Preface

The Laboratory of Hyperbaric Physiology of the Medical Clinic of the University of Zurich came into existence in 1960 thanks to private initiative and a readiness to undertake risks; the successful start was made possible with help from the French Navy and the United States Navy. A prerequisite for the development of the laboratory was also the benevolence of the authorities of the University of Zurich toward a research project from which scarcely any practical use could be expected for the land-locked country of Switzerland. The development of the laboratory and the systematic research were supported generously from 1964 by Shell Internationale Petroleum Maatschappij of The Hague.

The basic theme of the research was always the well-being and functional ability of the human being in an atmosphere of abnormal pressure and or abnormal composition.

Many connections became obvious with respiratory physiology, circulatory physiology, and physiology at great heights, and close contact with other special laboratories of the Medical Clinic proved very valuable. With a relatively small number of steady collaborators it was possible to master an extensive experimental program. Special thanks are due to Mr. Benno Schenk, who as technical head was responsible for the exact performance of all the hyperbaric experiments.

Without the enthusiasm and willingness for enterprise of the many voluntary collaborators the program of experiments could not have been realized. Mr. Rino Gamba, who participated from 1964 until 1968 in all of the important experiments at depths of 30, 220, and 300 m, is mentioned here as representative of all the voluntary collaborators.

Decompression was the principal problem encountered during preparation for the first deep diving trials. The persistent reexamination and expansion of the original concept finally yielded a method of decompression that is theoretically sound and has been tested widely for nitrogen and helium. In research there are no terminal solutions, but the Swiss practice of decompression has reached a state that justifies a summary description. So much detail has been amassed in the special literature that it is scarcely possible to read it all, but what has been lacking is the

description of a method by which a low-risk decompression can be calculated for every imaginable exposure upon the basis of pressure, time, and gas breathed.

In Zurich, diving medicine and research on decompression are applied research related to internal medicine. This monograph is intended not only for the specialists in hyperbaric medicine and hyperbaric technic, but also for physiologists, internists, neurologists, specialists in intensive care, occupational physicians, and practitioners of medicine connected with insurance.

By avoiding the description of complicated biophysical models and mathematical derivations, for which he is not competent anyway, the author hopes to have improved the readability of the monograph and therefore also the understanding of that which he believes useful.

Zurich, May 1984

Hannes Keller climbing into the water tank of the pressure chamber of the French Navy in Toulon on 25 April 1961. The first simulated dive corresponding to a depth of 300 m

Contents

1	<i>Introduction</i>	1
2	<i>Physical and Biological Bases</i>	4
2.1	Pressure, Force, Work	4
2.2	Composition of Atmospheric Air	5
2.3	Absorption and Release of Gas in the Lungs	5
2.4	Transport of Gases in the Circulatory System	6
2.5	Saturation with Nitrogen While Breathing Air at Normal Pressure	8
3	<i>Abnormal Atmosphere</i>	9
3.1	Alteration of the Composition of Gases at Normal Pressure	9
3.1.1	Hyperoxia	9
3.1.2	Replacement of Nitrogen by Helium or Other Inert Gases	9
3.1.3	The Pressure Cabin	10
3.2	Increased and Reduced Ambient Pressure	10
3.2.1	Altitude and Hypoxia	10
3.2.2	Equalization of Pressure in the Gas-Filled Spaces, Barotrauma	12
3.3	Uptake and Release of Inert Gases by the Tissues	14
3.3.1	Half-Value Times, the Mathematical Bases	14
3.3.2	Longest Half-Value Time for Nitrogen and Helium in Man	14
3.4	Decompression	15
3.4.1	“Explosive” Decompression	15
3.4.2	Tolerated Partial Pressure of Nitrogen at an Ambient Pressure of 1.0 Bar	16
3.4.3	Tolerated Pressure of Nitrogen at Overpressure	18

VIII Contents

3.4.4	Differences Between Nitrogen and Helium and Experimental Bases for the ZH-L ₁₂ System . . .	19
3.4.5	Identification of the Half-Value Times with Tissues . . .	24
3.5	Calculation of Safe Decompression	26
3.5.1	Tolerated Pressure of Inert Gas as Dependent on Half-Value Time and Ambient Pressure	26
3.5.2	Twelve Pairs of Coefficients for Sixteen Half-Value Times of Helium and Nitrogen (ZH-L ₁₂)	26
3.5.3	Comparisons Between Decompression Using ZH-L ₁₂ and the US Navy and Royal Navy Tables After Dives with Air	29
3.6	Experimental Experiences with ZH-L ₁₂	32
3.6.1	Exposures with Air	33
3.6.2	Exposures with Helium and with Mixed Gases	34
3.7	Summary of the Arguments for the ZH-L ₁₂ System . . .	38
3.8	Rules for the Calculation of Decompression Tables . .	40
3.8.1	Decompression Tables and Individual Decompression	40
3.8.2	Dives Using Air	40
3.8.3	Deep Diving Using Helium and Mixed Gases	42
3.9	Saturation Diving and Excursions	43
3.10	Flying After Diving	45
3.11	Testing Decompression Tables	52
4	<i>Decompression Sickness</i>	53
4.1	Pathogenesis	53
4.2	Symptomatology	54
4.2.1	Decompression Sickness of the Central Nervous System	54
4.2.2	Decompression Sickness of the Skin, Muscles, Bones, and Joints	54
4.3	Treatment	55
4.3.1	General Rules	56
4.3.2	Decompression Sickness of the Central Nervous System	57
4.3.3	Decompression Sickness of the Joints and Bones . . .	60
4.3.4	Decompression Sickness After Deep Diving with Helium	61
4.4	Transport of the Injured Diver	62

5	<i>Appendix: Calculation of Low-Risk, Decompression and Decompression Tables</i>	63
5.1	Calculation of Inert Gas Pressure in Tissues	63
5.2	Decompression Tables for Dives with Air at Various Altitudes	67
6	<i>Literature</i>	83
7	<i>Subject Index</i>	85
