Respiratory System on Earth	7
1.4.1	Anatomic Basics	7
1.4.2	Respiratory Control	8
1.5	The Respiratory System in Space	9
	References	9
2	The Cardiovascular System in Space	11
2.1	Hypotheses from Terrestrial Experiments	11
2.1.1	Bed Rest Studies	12
2.1.2	Immersion Studies	14
2.1.3	Parabolic Flights	16
2.1.4	Centrifuge Experiments	19
2.2	Adaptations to Microgravity	20
2.2.1	Acute Adaptations	20
2.2.2	Long-Term Adaptations	26
2.3	Adaptations Upon Return	29
	References	31
3	Red Blood Cells in Space	35
3.1	Red Blood Cells and Erythropoietin	35
3.2	Physiological Erythropoietin Regulation under Different Terrestrial Settings	40
3.3	Short-, Medium-, and Long-term Exercise at Sea Level and Its Impact on Erythropoietin	41
3.3.1	Erythropoietin Under Simulated Microgravity Conditions	44

3.4	Erythropoietin in Microgravity	47
3.5	Conclusion	52
	References	53
4	Respiration and Respiratory Control	57
4.1	Short-Term Weightlessness—Results from Parabolic Flight Experiments	58
4.2	Results from Spaceflight Before Spacelab and MIR Era	60
4.3	Results from Space Flight in Spacelab, MIR, and ISS Missions	61
4.4	Immersion and Bed Rest Studies Do Not Mimic μg Effects on the Respiratory System	63
4.5	Conclusions	63
	References	63
5	Countermeasures	67
5.1	Exercise Pre-, During-, and Post-mission	67
5.2	Passive Countermeasures	68
5.2.1	Lower Body Negative Pressure	68
5.2.2	Gravity Suits	69
5.2.3	Fluid Loading and Pharmaceuticals	71
5.2.4	Artificial Gravity	72
5.3	Outlook and Broader Applications	72
	References	73

List of Authors

Hans-Joachim Appel-Coriolano is professor at the Institute for Physiology and Anatomy, German Sport University Cologne, and Editor of the International Journal of Sports Medicine.

Hanns-Christian Gunga is full professor at the Department of Physiology at the Charité, Medical University Berlin, and Director of the Institute of Physiology, Center for Space Medicine and Extreme Environments in Berlin, Charité Cross-Over, Germany.

Uwe Hoffmann is Research Scientist and lecturer at the German Sport University Cologne, Institute of Physiology and Anatomy, Cologne, Germany.

Victoria Weller von Ahlefeld has a Bachelor's in Astrophysics and currently is working as a research assistant at the Center for Space Medicine and Extreme Environments in Berlin, Charité CrossOver, Germany.

Andreas Werner is working as a flight physiologist and specialist for high altitude and acceleration medicine at the Aerospace Center for Medicine, German Airforce, Königsbruck, Germany.
