

# Lecture Notes in Mathematics

Edited by J.-M. Morel, F. Takens and B. Teissier

## Editorial Policy

for the publication of monographs

1. Lecture Notes aim to report new developments in all areas of mathematics – quickly, informally and at a high level. Monograph manuscripts should be reasonably self-contained and rounded off. Thus they may, and often will, present not only results of the author but also related work by other people. They may be based on specialized lecture courses. Furthermore, the manuscripts should provide sufficient motivation, examples and applications. This clearly distinguishes Lecture Notes from journal articles or technical reports which normally are very concise. Articles intended for a journal but too long to be accepted by most journals, usually do not have this “lecture notes” character. For similar reasons it is unusual for doctoral theses to be accepted for the Lecture Notes series.

2. Manuscripts should be submitted (preferably in duplicate) either to one of the series editors or to Springer-Verlag, Heidelberg. In general, manuscripts will be sent out to 2 external referees for evaluation. If a decision cannot yet be reached on the basis of the first 2 reports, further referees may be contacted: the author will be informed of this. A final decision to publish can be made only on the basis of the complete manuscript, however a refereeing process leading to a preliminary decision can be based on a pre-final or incomplete manuscript. The strict minimum amount of material that will be considered should include a detailed outline describing the planned contents of each chapter, a bibliography and several sample chapters.

Authors should be aware that incomplete or insufficiently close to final manuscripts almost always result in longer refereeing times and nevertheless unclear referees’ recommendations, making further refereeing of a final draft necessary.

Authors should also be aware that parallel submission of their manuscript to another publisher while under consideration for LNM will in general lead to immediate rejection.

3. Manuscripts should in general be submitted in English.

Final manuscripts should contain at least 100 pages of mathematical text and should include

- a table of contents;
- an informative introduction, with adequate motivation and perhaps some historical remarks: it should be accessible to a reader not intimately familiar with the topic treated;
- a subject index: as a rule this is genuinely helpful for the reader.

# Preface

Bond markets differ in one fundamental aspect from standard stock markets. While the latter are built up by a finite number of traded assets, the underlying basis of a bond market is the entire term structure of interest rates: an infinite-dimensional variable which is not directly observable. On the empirical side this necessitates curve-fitting methods for the daily estimation of the term structure. Pricing models on the other hand, are usually built upon stochastic factors representing the term structure in a finite-dimensional state space, making them computationally tractable.

This research monograph brings together curve-fitting methods and factor models for the term structure of interest rates within the Heath–Jarrow–Morton (henceforth HJM) framework [35], which basically unifies all continuous interest rate models. We provide appropriate consistency conditions and explore some important examples.

The HJM framework can be seen as a generic description of the arbitrage-free movements of the forward curve (the term structure of forward rates), driven by a Brownian motion. The no-arbitrage requirement leads to a restriction on the drift of any single forward rate process (HJM drift condition). The (infinite-dimensional) state variable in an HJM model is the entire forward curve. As such, any initial forward curve can be taken as model input. But, by the HJM drift condition, there is a limitation on the shapes of the curves produced by the model. For instance, a flat initial forward curve cannot move only by parallel shifts, unless it remains constant over time. This fact has been known by the experts for a long time. Such consistency considerations for HJM models and finite-dimensional manifolds of curves (such as the set of flat curves) form an essential part of this book.

On the empirical side there exist commonly used methods for fitting the current forward curve. Any curve-fitting method can be represented as a parametrized family of smooth curves  $\mathcal{G} = \{G(\cdot, z) \mid z \in \mathcal{Z}\}$  with some finite-dimensional parameter set  $\mathcal{Z}$ . A lot of cross-sectional data, that is, daily estimations of  $z$ , is available, and one may ask for a suitable stochastic model for  $z$  that provides accurate prices for interest rate based derivatives. However, this requires the absence of arbitrage. In this book, we characterize all consistent  $\mathcal{Z}$ -valued state space Itô processes  $Z$  which, by definition, provide an arbitrage-free model when representing the parameter  $z$ . That is, the fac-

tor model  $G(T - t, Z_t)$  has to satisfy the HJM drift condition. It turns out that selected common curve-fitting methods do not go well with the HJM framework.

We then consider the preceding consistency problem from a geometric point of view, as proposed by Björk and Christensen [8]. First, the HJM methodology is completely recaptured within a functional analytic framework, which also incorporates an infinite-dimensional driving Brownian motion. We then rigorously perform the change of parametrization due to Musiela [46] and arrive at a stochastic equation in a Hilbert space  $H$ , describing the arbitrage-free evolution of the forward curve. The family  $\mathcal{G}$  can now be seen as a subset of  $H$  and the above consistency considerations yield a stochastic invariance problem for the previously derived stochastic equation. Under the assumption that  $\mathcal{G}$  is a regular submanifold of  $H$ , we derive sufficient and necessary conditions for its invariance. Expressed in local coordinates they turn out to equal the HJM drift condition. In conclusion, we provide a general tool for exploiting the interplay between curve-fitting methods and HJM factor models.

Classical models, such as the Vasicek [56] and Cox–Ingersoll–Ross (henceforth CIR) [18] short rate models, and the popular Brace–Gatarek–Musiela (henceforth BGM) [13] LIBOR rate (short for London Interbank Offered Rate) model, are shown to fit well into our framework. By their very definition, affine HJM models are consistent with finite-dimensional linear submanifolds of  $H$ . A straight application of our results yields a complete characterization of all affine HJM models, as obtained by Duffie and Kan [23].

Many phenomena, say in physics or economics, are described by stochastic equations in finite or infinite dimension. Some parts of this book (Chapters 2 and 6) are of general form. The results can (and hopefully will) also be applied to fields other than interest rate theory.

As for the mathematical prerequisites, the reader is expected to be familiar with elementary stochastic calculus and probability theory. This book provides a short introduction both to the basic terminology in the theory of interest rates and to stochastic analysis and equations in infinite dimension.

This monograph is based on my Ph.D. thesis [27], which I wrote under the supervision of F. Delbaen at the Swiss Federal Institute of Technology (ETH) Zurich. It is a great pleasure to thank him here for his guidance throughout my Ph.D. studies. I am deeply grateful to T. Björk for his vital support, which made this publication possible. Further thanks go to B. J. Christensen, G. Da Prato, R. Cont, D. Heath, W. Schachermayer, D. Duffie and in particular to J. Zabczyk for their interest, support and hospitality. I thank Manuela for her love and encouragement over the last years. Financial support from Credit Suisse is gratefully acknowledged.

Stanford, January 2001

# Contents

<b>1. Introduction</b> .....	1
1.1 Bond Markets .....	1
1.2 Forward Curve Fitting Methods and Factor Models .....	3
1.3 The HJM Methodology .....	4
1.4 Invariant Manifolds .....	7
1.5 Outline .....	9
1.6 Remark on Notation .....	10
<b>2. Stochastic Equations in Infinite Dimensions</b> .....	13
2.1 Infinite Dimensional Brownian Motion .....	13
2.2 The Stochastic Integral .....	16
2.3 Fundamental Tools .....	19
2.3.1 Itô's Formula .....	19
2.3.2 The Stochastic Fubini Theorem .....	20
2.3.3 Girsanov's Theorem .....	21
2.4 Stochastic Equations .....	23
2.4.1 Mild, Weak and Strong Solutions .....	23
2.4.2 Existence and Uniqueness .....	26
<b>3. Consistent State Space Processes</b> .....	29
3.1 Itô Process Factor Models .....	29
3.2 Exponential-Polynomial Families .....	33
3.3 Auxiliary Results .....	38
3.4 The Case $BEP(1, n)$ .....	41
3.5 The General Case $BEP(K, n)$ .....	44
3.6 The Diffusion Case .....	51
3.7 Applications .....	54
3.7.1 The Nelson–Siegel Family .....	54
3.7.2 The Svensson Family .....	54
3.8 Conclusions .....	56
<b>4. The HJM Methodology Revisited</b> .....	57
4.1 Term Structure Movements .....	57
4.2 The Musiela Parametrization .....	58

4.3	Arbitrage-free Term Structure Movements	60
4.4	Contingent Claim Valuation	66
4.4.1	When Is $Z(\cdot, T)$ a True $\mathbb{Q}$ -Martingale?	66
4.4.2	The Forward Measure	67
4.4.3	Forward LIBOR Rates	68
4.4.4	Caps	69
